- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input combines the masks. How masks are combined is handled in the Paint mode menu in the Inspector.

Basic Node Setup

The Polygon node can be used to generate a detailed spline shape or combined with other masks for even more complex shapes. In the node tree below, the Polygon mask is used to generate detailed shape as a solid matte on the Delta Keyer.

A Polygon node generates a detailed shape as a Solid matte.
Inspector

Controls Tab
The Controls tab is used to refine how the polyline appears after drawing it in the viewer.

Show View Controls
The Show View Controls checkbox is used to enable/disable the display of the mask’s onscreen controls in the viewer. Onscreen controls, including center position, polylines, angles, and others, do not appear when this checkbox is disabled, even when the node is selected.

Level
The Level control sets the transparency level of the pixels in the mask channel. When the value is 1.0, the mask is completely opaque (unless it has a soft edge). Lower values cause the mask to be partially transparent. The result is identical to lowering the blend control of an effect.

NOTE: Lowering the level of a mask lowers the values of all pixels covered by the mask in the mask channel. For example, if a Circle mask is placed over a Rectangle mask, lowering the level of the Circle mask lowers the values of all of the pixels in the mask channel, even though the Rectangle mask beneath it is still opaque.

Filter
This control selects the filtering algorithm used when applying Soft Edge to the mask.

— Box: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.

— Bartlett: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.
— **Multi-box:** When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”
— **Gaussian:** The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

**Soft Edge**
Use the Soft Edge slider to blur (feather) the mask, using the selected filter. Higher values cause the edge to fade off well beyond the boundaries of the mask. A value of 0.0 creates a crisp, well-defined edge.

**Border Width**
The Border Width control adjusts the thickness of the mask’s edge. When the solid checkbox is toggled on, the border thickens or narrows the mask. When the mask is not solid, the mask shape draws as an outline, and the width uses the Border Width setting.

**Paint Mode**
Connecting a mask to the effect mask input displays the Paint mode menu. The Paint mode is used to determine how the incoming mask for the effect mask input and the mask created in the node are combined.
— **Merge:** Merge is the default for all masks. The new mask is merged with the input mask.
— **Add:** The mask’s values add to the input mask’s values.
— **Subtract:** In the intersecting areas, the new mask values subtract from the input mask’s values.
— **Minimum:** Comparing the input mask’s values and the new mask, this displays the lowest (minimum) value.
— **Maximum:** Comparing the input mask’s values and the new mask, this displays the highest (maximum) value.
— **Average:** This calculates the average (half the sum) of the new mask and the input mask.
— **Multiply:** This multiplies the values of the input mask by the new mask’s values.
— **Replace:** The new mask completely replaces the input mask wherever they intersect. Areas that are zero (completely black) in the new mask do not affect the input mask.
— **Invert:** Areas of the input mask that are covered by the new mask are inverted; white becomes black and vice versa. Gray areas in the new mask are partially inverted.
— **Copy:** This mode completely discards the input mask and uses the new mask for all values.
— **Ignore:** This mode completely discards the new mask and uses the input mask for all values.

**Invert**
Selecting this checkbox inverts the entire mask. Unlike the Invert Paint mode, the checkbox affects all pixels, regardless of whether the new mask covers them or not.

**Solid**
When the Solid checkbox is enabled, the mask is filled to be transparent (white) unless inverted. When disabled, the spline is drawn as just an outline whose thickness is determined by the Border Width slider.

**Center X and Y**
These controls adjust the position of the polygon spline mask.
Size
Use the Size control to adjust the scale of the polygon spline effect mask, without affecting the relative behavior of the points that compose the mask or setting a keyframe in the mask animation.

X, Y, and Z Rotation
Use these three controls to adjust the rotation angle of the mask along any axis.

Fill Method
The Fill Method menu offers two different techniques for dealing with overlapping regions of a polyline. If overlapping segments in a mask are causing undesirable holes to appear, try switching the setting of this control from Alternate to Non Zero Winding.

Right-Click Here for Shape Animation
By default, all polygon spline masks are animated when they are created. The initial keyframe is set to the current time, and any changes to the shape at different times create new keys.

Right-clicking on this label displays a contextual menu that offers options for removing or re-adding animation to the mask, or publishing and connecting the masks together.

Common Controls

Image and Settings Tabs
The Image and Settings tabs in the Inspector are also duplicated in other mask nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Adding Points

Adding Points to a polygonal effect mask is relatively simple. Immediately after adding the node to the Node Editor, there are no points, but the tool will be in Click Append mode. Click once in the viewer wherever a point is required for the mask. Continue clicking to draw the shape of the mask. When the shape is complete, click on the initial point again to close the mask.

When the shape is closed, the mode of the polyline will change to Insert and Modify. This allows for the adjusting and adding of additional points to the mask by clicking on segments of the polyline. To lock down the mask's shape and prevent accidental changes, switch the Polyline mode to Done using the Polyline toolbar or contextual menu.

B-Spline Mask Polygon toolbar

When a Polygon (or B-Spline) mask is added to a node, a toolbar appears above the viewer, offering easy access to modes. Hold the pointer over any button in the toolbar to display a tooltip that describes that button's function.

— Click: Click is the default option when creating a polyline (or B-Spline) mask. It is a Bézier style drawing tool. Clicking sets a control point and appends the next control point when you click again in a different location.
— **Draw**: Draw is a freehand drawing tool. It creates a mask similar to drawing with a pencil on paper. You can create a new mask using the Draw tool, or you can extend an existing open spline by clicking the Draw tool and starting to draw from the last control point.

— **Insert**: Insert adds a new control point along the spline.

— **Modify**: Modify allows you to safely move or smooth any exiting point along a spline without worrying about adding new points accidentally.

— **Done**: Prevents any point along the spline from being moved or modified. Also, new points cannot be added. You can, however, move and rotate the entire spline.

— **Closed**: Closes an open spline.

— **Smooth**: Changes the selected control point from a linear to a smooth curve.

— **Linear**: Changes the selected control point from a smooth curve to linear.

— **Select All**: Selects all the control points on the spline.

— **Keys**: Shows or hides the control points along the spline.

— **Handles**: Shows or hides the Bézier handles along the polyline.

— **Shape**: Places a reshape rectangle around the selected spline shape. Using the reshape rectangle, you can deform groups of control points or entire shapes much easier than modifying each point.

— **Delete**: Deletes the selected control point(s).

— **Reduce**: Opens a Freehand precision window that can be used to reduce the number of controls points on a spline. This can make the paint stroke easier to modify, especially if it has been created using the Draw tool.

— **Publish menu**: You can use the publish menu to select between publishing the control points or the path. Publishing is a form of parameter linking, it makes the selected item available for use by other controls. It also allows you to attach a control point to a tracker.

— **Follow Points**: Allows a selected point to follow the path of a published point. The point follows the published point using an offset position.

— **Double Poly**: Allows softening part of the spline curve while keeping other portions of the curve sharp. The double polyline is composed of two shapes, an inner and outer shape. The inner shape is the original shape from the single polyline, whereas the outer shape is used to determine the spread of the softness. The further the outer shape gets from the inner shape, the softer that segment of the shape becomes. Both polylines start with exactly the same shape as the original single polyline, keeping the mask sharp to start. Any animation already applied to the shape remains. To select the outer shape, press the Tab key to cycle between the onscreen controls until the dashed outline is visible, or you can select the outer polyline using the contextual menu’s Controls > Outer Polygon menu.

— **Multiframe**: Multiframe is a method of adjusting control points across multiple keyframes. The default setting of none only adjusts the control point of a spline on the current keyframe. Setting the menu to All adjusts the controls point for all keyframes. Prev settings adjust the current and previous keyframe while Next adjusts the current and next keyframe.

— **Onion Skinning**: Enabling onion skinning displays a mix in the viewer of the spline animation. It is useful when aligning spline animation and motion. Selecting Onion Skin Settings from the drop down menu allows you to set the number of overlapping frames.
— **Roto Assist:** Enable the Roto Assist button when you begin painting with the Polyline Stroke tool. The polyline points snap to the closest edge as you click to add points to the shape. A cyan outline indicates the points that have snapped to an edge. There are three main Roto Assist options selectable through the drop down menu:

— **Multiple Points:** When enabled, a single click on a high contrast edge adds multiple points to define the entire edge, instead of having to add each point individually. This is a one time only click. The second click reverts to single point edge detection.

— **Distance 8:** Opens a dialog where you can set the pixel range within which searching for an edge takes place.

— **Reset:** Used for resetting the snap attribute of all snapped points. After resetting, the points become unavailable for tracking.

Change the way the toolbar is displayed by right-clicking on the toolbar and selecting from the options displayed in the toolbar’s contextual menu. The functions of the buttons in this toolbar are explained in depth in the Polylines chapter.

**Ranges Mask [RNG]**

The Ranges node

**Ranges Mask Node Introduction**

Similar to Bitmap mask, the Ranges mask allows images from the node tree to act as masks for nodes and effects. Instead of creating a simple luminance-based mask from a given channel, Ranges allows spline-based selection of low, mid and high ranges, akin to Color Corrector.

**Inputs**

The Ranges mask node includes two inputs in the Node Editor.

— **Input:** The orange input accepts a 2D image from which the mask will be created.

— **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input combines the masks. How masks are combined is handled in the Paint mode menu in the Inspector.

**Basic Node Setup**

The Ranges node is not required for connecting an image into the effect mask input, but like the Bitmap node, it does provide options that are otherwise unavailable. It allows for selecting channels other than RGBA for the mask, as well as softness and clipping. In the node tree below, the Ranges node takes the composite out of the merge, creating a mask for the color correction.
A Ranges node selects a specific range in the image to create a mask.

Inspector

Ranges Mask controls

Controls Tab

The Controls tab is used to refine how the image connected to the orange input converts into the ranges mask.

Show View Controls

The Show View Controls checkbox is used to enable/disable the display of the mask’s onscreen controls in the viewer. Onscreen controls, including center position, polylines, angles, and others, do not appear when this checkbox is disabled, even when the node is selected.
**Level**

The Level control sets the transparency level of the pixels in the mask channel. When the value is 1.0, the mask is completely opaque (unless it has a soft edge). Lower values cause the mask to be partially transparent. The result is identical to lowering the blend control of an effect.

**NOTE:** Lowering the level of a mask lowers the values of all pixels covered by the mask in the mask channel. For example, if a Circle mask is placed over a Rectangle mask, lowering the level of the Circle mask lowers the values of all of the pixels in the mask channel, even though the Rectangle mask beneath it is still opaque.

**Filter**

This control selects the filtering algorithm used when applying Soft Edge to the mask.

- **Box:** This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.
- **Bartlett:** Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.
- **Multi-box:** When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”
- **Gaussian:** The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

**Soft Edge**

Use the Soft Edge slider to blur (feather) the mask, using the selected filter. Higher values cause the edge to fade off well beyond the boundaries of the mask. A value of 0.0 creates a crisp, well-defined edge.

**Paint Mode**

Connecting a mask to the effect mask input displays the Paint mode menu. The Paint mode is used to determine how the incoming mask for the effect mask input and the mask created in the node are combined.

- **Merge:** Merge is the default for all masks. The new mask is merged with the input mask.
- **Add:** The mask’s values add to the input mask’s values.
- **Subtract:** In the intersecting areas, the new mask values subtract from the input mask’s values.
- **Minimum:** Comparing the input mask’s values and the new mask, this displays the lowest (minimum) value.
- **Maximum:** Comparing the input mask’s values and the new mask, this displays the highest (maximum) value.
- **Average:** This calculates the average (half the sum) of the new mask and the input mask.
- **Multiply:** This multiplies the values of the input mask by the new mask’s values.
— **Replace:** The new mask completely replaces the input mask wherever they intersect. Areas that are zero (completely black) in the new mask do not affect the input mask.

— **Invert:** Areas of the input mask that are covered by the new mask are inverted; white becomes black and vice versa. Gray areas in the new mask are partially inverted.

— **Copy:** This mode completely discards the input mask and uses the new mask for all values.

— **Ignore:** This mode completely discards the new mask and uses the input mask for all values.

**Invert**

Selecting this checkbox inverts the entire mask. Unlike the Invert Paint mode, the checkbox affects all pixels, regardless of whether the new mask covers them or not.

**Center X and Y**

These controls adjust the position of the ranges mask.

**Fit Input**

This menu is used to select how the image source is treated if it does not fit the dimensions of the generated mask.

For example, below, a 720 x 576 image source (yellow) is used to generate a 1920 x 1080 mask (gray).

— **Crop:** If the image source is smaller than the generated mask, it is placed according to the X/Y controls, masking off only a portion of the mask. If the image source is larger than the generated mask it is placed according to the X/Y controls and cropped off at the borders of the mask.

— **Stretch:** The image source is stretched in X and Y to accommodate the full dimensions of the generated mask. This might lead to visible distortions of the image source.

— **Inside:** The image source is scaled uniformly until one of its dimensions (X or Y) fits the inside dimensions of the mask. Depending on the relative dimensions of the image source and mask background, either the image source’s width or height may be cropped to fit the respective dimension of the mask.
— **Width:** The image source is scaled uniformly until its width (X) fits the width of the mask. Depending on the relative dimensions of the image source and mask, the image source’s Y dimension might not fit the mask’s Y dimension, resulting in either cropping of the image source in Y or the image source not covering the mask’s height entirely.

— **Height:** The image source is scaled uniformly until its height (Y) fits the height of the mask. Depending on the relative dimensions of the image source and mask, the image source’s X dimension might not fit the mask’s X dimension, resulting in either cropping of the image source in X or the image source not covering the mask’s width entirely.

— **Outside:** The image source is scaled uniformly until one of its dimensions (X or Y) fits the outside dimensions of the mask. Depending on the relative dimensions of the image source and mask, either the image source’s width or height may be cropped or not fit the respective dimension of the mask.

**Channel**

The Channel menu determines the Channel of the input image used to create the mask. Choices include the red, green, blue, and alpha channels; the hue, luminance, or saturation values; or the auxiliary coverage channel of the input image (if one is provided).
**Shadows/Midtones/Highlights**

These buttons are used to select which range is output by the node as a mask. White pixels represent pixels that are considered to be part of the range, and black pixels are not included in the range. For example, choosing Shadows would show pixels considered to be shadows as white, and pixels that are not shadows as black. Mid gray pixels are only partly in the range and do not receive the full effect of any color adjustments to that range.

**Channel**

The Channel selection buttons shown in this tab can be used to extract a mask from the range of a specific color channel. By default, Fusion uses the luminance channel when the color ranges are examined.

**Mini Spline Editor**

The extent of the ranges is selected by manipulating the spline handles. There are four spline points, each with one Bézier handle. The two handles at the top represent the start of the shadow and highlight ranges; the two handles at the bottom represent the end of the range. The Bézier handles are used to control the falloff.

The midtones range has no specific control, since its range is understood to be the space between the shadow and highlight ranges. In other words, after low and high masks have been applied, midtones are everything else.

The X and Y text controls below the Mini Spline Editor can be used to enter precise positions for the selected Bézier point or handle.

**Presets**

This sets the splines to two commonly-used configurations. The Simple button gives a straightforward linear-weighted selection, while the Smooth button uses a more natural falloff.

**Common Controls**

**Image and Settings Tabs**

The Image and Settings tabs in the Inspector are also duplicated in other mask nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**Rectangle Mask [REC]**

The Rectangle node

**Rectangle Mask Node Introduction**

The Rectangle mask creates simple square or rectangular masks. By default, it creates a rectangle in the same aspect ratio as the comp, but independent control is offered over the width, height, and angle, providing for a wide variety of rectangular shapes.
**Inputs**

The Rectangle mask node includes a single effect mask input.

- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input combines the masks. How masks are combined is handled in the Paint mode menu in the Inspector.

**Basic Node Setup**

The Rectangle mask node is useful for generating rectangular shapes. Below, the Rectangle mask is used to generate a colored square by cutting a square shape from a background node.

A Rectangle mask node creating a colored square by masking a Background node

**Inspector**

Rectangle Mask controls

**Controls Tab**

The Controls tab is used to refine how the rectangle appears after drawing it in the viewer.

**Show View Controls**

The Show View Controls checkbox is used to enable/disable the display of the mask's onscreen controls in the viewer. Onscreen controls, including center position, polylines, angles, and others, do not appear when this checkbox is disabled, even when the node is selected.
**Level**

The Level control sets the transparency level of the pixels in the mask channel. When the value is 1.0, the mask is completely opaque (unless it has a soft edge). Lower values cause the mask to be partially transparent. The result is identical to lowering the Blend control of an effect.

**NOTE:** Lowering the level of a mask lowers the values of all pixels covered by the mask in the mask channel. For example, if a Circle mask is placed over a Rectangle mask, lowering the level of the Circle mask lowers the values of all the pixels in the mask channel, even though the Rectangle mask beneath it is still opaque.

**Filter**

This control selects the filtering algorithm used when applying Soft Edge to the mask.

- **Box:** This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.
- **Bartlett:** Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.
- **Multi-box:** When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”
- **Gaussian:** The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

**Soft Edge**

Use the Soft Edge slider to blur (feather) the mask, using the selected filter. Higher values cause the edge to fade off well beyond the boundaries of the mask. A value of 0.0 creates a crisp, well-defined edge.

**Border Width**

The Border Width control adjusts the thickness of the mask’s edge. When the solid checkbox is toggled on, the border thickens or narrows the mask. When the mask is not solid, the mask shape draws as an outline, and the width uses the Border Width setting.

**Paint Mode**

Connecting a mask to the effect mask input displays the Paint mode menu. The Paint mode is used to determine how the incoming mask for the effect mask input and the mask created in the node are combined.

- **Merge:** Merge is the default for all masks. The new mask is merged with the input mask.
- **Add:** The mask’s values add to the input mask’s values.
- **Subtract:** In the intersecting areas, the new mask values subtract from the input mask’s values.
- **Minimum:** Comparing the input mask’s values and the new mask, this displays the lowest (minimum) value.
- **Maximum:** Comparing the input mask’s values and the new mask, this displays the highest (maximum) value.
- **Average:** This calculates the average (half the sum) of the new mask and the input mask.
— **Multiply**: This multiplies the values of the input mask by the new mask’s values.
— **Replace**: The new mask completely replaces the input mask wherever they intersect. Areas that are zero (completely black) in the new mask do not affect the input mask.
— **Invert**: Areas of the input mask that are covered by the new mask are inverted: white becomes black and vice versa. Gray areas in the new mask are partially inverted.
— **Copy**: This mode completely discards the input mask and uses the new mask for all values.
— **Ignore**: This mode completely discards the new mask and uses the input mask for all values.

**Invert**

Selecting this checkbox inverts the entire mask. Unlike the Invert Paint mode, this checkbox affects all pixels, regardless of whether the new mask covers them.

**Solid**

When the Solid checkbox is enabled, the mask is filled to be transparent (white) unless inverted. When disabled, the spline is drawn as just an outline whose thickness is determined by the Border Width slider.

**Center X and Y**

These controls adjust the position of the Rectangle mask.

**Width and Height**

Use these controls to change the X or Y scale of the rectangular effect mask independently of each other. Alternatively, drag the edges of the rectangle in the viewer to interactively adjust its size.

**Corner Radius**

Corner Radius allows the corners of the Rectangle mask to be rounded. A value of 0.0 is not rounding at all, which means that the rectangle has sharp corners. A value of 1.0 applies the maximum amount of rounding to the corners.

**Angle**

Change the rotation angle of an effect mask by moving the Angle control left or right. Values can be entered in the provided input boxes. Alternatively, use the onscreen controls by dragging the little circle at the end of the dashed angle line to interactively adjust the rotation of the ellipse.

**Common Controls**

**Image and Settings Tabs**

The Image and Settings tabs in the Inspector are also duplicated in other mask nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Triangle Mask [TRI]

The Triangle node

Triangle Mask Node Introduction

The Triangle mask creates simple triangular masks. It is unique in that it has no Center, Size, or Angle control. Unlike most other types of masks, all three points of the triangle can attach to a tracker or motion path.

Inputs

The Triangle mask node includes a single effect mask input.

- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input combines the masks. How masks are combined is handled in the Paint mode menu in the Inspector.

Basic Node Setup

The Triangle mask node is useful for generating triangular shapes. Below, the Triangle mask is used to generate a colored triangle by cutting a triangular shape from a background node.

A Triangle mask node creating a colored Triangle shape by masking a Background node.
Inspector

Triangle Mask controls

Controls Tab

The Controls tab is used to refine how the triangle appears after drawing it in the viewer.

Show View Controls

The Show View Controls checkbox is used to enable/disable the display of the mask’s onscreen controls in the viewer. Onscreen controls, including center position, polylines, angles, and others, do not appear when this checkbox is disabled, even when the node is selected.

Level

The Level control sets the transparency level of the pixels in the mask channel. When the value is 1.0, the mask is completely opaque (unless it has a soft edge). Lower values cause the mask to be partially transparent. The result is identical to lowering the Blend control of an effect.

NOTE: Lowering the level of a mask lowers the values of all pixels covered by the mask in the mask channel. For example, if a Circle mask is placed over a Rectangle mask, lowering the level of the Circle mask lowers the values of all the pixels in the mask channel, even though the Rectangle mask beneath it is still opaque.

Filter

This control selects the filtering algorithm used when applying Soft Edge to the mask.

— Box: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.

— Bartlett: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.

— Multi-box: When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”

— Gaussian: The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.
**Soft Edge**

Use the Soft Edge slider to blur (feather) the mask, using the selected filter. Higher values cause the edge to fade off well beyond the boundaries of the mask. A value of 0.0 creates a crisp, well-defined edge.

**Border Width**

The Border Width control adjusts the thickness of the mask’s edge. When the solid checkbox is toggled on, the border thickens or narrows the mask. When the mask is not solid, the mask shape draws as an outline, and the width uses the Border Width setting.

**Paint Mode**

Connecting a mask to the effect mask input displays the Paint mode menu. The Paint mode is used to determine how the incoming mask for the effect mask input and the mask created in the node are combined.

- **Merge**: Merge is the default for all masks. The new mask is merged with the input mask.
- **Add**: The mask’s values add to the input mask’s values.
- **Subtract**: In the intersecting areas, the new mask values subtract from the input mask’s values.
- **Minimum**: Comparing the input mask’s values and the new mask, this displays the lowest (minimum) value.
- **Maximum**: Comparing the input mask’s values and the new mask, this displays the highest (maximum) value.
- **Average**: This calculates the average (half the sum) of the new mask and the input mask.
- **Multiply**: This multiplies the values of the input mask by the new mask’s values.
- **Replace**: The new mask completely replaces the input mask wherever they intersect. Areas that are zero (completely black) in the new mask do not affect the input mask.
- **Invert**: Areas of the input mask that are covered by the new mask are inverted: white becomes black and vice versa. Gray areas in the new mask are partially inverted.
- **Copy**: This mode completely discards the input mask and uses the new mask for all values.
- **Ignore**: This mode completely discards the new mask and uses the input mask for all values.

**Invert**

Selecting this checkbox inverts the entire mask. Unlike the Invert Paint mode, this checkbox affects all pixels, regardless of whether the new mask covers them.

**Solid**

When the Solid checkbox is enabled, the mask is filled to be transparent (white) unless inverted. When disabled, the spline is drawn as just an outline whose thickness is determined by the Border Width slider.

**Point 1, Point 2, Point 3**

These controls show the position coordinates of the three corners of the triangle. Each point can be published, connected to other controls, animated with a path, or attached to trackers. These tasks are performed by right-clicking the Position control or directly on the point in the viewer.

**Common Controls**

**Image and Settings Tabs**

The Image and Settings tabs in the Inspector are also duplicated in other mask nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Wand Mask [WND]

The Wand node

Wand Mask Node Introduction

The Wand mask masks an image based on a wand-style selection, similar to the Magic Wand tool found in Adobe Photoshop. As with a Bitmap mask, any image in the composition can be the source of the mask. Generally, the default is most useful, where the source image is the input of the node to which the mask is applied.

When adding a Wand mask to a node, a crosshair appears in the viewers. This crosshair should be positioned in the image to select the color used to create the Wand mask. The mask is created by examining the pixel color beneath the selection point and adding that color to the mask. The mask then expands to examine the pixels surrounding the selection point. Surrounding pixels are added to the mask if they are the same color. The mask stops expanding when no connecting pixels fall within the color range of the mask.

Inputs

The Wand mask node includes two inputs in the Node Editor.

— **Input:** The orange input accepts a 2D image from which the mask is created.

— **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input combines the masks. How masks are combined is handled in the Paint mode menu in the Inspector.

Basic Node Setup

The Wand mask node is not required for connecting an image into the effect mask input, but like the Bitmap node, it does provide options that are otherwise unavailable. It allows for selecting channels other than RGBA for the mask, as well as softness and clipping. In the node tree below, the Wand node takes the composite out of the merge, creating a mask for the color correction.

A Wand node selects a specific area in the image to create a mask.
Controls Tab

The Controls tab is used to refine how the mask appears after the Wand makes a selection in the viewer.

Show View Controls

The Show View Controls checkbox is used to enable/disable the display of the mask’s onscreen controls in the viewer. Onscreen controls, including center position, polylines, angles, and others, do not appear when this checkbox is disabled, even when the node is selected.

Level

The Level control sets the transparency level of the pixels in the mask channel. When the value is 1.0, the mask is completely opaque (unless it has a soft edge). Lower values cause the mask to be partially transparent. The result is identical to lowering the Blend control of an effect.

NOTE: Lowering the level of a mask lowers the values of all pixels covered by the mask in the mask channel. For example, if a Circle mask is placed over a Rectangle mask, lowering the level of the Circle mask lowers the values of all the pixels in the mask channel, even though the Rectangle mask beneath it is still opaque.

Filter

This control selects the filtering algorithm used when applying Soft Edge to the mask.

— **Box**: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.

— **Bartlett**: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.

— **Multi-box**: When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”
— **Gaussian:** The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

**Soft Edge**

Use the Soft Edge slider to blur (feather) the mask, using the selected filter. Higher values cause the edge to fade off well beyond the boundaries of the mask. A value of 0.0 creates a crisp, well-defined edge.

**Paint Mode**

Connecting a mask to the effect mask input displays the Paint mode menu. The Paint mode is used to determine how the incoming mask for the effect mask input and the mask created in the node are combined.

— **Merge:** Merge is the default for all masks. The new mask is merged with the input mask.
— **Add:** The mask's values add to the input mask's values.
— **Subtract:** In the intersecting areas, the new mask values subtract from the input mask's values.
— **Minimum:** Comparing the input mask's values and the new mask, this displays the lowest (minimum) value.
— **Maximum:** Comparing the input mask's values and the new mask, this displays the highest (maximum) value.
— **Average:** This calculates the average (half the sum) of the new mask and the input mask.
— **Multiply:** This multiplies the values of the input mask by the new mask's values.
— **Replace:** The new mask completely replaces the input mask wherever they intersect. Areas that are zero (completely black) in the new mask do not affect the input mask.
— **Invert:** Areas of the input mask that are covered by the new mask are inverted; white becomes black and vice versa. Gray areas in the new mask are partially inverted.
— **Copy:** This mode completely discards the input mask and uses the new mask for all values.
— **Ignore:** This mode completely discards the new mask and uses the input mask for all values.

**Invert**

Selecting this checkbox inverts the entire mask. Unlike the Invert Paint mode, this checkbox affects all pixels, regardless of whether the new mask covers them.

**Selection Point**

The Selection Point is a pair of X and Y coordinates that determines where in the source image the Wand mask derives its initial color sample. This control is also seen as a crosshair in the viewers. The selection point can be positioned manually, connected to a tracker, path, or other expressions.

**Color Space**

The Color Space button group determines the color space used when selecting the source color for the mask. The Wand mask can operate in RGB, YUV, HLS, or LAB color spaces.

**Channel**

The Channel button group is used to select whether the color that is masked comes from all three color channels of the image, the alpha channel, or an individual channel only.

The exact labels of the buttons depend on the color space selected for the Wand mask operation. If the color space is RGB, the options are R, G, or B. If YUV is the color space, the options are Y, U, or V.
Range
The Range slider controls the range of colors around the source color that are included in the mask. If the value is left at 0.0, only pixels of the same color as the source are considered part of the mask. The higher the value, the more that similar colors in the source are considered to be wholly part of the mask.

Range Soft Edge
The Range Soft Edge determines the falloff range of the colors selected. Any pixel within the range defined above are treated as 100% within the mask. If the soft range is set to 0.0, no other pixels are considered for the mask. Increasing the soft range increases the number of colors close to, but not quite within, the range included in the mask. These pixels are semitransparent in the mask.

The Common Controls

Nodes that create masks share several identical controls in the Inspector. This section describes controls that are common among mask nodes.

Inspector

Image Tab
The controls in this tab set the resolution and clipping method used by the generated mask.

Output Size
The Output size menu sets the resolution of the mask node’s output. The three options include the default resolution of the comp, the source input’s resolution on nodes that have an input, or a custom resolution.

Custom
When selecting Custom from the Output Size menu, the width, height, and pixel aspect of the mask created are locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the mask produced is changed to match. Disabling this option can be useful for building a composition at a different resolution than the eventual target resolution for the final render.

— Width and Height: This pair of controls is used to set the Width and Height dimensions of the mask to be created.
— Pixel Aspect: This control is used to specify the Pixel Aspect ratio of the created mask. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer monitor), and an aspect of 0.91 would create a slightly rectangular pixel (like an NTSC monitor).
— **Depth:** The Depth drop-down menu is used to set the pixel color depth of the image created by the mask. 32-bit pixels require four times the memory of 8-bit pixels but have far greater accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

**NOTE:** Right-click on the Width, Height, or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options sets the width, height, and pixel aspect to the values for that format.

**Clipping Mode**

This option determines how the domain of definition rendering handles edges. The Clipping mode is most important when blur or softness is applied, which may require samples from portions of the image outside the current domain.

— **Frame:** The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame is treated as black/transparent.

— **None:** Setting this option to None does not perform any source image clipping. Any data required to process the node’s effect that would usually be outside the upstream DoD is treated as black/transparent.

**Settings Tab**

The Settings tab in the Inspector can be found on every tool in the Mask category. The Settings controls are even found on third-party plug-in tools. The controls are consistent and work the same way for each tool, although some tools do include one or two individual options, which are also covered here.
Motion Blur

- **Motion Blur:** This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.

- **Quality:** Quality determines the number of samples used to create the blur. A quality setting of 2 causes Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.

- **Shutter Angle:** Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one full frame exposure. Higher values are possible and can be used to create interesting effects.

- **Center Bias:** Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.

- **Sample Spread:** Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

Use GPU

The Use GPU menu has three settings. Setting the menu to Disable turns off hardware-accelerated rendering using the graphics card in your computer. Enabled uses the hardware, and Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 107

Matte Nodes

This chapter details the Matte nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Alpha Divide [ADV]

The Alpha Divide node

Alpha Divide Node Introduction
As the name gives away, the Alpha Divide's sole purpose is to divide an incoming image’s color channels by its alpha channel. When you color correct an image that contains a premultiplied alpha channel, first apply an Alpha Divide node before any color correction node to create a non-premultiplied image. Then you can perform the color correction. After the color correction, add an Alpha Multiply node to return the image to its premultiplied state.

Inputs
The Alpha Divide node includes two inputs in the Node Editor.

- **Input**: The orange input accepts a 2D image with a premultiplied Alpha.
- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the Alpha divide occurs. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup
The Alpha Divide node is placed before any color correction is done to an image with a premultiplied Alpha channel. Here the MediaIn node is assumed to have a premultiplied Alpha channel. The Alpha Divide node is inserted, and then color correction nodes operate on the “straight” Alpha. An Alpha Multiply node is placed at the end of the chain to premultiply the Alpha channel again. If only a single color correction node is used, then the Pre-Divide/Post-Multiply checkbox on the Options tab can be used in place of the Alpha Divide/Alpha Multiple nodes.

Inspector
This node has no controls.
Alpha Multiply Node Introduction

As the name gives away, the Alpha Multiply’s sole purpose is to multiply an image's color channels by its alpha channel. When you color correct an image that contains a premultiplied alpha channel, first apply an Alpha Divide node before any color correction node to create a non-premultiplied image. Then you can perform the color correction. After the color correction, add an Alpha Multiply node to return the image to its premultiplied state.

Inputs

The Alpha Multiply node includes two inputs in the Node Editor.

- **Input**: The orange input accepts a 2D image with a “straight” or non-premultiplied alpha.
- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the Alpha multiply occurs. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

The Alpha Multiply node is placed after color correction is done to an image with a premultiplied Alpha channel. Here the MediaIn node is assumed to have a premultiplied Alpha channel. The Alpha Divide node is inserted, and then color correction nodes operate on the “straight” Alpha. An Alpha Multiply node is placed at the end of the chain to premultiply the Alpha channel again. If only a single color correction node is used, then the Pre-Divide/Post-Multiply checkbox on the Options tab can be used in place of the Alpha Divide/Alpha Multiple nodes.

Inspector

This node has no controls.
Chroma Keyer [CKY]

The Chroma Keyer node

Chroma Keyer Node Introduction

The Chroma Keyer node creates an alpha channel (matte) for an image by removing selected colors from the scene. Unlike the Delta Keyer or Primatte, which use specific optimizations for keying from blue and green colors, the Chroma Keyer works equally well with any color.

**NOTE:** When working with blue- or green-screen shots, it is best to use the Delta Keyer or Primatte node, rather than the more general purpose Chroma Keyer node.

Inputs

The Chroma Keyer node includes four inputs in the Node Editor.

— **Input:** The orange input accepts a 2D image that contains the color you want to be keyed for transparency.

— **Garbage Matte:** The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be made transparent. The garbage matte is applied directly to the alpha channel of the image.

— **Solid Matte:** The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be fully opaque.

— **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the alpha multiply occurs. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

The Chroma Keyer node takes in a 2D image like the MediaIn node below and removes a color that you identify by dragging over it in the viewer. The result is that the selected color is replaced with transparency, allowing you to composite the image as the foreground in a Merge node.
A Chomra Keyer node creating transparency on the MediaIn node.

**Inspector**

The Chroma Key tab

**Chroma Key Tab**

The Chroma Key tab is used to make the initial selection of color for keying.

**Key Type**

The Key Type menu determines the selection method used for the matte creation.

- Chroma: The Chroma method creates a matte based on the RGB values of the selected color range.
- Color: The Color method creates a matte based on the hue of the selected color range.

**Color Range**

Colors are made transparent by selecting the Chroma Keyer node in the node tree, and then dragging a selection around the colors in the viewer. The range controls update automatically to represent the current color selection. You can tweak the range sliders slightly, although most often selecting colors in the displays is all that is required.

**Lock Color Picking**

When this checkbox is activated, selecting colors from the viewer is disabled to prevent accidental addition to the range. It is a good idea to activate this checkbox once you make the color selection for the matte. All other controls in the node remain editable.

**Soft Range**

This control softens the selected color range, adding additional colors into the matte.
**Reset Color Ranges**

Clicking this button resets the Chroma Keyer’s range controls, discarding all color selections. All other sliders and controls maintain their values.

![Chroma Key Image tab](image)

The Chroma Key Image tab

**Image Tab**

The Image tab primarily handles removing spill color on the foreground subject. Color spill occurs when light containing the color you are removing is reflected onto the foreground subject.

**Spill Color**

This menu selects the color used as the base for all spill suppression techniques.

**Spill Suppression**

This slider sets the amount of spill suppression applied to the foreground subject.

When this slider is set to 0, no spill suppression is applied.

**Spill Method**

This menu selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color and is the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue. Use this mode only for very troublesome shots. Most likely you will have to add strong color correction after the key to get, for example, your skin tones back.

**Fringe Gamma**

This control is used to adjust the brightness of the fringe or halo that surrounds the keyed image.

**Fringe Size**

This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**

Fringe Shape forces the fringe toward the external edge of the image or toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size slider’s value is large.
Cyan/Red, Magenta/Green, and Yellow/Blue

Use these three controls to color correct the fringe of the image. This is useful for correcting semitransparent pixels that still contain color from the original background to match the new background.

The Chroma Key Matte tab

Matte Tab

The Matte tab refines the softness, density, and overall fit of the resulting matte.

Filter

This control selects the filtering algorithm used when applying blur to the matte.

— **Box**: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.

— **Bartlett**: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.

— **Multi-box**: When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”

— **Gaussian**: The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

Blur

Matte Blur blurs the edge of the matte based on the Filter menu setting. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur applied to the matte.

Clipping Mode

This option determines how edges are handled when performing domain of definition rendering. This is profoundly important when blurring the matte, which may require samples from portions of the image outside the current domain.
— **Frame:** The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

— **Domain:** Setting this option to Domain will respect the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

— **None:** Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD will be treated as black/transparent.

**Contract/Expand**

This slider shrinks or grows the semitransparent areas of the matte. Values above 0.0 expand the matte, while values below 0.0 contract it.

This control is usually used in conjunction with the Matte Blur to take the hard edge of a matte and reduce fringing. Since this control affects only semitransparent areas, it will have no effect on a matte’s hard edge.

**Gamma**

Matte Gamma raises or lowers the values of the matte in the semitransparent areas. Higher values cause the gray areas to become more opaque, and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

Since this control affects only semitransparent areas, it will have no effect on a matte’s hard edge.

**Threshold**

This range slider sets the lower threshold using the handle on the left and sets the upper threshold using the handle on the right.

Any value below the lower threshold setting becomes black or transparent in the matte.

Any value above the upper threshold setting becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

This control is often used to reject salt and pepper noise in the matte.

**Restore Fringe**

This restores the edge of the matte around the keyed subject. Often when keying, the edge of the subject where you have hair is clipped out. Restore Fringe brings back that edge while keeping the matte solid.

**Invert Matte**

When this checkbox is selected, the alpha channel created by the keyer is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

**Solid Matte**

Solid Mattes are mask nodes or images connected to the solid matte input on the node. The solid matte is applied directly to the alpha channel of the image. Generally, solid mattes are used to hold out keying in areas you want to remain opaque, such as someone with blue eyes against a blue screen.

Enabling Invert will invert the solid matte, before it is combined with the source alpha.
**Garbage Matte**

Garbage mattes are mask nodes or images connected to the garbage matte input on the node. The garbage matte is applied directly to the alpha channel of the image. Generally, garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a garbage matte with the opposite effect of the matte applied to the keyer.

Enabling Invert will invert the garbage matte, before it is combined with the source alpha.

**Post-Multiply Image**

Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered premultiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information on these Merge node settings, see Chapter 35, “Composite Nodes,” in the Fusion Reference Manual or Chapter 95 in the DaVinci Resolve Reference Manual.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**Clean Plate**

![The Clean Plate node](image)

**Clean Plate Node Introduction**

The Clean Plate tool is a pre-keying node used to generate an image of the green or blue color screen to smooth out the lighting differences. The output of the Clean Plate is later connected to the Clean Plate input on the Delta Keyer so it can key fine detail without choking or clipping the matte.

**How to Create a Clean Plate**

Creating a clean plate is the opposite of creating a key. When keying, you try to remove the green or blue color. When creating a clean plate, you try to keep as much of the blue- or green-screen as possible. By
box selecting areas of the screen color in the viewer, you end up with an image of the green/blue screen. A transparent cutout represents everything that is not part of the blue or green screen.

Once you have the selection, the Erode control expands the pre-matte, removing any small pixels of non-green/blue screen around the edges. Then, growing the pre-matte fills in the holes until you have a solid blue or green image.

**Inputs**

The Clean Plate node includes three inputs in the Node Editor.

- **Input**: The orange input accepts a 2D image that contains the green or blue screen.
- **Garbage Matte**: The white garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be excluded from the clean plate. For a clean plate, garbage mattes should contain areas that are not part of the blue or green screen.
- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the clean plate is generated. An effects mask is applied to the tool after the tool is processed.

**Basic Node Setup**

The Clean Plate node and the Delta Keyer are two separate branches stemming from the main image you want to key. The green-screen or blue-screen clip is breached to connect to both the orange image input on the Clean Plate and the orange image input on the Delta Keyer. The output of the clean plate is then connected to the magenta clean plate input on the Delta Keyer. The output of the Delta Keyer is then used as the foreground to a Merge.
The Clean Plate tab

**Plate Tab**

The Plate tab contains the primary tools for creating a clean plate. Using this tab, you drag over the areas in the viewer, and then use the Erode and Grow Edges sliders to create the clean plate.

**Method**

The Method menu selects the type of color selection you use when sampling colors in the viewer.

- **Color**: Color uses a difference method to separate the background color. This works well on screen colors that are even.
- **Ranges**: Ranges uses a chroma range method to separate the background color. This is a better option for shadowed screen or screens that have different colors.

**Matte Threshold**

This range slider sets the lower threshold using the handle on the left and sets the upper threshold using the handle on the right.

Any value below the lower threshold becomes black or transparent in the matte.

Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values. This control is often used to reject salt and pepper noise in the matte.

**Erode**

The Erode slider decreases the size of the screen area. It is used to eat away at small non-screen color pixels that may interfere with creating a smooth green- or blue-screen clean plate.

**Crop**

Crop trims in from the edges of the image.
Grow Edges
The Grow Edges slider expands the color of the edges to fill in holes until fully green or blue screen is created.

Fill
The Fill checkbox fills in remaining holes with color from the surrounding screen color.

Time Mode
— **Sequence**: Generates a new clean plate every frame.
— **Hold Frame**: Holds the clean plate at a single frame.

The Clean Plate Mask tab

Mask Tab
The Mask tab is used to invert the mask connected to the garbage mask input on the node. The garbage mask can be applied to clear areas before growing edges or filling remaining holes.

Invert
Invert uses the transparent parts of the mask to clear the image.

Common Controls

Settings Tab
The Settings tab in the Inspector is also duplicated in other matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Delta Keyer

Delta Keyer Node Introduction
The Delta Keyer is an advanced color difference keyer, with many features and controls for tuning the matte and separating the subject from a blue or green screen.
It contains several keying systems: the Key tab is the master difference keyer and Pre-Matte is a built-in clean plate to smooth out screen color. Tuning, Fringe, and Matte finish the keying process. The tabs are laid out in the rough order you tend to use them.

**Inputs**

The Delta Keyer node includes five inputs in the Node Editor.

- **Input**: The orange input accepts a 2D image that contains the color you want to be keyed for transparency.
- **Garbage Matte**: The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be made transparent. The garbage matte is applied directly to the alpha channel of the image.
- **Solid Matte**: The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be fully opaque.
- **Clean Plate**: Accepts the resulting image from the Clean Plate node.
- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the keying occurs. An effects mask is applied to the tool after the tool is processed.

**Basic Node Setup**

A single Delta keyer rarely gets perfect results because most green- or blue-screen shots have problems that the keyer is not made to handle. Keyers often need the help of garbage mattes or solid mattes created with a Polygon or B-Spline node. Shots can also require more than just one keyer to achieve perfect results. That is shown in one of the examples below, where one Delta Keyer is used to create a hard inner white matte, while a second Delta Keyer is used to capture the soft edges. The core matte below is then connected into the solid matte input on the second Delta Keyer. Color correction, including spill suppression, is best handled as a separate branch in your node tree. Separating your matte from your color correction using underlays makes it clear what branch of nodes is performing what operation.

Starting point for a Delta Keyer setup
An expanded key setup with two Delta Keyers, a Polygon and B-Spline nodes for mattes, and a branch for color correction

**Inspector**

**Key Tab View Mode**

At the top of the Inspector is the View Mode menu. The default selection shows the final result. You can change the view to see various intermediate stages of the keying process.

- **Pre Matte**: Displays the output of the Pre Matte key.
- **Matte**: Displays the alpha of the key before being combined with solid and garbage masks. When displaying the matte, set the viewer to show the alpha channel.
- **Tuning Ranges**: Displays a false color for Shadow, Midtone, and Highlight ranges of the image. Shadows are in the red channel, Midtones are in the green channel, and Highlights are in the blue channel.
- **Status**: Displays information to indicate areas that are solid, transparent, or in between. It also displays areas that have been affected by matte adjustments, such as thresholding or erode/dilate and areas affected by the solid mask.
- **Intermediate Result**: The untouched source image color channels combined with the final matte. Optionally, combine this output with additional Delta Keyer nodes.
- **Final Result**: The final keyed image with spill suppression, ready to merge onto a scene.
The Key tab is where most keying begins. It is used to select the screen color.

**Background Color**
This is the color of the blue or green screen, sometimes called the screen color. To create the key with the Delta Keyer, use the background color Eyedropper to select the screen color from the image.

**Pre-Blur**
Applies a blur before generating the alpha. This can help with certain types of noise, edge enhancements, and artifacts in the source image.

**Gain**
Gain increases the influence of the screen color, causing those areas to become more transparent.

**Balance**
A color difference keyer, like the Delta Keyer, compares the differences between the dominant channel determined by the selected background color and the other two channels. Adjusting balance determines the proportions of the other two channels. A value of 0 uses the minimum of the other two channels, where a value of 1 uses the maximum. A value of 0.5 uses half of each.
**Lock Alpha/Spill Removal Color Balance Reference**

Unlocking this allows you to use different color references when generating the alpha and when determining how much of the background color to subtract from the image. When enabled, spill and color are combined.

**Color Balance Reference**

The Color balance reference controls adjust for lighting or white balance that might be reducing background color purity and saturation. A correction is applied based on the reference of a neutral-colored object when generating the key and determining the amount of background color subtraction, without altering the background color that is subtracted.

---

**Pre Matte Tab**

The Pre Matte tab is in some ways a garbage matte keyer that occurs before the delta keyer process. It is used to even out the screen color before a more delicate key is done. After selecting the initial screen color, you can switch to the Pre Matte tab and view the PreMatte Out from view mode menu at the top of the Inspector. The Pre Matte works on ranges of color, so you start by dragging a bounding box around areas where lighting is different from the initial screen color pick. Use the Soft range to expand, and Erode to cut away the edges.

Once you have a more even screen selection, you can move to the Matte tab.

**Soft Range**

The Soft Range extends the range of selected color and rolloff of the screen color.

**Erode**

Erode contracts the edge of the pre matte, so the edge detail does not clip.

**Blur**

This softens the edges of the pre matte.
Pre Matte Range
These controls update automatically to represent the current color selection. The controls tweak the selection slightly, although selecting colors in the viewer is all that is required.

Lock Color Picking
When this checkbox is activated, it prevents the accidental growth of the selected range by selecting more colors from the view. It is a good idea to activate this checkbox after selecting the color for the matte. All other controls in the node remain editable.

Reset Pre Matte Ranges
This button discards all color selection by resetting the ranges but maintains all other slider and control values.

Matte Tab
The Matte tab refines the alpha of the key, combined with any solid and garbage masks connected to the node. When using the matte tab, set the viewer to display the alpha channel of the Delta Keyer’s final output.

Threshold
This range slider sets the lower threshold using the handle on the left and sets the upper threshold using the handle on the right.

Any value below the lower threshold setting becomes black or transparent in the matte.

Any value above the upper threshold setting becomes white or opaque in the matte. All values within the range maintain their relative transparency values.
**Restore Fringe**
This restores the edge of the matte around the keyed subject. Often when keying, clipping occurs around the edge of the subject where there is hair. Restore Fringe brings back that edge while keeping the matte solid.

**Erode/Dilate**
Expands or contracts the matte.

**Blur**
Softens the matte.

**Clean Foreground**
Fills slightly transparent (light gray) areas of the matte.

**Clean Background**
Clips the bottom dark range of the matte.

**Replace Mode**
Determines how matte adjustments restore color to the image.

- **None**: No color replacement. Matte processing does not affect the color.
- **Source**: The color from the original image.
- **Hard Color**: A solid color.
- **Soft Color**: A solid color weighted by how much background color was originally removed.

**Replace Color**
The color used with the Hard Color and Soft Color replace modes.

---

The Delta Keyer Fringe tab

**Fringe Tab**
The Fringe tab handles the majority of spill suppression in the Delta Keyer. Spill suppression is a form of color correction that attempts to remove the screen color from the fringe of the matte.

Spill is the transmission of the screen color through the semitransparent areas of the alpha channel. In the case of blue- or green-screen keying, this usually causes the color of the background to become apparent in the edges of the foreground subject.
**Spill Method**
This selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color and is the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue screens. Use this mode only for very troublesome shots.

**Spill Suppression**
When this slider is set to 0, no spill suppression is applied to the image. Increasing the slider increases the strength of the spill method.

**Fringe Gamma**
This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.

**Fringe Size**
This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**
Fringe Shape presses the fringe toward the external edge of the image or pulls it toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size value is large.

**Cyan/Red, Magenta/Green, and Yellow/Blue**
Use these three controls to color correct the fringe of the image.

This is useful for correcting semitransparent pixels that still contain color from the original background to match the new background.

![The Delta Keyer Tuning tab](image-url)
**Tuning Tab**

The Tuning tab is an advanced tab that allows you to determine the size of the shadow, midtone, and highlight ranges. By modifying the ranges, you can select the strength of the matte and spill suppression based on tonal values.

**Range Controls**

The range controls define how much color is considered to fall into the shadows, midtones, and highlights areas of the image. The spline controls allow for easy adjusting of the tonal ranges of each Shadow and Highlight tonal map.

**Simple/Smooth**

The Simple button sets the range to be linear. The Smooth button sets a smooth tonal gradient for the ranges.

**Lock Alpha/Spill Removal Tuning**

When this checkbox is disabled, separate tuning controls are used when generating the alpha and when determining how much of the background color to subtract from the image.

- **Shadows**: Adjusts the strength of the key in darker areas of the background.
- **Midtones**: Adjusts the strength of the key in midtone areas of the background.
- **Highlights**: Adjusts the strength of the key in brighter areas of the background.

![Delta Keyer Mask tab](image)

The Delta Keyer Mask tab

**Mask Tab**

The Mask tab determines how the solid and garbage mattes are applied to the key.
**Solid Source Alpha**

Used to combine the existing alpha from the source image with the solid mask.

- **Ignore**: Does not combine the alpha from the source image.
- **Add**: Solid areas of the source image alpha are made solid in the solid mask.
- **Subtract**: Transparent areas of the source image alpha are made transparent in the solid mask.

**Solid Replace Mode**

This determines how the solid mask restores color to the image.

- **None**: No color replacement. The solid mask does not affect the color.
- **Source**: The color from the original image.
- **Hard Color**: A solid color.
- **Soft Color**: A solid color weighted by how much background color was originally removed.

**Solid Replace Color**

The color used with the Hard Color and Soft Color replace modes.

- **Invert**: Inverts the solid mask, before it is combined with the source alpha.

**Garbage Mask**

- **Invert**: Normally, solid areas of a garbage mask remove the image. When inverted, the transparent areas of the mask remove the image.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**Difference Keyer [DfK]**

![The Difference Keyer node]

**Difference Keyer Node Introduction**

Difference keying is a process that produces a matte based on the differences between two images. A difference key uses two input images: one containing the subject with the background and another containing the background without the subject.

Although the process sounds reasonable at first glance, subtle variations in the camera position from shot to shot usually make it difficult to get clean results. Think of the futile attempt of trying to key smoke
in front of a brick wall and using a clean plate of the brick wall as your difference input. Part of the wall’s structure is always visible in this keying method. Instead, a Difference Keyer is often used to produce a rough matte that is combined with other nodes to produce a more detailed matte.

Inputs

The Difference Keyer node includes four inputs in the Node Editor.

- **Background**: The orange background input accepts a 2D image that contains just the set without your subject.
- **Foreground**: The green foreground input accepts a 2D image that contains the shot with your subject in the frame.
- **Garbage Matte**: The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be made transparent.
- **Solid Matte**: The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be fully opaque.
- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the difference matte occurs. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

When you do not have content shot on a blue or green screen, the Difference Keyer can be one node in a chain of many used to extract an object from the background. The example below has the MediaIn1 as the main subject and a clean background shot without the subject (Background). A B-Spline is used to limit the area the Difference Keyer must deal with for extraction. The result is a matte that can be used to help but not solve the key.

A Difference Keyer with two inputs: one of the subject on a background and the other of just the background
Inspector

The Difference Keyer Controls tab

Controls Tab

The Controls tab in the Difference Keyer contains all the parameters for adjusting the quality of the matte.

Threshold

This range slider sets the lower threshold using the handle on the left and sets the upper threshold using the handle on the right. Adjusting them defines a range of difference values between the images to create a matte.

A difference below the lower threshold setting becomes black or transparent in the matte.

Any difference above the upper threshold setting becomes white or opaque in the matte.

The difference values in the range in between create a grayscale matte.

Filter

This control selects the filtering algorithm used when applying a blur to the matte.

— **Box**: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.

— **Bartlett**: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.

— **Multi-box**: When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”

— **Gaussian**: The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.
Blur
This blurs the edge of the matte using the method selected in the Filter menu. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur.

Clipping Mode
This option determines how edges are handled when performing domain of definition rendering. This is profoundly important when blurring the matte, which may require samples from portions of the image outside the current domain.

— **Frame:** The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame is treated as black/transparent.
— **Domain:** Setting this option to Domain respects the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.
— **None:** Setting this option to None does not perform any source image clipping at all. This means that any data required to process the node’s effect that would usually be outside the upstream DoD is treated as black/transparent.

Contract/Expand
This slider shrinks or grows the semitransparent areas of the matte. Values above 0.0 expand the matte, while values below 0.0 contract it.

This control is usually used in conjunction with the blur to take the hard edge of a matte and reduce fringing. Since this control affects only semitransparent areas, it has no effect on a matte’s hard edge.

Gamma
Matte Gamma raises or lowers the values of the matte in the semitransparent areas. Higher values cause the gray areas to be more opaque, and lower values cause the gray areas to be more transparent. Wholly black or white regions of the matte remain unaffected.

Invert
Selecting this checkbox inverts the matte, causing all transparent areas to be opaque and all opaque areas to be transparent.

Solid Matte
Solid Mattes are mask nodes or images connected to the solid matte input on the node. The solid matte is applied directly to the alpha channel of the image. Generally, solid mattes are used to hold out keying in areas you want to remain opaque, such as someone with blue eyes against a blue screen.

Enabling Invert, inverts the solid matte before it is combined with the source alpha.

Garbage Matte
Garbage mattes are mask nodes or images connected to the garbage matte input on the node. The garbage matte is applied directly to the alpha channel of the image. Generally, garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a garbage matte with the opposite effect of the matte applied to the keyer.
Enabling Invert inverts the garbage matte before it is combined with the source alpha.

**Post-Multiply Image**

Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox, and the image can no longer be considered premultiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information on these Merge node settings, see Chapter 35, “Composite Nodes” in the Fusion Reference Manual or Chapter 95 in the DaVinci Resolve Reference Manual.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**Luma Keyer [LKY]**

The Luma Keyer node

**Luma Keyer Node Introduction**

The Luma Keyer node uses the overall luminance of an image to create an Alpha channel. The label of this node may seem misleading since it allows pulling mattes from almost any channel. In some respects, it is more accurate to call this node an all-purpose channel keyer, but its primary purpose is for extracting alpha channels based on luminance.

**Inputs**

The Luma Keyer node includes four inputs in the Node Editor.

- **Input**: The orange input accepts a 2D image that contains the luminance values you want to be keyed for transparency.
- **Garbage Matte**: The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be made transparent. The garbage matte is applied directly to the alpha channel of the image.
- **Solid Matte**: The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be fully opaque.
— **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the luminance key occurs. An effects mask is applied to the tool after the tool is processed.

**Basic Node Setup**

The Luma Keyer takes an input from an image with significant luminance difference to extract a key. You can then use the output of the Luma Keyer into any mask input.

![Diagram showing Luma Keyer output connecting into an effect mask on a Merge node](image)

**Inspector**

![Inspector tab for LumaKeyer1 showing controls](image)

**Controls Tab**

The Controls tab in the Luma Keyer contains all the parameters for adjusting the quality of the matte.

**Channel**

This menu selects the color channel used for creating the matte. Select from the Red, Green, Blue, Alpha, Hue, Luminance, Saturation, and Depth (Z-buffer) channels.
Threshold
This range slider sets the lower threshold using the handle on the left and sets the upper threshold using
the handle on the right. Adjusting them defines a range of luminance values to create a matte.

A value below the lower threshold setting becomes black or transparent in the matte.

Any value above the upper threshold setting becomes white or opaque in the matte.

The values within the range create a grayscale matte.

Filter
This control selects the filtering algorithm used when applying a blur to the matte.

— **Box**: This is the fastest method but at reduced quality. Box is best suited for minimal
  amounts of blur.
— **Bartlett**: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed
  and quality.
— **Multi-box**: When selecting this filter, the Num Passes slider appears and lets you control the quality.
  At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above,
  results are usually as good as Gaussian, in less time and with no edge “ringing.”
— **Gaussian**: The Gaussian filter uses a true Gaussian approximation and gives excellent results, but
  it is a little slower than the other filters. In some cases, it can produce an extremely slight edge
  “ringing” on floating-point pixels.

Blur
This blurs the edge of the matte using the method selected in the Filter menu. A value of zero results in a
sharp, cutout-like hard edge. The higher the value, the more blur.

Clipping Mode
This option determines how edges are handled when performing domain of definition rendering. This is
profoundly important when blurring the matte, which may require samples from portions of the image
outside the current domain.

— **Frame**: The default option is Frame, which automatically sets the node’s domain of definition to use
  the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD
  is smaller than the frame, the remaining area in the frame is treated as black/transparent.
— **Domain**: Setting this option to Domain respects the upstream domain of definition when applying
  the node’s effect. This can have adverse clipping effects in situations where the node employs a
  large filter.
— **None**: Setting this option to None does not perform any source image clipping at all. This means
  that any data required to process the node’s effect that is usually outside the upstream DoD is
  treated as black/transparent.
**Contract/Expand**
This slider shrinks or grows the semitransparent areas of the matte. Values above 0.0 expand the matte, while values below 0.0 contract it.

This control is usually used in conjunction with the blur to take the hard edge of a matte and reduce fringing. Since this control affects only semitransparent areas, it has no effect on a matte’s hard edge.

**Gamma**
Matte Gamma raises or lowers the values of the matte in the semitransparent areas. Higher values cause the gray areas to be more opaque, and lower values cause the gray areas to be more transparent. Wholly black or white regions of the matte remain unaffected.

**Invert**
Selecting this checkbox inverts the matte, causing all transparent areas to be opaque and all opaque areas to be transparent.

**Solid Matte**
Solid mattes are mask nodes or images connected to the solid matte input on the node. The solid matte is applied directly to the alpha channel of the image. Generally, solid mattes are used to hold out keying in areas you want to remain opaque, such as someone with blue eyes against a blue screen.

Enabling Invert inverts the solid matte before it is combined with the source alpha.

**Garbage Matte**
Garbage mattes are mask nodes or images connected to the garbage matte input on the node. The garbage matte is applied directly to the alpha channel of the image. Generally, garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a garbage matte with the opposite effect of the matte applied to the keyer.

Enabling Invert inverts the garbage matte before it is combined with the source alpha.

**Post-Multiply Image**
Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered premultiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information on these Merge node settings, see Chapter 35, “Composite Nodes,” in the Fusion Reference Manual or Chapter 95 in the DaVinci Resolve Reference Manual.

**Common Controls**

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Matte Control [MAT]

Matte Control Node Introduction

Keyer nodes are used to create an alpha channel on an image that does not have one. The Matte Control node is used to combine and manipulate the alpha channels embedded in images as well as masks created by masking tools.

Typically, you add this node to copy a color channel or alpha channel from the foreground input to the background input, or to combine alpha channels from the two images.

Inputs

The Matte Control node includes four inputs in the Node Editor.

— **Background:** The orange background input accepts a 2D image that receives the foreground image alpha channel (or some other channel you want to copy to the background).

— **Foreground:** The green foreground input accepts a 2D image that contains an alpha channel (or some other channel) you want to be applied to the background image.

— **Garbage Matte:** The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the foreground/background combination that fall within the matte to be made transparent.

— **Solid Matte:** The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the foreground/background combination that fall within the matte to be fully opaque.

— **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the matte control occurs. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

Below, the Matte Control node is set up to copy the foreground (green) input’s alpha channel into the background (orange) input. The output of the Matte Control is then an image with an alpha channel used as the foreground composite in the Merge node.
A Matte Control embedded an alpha from the foreground input to the background input.

**Inspector**

**Matte Tab**

The Matte tab combines and modifies alpha or color channels from an image in the foreground input with the background image.

**Combine**

Use this menu to select which operation is applied. The default is set to None for no operation.

- **None**: This causes the foreground image to be ignored.
- **Combine Red**: This combines the foreground red channel to the background alpha channel.
- **Combine Green**: This combines the foreground green channel to the background alpha channel.
- **Combine Blue**: This combines the foreground blue channel with the background alpha channel.
- **Combine Alpha**: This combines the foreground alpha channel with the background alpha channel.
- **Solid**: This causes the background alpha channel to become completely opaque.
- **Clear**: This causes the background alpha channel to become completely transparent.
**Combine Operation**

Use this menu to select the method used to combine the foreground channel with the background.

- **Copy:** This copies the foreground source over the background alpha, overwriting any existing alpha in the background.
- **Add:** This adds the foreground source to the background alpha.
- **Subtract:** This subtracts the foreground source from the background alpha.
- **Inverse Subtract:** This subtracts the background alpha from the foreground source.
- **Maximum:** This compares the foreground source and the background alpha and takes the value from the pixel with the highest value.
- **Minimum:** This compares the foreground source and the background alpha and takes the value from the pixel with the lowest value.
- **And:** This performs a logical AND on the two values.
- **Or:** This performs a logical OR on the values.
- **Merge Over:** This merges the foreground source channel over the background alpha channel.
- **Merge Under:** This merges the foreground source channel under the background alpha channel.

**Filter**

Selects the Filter that is used when blurring the matte.

- **Box Blur:** This option applies a Box Blur effect to the whole image. This method is faster than the Gaussian blur but produces a lower-quality result.
- **Bartlett:** Bartlett applies a more subtle, anti-aliased blur filter.
- **Multi-Box:** Multi-Box uses a box filter layered in multiple passes to approximate a Gaussian shape. With a moderate number of passes (e.g., four), a high-quality blur can be obtained, often faster than the Gaussian filter and without any ringing.
- **Gaussian:** Gaussian applies a smooth, symmetrical blur filter, using a sophisticated constant-time Gaussian approximation algorithm. In extreme cases, this algorithm may exhibit ringing; see below for a discussion of this. This mode is the default filter method.

**Blur**

This blurs the edge of the matte using a standard, constant speed Gaussian blur. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur is applied to the matte.

**Clipping Mode**

This option determines how edges are handled when performing domain of definition rendering. This is profoundly important when blurring the matte, which may require samples from portions of the image outside the current domain.

- **Frame:** The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame is treated as black/transparent.
- **Domain:** Setting this option to Domain respects the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.
— **None:** Setting this option to None does not perform any source image clipping at all. This means that any data required to process the node’s effect that is usually outside the upstream DoD is treated as black/transparent.

**Contract/Expand**
This shrinks or grows the matte similar to an Erode Dilate node. Contracting the matte reveals more of the foreground input, while expanding the matte reveals more of the background input. Values above 0.0 expand the matte, and values below 0.0 contract it.

**Gamma**
This raises or lowers the values of the matte in the semitransparent areas. Higher values cause the gray areas to become more opaque, and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

**Threshold**
Any value below the lower threshold becomes black or transparent in the matte. Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

**Restore Fringe**
This restores the edge of the matte around the keyed subject. Often when keying, the edge of the subject where you have hair is clipped out. Restore Fringe brings back that edge while keeping the matte solid.

**Invert Matte**
When this checkbox is selected, the alpha channel of the image is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

**Solid Matte**
Solid mattes are mask nodes or images connected to the solid matte input on the node. The solid matte is applied directly to the alpha channel of the image. Generally, solid mattes are used to hold out areas you want to remain opaque, such as someone with blue eyes against a blue screen.

Enabling Invert inverts the solid matte before it is combined with the source alpha.

**Garbage Matte**
Garbage mattes are mask nodes or images connected to the garbage matte input on the node. The garbage matte is applied directly to the alpha channel of the image. Generally, garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a garbage matte with the opposite effect of the matte applied to the keyer.

Enabling Invert inverts the garbage matte before it is combined with the source alpha.

**Post-Multiply Image**
Selecting this option multiplies the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.
Deselect this checkbox and the image can no longer be considered premultiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information on these Merge node settings, see Chapter 35, “Composite Nodes,” in the Fusion Reference Manual or Chapter 95 in the DaVinci Resolve Reference Manual.

The Matte Control Spill tab

**Spill Tab**

The Spill tab handles spill suppression in the Matte Control. Spill suppression is a form of color correction that attempts to remove the screen color from the fringe of the matte.

Spill is the transmission of the screen color through the semitransparent areas of the alpha channel. In the case of blue- or green-screen keying, this usually causes the color of the background to become apparent in the edges of the foreground subject.

**Spill Color**

This menu selects the color used as the base for all spill suppression techniques.

**Spill Suppression**

When this slider is set to 0, no spill suppression is applied to the image. Increasing the slider increases the strength of the spill method.

**Spill Method**

This selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color and is the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue screen. Use this mode only for very troublesome shots.

**Fringe Gamma**

This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.
**Fringe Size**
This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**
Fringe Shape presses the fringe toward the external edge of the image or pulls it toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size value is large.

**Cyan/Red, Magenta/Green, and Yellow/Blue**
Use these three controls to color correct the fringe of the image.

This is useful for correcting semitransparent pixels that still contain color from the original background to match the new background.

**Common Controls**
**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**Primatte [Pri]**

The Primatte node

---

**NOTE:** Primatte is only available in Fusion Studio.

**Primatte Node Introduction**
Primatte is an advanced keying tool for Fusion Studio. To use Primatte effectively, you must understand how it works. Using a series of selection buttons, Primatte assigns RGB pixels into one of the four specific zones.

- **Zone 1:** Complete background image.
- **Zone 2:** Foreground image with spill suppression and transparency.
- **Zone 3:** Foreground image with spill suppression only.
- **Zone 4:** Complete foreground image.

Depending on the type of blue- or green-screen content, you may find that the Delta Keyer or the Primatte keyer handles the specific keying task better. There is no one-solution-fits-all when it comes to keying, and in some cases, the combination of the two keyers may prove to be the best solution.
Inputs

The Primatte node includes six inputs in the Node Editor. Unlike every other tool in Fusion, the primary orange input is labeled as the Foreground input, since it accepts the green-screen or blue-screen image. The background input on the Primatte node is the green input; this is an optional input that allows Primatte to create the final merged composite.

- **Foreground Input**: The orange input accepts a 2D image that contains blue or green screen.
- **Background Input**: The green (optional) input accepts a 2D image layered as the background in the composite. If no image is connected, Primatte outputs the keyed foreground. Connecting an image to the background input activates Primatte’s advanced edge blending options.
- **Replacement Image**: The magenta (optional) input accepts a 2D image used as a source of Primatte’s spill suppression color correction.
- **Garbage Matte**: The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be made transparent. The garbage matte is applied directly to the alpha channel of the image.
- **Solid Matte**: The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be fully opaque.
- **Effect Mask**: The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the keying occurs. An effects mask is applied to the tool after the tool is processed.

**NOTE**: Connecting the background input without connecting the replacement image input uses the background image as the replacement image surf spill suppression.

Basic Node Setup

A single Primatte keyer can rarely get perfect results because most green- or blue-screen shots have problems the keyer is not made to handle. Keyers often need the help of garbage mattes or solid mattes created with a Polygon or B-Spline node. Shots can also require more than just one keyer to achieve perfect results. Below, the Primatte node has the blue-screen content connected to the orange input. Unlike other Fusion nodes, the foreground gets connected to the orange input. The result is an image with alpha that can then be connected into the foreground of a Merge node.
A Primatte node combined with a polygon matte as a garbage matte and connected to the foreground of a Merge

**Primatte Tab View Mode**

At the top of the Inspector is the View Mode menu. The default selection shows the final Composite result. You can change the view to see various intermediate stages of the keying process.

— **Black**: Displays the foreground subject on a black or transparent background.

— **Composite**: The final keyed image with spill suppression, composited over the image connected to the green Background Input on the node.

— **Defocus Foreground**: Displays the output of the Pre Matte key.

— **Processed Foreground**: Displays the alpha of the key before being combined with solid and garbage masks. When displaying the matte, set the viewer to show the alpha channel.

— **Hybrid Matte**: Displays the matte generated when the Hybrid Rendering checkbox is enabled. Best viewed when adjusting the Hybrid Blur and Hybrid Erode sliders.

— **Lighting Foreground**: Displays the foreground subject over the optimized artificial backing screen that the Adjust Lighting mode creates.

— **Lighting Background**: Displays the optimized artificial backing screen that the Adjust Lighting mode creates.
The Primatte tab Inspector

**Primatte Tab**

The core functionality for Primatte is found in the Primatte tab. The basic workflow is based on selecting one of the operational mode buttons and then scrubbing over areas in the viewer.

**Lock Color Picking**

Activate this button once you finished adjusting your key to prevent making accidental changes in the viewer.

**Auto Compute**

The Auto Compute button is likely the first button pressed when starting to key your footage. Primatte automagically analyzes the original foreground image, determines the backing color, and sets it as the central backing color. Then, using that information, another analysis determines the foreground areas. A Clean FG Noise operation is performed using the newly determined foreground areas, and Primatte renders the composite.

**NOTE:** The Auto Compute button may make the next three buttons—Select Background Color, Clean Background Noise, and Clean Foreground Noise—unnecessary and make your keying operation much more straightforward. Clicking Auto Compute automatically senses the backing screen color, eliminates it, and even gets rid of some foreground and background noise. If you get good results, then jump ahead to the Spill Removal tools. If you don’t get satisfactory results, continue from this point using the three buttons described below.

**Select Background Color**

Clicking the Select Background Color button allows you to select the screen color by scrubbing in the viewer. It uses the traditional Primatte method of taking the sampled backing screen color, projecting
a line in the opposite direction on the hue wheel, and generating artificial pixels that may represent the
FG object. Then, using the artificially generated foreground pixels, it internally does the Clean FG Noise
operation and creates the shape of the middle and outer polyhedrons. It then renders the composite
using these generated polyhedrons. This does not automatically use the Adjust Lighting functionality, as
it must be selected in a separate operation.

Clean Background Noise
Clicking this button helps to remove any white regions in the dark screen area (“noise”), or shades of the
screen color that did not get picked up on the first sample. Once you click the button, scrub the mouse
pointer over areas in the viewer to sample white-ish noise regions.

Clean Foreground Noise
If there are dark transparent regions in the middle of the mostly white opaque foreground object, click
the Clean Foreground Noise button and scrub over the dark pixels in the foreground area until that area
is as white as possible.

Spill Sponge
The Spill Sponge is the quickest method for removing color spill on your subject. Click the Spill Sponge
button and scrub the mouse pointer over a screen color pixel, and the screen color disappears from
the selected color region and is replaced by a complementary color, a selected color, or a color from a
replacement image. These options are set in the Replace tab. Additionally, use the tools under the Fine
Tuning tab or use the Spill(+) and Split(-) features to adjust the spill.

Matte Sponge
Sometimes in the Primatte operation, a 100% opaque, foreground area (all white) becomes slightly
transparent (gray). To clean those transparent areas, click the Matte Sponge button and scrub over the
transparent pixels. All the spill-suppression information remains intact.

Restore Detail
Clicking Restore Detail and scrubbing over background regions in the viewer turns completely
transparent areas translucent. This operation is useful for restoring lost hair details, thin wisps of smoke,
and the like.

Make Foreground Transparent
When this button is selected, the opaque foreground color region sampled in the viewer becomes
slightly translucent. This operation is useful for the subtle tuning of foreground subjects, which are
otherwise 100 percent covered with smoke or clouds. It can be used only one time on a particular color.
For a more flexible way to thin out a color region, and to be able to take multiple samples, use the
Matte(-) tool.

Spill(+)
Clicking the Spill(+) button returns the color spill to the sampled pixel color (and all colors like it) in
the amount of one Primatte increment. This tool can be used to move the sampled color more in the
direction of the color in the original foreground image. It can be used to nullify a Spill(-) step.

Spill(-)
Clicking the Spill(-) button removes from the sampled pixel color (and all colors like it) in the amount of
one Primatte increment. If spill color remains, another click using this operational mode tool removes
more of the color spill. Continue using this tool until all color spill has been removed from the sampled
color region.
Matte(+)  
Clicking the Matte(+) button makes the matte more opaque for the sampled pixel color (and all colors like it) in the amount of one Primatte increment. If the matte is still too translucent or thin, another click using this operational mode tool makes the sampled color region even more opaque. This can be used to thicken smoke or make a shadow darker to match shadows in the background imagery. It can only make these adjustments to the density of the color region on the original foreground image. It can be used to nullify a Matte(-) step.

Matte(-)  
Clicking the Matte(+) button makes the matte more translucent for the sampled pixel color (and all colors like it) in the amount of one Primatte increment. If the matte is still too opaque, another click using this operational mode tool makes the sampled color region even more translucent. This can be used to thin out smoke or make a shadow thinner to match shadows in the background imagery.

Detail(+)  
When this button is selected, the foreground detail becomes less visible for the sampled pixel color (and all colors like it) in the amount of one Primatte increment. If there is still too much detail, another click using this operational mode tool makes more of it disappear. This can be used to remove smoke or wisps of hair from the composite. Sample where detail is visible, and it disappears. This is for moving color regions into the 100% background region. It can be used to nullify a Detail(-) step.

Detail(-)  
When this button is selected, foreground detail becomes more visible for the sampled pixel color (and all colors like it) in the amount of one Primatte increment. If detail is still missing, another click using this operational mode tool makes detail more visible. This can be used to restore lost smoke or wisps of hair. Sample where the smoke or hair just disappears and it returns to visibility. Use this for restoring color regions that were moved into the 100% background region. It may start to bring in background noise if shooting conditions were not ideal on the foreground image.

Algorithms  
There are three keying algorithms available in the Primatte keyer:

— **Primatte**: The Primatte algorithm mode delivers the best results and supports both the Solid Color and the Complement Color spill suppression methods. This algorithm uses three multifaceted polyhedrons (as described later in this section) to separate the 3D RGB colorspace. It is also the default algorithm mode and, because it is computationally intensive, it may take the longest to render.

— **Primatte RT**: Primatte RT is the simplest algorithm and therefore the fastest. It uses only a single planar surface to separate the 3D RGB colorspace (as described later in this section) and, as a result, does not separate the foreground from the backing screen as carefully as the above Primatte algorithm. Another disadvantage of the Primatte RT algorithm is that it does not work well with less saturated backing screen colors, and it does not support the Complement Color spill suppression method.

— **Primatte RT+**: Primatte RT+ is in between the above two options. It uses a six planar surface color separation algorithm (as described later in this section) and delivers results in between the other two options in both quality and performance. Another disadvantage of the Primatte RT+ algorithm is that it does not work well with less saturated backing screen colors, and it does not support the Complement Color spill suppression method.
Hybrid Rendering
After sampling the backing screen color and producing acceptable edges around the foreground object, you sometimes find a transparent area within the foreground subject. This can occur when the foreground subject contains a color that is close to the backing screen color. Removing this transparency with the Clean FG Noise mode can cause the edge of the foreground subject to pick up a fringe that is close to the backing screen color. Removing the fringe is very difficult without sacrificing quality somewhere else on the image. The Hybrid Render mode internally creates two keying operations: Body and Edge. The optimized Edge operation gets the best edge around the foreground subject without any fringe effect. The Body operation deals with transparency within the foreground subject. The resultant matte is created by combining these two mattes, and then blurring and eroding the foreground subject in the Body matte and combining it with the edge matte.

To use Hybrid Rendering, start by keying the main foreground area using the Select Background Color mode (or any of the other Primatte backing screen detection methods). Activate the Hybrid Rendering checkbox. Lastly, select the Clean FG Noise button and scrub over the transparent area. The Hybrid Render mode performs the “Body/Edge” operation. The result is a final composite with perfect edges around the foreground subject with a solid foreground subject.

Hybrid Blur
Blurs the Body matte that has been automatically generated when Hybrid Rendering is activated.

Hybrid Erode
This slider dilates or erodes the Hybrid matte. You can view the results by selecting Hybrid matte in the View Mode menu.

Adjust Lighting
Before applying the Adjust Lighting operation, it is necessary to determine the backing screen color using Auto Compute or Select Background Color. After performing one of those operations, click on the Adjust Lighting button. Primatte generates an artificial clean plate and uses it to generate an evenly lit backing screen behind the foreground object. The default setting should detect all the areas that contain foreground pixels and deliver a smooth backing screen for the keying.

Lighting Threshold
Should Adjust Lighting fail to produce a smoother backing screen, adjust the Lighting Threshold slider while viewing the Lighting Background setting in the View Mode menu. This displays the optimized artificial backing screen that the Adjust Lighting mode creates.

Crop
This button reveals the Crop sliders to create a rectangular garbage matte with the Primatte node. As opposed to Fusion’s Crop tool, this does not change the actual image size.

Reset
Resets all the Primatte key control data back to a blue- or green-screen.

Soft Reset
Resets just the Primatte parameters used since the Select Background Color operation was last completed.
Fine Tuning Tab
The Fine Tuning tab can make refined adjustments to the spill suppression, density of the matte, and semitransparent areas. These sliders provide a bit more granularity over the Spill(+)(-), Matte(+)(-) and Detail(+)(-) buttons in the Primatte tab.

Selected Color
This shows the color selected (or registered) by the scrubbing in the viewer while the Fine Tuning tab is selected.

Fine Tuning Sliders
The color of the scrubbed pixel is registered as a reference color for fine tuning. It is displayed in the Color swatch. To perform the tuning operation, sample a color region on the image, and adjust one of the Fine Tuning sliders to achieve the desired effect.

Spill
The Spill slider can be used to remove spill from the selected color region. The more to the right the slider moves, the more spill is removed. The more to the left the slider moves, the closer the color component of the selected region is to the color in the original foreground image. If moving the slider to the right does not remove the spill, resample the color region and move the slider again.

These slider operations are additive. The result achieved by moving the slider to the right can also be achieved by clicking on the color region using the Spill(-) operational mode.

Transparency
The Transparency slider makes the matte more translucent in the selected color region. Moving this slider to the right makes the selected color region more transparent. Moving the slider to the left makes the matte more opaque. If moving the slider to the right does not make the color region translucent enough, resample the color region and again move the slider to the right. These slider operations are additive. The result achieved by moving the slider to the right can also be achieved by clicking on the color region using the Matte(-) operational mode.
**Detail**

The Detail slider can be used to restore lost detail. After selecting a color region, moving this slider to the left makes the selected color region more visible. Moving the slider to the right makes the color region less visible. If moving the slider to the left does not make the color region visible enough, resample the color region and again move the slider to the left.

These slider operations are additive. This result achieved by moving the slider to the left can also be achieved by clicking on the color region using the Detail(-) operational mode.

![Image of the Detail slider](image)

The Primatte Replace tab

**Replace Tab**

The Replace tab allows you to choose between the three methods of color spill replacement as covered in detail in the Spill Sponge section above. There are three options for the replacement color when removing the spill. These options are selected from the Replace mode menu.

**Replace Mode**

— **Complement**: Replaces the spill color with the complement of the screen color. This mode maintains fine foreground detail and delivers the best-quality results. If foreground spill is not a significant problem, this mode is the one that should be used. However, if the spill intensity on the foreground image is rather significant, this mode may often introduce serious noise in the resultant composite.

— **Image**: Replaces the spill color with colors from a defocused version of the background image or the Replace image, if one is connected to the Replace input (magenta) on the node. This mode results in a good color tone on the foreground subject even with a high-contrast background. On the negative side, the Image mode occasionally loses the fine edge detail of the foreground subjects. Another problem can occur if you later change the size of the foreground image against the background. Since the background/foreground alignment would change, the applied color tone from the defocused image might not match the new alignment.

— **Color**: Replaces the spill color with a solid color. When this option is selected, a color swatch and R,G,B sliders are displayed for selecting the color. Changing the palette color for the solid replacement, you can select a good spill replacement that matches the composite background. Its strength is that it works fine with even severe spill conditions. On the negative side, when using the Solid Color Replacement mode, fine detail on the foreground edge tends to be lost. The single palette color sometimes cannot make a good color tone if the background image has some high-contrast color areas.
Degrain Tab

The Degrain tab is used when a foreground image is highly compromised by film grain. As a result of the grain, when backing screen noise is completely removed, the edges of the foreground object often become harsh and jagged, leading to a poor key.

Grain Size

The Grain Size selector provides a range of grain removal from Small to Large. If the foreground image has a large amount of film grain-induced pixel noise, you may lose a good edge to the foreground object when trying to clean all the grain noise with the Clean Background Noise Operation Mode. These tools clean up the grain noise without affecting the quality of the key.

- **None**: No degraining is performed.
- **Small**: The average color of a small region of the area around the sampled pixel. This should be used when the grain is very dense.
- **Medium**: The average color of a medium-sized region of the area around the sampled pixel. This should be used when the grain is less dense.
- **Large**: The average color of a larger region of the area around the sampled pixel. This should be used when the grain is very loose.

Grain Tolerance

Adjusting this slider increases the effect of the Clean Background Noise tool without changing the edge of the foreground object.
**Matte Tab**

The Matte tab refines the alpha of the key, combined with any solid and garbage masks connected to the node. When using the Matte tab, set the viewer to display the alpha channel of Primatte’s final output.

**Filter**

This control selects the filtering algorithm used when applying blur to the matte.

- **Box**: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.
- **Bartlett**: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.
- **Multi-Box**: When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”
- **Gaussian**: The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

**Blur**

Matte Blur blurs the edge of the matte based on the Filter menu setting. A value of zero results in a sharp, cut-out-like hard edge. The higher the value, the more blur applied to the matte.

**Blur Inward**

Activating the Blur Inward checkbox generates the blur toward the center of the foreground subject. Conventional blurring or defocus affects the matte edges in both directions (inward and outward) and sometimes introduces a halo artifact around the edge in the composite view. Blur Inward functions only in the inward direction of the foreground subject (toward the center of the white area). The final result removes small and dark noise in the screen area without picking them up again in the Clean Background Noise mode. It can sometimes result in softer, cleaner edges on the foreground objects.

**Contract/Expand**

This slider shrinks or grows the semitransparent areas of the matte. Values above 0.0 expand the matte, while values below 0.0 contract it.

This control is usually used in conjunction with the Matte Blur to take the hard edge of a matte and reduce fringing. Since this control affects only semitransparent areas, it will have no effect on a matte’s hard edge.

**Gamma**

Matte Gamma raises or lowers the values of the matte in the semitransparent areas. Higher values cause the gray areas to become more opaque, and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

Since this control affects only semitransparent areas, it will have no effect on a matte’s hard edge.

**Threshold**

This range slider sets the lower threshold using the handle on the left and sets the upper threshold using the handle on the right.
Any value below the lower threshold setting becomes black or transparent in the matte.

Any value above the upper threshold setting becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

This control is often used to reject salt and pepper noise in the matte.

**Restore Fringe**

This restores the edge of the matte around the keyed subject. Often when keying, the edge of the subject where you have hair is clipped out. Restore Fringe brings back that edge while keeping the matte solid.

**Invert Matte**

When this checkbox is selected, the alpha channel created by the keyer is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

**Solid Matte**

Solid mattes are mask nodes or images connected to the solid matte input on the node. The solid matte is applied directly to the alpha channel of the image. Generally, solid mattes are used to hold out keying in areas you want to remain opaque, such as someone with blue eyes against a blue screen.

Enabling Invert inverts the solid matte before it is combined with the source alpha.

**Garbage Matte**

Garbage mattes are mask nodes or images connected to the garbage matte input on the node. The garbage matte is applied directly to the alpha channel of the image. Generally, garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a garbage matte with the opposite effect of the matte applied to the keyer.

Enabling Invert inverts the garbage matte before it is combined with the source alpha.

**Post-Multiply Image**

Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered premultiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information on these Merge node settings, see Chapter 35, “Composite Nodes,” in the Fusion Reference Manual or Chapter 95 in the DaVinci Resolve Reference Manual.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Matte nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
How to Key with Primatte

You begin keying with Primatte by connecting the blue- or green-screen shot to the orange foreground input on the Primatte node and the background shot for the composite into the green background input. Once the connections are made, there are four main steps to using the Primatte:

1. Select Background Color.
2. Clean the Background Noise.
3. Clean the Foreground Noise.
4. Remove Spill.

Selecting Background Color

- In the Inspector, click the Select Background Color button.
- Position the mouse pointer over the blue/green-screen area in the viewer, somewhere near the foreground subject.
- Drag over the background color.

Primatte averages the pixels to get a single color. Sometimes Primatte works best when only a single pixel is sampled instead of a range of pixels.

Should you have difficulties with your keying, try the Select Background Color operation again with a single dark screen pixel or single light screen pixel.

Instead, if you want to make a rectangular selection, use the Box button in the top left-hand corner of the viewer. The Median button is the same as Line selection, except that each point sampled is the result of a 3 x 3 region based on where you click and then apply a median filter. This can potentially reduce any noisy pixels.

Clean Background Noise

If there are any white or light gray regions in the dark screen area, this is referred to as “noise.” Technically, it is varying shades of the screen color that did not get picked up on the first sample and should be removed. You remove background noise using the Clean Background Noise button.

1. From the View Mode menu in the Inspector, select Black.
2. Above the viewer, click the Alpha Channel/RGB button.
   - The image displayed changes to a black and white “matte” view of the image.
3. Click the Clean Background Noise button.
4 Drag the mouse pointer through these white or light gray regions that should be pure black. Primatte processes the selection and eliminates the noise.

5 Repeat this procedure as often as necessary to clear the noise from the background areas. Selecting Gain/Gamma from the viewer’s Options menu to increase the brightness or gamma allows you to see noise that would otherwise be invisible.

Primatte viewer Options menu

You do not need to remove every single white pixel to get good results. Most pixels displayed as a dark color close to black in a key image are considered transparent and virtually allow the background to be the final output in that area. Consequently, there is no need to eliminate all noise in the screen portions of the image. In particular, if an attempt is made to remove noise around the foreground subject meticulously, a smooth composite image is often difficult to generate.

**TIP:** When clearing noise from around loose, flying hair or any background/foreground transitional area, be careful not to select any of the areas near the edge of the hair. Leave a little noise around the hair as this can be cleaned up later using the Fine Tuning tools.

**Clean Foreground Noise**

If there are dark regions in the middle of the mostly white foreground subject, the key is not 100% in those areas. Using Clean Foreground Noise can make the matte as white as possible.

1 Keep the View Mode menu set to Black and the viewer set to the Alpha Channel.
2 Click the Clean Foreground Noise button.
3 Drag the mouse pointer through these dark pixels in the foreground that should be pure white. Primatte processes the selection and eliminates the noise.
4 Repeat this procedure as often as necessary to clear the noise from the foreground areas.
5 If enabled, disable Gain/Gamma from the viewer’s Options menu to return to a regular viewer.

**Removing Spill**

The first three sections created a clean matte. At this point, the foreground can be composited onto any background image. However, if there is color spill on the foreground subject, a final operation is necessary to remove that screen spill for a more natural-looking composite.

1 From the View Mode menu, select Composite.
2. Above the viewer, click the Alpha/RGB toggle button to see the RGB image.

There are two ways in Primatte to remove the spill color:

**Spill Sponge**

The quickest method is to select the Spill Sponge button and then sample the spill areas away. Additional spill removal can be done using the tools under the Fine Tuning tab or by using the Spill(-) button.

**Fine Tuning Tab**

To use the Fine Tuning tab for spill, first scrub over the spill color in the viewer. For most images, adjusting the Spill slider is all that is required to remove any remaining spill.

**NOTE:** When using the slider in the Fine Tuning tab to remove spill, spill color replacement is replaced based on the setting of the Spill Replacement options.

You can use the other two sliders in the same way for different key adjustments. The Detail slider controls the matte softness for the color that is closest to the background color. For example, you can recover lost rarefied smoke in the foreground by selecting the Fine Tuning mode, clicking on the area of the image where the smoke starts to disappear and moving the Detail slider to the left. The Transparency slider controls the matte softness for the color that is closest to the foreground color. For example, if you have thick and opaque smoke in the foreground, you can make it semitransparent by moving the Transparency slider to the right after selecting the pixels in the Fine Tuning mode.

**Ultra Keyer [UKY]**

The Ultra Keyer node

**Ultra Keyer Node Introduction**

Like the newer Delta Keyer, the Ultra Keyer node has two keyers built in to it: a pre-matte keyer acts as a garbage matte creator and the color difference keyer that extracts fine detail and transparency. Generally, you start with the Delta Keyer as your first keyer of choice. If you do not get good results, try Primatte if you are using Fusion Studio. A good third choice is to try the Ultra Keyer.
**Inputs**

The Ultra Keyer node includes four inputs in the Node Editor.

- **Input:** The orange input accepts a 2D image that contains the color you want to be keyed for transparency.
- **Garbage Matte:** The gray garbage matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be made transparent. The garbage matte is applied directly to the alpha channel of the image.
- **Solid Matte:** The white solid matte input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input causes areas of the image that fall within the matte to be fully opaque.
- **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps masks. Connecting a mask to this input limits the pixels where the keying occurs. An effects mask is applied to the tool after the tool is processed.

**Basic Node Setup**

A single keyer can rarely get perfect results because most green- or blue-screen shots have problems the keyer is not made to handle. Keyers often need the help of garbage mattes or solid mattes created with a Polygon or B-Spline node. Shots can also require more than just one keyer to achieve perfect results. Below, the Ultra Keyer node has the blue-screen content connected to the orange input. The result is an image with alpha that can then be connected into the foreground of a Merge node.

An Ultra Keyer node combined with polygon matte as a garbage matte and connected to the foreground of a Merge
The Ultra Keyer Pre-Matte tab

**Pre-Matte Tab**

The Pre-Matte tab is where most keying begins. It is used to select the screen color and smooth out the color of the screen.

**Background Color**

The Background Color is used to select the color of the blue or green screen of the images. It is good practice to select the screen color close to the subject to be separated from the screen background.

**Red Level, Green Level, Blue Level**

These color sliders tune the level of the difference channels to help separate the color. When the background color is green, Red and Blue level options are provided. When the background color is blue, Red and Green level options are provided.

**Background Correction**

Depending on the background color selected above, the keyer iteratively merges the pre-keyed image over either a blue or green background before processing it further.

In some instances, this leads to better, more subtle edges.

**Matte Separation**

Matte Separation performs a pre-process on the image to help separate the foreground from the background before color selection. Generally, increase this control while viewing the alpha to eliminate the bulk of the background, but stop just before it starts cutting holes in the subject or eroding fine detail on the edges of the matte.
**Pre-Matte Range**
These R,G,B, and Luminance range controls update automatically to represent the current color selection. Colors are selected by selecting the Ultra Keyer node’s tile in the node tree and dragging the Eyedropper into the viewer to select the colors to be used to create the matte. These range controls can be used to tweak the selection slightly, although selecting colors in the viewer is all that is required.

**Lock Color Picking**
This checkbox prevents accidentally selecting more colors from the view. It is a good idea to activate this checkbox once the color selection is made for the matte. All other controls in the node remain editable.

**Pre Matte Size**
The Pre Matte Size control can be used to soften the general area around the keyed image. This is used to close holes in the matte often caused by spill in semitransparent areas of the subject. This can cause a small halo around the subject, which can be removed using the Matte Contract tools found later in the tool.

**Reset Pre Matte Ranges**
This discards all color selection by resetting the ranges but maintains all other slider and control values.

![Image of Ultra Keyer Image tab](image)

**Image Tab**
The Image tab handles the majority of spill suppression in the Ultra Keyer. Spill suppression is a form of color correction that attempts to remove the screen color from the fringe of the matte.

Spill is the transmission of the screen color through the semitransparent areas of the alpha channel. In the case of blue- or green-screen keying, this usually causes the color of the background to become apparent in the edges of the foreground subject.

**Spill Suppression**
When this slider is set to 0, no spill suppression is applied to the image. Increasing the slider increases the strength of the spill method.
**Spill Method**
This selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color and is the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue screens. Use this mode only for very troublesome shots.

**Fringe Gamma**
This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.

**Fringe Size**
This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**
Fringe Shape presses the fringe toward the external edge of the image or pulls it toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size value is large.

**Cyan/Red, Magenta/Green, and Yellow/Blue**
Use these three controls to color correct the fringe of the image.

This is useful for correcting semitransparent pixels that still contain color from the original background to match the new background.
**Matte Tab**

The Matte tab refines the alpha of the key, combined with any solid and garbage masks connected to the node. When using the Matte tab, set the viewer to display the alpha channel of the Delta Keyer’s final output.

**Filter**

This control selects the filtering algorithm used when applying blur to the matte.

- **Box**: This is the fastest method but at reduced quality. Box is best suited for minimal amounts of blur.
- **Bartlett**: Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.
- **Multi-Box**: When selecting this filter, the Num Passes slider appears and lets you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 passes and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”
- **Gaussian**: The Gaussian filter uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce an extremely slight edge “ringing” on floating-point pixels.

**Blur**

Matte Blur blurs the edge of the matte based on the Filter menu setting. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur applied to the matte.

**Clipping Mode**

This option determines how edges are handled when performing domain of definition rendering. This is profoundly important when blurring the matte, which may require samples from portions of the image outside the current domain.

- **Frame**: The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining areas in the frame are treated as black/transparent.
- **Domain**: Setting this option to Domain respects the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.
- **None**: Setting this option to None does not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD is treated as black/transparent.

**Contract/Expand**

This slider shrinks or grows the semitransparent areas of the matte. Values above 0.0 expand the matte, while values below 0.0 contract it.

This control is usually used in conjunction with the Matte Blur to take the hard edge of a matte and reduce fringing. Since this control affects only semitransparent areas, it has no effect on a matte’s hard edge.
Gamma
Matte Gamma raises or lowers the values of the matte in the semitransparent areas. Higher values cause the gray areas to become more opaque, and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

Since this control affects only semitransparent areas, it will have no effect on a matte's hard edge.

Threshold
This range slider sets the lower threshold using the handle on the left and sets the upper threshold using the handle on the right.

Any value below the lower threshold setting becomes black or transparent in the matte.

Any value above the upper threshold setting becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

This control is often used to reject salt and pepper noise in the matte.

Restore Fringe
This restores the edge of the matte around the keyed subject. Often when keying, the edge of the subject where you have hair is clipped out. Restore Fringe brings back that edge while keeping the matte solid.

Invert Matte
When this checkbox is selected, the alpha channel created by the keyer is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

Solid Matte
Solid mattes are mask nodes or images connected to the solid matte input on the node. The solid matte is applied directly to the alpha channel of the image. Generally, solid mattes are used to hold out keying in areas you want to remain opaque, such as someone with blue eyes against a blue screen.

Enabling Invert inverts the solid matte before it is combined with the source alpha.

Garbage Matte
Garbage mattes are mask nodes or images connected to the garbage matte input on the node. The garbage matte is applied directly to the alpha channel of the image. Generally, garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a garbage matte with the opposite effect of the matte applied to the keyer.

Enabling Invert inverts the garbage matte before it is combined with the source alpha.

Post-Multiply Image
Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered premultiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.
For more information on these Merge node settings, see Chapter 35, “Composite Nodes,” in the Fusion Reference Manual or Chapter 95 in the DaVinci Resolve Reference Manual.

**Subtract Background**

This option color corrects the edges when the screen color is removed and anti-aliased to a black background. By enabling this option, the edges potentially become darker. Disabling this option allows you to pass on the color of the screen to use in other processes down the line.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other matte nodes. These common controls are described in detail in the following “The Common Controls” section.

### The Common Controls

Nodes that handle matte operations share a number of identical controls in the Inspector. This section describes controls that are common among matte nodes.

**Inspector**

Common Matte settings Inspector
Settings Tab

The Settings tab in the Inspector can be found on every tool in the Matte category. The controls are consistent and work the same way for each tool.

Blend

The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Usually, this causes the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0

The tool is processed even when the input value is zero. This can be useful if this node is scripted to trigger another task, but the value is set to 0.0.

Red/Green/Blue/Alpha Channel Selector

These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur is first applied to the image, and then the red channel from the original input is copied back over the red channel of the result.

There are some exceptions, such as tools where deselecting these channels causes the tool to skip processing that channel entirely. In that case, there are a set of RGBA buttons on the Controls tab in the tool. The buttons in the Settings and the Controls tabs are identical.

Apply Mask Inverted

Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

Multiply by Mask

Selecting this option causes the RGB values of the masked image to be multiplied by the mask channel’s values. This causes all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

Use Object/Use Material (Checkboxes)

Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels are used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

Correct Edges

This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Object ID/Material ID (Sliders)

Use these sliders to select which ID is used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the view. The image or sequence must have been rendered from a 3D software package with those channels included.

Clipping Mode

This option determines how edges are handled when performing domain of definition rendering. This is profoundly important when blurring the matte, which may require samples from portions of the image outside the current domain.

- **Frame**: The default option is Frame, which automatically sets the node's domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame is treated as black/transparent.
- **Domain**: Setting this option to Domain respects the upstream domain of definition when applying the node's effect. This can have adverse clipping effects in situations where the node employs a large filter.
- **None**: Setting this option to None does not perform any source image clipping at all. This means that any data required to process the node's effect that would normally be outside the upstream DoD is treated as black/transparent.

Use GPU

The Use GPU menu has three settings. Setting the menu to Disable turns off GPU hardware-accelerated rendering. Enabled uses the GPU hardware for rendering the node. Auto uses a capable GPU if one is available, and falls back to software rendering when a capable GPU is not available.

Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node are displayed in the Inspector. Dragging a connected node from the node tree into the field hides that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line reappears.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 108

Metadata Nodes

This chapter details the Metadata nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Copy Metadata [META] 2315
Set Metadata [SMETA] 2316
Set Timecode [TCMETA] 2317
The Common Controls 2319
Copy Metadata Node Introduction

Copy Metadata combines, replaces, or clears the metadata in your image. Metadata can be viewed in a subview of the viewer.

Inputs

The two inputs on the Copy Metadata node are used to connect two 2D images.

— Background Input: The orange background input is used for the primary 2D image that is output from the node.

— Foreground Input: The green foreground input is used for the secondary 2D image that contains metadata you want merge or overwrite onto the background image.

Basic Node Setup

The Copy Metadata node takes metadata from the foreground input (green) and copies it into the background input (orange). The output is the background input with modified metadata.

Inspector

The Copy Metadata Controls tab

A Copy Metadata node copies metadata from the foreground and embeds it into the background clip
Controls Tab
The Controls tab configures how metadata coming from the foreground input image gets added to the background input image.

Operation
The Operation menu determines how the metadata of the foreground and background inputs are treated.

- **Merge (Replace Duplicates):** All values are merged, but values with duplicate names are taken from the foreground input.
- **Merge (Preserve Duplicates):** All values are merged, but values with duplicate names are taken from the background input.
- **Replace:** The metadata in the foreground replaces the entire metadata in the background.
- **Clear:** All metadata is discarded.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Metadata nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Set Metadata [SMETA]

The Set Metadata node

Set Metadata Node Introduction
Set Metadata allows you to create new Name = Value pairs in the metadata. Metadata can be viewed in a subview of the viewer.

Inputs
The single input on the Set Metadata node is used to connect a 2D image that gets metadata added.

- **Background Input:** The orange background input is used for the primary 2D image that is output from the node with the new metadata.

Basic Node Setup
The Set Metadata node embeds new metadata into the background input (orange). The output is the background input with new metadata.
A Set Metadata node creates new metadata and embeds it into the background clip.

**Inspector**

The Set Metadata Controls tab

**Controls Tab**

The Controls tab is where you set up the name of the metadata field and the value or information regarding the metadata.

**Field Name**

The name of the metadata value. Do not use spaces.

**Field Value**

The value assigned to the name above.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Metadata nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**Set Timecode [TCMETA]**

The Set Timecode node

**Set Timecode Node Introduction**

Set Timecode inserts dynamic timecode values into the metadata table based on the FPS settings.
**Inputs**

The single input on the Set Timecode node is used to connect a 2D image that gets timecode added.

— **Background Input:** The orange background input is used for the primary 2D image that is output from the node with the new timecode.

**Basic Node Setup**

The Set Timecode node embeds new timecode metadata into the background input (orange). The output is the background input with updated timecode.

A Set Timecode node inserts new timecode metadata into the background clip.

**Inspector**

The Set Timecode Controls tab

**Controls Tab**

The Controls tab sets the clip’s starting timecode metadata based on FPS, hours, minutes, seconds, and frames.

**FPS**

You can choose from a variety of settings for frames per second.

Since this is a Fuse, you can easily adapt the settings to your needs by editing the appropriate piece of code for the buttons:

```csharp
MBTNC_StretchToFit = true,
{ MBTNC_AddButton = "24" },
{ MBTNC_AddButton = "25" },
{ MBTNC_AddButton = "30" },
{ MBTNC_AddButton = "48" },
{ MBTNC_AddButton = "50" },
{ MBTNC_AddButton = "60" },
})
```
as well as for the actual values:

\[
\text{local rates} = \{ 24, 25, 30, 48, 50, 60 \}
\]

**Hours/Minutes/Seconds/Frames Sliders**

Define an offset from the starting frame of the current comp.

**Print to Console**

Verbose output of the Timecode/Frame value in the Console.

The Timecode/Frames conversion is done according to the FPS settings. The result might look like this:

- **TimeCode:** 00:00:08:15
- **Frames:** 207

### Common Controls

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Metadata nodes. These common controls are described in detail in the following “The Common Controls” section.

### The Common Controls

Nodes that handle metadata operations share several identical controls in the Inspector. This section describes controls that are common among Metadata nodes.

**Inspector**

The Common Metadata Settings tab
Settings Tab
The Settings tab in the Inspector can be found on every tool in the Metadata category. The controls are consistent and work the same way for each tool.

Use Object/Use Material (Checkboxes)
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels are used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

Correct Edges
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Object ID/Material ID (Sliders)
Use these sliders to select which ID is used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the view. The image or sequence must have been rendered from a 3D software package with those channels included.

Comments
The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts
Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 109

Miscellaneous Nodes

This chapter details miscellaneous nodes within Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing Medialn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Auto Domain [ADoD]

Auto Domain Node Introduction

The Auto Domain node automatically sets the image’s domain of definition (DoD) based on bounds of the input image’s background Canvas color. It does not change the image’s physical dimensions. Some EXR images come with optimized DoDs already set, but other formats do not. For formats other than EXR, this node can speed up compositions by optimizing the DoD based on the content rather than the frame's dimensions.

For example, a CG character rarely takes up the entire frame of an image. With this type of image, the Auto Domain node sets the DoD to a rectangular region by comparing image pixels with the Canvas color. The Canvas color indicates what color the pixels are outside the DoD. By default, unless a Canvas color is set using the Set Canvas Color node, the color is set to black. This default works well when an image has a premultiplied alpha channel. The result is a DoD that encompasses the portion of the clip that contains only the character. The DoD is updated on each frame to accommodate changes, such as a character walking closer to the camera. However, if a clip does not contain an alpha channel, the Set Canvas Color node can be used to define the Canvas color as solid alpha with a color that matches the solid background.

**NOTE:** The Domain of Definition is a bounding box that encompasses pixels that have a nonzero value. The DoD is used to limit image-processing calculations and speeds up rendering.

Inputs

The single input on the Auto Domain node is used to connect a 2D image and an effect mask, which can be used to limit the blurred area.

- **Input:** The orange input is used for the primary 2D image that is blurred.
- **Effect Mask:** The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the blur to only those pixels within the mask.
Basic Node Setup

The example below assumes that the image does not contain an alpha channel but a CG character rendered against a black background. This is common for different render passes like specular or shadows, for example. The image is connected to a Set Canvas Color node, which sets the Canvas color to black with a solid alpha. The Set Canvas Color then connects to the Auto Domain node, which detects the pixels and sets the DoD. If the original image contained a premultiplied alpha channel, the Set Canvas Color would not be needed, and the image could be connected directly into the Auto Domain node.

An Auto Domain node automatically limits the area of image processing.

Inspector

The Auto Domain Controls tab

Controls Tab

In most cases, the Auto Domain node automatically calculates the DoD bounding box; however, the rectangular shape can be modified using the Controls tab in the Inspector.

Left

Defines the left border of the search area of the ADoD. Higher values on this slider move the left border toward the right, excluding more data from the left margin.

1 represents the right border of the image; 0 represents the left border. The slider defaults to 0 (left border).

Bottom

Defines the bottom border of the search area of the ADoD. Higher values on this slider move the bottom border toward the top, excluding more data from the bottom margin.

1 represents the top border of the image; 0 represents the bottom border. The slider defaults to 0 (bottom border).
Right
Defines the right border of the search area of the ADoD. Higher values on this slider move the right border toward the left, excluding more data from the right margin.

1 represents the right border of the image; 0 represents the left border. The slider defaults to 1 (right border).

Top
Defines the top border of the search area of the ADoD. Higher values on this slider move the top border toward the bottom, excluding more data from the top margin.

1 represents the top border of the image; 0 represents the bottom border. The slider defaults to 1 (top border).

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Change Depth [CD]

Change Depth Node Introduction
The Change Depth node has one simple use, and that is to change the bits per color channel used to process a node. This node is often used after color correcting 32-bit floating-point image files, converting them from float processing to 16-bit per channel to preserve memory and performance.

It can also be useful if, from a certain point in your node tree, you feel the need to process your images in a higher bit depth than their original one or to reduce the bit depth to save memory.

Inputs
The single input on the Change Depth node is used to connect a 2D image and an effect mask, which can be used to limit the blurred area.

— **Input:** The orange input is used for the primary 2D image to be converted.
— **Effect Mask:** The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes or bitmaps from other tools. Connecting a mask to this input limits the blur to only those pixels within the mask.
Basic Node Setup

Below, a Loader node in Fusion Studio is color corrected and then down converted from a floating-point image to a 16-bit image to save image-processing time and memory.

A Change Depth node placed after color correction is done on a floating-point image.

Inspector

The Change Depth Controls tab

Controls Tab

The two controls for this node are the Depth menu and the Dither menu. These two menus are used to convert and adjust the color depth of the image.

Depth

The Keep setting doesn’t do anything to the image but instead keeps the input depth. The other options change the bit depth of the image to the respective value.

Dither

When down converting from a higher bit depth, it can be useful to add Error Diffusion or Additive Noise to camouflage artifacts that result from problematic (high-contrast) areas.

Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Custom Tool [CT]

Custom Tool Node Introduction

The Custom Tool node is the most complex and the most powerful node in Fusion. It is used to create custom expressions and filters to modify an image. In addition to providing three image inputs, the Custom Tool node allows for the connection of up to eight numeric inputs and as many as four XY position values from other controls and parameters in the node tree.

Per-pixel calculations can be performed on the Red, Green, Blue, Alpha, Z, Z-Coverage, UV texture coords, XYZ Normals, RGBA background color, and XY motion vector channels of the images.

You should be moderately experienced with scripting, or C++ programming, to understand the structure and terminology used by the Custom Tool node.

Inputs

The Custom Tool node has three image inputs, a matte input, and an effect mask input.

— **Input:** The orange, green, and magenta inputs combine 2D images to make your composite. When entering them into the Custom Tool fields, they are referred to as c1, c2 and c3 (c standard for all three R, G, B channels)

— **Matte Input:** The white input is for a matte created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a matte to this input allows a matte to be combined into any equation. When entering the matte into the Custom Tool fields, it is referred to as m1.

— **Effect Mask:** The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the Custom Tool effect to only those pixels within the mask.

Basic Node Setup

The Custom Tool below takes two image inputs and a matte input, and then combines them using some calculation. The result can be output to a Merge or other image-processing nodes.
A Custom Tool is used to build your own effects using C++ and scripting.

**Inspector**

The Custom Tool Controls tab

**Controls Tab**

**Point in 1-4, X and Y**

These four controls are 2D X and Y center controls that are available to expressions entered in the Setup, Intermediate, and Channels tabs as variables p1x, p1y, ..., p4x, p4y. They are normal positional controls and can be animated or connected to modifiers as any other node might.

**Number in 1-8**

The values of these controls are available to expressions entered in the Setup, Intermediate, and Channels tabs as variables n1, n2, n3, ..., n8. They are normal slider controls and can be animated or connected to modifiers exactly as any other node might.

**LUT in 1-4**

The Custom Tool node provides 4 LUT splines. The values of these controls are available to expressions entered in the Setup, Intermediate, and Channels tabs using the getlut# function. For example, setting the R, G, B, and A expressions to getlut1(r1), getlut2(g1), getlut3(b1), and getlut4(a1), respectively, would cause the Custom Tool node to mimic the Color Curves node.
These controls can be renamed using the options in the Config tab to make their meanings more apparent, but expressions still see the values as n1, n2, ..., n8.

**Custom Tool Setup Tab**

The Custom Tool Setup tab

**Setup 1-4**

Up to four separate expressions can be calculated in the Setup tab of the Custom Tool node. The Setup expressions are evaluated once per frame before any other calculations are performed. The results are then made available to the other expressions in the Custom Tool node as variables s1, s2, s3, and s4.

**NOTE:** Because these expressions are evaluated once per frame only and not for each pixel, it makes no sense to use per-pixel variables like X and Y or channel variables like r1, g1, b1. Allowable values include constants, variables such as n1..n8, time, W and H, and functions like sin() or getr1d().
The Custom Tool Intermediate tab

**Intermediate 1-4**

An additional four expressions can be calculated in the Inter tab. The Inter expressions are evaluated once per pixel after the Setup expressions are evaluated but before the Channel expressions are evaluated. Per-pixel channel variables like r1, g1, b1, and a1 are allowable. Results are available as variables i1, i2, i3, and i4.

The Custom Tool Config tab
Random Seed

Use this to set the seed for the rand() and rands() functions. Click the Randomize button to set the seed to a random value. This control may be needed if multiple Custom Tool nodes are required with different random results for each.

Number Controls

There are eight sets of Number controls, corresponding to the eight Number In sliders in the Controls tab. Uncheck the Show Number checkbox to hide the corresponding Number In slider, or edit the Name for Number text field to change its name.

Point Controls

There are four sets of Point controls, corresponding to the four Point In controls in the Controls tab. Uncheck the Show Point checkbox to hide the corresponding Point In control and its crosshair in the viewer. Similarly, edit the Name for Point text field to change the control’s name.

Custom Tool Channels Tab

![Custom Tool Channel tab]

The Custom Tool Channel tab

RGBA, Z, UV Expressions, and XYZ Normal Expressions

The Channel tab is used to set up one expression per each available channel of the image. Each expression is evaluated once per pixel. The result creates the value for that pixel in the output of the image.

Color Channel expressions (RGBA) should generally return floating-point values between 0.0 and 1.0. Values beyond this are clipped if the destination image is an integer. Other expression fields should produce values appropriate to their channel (e.g., between -1.0 and 1.0 for Vector and Normal fields, 0.0 to 1.0 for Coverage, or any value for Depth). The Channel expressions may use the results from both the Setup expressions (as variables s1–s4) and Inter expressions (as variables i1–i4).

**NOTE:** Use c1, c2, c3 to refer to the value of a pixel in the current channel. This makes copying and pasting expressions easier. For example, if c1/2 is typed as the red expression, the result would be half the value of the red pixel from image 1, but if the expression is copied to the blue channel, now it would have the value of the pixel from the blue channel.

To refer to the red value of the current pixel in input 1, type r1. For the image in input 2, it would be r2.

- `get[ch][#]b(x, y)` Read pixel at x,y, or 0 if out of bounds—e.g., `getr1b(0,0)`
- `get[ch][#]d(x, y)` Read pixel at x,y or edge pixel if out of bounds—e.g., `getr1d(0,0)`
- `get[ch][#]w(x, y)` Read pixel at x,y or wrap if out of bounds—e.g., `getr1w(0,0)`

**NOTE:** There are a variety of methods used to refer to pixels from locations other than the current one in an image.

In the above description, [ch] is a letter representing the channel to access. The [#] is a number representing the input image. So to get the red component of the current pixel (equivalent to r), you would use `getr1b(x,y)`. To get the alpha component of the pixel at the center of image 2, you would use `geta2b(0.5, 0.5)`.

- `getr1b(x,y)` Output the red value of the pixel at position x, y, if there were a valid pixel present. It would output 0.0 if the position were beyond the boundaries of the image (all channels).
- `getr1d(x,y)` Output the red value of the pixel at position x, y. If the position specified were outside of the boundaries of the image, the result would be from the outer edge of the image (RGBA only).
- `getr1w(x,y)` Output the red value of the pixel at position x, y. If the position specified were outside of the boundaries of the image, the x and y coordinates would wrap around to the other side of the image and continue from there (RGBA only).

To access other channel values with these functions, substitute the r in the above examples with the correct channel variable (r, g, b, a and, for the `getr1b()` functions only, z, and so on), as shown above. Substitute the 1 with either 2 or 3 in the above examples to access the images from the other image inputs.

</table>

### Example

The following examples are intended to help you understand the various components of the Custom Tool node.

#### Rotation

To rotate an image, we need the standard equations for 2D rotation:

\[
x' = x \times \cos(\theta) - y \times \sin(\theta) \\
y' = x \times \sin(\theta) + y \times \cos(\theta)
\]

Using the n1 slider for the angle \( \theta \) and a sample function, we get (for the red channel):

\[
\text{getr1b}(x \times \cos(n1) - y \times \sin(n1), x \times \sin(n1) + y \times \cos(n1))
\]

This calculates the current pixel’s \((x, y)\) position rotated around the origin at \((0,0)\) (the bottom-left corner), and then fetches the red component from the source pixel at this rotated position. For centered rotation, we need to subtract 0.5 from our \(x\) and \(y\) coordinates before we rotate them, and add 0.5 back to them afterward:

\[
\text{getr1b}((x-.5) \times \cos(n1) - (y-.5) \times \sin(n1) + .5, (x-.5) \times \sin(n1) + (y-.5) \times \cos(n1) + .5)
\]
Which brings us to the next lesson: Setup and Intermediate Expressions. These are useful for speeding things up by minimizing the work that gets done in the Channel expressions. The Setup expressions are executed only once, and their results don’t change for any pixel, so you can use these for s1 and s2, respectively.

\[ \cos(n1) \sin(n1) \]

Intermediate expressions are executed once for each pixel, so you can use these for i1 and i2:

\[ (x-.5) \times s1 - (y-.5) \times s2 + .5 \]
\[ (x-.5) \times s2 + (y-.5) \times s1 + .5 \]

These are the x and y parameters for the getr1b() function from above, but with the Setup results, s1 and s2, substituted so that the trig functions are executed only once per frame, not every pixel. Now you can use these intermediate results in your Channel expressions:

\[ \text{getr1b}(i1, i2) \]
\[ \text{getg1b}(i1, i2) \]
\[ \text{getb1b}(i1, i2) \]
\[ \text{geta1b}(i1, i2) \]

With the Intermediate expressions substituted in, we only have to do all the additions, subtractions, and multiplications once per pixel, instead of four times. As a rule of thumb, if it doesn’t change, do it only once.

This is a simple rotation that doesn’t take into account the image aspect at all. It is left as an exercise for you to include this (sorry). Another improvement could be to allow rotation around points other than the center.

**Filtering**

Our second example duplicates the functionality of a 3 x 3 Custom Filter node set to average the current pixel together with the eight pixels surrounding it. To duplicate it with a Custom Tool node, add a Custom Tool node to the node tree, and enter the following expressions into the Setup tab.

(Leave the node disconnected to prevent it from updating until we are ready.)

\[ S1 \]
\[ 1.0/w1 \]
\[ S2 \]
\[ 1.0/h1 \]

These two expressions are evaluated at the beginning of each frame. S1 divides 1.0 by the current width of the frame, and S2 divides 1.0 by the height. This provides a floating-point value between 0.0 and 1.0 that represents the distance from the current pixel to the next pixel along each axis.

Now enter the following expression into the first text control of the Channel tab (r).

\[ \frac{(\text{getr1w}(x-s1, y-s2) + \text{getr1w}(x, y-s2) + \text{getr1w}(x+s1, y-s2) + \text{getr1w}(x+s1, y) + \text{getr1w}(x-s1, y) + r1 + \text{getr1w}(x-s1, y+s2) + \text{getr1w}(x, y+s2) + \text{getr1w}(x+s1, y+s2))}{9} \]
This expression adds together the nine pixels above the current pixel by calling the getr1w() function nine times and providing it with values relative to the current position. Note that we referred to the pixels by using x+s1, y+s2, rather than using x+1, y+1.

Fusion refers to pixels as floating-point values between 0.0 and 1.0, which is why we created the expressions we used in the Setup tab. If we had used x+1, y+1 instead, the expression would have sampled the same pixel over and over again. (The function we used wraps the pixel position around the image if the offset values are out of range.)

That took care of the red channel; now use the following expressions for the green, blue, and alpha channels.

\[
\frac{( \text{getgw}(x-s1, y-s2) + \text{getgw}(x, y-s2) + \text{getgw}(x+s1, y-s2) + \text{getgw}(x+s1, y) + \text{getgw}(x-s1, y) + g1 + \text{getgw}(x-s1, y+s2) + \text{getgw}(x, y+s2) + \text{getgw}(x+s1, y+s2) )}{9}
\]

\[
\frac{( \text{getbw}(x-s1, y-s2) + \text{getbw}(x, y-s2) + \text{getbw}(x+s1, y-s2) + \text{getbw}(x+s1, y) + \text{getbw}(x-s1, y) + b1 + \text{getbw}(x-s1, y+s2) + \text{getbw}(x, y+s2) + \text{getbw}(x+s1, y+s2) )}{9}
\]

\[
\frac{( \text{getaw}(x-s1, y-s2) + \text{getaw}(x, y-s2) + \text{getaw}(x+s1, y-s2) + \text{getaw}(x+s1, y) + \text{getaw}(x-s1, y) + a1 + \text{getaw}(x-s1, y+s2) + \text{getaw}(x, y+s2) + \text{getaw}(x+s1, y+s2) )}{9}
\]

It’s time to view the results. Add a Background node set to a solid color and change the color to a pure red. Add a hard-edged Rectangular effects mask and connect it to the expression just created.

For comparison, add a Custom Filter node and duplicate the settings from the image above. Connect a pipe to this node from the background to the node and view the results. Alternate between viewing the Custom Tool node and the Custom Filter while zoomed in close to the top corners of the effects mask.

Of course, the Custom Filter node renders a lot faster than the Custom Tool node we created, but the flexibility of the Custom Tool node is its primary advantage. For example, you could use an image connected to input 2 to control the median applied to input one by changing all instances of getr1w, getg1w, and getb1w in the expression to getr2w, getg2w, and getb2w, but leaving the r1, g1, and b1s as they are.

This is just one example; the possibilities of the Custom Tool node are limitless.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Fields [Flds]

The Fields node

Fields Node Introduction

The Fields node is a robust multipurpose utility offering several functions related to interlaced video frames. It interpolates video fields into frames or video frames into fields. Although the interlace preference and method type is defined in the MediaIn or Loader, and generators, this node can be used to assist in the standards conversion of PAL to NTSC and provides the ability to process fields and frames for specific portions of a node tree.

This node can also interlace two separate images together into a single interlace image. The background input is the dominate field 1 and the foreground is field 2.

Inputs

The single input on the Fields node is used to connect a 2D image and an effect mask, which can be used to limit the blurred area.

- **Stream1 Input**: The orange background input is used for the primary 2D image that is interpolated or converted.
- **Stream2 Input**: The optional green foreground input is only used when merging two interlaced images together.

Basic Node Setup

The Fields node below is used to convert the background image from a PAL interlaced format to progressive frames.

The background image can be modified to various interlaced formats.
Inspector

The Fields Controls tab

Controls Tab
The Controls tab includes two menus. The Operation menu is used to select the type of field conversion performed. The Process Mode menu is used to select the field’s format for the output image.

Operation Mode

Operation Menu

— **Do Nothing**: This causes the images to be affected by the Process Mode selection exclusively.

— **Strip Field 2**: This removes field 2 from the input image stream, which shortens the image to half of the original height.

— **Strip Field 1**: This removes field 1 from the input image stream, which shortens the image to half of the original height.

— **Strip Field 2 and Interpolate**: This removes field 2 from the input image stream and inserts a field interpolated from field 1 so that image height is maintained. Should be supplied with frames, not fields.

— **Strip Field 1 and Interpolate**: This removes field 1 from the input image stream and inserts a field interpolated from field 2 so that image height is maintained. Should be supplied with frames, not fields.

— **Interlace**: This combines fields from the input image stream(s). If supplied with one image stream, each pair of frames are combined to form half of the number of double-height frames. If supplied with two image streams, single frames from each stream are combined to form double-height images.

— **De-Interlace**: This separates fields from one input image stream. This will produce double the amount of half-height frames.
Reverse Field Dominance

When selected, the Field Order or Dominance of the image will be swapped.

Process Mode Menu

- **Full Frames**: This forces Frame Processing. Useful for processing frames in a part of a node tree that is otherwise field processing.
- **NTSC Fields**: This forces NTSC Field Processing. Useful for processing fields in a part of a node tree that is otherwise frame processing.
- **PAL Fields**: This forces PAL Field Processing. Useful for processing fields in a part of a node tree that is otherwise frame processing.
- **PAL Fields (Reversed)**: This forces PAL-swapped Field Processing.
- **NTSC Fields (Reversed)**: This forces NTSC-swapped Field Processing.
- **Auto**: This attempts to match the mode of its input images. Fields are used if the input types are mixed.

Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Frame Average [Avg]

The Frame Average node

Frame Average Node Introduction

The Frame Average node averages together a series of frames to simulate clips shot with long shutter speeds. Aside from motion blur-style effects, it can be useful for time warps or noise removal.
**Inputs**

The single input on the Frame Average node is used to connect a 2D image that will have the averaging applied.

— **Input**: The orange input is used for the primary 2D image that will be averaged.

**Basic Node Setup**

The image connected to the orange input is frame averaged based on the settings in the Inspector.

A Frame Average node blends the input image's frames.

**Inspector**

The Frame Average Controls tab

![Frame Average Controls tab](image)

**Controls Tab**

The Controls tab contains the parameters for setting the duration and guidance of the averaged frames.

**Sample Direction**

The Sample Direction menu determines if the averaged frames are taken before the current frame, after, or a mix of the two.

— **Forward**: Averages the number of frames set by the Frames slider after the current frame.
— **Both**: Averages the number of frames set by the Frames slider, taking frames before and after the current frame.
— **Backward**: Averages the number of frames set by the Frames slider before the current frame.

**Missing Frames**

This control determines the behavior if a frame is missing from the clip.

— **Duplicate Original**: Uses the last original frame until a new frame is available.
— **Blank Frame**: Leaves missing frames blank.

**Frames**

This slider sets the number of frames that are averaged.
Keyframe Stretcher [KfS]

The Keyframe Stretcher node

Keyframe Stretcher Node Introduction

The Keyframe Stretcher node is inserted after animated nodes, so the keyframes stretch and the comp’s duration is modified. It is used to scale the keyframes on the animation curve to the current duration of the clip. This is particularly useful when creating title templates in Fusion for use in DaVinci Resolve’s Edit or Cut page.

**TIP:** The Keyframe Stretcher can be used on a single parameter by applying the Keystretcher modifier.

Inputs

The single input on the Keyframe Stretcher node is used to connect a 2D image that contains keyframe animation.

— **Input:** The orange input is used for any node with keyframed animation. The input can be a Merge node that is not animated but contains foreground and background nodes that are animated.

Basic Node Setup

The Keyframe Stretcher is added just before the Media Out or Saver node. All nodes that include animation before the Keyframe Stretcher are modified if the comp changes duration.

A Keyframe Stretcher changing the animation of two text nodes.

The diagram below shows the original 50-frame animation added to a parameter. The Keyframe Stretcher Start and End would be set to 0 and 50. The second keyframe is set at frame 10, and the third
keyframe is set at frame 40. Setting the Stretch Start to frame 11 and the Stretch End to frame 39 will keep the existing keyframes at the same speed (number of frames.) The middle will be stretched.

Original 50-frame animation

In the below example, the duration of the clip is extended to 75 frames. The first 10 frames and the last 10 frames of the animation run at the same speed as the original animation, while any animation in the middle is stretched to fill the difference.

**NOTE:** The actual Spline Editor will show only the original keyframe positions. The splines are not changed by the Keyframe Stretcher; only the animation is changed.

Animation modified to 75 frames but stretching only the middle of the animation

**Inspector**

The Keyframe Stretcher Keyframes tab
Keyframes Tab
The Keyframes tab includes Source controls for setting the source duration and Stretch controls for setting the area of the animation that gets modified.

Source Start/Source End
A source range is specified using the Source Start and Source End controls. These are typically set to match the full range of the animation spline on the Keyframes control.

Stretch Start/Stretch End
The Stretch Start and Stretch End controls let you specify a middle zone where keyframes will be stretched or squished. Handles outside the range will not get scaled. Any keyframes outside the Stretch Start and End range always remain the same number of frames from the Start and End.

Any keyframe adjustments to the original control will be correspondingly scaled back to the source curve and will match the original timing as expected.

Stretch Edges Instead
Enabling the Stretch Edges Instead checkbox overrides the Stretch Start and Stretch End controls and stretches the edges of the animation.

Run Command [Run]

Run Command Node Introduction
The Run Command node is used to execute an external command or batch file at specific points during a render. You can choose to run a command at the start or the end of a render. Or you can have the command execute once for each frame.

The Run Command can be used to net render other command line applications using the Fusion Render Manager, as well as a host of other useful functions.

Inputs
The single input on the Run Command node is used to pass through a 2D image.

Input: The optional orange image input is not required for this node to operate. However, if it is connected to a node's output, the Run Command will only launch after the connected node has finished rendering. This is often useful when connected to a Saver, to ensure that the output frame has been fully saved to disk first. If the application launched returns a non-zero result, the node will also fail.
**Basic Node Setup**

The Run Command node can be connected after a Saver and run once the final frame is completed.

![Run Command placed after a Saver node.]

**Inspector**

The Run Command Frame tab

**Frame Tab**

The Frame tab is where the command to execute is selected and modified.

**Hide**

Enable the Hide checkbox to prevent the application or script from displaying a window when it is executed.

**Wait**

Enable this checkbox to cause the node to wait for a remote application or tool to exit before continuing. If this checkbox is disabled, the Fusion continues rendering without waiting for the external application.

**Frame Command**

This field is used to specify the path for the command to be run after each frame is rendered. The Browse button can be used to identify the path.

**Interactive**

This checkbox determines whether the launched application should run interactively, allowing user input.

**Number A (%a) and Number B (%b)**

Various wildcards can be used with the frame commands; these wildcards will be substituted at render time with the correct values.
— %a: Outputs the number from the Number A thumbwheel control.
— %b: Outputs the number from the Number B thumbwheel control.
— %t: Outputs the current frame number (without zero padding).
— %s: Substitutes using the text from the large text entry field.

If you want to add zero paddings to the numbers generated by %t, refer to the wildcard with %0x, where x is the number of characters with which to pad the value. This also works for %a and %b.

For example, test%04t.tga would return the following values at render time:

```
test0000.tga
test0001.tga
test0009.tga
test0010.tga
```

You may also pad a value with spaces by calling the wildcard as %x, where x is the number of spaces with which you would like to pad the value.

Start and End Tabs

The Start and End tabs contain a file browser for a command to be run when the composition starts to render and when the composition is done rendering.

Example

To copy the saved files from a render to another directory as each frame is rendered, save the following text in a file called copyfile.bat to your C\ directory (the root folder).

```
@echo off
set parm=%1 %2
copy %1 %2 set parm=
```

Create or load any node tree that contains a Saver. The following example assumes a Saver is set to output D\ test0000.exr, test0001.exr, etc. You may have to modify the example to match.

Add a Run Command node after the Saver to ensure the Saver has finished saving first. Now enter the following text into the Run Command node’s Frame Command text box:

```
C\copytest.bat D\test%04f.exr C\n```
Select the Hide Frame command checkbox to prevent the Command Prompt window from appearing briefly after every frame.

When this node tree is rendered, each file will be immediately copied to the C\ directory as it is rendered.

The Run Command node could be used to transfer the files via FTP to a remote drive on the network, to print out each frame as it is rendered, or to execute a custom image-processing tool.

The Run Command node is not restricted to executing simple batch files. FusionScript, VBScript, Jscript, CGI, and Perl files could also be used, as just a few examples.

### Common Controls

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

### Set Domain [DoD]

The Set Domain node

**Set Domain Node Introduction**

Set Domain is used to adjust or set the active area of an image or the area of the image considered to have valid data.

It does not change the image's physical dimensions. Downstream nodes will not process anything outside the Domain of Definition (DoD), thus speeding up rendering of computation-intensive nodes.

This node provides an absolute mode, for setting the domain of definition manually, and a relative mode for adjusting the existing domain of definition.

**Inputs**

The two inputs on the Set Domain node are used to connect 2D images.

- **Input:** The orange background input must be connected. It accepts a 2D image with the DoD you want to replace or adjust.
- **Foreground:** The green image input is optional but also accepts a 2D image as its input. When the foreground input is connected, the Set Domain node will replace the Background input’s domain of definition with the foreground’s DoD.
Basic Node Setup

The example below assumes an image is connected to a Set Domain node to manually configure the DoD.

A Set Domain node manually sets the area to limit image processing.

Inspector

The Set Domain Controls tab in Set mode

Controls Tab

Mode

The Mode menu has two choices depending on whether you want to adjust or offset the existing domain or set precise values for it.

The same operations can be performed in Set or in Adjust mode. In Adjust mode, the sliders default to 0, marking their respective full extent of the image. Positive values shrink the DoD while negative values expand the DoD to include more data.

Set mode defaults to the full extent of the visible image. Sliders default to a scale of 0-1 from left to right and bottom to top.

Left

Defines the left border of the DoD. Higher values on this slider move the left border toward the right, excluding more data from the left margin.

1 represents the right border of the image; 0 represents the left border. The slider defaults to 0 (left border).

Bottom

Defines the bottom border of the DoD. Higher values on this slider move the bottom border toward the top, excluding more data from the bottom margin.

1 represents the top border of the image; 0 represents the bottom border. The slider defaults to 0 (bottom border).
Right
Defines the right border of the DoD. Higher values on this slider move the right border toward the left, excluding more data from the right margin.

1 represents the right border of the image; 0 represents the left border. In Set mode, the slider defaults to 1 (right border).

Top
Defines the top border of the DoD. Higher values on this slider move the top border toward the bottom, excluding more data from the top margin.

1 represents the top border of the image; 0 represents the bottom border. In Set mode, the slider defaults to 1 (top border).

The Set Domain Controls tab in Adjust mode

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Time Speed [TSpd]

The Time Speed node

Time Speed Node Introduction
The Time Speed node allows image sequences to be sped up, slowed down, reversed, or delayed. Image Interpolation offers smooth, high-quality results. Time Speed should be used for static speed changes or to introduce delays in the footage. To apply animated changes in time, such as accelerating or decelerating time, use a Time Stretcher instead.
When operating in Flow mode, Optical Flow data is required. This node does not generate optical flow directly. You have to create it upstream using an Optical Flow node or by loading the forward/reverse vector channels from the image.

TimeSpeed does not interpolate the aux channels but instead destroys them. In particular, the Vector/BackVector channels are consumed and destroyed after computation.

Add an Optical Flow after the Time Speed node if you want to generate flow vectors for the retimed footage.

**Inputs**

The single input on the Time Speed node is used to connect a 2D image that will be retimed.

— **Input**: The orange input is used for the primary 2D image that will be retimed.

**Basic Node Setup**

The Time Speed node setup is as simple as connecting a 2D image into the orange background input of the node.

A MediaIn node having its speed changed in the Time Speed node.

**Inspector**

The Time Speed Controls tab

**Speed**

This control is used to adjust the Speed, in percentage values, of the outgoing image sequence. Negative values reverse the image sequence. 200% Speed is represented by a value of 2.0, 100% by 1.0, 50% by 0.5, and 10% by 0.1.

The Speed control cannot be animated.

**Delay**

Use this control to Delay the outgoing image sequence by the specified number of frames. Negative numbers offset time back, and positive numbers advance time.
Interpolate Mode

This menu determines how the time speed is processed in order to improve its visual playback quality, especially in the case of clips that are slowed down. There are three choices in the menu.

— **Nearest**: The most processor efficient and least sophisticated method of processing; frames are either dropped for fast motion or duplicated for slow motion.
— **Blend**: Also processor efficient, but can produce smoother results; adjacent duplicated frames are dissolved together to smooth out slow or fast motion effects.
— **Flow**: The most processor intensive but highest quality method of speed effect processing. Using vector channels pre-generated from an Optical Flow node, new frames are generated to create slow or fast motion effects. The result can be exceptionally smooth when motion in a clip is linear. However, two moving elements crossing in different directions or unpredictable camera movement can cause unwanted artifacts.

Sample Spread

This slider is displayed only when Interpolation is set to Blend. The slider controls the strength of the interpolated frames on the current frame. A value of 0.5 blends 50% of the frame before and 50% of the frame ahead and 0% of the current frame.

Depth Ordering

This menu is displayed only when Interpolation is set to Flow. The Depth Ordering is used to determine which parts of the image should be rendered on top. This is best explained by example.

In a locked-off camera shot where a car is moving through the frame, the background does not move, so it produces small, or slow, vectors. The car produces larger, or faster, vectors.

The Depth Ordering, in this case, is Fastest on Top, since the car draws over the background.

In a shot where the camera pans to follow the car, the background has faster vectors, and the car has slower vectors, so the Depth ordering method would be Slowest on Top.

Clamp Edges

This checkbox is displayed only when Interpolation is set to Flow. Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges can cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to use clamp edges only to correct small gaps around the edges of an interpolated frame.

Edge Softness

This slider is only displayed when Interpolation is set to Flow and Clamp Edges is enabled. It helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you have only one checkbox enabled, you can use a larger softness at around 0.03.
**Source Frame and Warp Direction**

These checkboxes are displayed only when Interpolation is set to Flow. These controls determine which frames and which vectors are used to create the in-between frames. Each method ticked on will be blended into the result.

- **Prev Forward**: Takes the previous frame and uses the Forward vector to interpolate the new frame.
- **Next Forward**: Takes the next frame in the sequence and uses the Forward vector to interpolate the new frame.
- **Prev Backward**: Takes the previous frame and uses the Back Forward vector to interpolate the new frame.
- **Next Backward**: Takes the next frame in the sequence and uses the Back vector to interpolate the new frame.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**Time Stretcher [TSt]**

The Time Stretcher node is similar to the Time Speed node but permits the speed of the clip to be animated. Full spline control of the effect is provided, including smoothing. As a result, the Time Stretcher can be used to animate a single clip to 200, back to normal speed, pause for a second, and then play backward (like a VCR rewinding).

Image interpolation offers smooth, high-quality results, all using a spline curve to adjust time nonlinearly. To apply constant time changes such as frame rate changes, use a Time Speed instead.

When operating in Flow mode, Optical Flow data is required. This node does not generate optical flow directly; you must create it manually upstream using an Optical Flow node or by loading the forward/reverse vector channels from disk.

Flow Stretcher does not interpolate the aux channels but instead destroys them. In particular, the Vector/BackVector channels are consumed/destroyed. Add an Optical Flow after the Flow Stretcher if you want to generate flow vectors for the retimed footage.
Inputs
The single input on the Time Stretcher node is used to connect a 2D image that will be time stretched.

— **Input:** The orange input is used for the primary 2D image that will be time stretched.

Basic Node Setup
Like the Time Speed node, the Time Stretcher setup is as simple as connecting a 2D image into the orange background input of the node.

![Time Stretcher node setup](image)

A MediaIn node having its time ramped to various speeds in the Time Stretcher node.

Inspector
The Time Stretcher controls

Source Time
This control designates from which frame in the original sequence to begin sampling.

When a Time Stretcher node is added to the node tree, the Source Time control already contains a Bézier spline with a single keyframe set to 0.0. The keyframe position is determined by the current time when the node is added to the node tree.

**NOTE:** The Source Time spline may not be immediately visible until Edit is selected from the Source Time’s contextual menu, or Display all Splines is selected from the Spline Window’s contextual menu.

Interpolate Mode
This menu determines the how the time speed is processed in order to improve its visual playback quality, especially in the case of clips that are slowed down. There are three choices in the menu.

— **Nearest:** The most processor efficient and least sophisticated method of processing; frames are either dropped for fast motion or duplicated for slow motion.
— **Blend**: Also processor efficient but can produce smoother results; adjacent duplicated frames are dissolved together to smooth out slow or fast motion effects.

— **Flow**: The most processor intensive but highest quality method of speed effect processing. Using vector channels pre-generated from an Optical Flow node, new frames are generated to create slow or fast motion effects. The result can be exceptionally smooth when motion in a clip is linear. However, two moving elements crossing in different directions or unpredictable camera movement can cause unwanted artifacts.

**Sample Spread**

This slider is displayed only when Interpolation is set to Blend. The slider controls the strength of the interpolated frames on the current frame. A value of 0.5 blends 50% of the frame before and 50% of the frame ahead and 0% of the current frame.

**Depth Ordering**

This menu is displayed only when Interpolation is set to Flow. The Depth Ordering is used to determine which parts of the image should be rendered on top. This is best explained by example.

In a locked-off camera shot where a car is moving through the frame, the background does not move, so it produces small, or slow, vectors. The car produces larger, or faster, vectors.

The Depth Ordering in this case is Fastest on Top, since the car draws over the background.

In a shot where the camera pans to follow the car, the background has faster vectors, and the car has slower vectors, so the Depth ordering method would be Slowest on Top.

**Clamp Edges**

This checkbox is displayed only when Interpolation is set to Flow. Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges can cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to use clamp edges only to correct small gaps around the edges of an interpolated frame.

**Edge Softness**

This slider is displayed only when Interpolation is set to Flow and Clamp Edges is enabled. It helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you have only one checkbox enabled, you can use a larger softness at around 0.03.
Source Frame and Warp Direction

These checkboxes are displayed only when Interpolation is set to Flow. These controls determine which frames and which vectors are used to create the in-between frames. Each method ticked on will be blended into the result.

— **Prev Forward**: Takes the previous frame and uses the Forward vector to interpolate the new frame.
— **Next Forward**: Takes the next frame in the sequence and uses the Forward vector to interpolate the new frame.
— **Prev Backward**: Takes the previous frame and uses the Back Forward vector to interpolate the new frame.
— **Next Backward**: Takes the next frame in the sequence and uses the Back vector to interpolate the new frame.

Example

Make sure that the current time is either the first or last frame of the clip to be affected in the project. Add the Time Stretcher node to the node tree. This will create a single point on the Source Time spline at the current frame. The value of the Source Time will be set to zero for the entire Global Range.

Set the value of the Source Time to the frame number to be displayed from the original source, at the frame in time it will be displayed in during the project.

To shrink a 100-frame sequence to 25 frames, follow these steps:

1. Change the Current Time to frame 0.
2. Change the Source Time control to 0.0.
3. Advance to frame 24.
5. Check that the spline result is linear.
6. Fusion will render 25 frames by interpolating down the 100 frames to a length of 25.
7. Hold the last frame for 30 frames, and then play the clip backward at regular speed. Continue the example from above and follow the steps below.
8. Advance to frame 129.
9. Right-click on the Source Time control and select Set Key from the menu.
10. Advance to frame 229 (129 + 100).
11. Set the Source time to 0.0.

Common Controls

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Wireless Link [Wire]

Wireless Link Node Introduction
The Wireless Link node helps manage the tangle of connection lines in a node tree by wirelessly connecting one 2D node to another 2D node.

Although Wireless Links can be helpful, try to keep as much of a node tree as visible as possible; otherwise, you lose one of the main benefits of a node tree.

Inputs
There are no inputs on this node.

Basic Node Setup
There is no setup for this node. It is a free-standing node that connects “wirelessly” using the control in the Inspector.

Inspector
The Wireless Link Controls tab

Controls Tab
The Controls tab in the Wireless Link node contains a single Input field for the linked node.

Input
To use the Wireless Link node, in the Node Editor, drag the 2D node into the Input field of the Wireless Link node. Any change you make to the original node is wirelessly replicated in the Wireless Link node. You can use the output from the Wireless Link node to connect to a nearby node.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other miscellaneous nodes. These common controls are described in detail in the following “The Common Controls” section.
The Common Controls

Nodes that handle miscellaneous operations share a number of identical controls in the Inspector. This section describes controls that are common among miscellaneous nodes.

Inspector

The Common Miscellaneous Settings tab

Settings Tab

The Settings tab in the Inspector can be found on every tool in the miscellaneous nodes. The controls are consistent and work the same way for each tool.

Blend

The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this will cause the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0

The tool is processed even when the input value is zero. This can be useful if processing of this node is scripted to trigger another task, but the value of the node is set to 0.0.
**Red/Green/Blue/Alpha Channel Selector**
These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur will first be applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this will generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

**Apply Mask Inverted**
Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

**Multiply by Mask**
Selecting this option will cause the RGB values of the masked image to be multiplied by the mask channel’s values. This will cause all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

**Use Object/Use Material (Checkboxes)**
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels will be used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

**Correct Edges**
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

**Object ID/Material ID (Sliders)**
Use these sliders to select which ID will be used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the view. The image or sequence must have been rendered from a 3D software package with those channels included.

**Use GPU**
The Use GPU menu has three settings. Setting the menu to Disable turns off GPU hardware-accelerated rendering. Enabled uses the GPU hardware for rendering the node. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.
Motion Blur

— **Motion Blur:** This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.

— **Quality:** Quality determines the number of samples used to create the blur. A quality setting of 2 will cause Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.

— **Shutter Angle:** Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one whole frame exposure. Higher values are possible and can be used to create interesting effects.

— **Center Bias:** Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.

— **Sample Spread:** Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 110

Optical Flow

This chapter details the Optical Flow nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Tween [Tw] 2368
The Common Controls 2371
Optical Flow Node Introduction

This node analyzes a clip connected to its input using an Optical Flow algorithm. Think of optical flow as a per-pixel motion vector that matches up features over several frames.

The computed optical flow is stored within the Vector and Back Vector aux channels of the output. These channels can be used in other nodes like the Vector Motion Blur or Vector Distort. However, Optical Flow must render twice when connecting it to a Time Stretcher or Time Speed node. These nodes require the channels A. FwdVec and B. BackVec in that order, but Optical Flow generates A. BackVec and A. FwdVec when it processes.

If you find that optical flow is too slow, consider rendering it out into OpenEXR files using a Saver node.

TIP: If the footage input flickers on a frame-by-frame basis, it is a good idea to deflicker the footage beforehand.

Inputs

The Optical Flow node includes a single orange image input.

— Input: The orange background input accepts a 2D image. This is the sequence of frames for which you want to compute optical flow. The output of the Optical Flow node includes the image and vector channels. The vector channels can be displayed by right-clicking in the viewer and choosing Channel > Vectors and then Options > Normalize Color Range.

Basic Node Setup

The Optical Flow node analyzes the frames connected to the background input. Trimming a Loader or MedianIn to only the range you need prevents analyzing unnecessary frames. The output of the node can then be connected to any node that takes advantage of vector channels, such as a Time Stretcher.

TIP: When analyzing Optical Flow vectors, consider adding a Smooth Motion node afterward with smoothing for forward/ backward vectors enabled.
An Optical Flow node generating motion vectors on-the-fly.

Alternatively, if you find the Optical Flow node too slow to analyze the frames, consider rendering it out to an OpenEXR format using a Saver node. Then import the rendered EXR file as your new image with embedded vector channels.

An Optical Flow node rendered out through a Saver node.

Inspector

Optical Flow advanced controls

Controls Tab (Advanced)

When you add an Optical Flow, Repair Frame, or Tween node to a Comp, a Method drop-down menu in the Inspector allows you to choose between an Advanced GPU-based algorithm or a Classic CPU-based algorithm. This Advanced method is the same Optical Flow algorithm used in other DaVinci Resolve pages.

Warp Count

Decreasing this slider makes the optical flow computations faster. To understand what this option does, you must understand that the optical flow algorithm progressively warps one image until it matches with the other image. After some point, convergence is reached, and additional warps become a waste of computational time. You can tweak this value to speed up the computations, but it is good to watch what the optical flow is doing at the same time.
**Iteration Count**

Decreasing this slider makes the computations faster. In particular, just like adjusting the Warp Count, adjusting this option higher will eventually yield diminishing returns and not produce significantly better results. By default, this value is set to something that should converge for all possible shots and can be tweaked lower fairly often without reducing the disparity’s quality.

**Smoothness**

This controls the smoothness of the optical flow. Higher smoothness helps deal with noise, while lower smoothness brings out more detail.

**Half Resolution**

The Half Resolution checkbox is used purely to speed up the calculation of the optical flow. The input images are resized down and tracked to produce the optical flow.

**Controls Tab (Classic)**

By choosing Classic from the Method drop-down menu in the Inspector, you can use the older CPU-based algorithm to maintain compatibility with Comps created in previous versions. This method may also be better suited for some Stereo3D processing.

When using the Classic method, a single slider at the top of the Inspector improves performance by generating proxies. The remaining Advanced section parameters tune the Optical Flow vector calculations. The default settings serve as a good standard. In most cases, tweaking of the advanced settings is not needed. Many deliver small or diminishing returns. However, depending on the settings, rendering time can easily vary by 10x. If you’re interested in reducing process time, it is best to start by experimenting with the Proxy, Number of Iterations, and Number of Warps sliders and changing the filtering to Bilinear.

**Proxy (for Tracking)**

The Proxy slider is used purely to speed up the calculation of the optical flow. The input images are resized down by the proxy scale and tracked to produce the optical flow. The computational time is roughly proportional to the number of pixels in the image. This means a proxy scale of 2 will give a 4x speedup, and a proxy scale of 3 will give a 9x speedup.

**Smoothness**

This controls the smoothness of the optical flow. Higher smoothness helps deal with noise, while lower smoothness brings out more detail.

**Edges**

This slider is another control for smoothness but applies it based on the color channel. It tends to have the effect of determining how edges in the flow follow edges in the color images. When it is set to a low value, the optical flow becomes smoother and tends to overshoot edges. When it is set to a high value, details from the color images start to slip into the optical flow, which is not desirable. Edges in the flow end up more tightly aligning with the edges in the color images. This can result in streaked-out edges when the optical flow is used for interpolation. As a rough guideline, if you are using the disparity to produce a Z-channel for post effects like Depth of Field, then set it lower in value. If you are using the disparity to perform interpolation, you might want it to be higher in value.
**Match Weight**
This control sets a threshold for how neighboring groups of foreground/background pixels are matched over several frames. When set to a low value, large structural color features are matched. When set to higher values, small sharp variations in the color are matched. Typically, a good value for this slider is in the [0.7, 0.9] range. When dealing with stereo 3D, setting this option higher tends to improve the matching results in the presence of differences due to smoothly varying shadows or local lighting variations between the left and right images. The user should still perform a color match or deflickering on the initial images, if necessary, so they are as similar as possible. This option also helps with local variations like lighting differences due to light passing through a mirror rig.

**Mismatch Penalty**
This option controls how the penalty for mismatched regions grows as they become more dissimilar. The slider provides a choice between a balance of Quadratic and Linear penalties. Quadratic strongly penalizes large dissimilarities, while Linear is more robust to dissimilar matches. Moving this slider toward Quadratic tends to give a disparity with more small random variations in it, while Linear produces smoother, more visually pleasing results.

**Warp Count**
Decreasing this slider makes the optical flow computations faster. In particular, the computational time depends linearly upon this option. To understand what this option does, you must understand that the optical flow algorithm progressively warps one image until it matches with the other image. After some point, convergence is reached, and additional warps become a waste of computational time. The default value in Fusion is set high enough that convergence should always be reached. You can tweak this value to speed up the computations, but it is good to watch what the optical flow is doing at the same time.

**Iteration Count**
Decreasing this slider makes the computations faster. In particular, the computational time depends linearly upon this option. Just like adjusting the Warp Count, adjusting this option higher will eventually yield diminishing returns and not produce significantly better results. By default, this value is set to something that should converge for all possible shots and can be tweaked lower fairly often without reducing the disparity’s quality.

**Filtering**
This option controls filtering operations used during flow generation. Catmull-Rom filtering will produce better results, but at the same time, turning on Catmull-Rom will increase the computation time steeply.

**Common Controls**

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Optical Flow nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
**Repair Frame Node Introduction**

Repair Frame replaces damaged or missing frames or portions of frames with scratches or other temporally transient artifacts. It requires three frames: the repair frame and two neighboring frames. An Optical Flow node is not required for generating motion vectors since the Repair Frame node computes the optical flow. However, this can make it slow to process.

Repair Frame will not pass through, but rather destroys, any aux channels after the computation is done.

See the Optical Flow node for controls and settings information.

**TIP:** If your footage varies in color from frame to frame, sometimes the repair can be noticeable because, to fill in the hole, Repair Frame must pull color values from adjacent frames. Consider using deflickering, color correction, or using a soft-edged mask to help reduce these kinds of artifacts.

**Inputs**

There are two inputs on the Repair Frame node. One is used to connect a 2D image that will be repaired and the other is for an effect mask.

- **Input:** The orange input is used for the primary 2D image that will be repaired.
- **Effect Mask:** The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the repairs to certain areas.

**Basic Node Setup**

The Repair Frame node analyzes the incoming MediaIn node and repairs single frame issues like dust or scratches.

A Repair Frame node set up to analyze a MediaIn node using internal optical flow analysis.
Inspector

The Repair Frame Controls tab

Controls Tab

The Controls tab includes options for how to repair the frames. It also includes controls for adjusting the optical flow analysis, identical to those controls in the Optical Flow node.

Depth Ordering

The Depth Ordering determines which parts of the image should be rendered on top by selecting either Fastest On Top or Slowest On Top. The examples below best explain these options.

In a locked-off camera shot where a car is moving through the frame, the background does not move, so it produces small, or slow, vectors, while the car produces larger, or faster, vectors.

The depth ordering in this case is Fastest On Top since the car draws over the background.

In a shot where the camera pans to follow the car, the background has faster vectors, and the car has slower vectors, so the Depth Ordering method is Slowest On Top.

Clamp Edges

Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges causes a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to use clamp edges only to correct small gaps around the edges of an interpolated frame.

Edge Softness

This slider is displayed only when Clamp Edges is enabled. The slider helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you have only one checkbox enabled, you can use a larger softness at around 0.03.
Source Frame and Warp Direction
These checkboxes allow you to choose which frames and vectors create the in-between frames. Each method ticked on will be blended into the result.

— **Prev Forward**: Takes the previous frame and uses the Forward vector to interpolate the new frame.
— **Next Forward**: Takes the next frame in the sequence and uses the Forward vector to interpolate the new frame.
— **Prev Backward**: Takes the previous frame and uses the Back Forward vector to interpolate the new frame.
— **Next Backward**: Takes the next frame in the sequence and uses the Back vector to interpolate the new frame.

Optical Flow Options
These settings tweak the optical flow analysis. See the Classic and Advanced Controls section for the Optical Flow node earlier in this chapter.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Optical Flow nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Smooth Motion [SM]

The Smooth Motion node

Smooth Motion Node Introduction
The Smooth Motion node smooths various AOV (Arbitrary Output Variables) channels in a clip using optical flow to look at neighboring frames. It can be used for smoothing the Disparity channel in a stereo 3D clip, where it helps reduce temporal edge/fringing artifacts, but it can also smooth a wide range of channels like vectors, normals, and Z.

It is required that the image connected to the input on the node have precomputed Vector and Back Vector channels; otherwise, this tool prints error messages in the Console window.

Check on the channels you want to temporally smooth. Be aware that if a channel selected for smoothing is not present, Smooth Motion will not fail, nor will it print any error messages.

It can also be used to smooth the Vector and Back Vector channels; however, sometimes, this can make the interpolated results worse if there are conflicting motions or objects in the shot that move around erratically, jitter, or bounce rapidly.
**TIP:** You can use two or more Smooth Motion nodes in sequence to get additional smoothing. With one Smooth Motion node, the previous, current, and next frames are examined for a total of 3; with two Smooth Motion nodes, 5 frames are examined; and with three Smooth Motion nodes, 7 frames are examined.

Another technique using two Smooth Motion nodes is to use the first Smooth Motion node to smooth the Vector and Back Vector channels. Use the second Smooth Motion to smooth the channels you want to smooth (e.g., Disparity). This way, you use the smoothed vector channels to smooth Disparity.

You can also try using the smoothed motion channels to smooth the motion channels.

**Inputs**

The Smooth Motion node includes a single orange image input.

— **Input:** The orange image input accepts a 2D image. This is the sequence of images for which you want to compute smooth motion. This image must have precomputed Vector and Back Vector channels either generated from an Optical Flow node or saved in EXR format with vector channels.

**Basic Node Setup**

The Smooth Motion node takes the output of the Optical Flow node for the required Vector and Back Vector channels. The Smooth Motion node can then be used to smooth those channels or AO channels.

A Smooth Motion node using Vector and Back Vector channels from the Optical Flow node.

**Inspector**

The Smooth Motion Controls tab
Controls Tab
The Controls tab includes checkboxes for the channels you want to smooth. If a channel selected for smoothing is not available in the input image, Smooth Motion will not fail, nor will it print any error messages to the Console.

Channel
Smooth Motion can be applied to more than just the RGBA channels. It can also be applied to the other AOV channels.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Optical Flow nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Tween [Tw]

Tween Node Introduction
Tween reconstructs a missing frame by interpolating between two neighboring frames using the optical flow. Tween is nearly identical in functionality to Time Speed and Time Stretcher. The major difference is that it works on two images that are not serial members of a sequence. As a consequence, it cannot use the Vector or Back Vector aux channels stored in the images. The Tween node manually generates the optical flow, so there is no need to add an Optical Flow node before the Tween node. The generated optical flow is thrown away and is not stored back into the output frames.

Since optical flow is based on color matching, it is a good idea to color correct your images to match ahead of time. Also, if you are having trouble with noisy images, it may also help to remove some of the noise ahead of time.

Tween destroys any input aux channels. See the Optical Flow node for controls and settings information.

Inputs
There are two image inputs on the Tween node and an effects mask input.

— Input 0: The orange input, labeled input 0, is the previous frame to the one you are generating.
— Input 1: The green input, labeled input 1, is the next frame after the one you are generating.
— Effect Mask: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the Tween to certain areas.
Basic Node Setup

The Tween node receives two inputs for the two neighboring frames to the one you are generating. Below, the previous frame, frame 01, is connected to the orange input 0. The next frame, frame 03, is connected to the green input 1. The Tween node will generate frame 02 and output the sequence.

The Tween node receives two neighboring frames and generates the middle one.

Inspector

The Tween Controls tab

Controls Tab

The Controls tab includes options for how to tween frames. It also includes controls for adjusting the optical flow analysis, identical to those controls in the Optical Flow node.

Interpolation Parameter

This option determines where the frame you are interpolating is, relative to the two source frames A and B. An Interpolation Parameter of 0.0 will result in frame A, a parameter of 1.0 will result in frame B, and a parameter of 0.5 will yield a result halfway between A and B.

Depth Ordering

The Depth Ordering determines which parts of the image should be rendered on top by selecting either Fastest On Top or Slowest On Top. The examples below best explain these options.
In a locked-off camera shot where a car is moving through the frame, the background does not move, so it produces small, or slow, vectors, while the car produces larger, or faster, vectors.

The Depth Ordering in this case is Fastest On Top since the car draws over the background.

In a shot where the camera pans to follow the car, the background has faster vectors, and the car has slower vectors, so the Depth Ordering method is Slowest On Top.

**Clamp Edges**

Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges causes a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to use Clamp Edges only to correct small gaps around the edges of an interpolated frame.

**Edge Softness**

This slider is displayed only when Clamp Edges is enabled. The slider helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you have only one checkbox enabled, you can use a larger softness at around 0.03.

**Source Frame and Warp Direction**

These checkboxes allow you to choose which frames and vectors create the in-between frames. Each method ticked on will be blended into the result.

- **Prev Forward**: Takes the previous frame and uses the Forward vector to interpolate the new frame.
- **Next Forward**: Takes the next frame in the sequence and uses the Forward vector to interpolate the new frame.
- **Prev Backward**: Takes the previous frame and uses the Back Forward vector to interpolate the new frame.
- **Next Backward**: Takes the next frame in the sequence and uses the Back vector to interpolate the new frame.

**Optical Flow Options**

These settings tweak the optical flow analysis. See the Class and Advanced Controls section for the Optical Flow node earlier in this chapter.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Optical Flow nodes. These common controls are described in detail in the following “The Common Controls” section.
The Common Controls

Nodes that handle optical flow operations share a number of identical controls in the Inspector. This section describes controls that are common among Optical Flow nodes.

Inspector

The Common Optical Flow Settings tab

Settings Tab

The Settings tab in the Inspector can be found on every tool in the Optical Flow category. The controls are consistent and work the same way for each tool.

Blend

The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this causes the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0

The tool is processed even when the input value is zero. This can be useful when this node process is scripted to trigger another task, but the value of the node is set to 0.0.
Red/Green/Blue/Alpha Channel Selector
These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur is first applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

Apply Mask Inverted
Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

Multiply by Mask
Selecting this option causes the RGB values of the masked image to be multiplied by the mask channel’s values. This causes all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

Use Object/Use Material (Checkboxes)
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels are used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

Correct Edges
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Object ID/Material ID (Sliders)
Use these sliders to select which ID is used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the view. The image or sequence must have been rendered from a 3D software package with those channels included.

Hide Incoming Connections
Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node are displayed in the Inspector. Dragging a connected node from the node tree into the empty field hides that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line reappears.
Comments
The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts
Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, see the Fusion scripting documentation.
Chapter 111

Paint Node

This chapter details the Paint node available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Keyboard Shortcuts 2382
Paint

Paint Node Introduction

Paint is an extremely flexible, stroke-based tool for wire and rig removal, image cloning, or to create custom masks and mattes rapidly. Fusion’s paint can even be used to create new images and artistic elements from scratch.

Each Paint node is made up of a series of brush strokes. These strokes are vector shapes with editable brush, size, and effect. A wide range of apply modes and brush types are available.

Most Brushstrokes styles are editable polylines for fine control. They can be animated to change shape, length, and size over time. The opacity and size of a stroke can be affected by velocity and pressure when used with a supported tablet.

Unlimited undo and redo of paint provides the ability to experiment before committing changes to an image sequence. Paint strokes can be reordered, deleted, and modified with virtually infinite flexibility.

Inputs

The two inputs on the Paint node are used to connect a 2D image and an effect mask which can be used to limit the painted area.

- **Input**: It is required to connect the orange input with a 2D image that creates the size of the “canvas” on which you paint.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the Paint to only those pixels within the mask.

Basic Node Setup

The Paint node always needs an input connection. The simplest setup is to paint directly on the incoming MediaIn node.
A more flexible setup is to use a Background node to set the size that matches the image you are painting on. In the Inspector, the background would be set to be fully transparent. Then, the Paint tool can be merged as the foreground over the actual image you want to paint on.

A Paint node merged over the top of a MediaIn for more flexibility

**Types of Paint Strokes**

To begin working with the Paint tool, first select the paint stroke type from the Paint toolbar above the viewer. There are ten stroke types to choose from as well as two additional tools for selecting and grouping paint strokes. The stroke types and tools are described below in the order they appear in the toolbar.

— **Multistroke:** Although this is the default selection and the first actual brush type in the toolbar, Multistroke is not typically the stroke type most often used. However, it’s perfect for those 100-strokes-per-frame retouching paint jobs like removing tracking markers. Multistroke is much faster than the Stroke type but is not editable after it is created. By default, Multistroke lasts for one frame and cannot be modified after it has been painted. Use the Duration setting in the Stroke controls to set the number of frames before painting. A shaded area of the Multistroke duration is visible but not editable in the Keyframes Editor. While Multistrokes aren’t directly editable, they can be grouped with the PaintGroup modifier, then tracked, moved, and rotated by animating the PaintGroup instead.

— **Clone Multistroke:** Similar to Multistroke but specifically meant to clone elements from one area or image to the other. Perfect for those 100-strokes-per-frame retouching paint jobs like removing tracking markers. Clone Multistroke is faster than the Stroke type but is not editable after it is created. By default, Clone Multistroke lasts for one frame and cannot be modified after it has been painted. Use the Duration setting in the Stroke controls to set the number of frames before painting. A shaded area of the Clone Multistroke duration is visible but not editable in the Keyframes Editor.
— **Stroke:** In most cases, the Stroke tool is what people think of when they think of paint and is the tool of choice for most operations. It is a fully animatable and editable vector-based paint stroke. It can become slow if hundreds of strokes are used in an image; when creating a lot of paint strokes, it is better to use Multistroke. The Stroke type has a duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor. When the painting is complete, choose the Select button in the Paint toolbar to avoid accidentally adding new strokes.

— **Polyline Stroke:** This provides the ability to create and manipulate a stroke in the same way that a Bézier path or polygon mask might be created. To add a Polyline Stroke, select the Polyline button and click in the viewer to add the first point. Continue clicking to add additional points to the polyline. This click append style is the default, but polyline strokes can also be created in draw append mode. Polylines can be tracked or connected to existing polylines like masks or animation paths. The Polyline Stroke has a default duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor.

— **Circle:** Creates a circular shape with animatable control over radius and center. The Circle type has a duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor.

— **Rectangle:** Creates a rectangular area. The Rectangle type has a duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor.

— **Copy Polyline:** Allows you to create a closed Polyline area with animatable offset to clone elements from one area or image to the other. The Copy Polyline type has a duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor.

— **Copy Circle/Rectangle:** A circular or rectangular shape area with animatable offset to clone elements from one image to the other. The Copy Circle/Rectangle type has a duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor.

— **Fill:** Similar to the Wand mask tool. This tool fills similarly colored adjacent pixels with a fill color based on the selected color channel. The tool has a duration of the entire global range. However, you can edit its duration at any time in the Keyframes Editor.

— **Paint Group:** Allows you to group multiple paint strokes with full control over center and size. Since Multistroke and Clone Multistroke styles cannot be tracked, grouping these paint stroke types and tracking the paint group is one common use of groups.

### Editing Options Toolbar

![Editing Options Toolbar](image)

Paint edit options are displayed in the viewer after a Polyline stroke is created.

Polyline-based paint strokes include a second toolbar in the viewer to select different editing options. The paint strokes that include this second toolbar are Polyline Stroke and Copy Polyline.
The Stroke style also displays this toolbar after the stroke is selected and the Make Editable button is clicked in the Inspector.

- **Click Append**: This is the default option when creating a polyline stroke. It works more like a Bézier pen drawing tool than a paintbrush tool. Clicking sets a control point and appends the next control point when you click again in a different location.

- **Draw Append**: This is a freehand drawing tool. It paints a stroke similar to drawing with a pencil on paper. You can create a new Polyline Stroke or Copy Polyline Stroke using the Draw tool, or you can extend a Stroke style after clicking the Make Editable button in the Inspector.

- **Insert**: Insert adds a new control point along the paint stroke spline.

- **Modify**: Modify allows you to move a point or smooth any exiting point along a spline without worrying about adding a new point accidentally.

- **Done**: Prevents any point along the spline from being moved or modified. Also, new points cannot be added. You can, however, move and rotate the entire spline.

- **Closed**: Closes an open polyline.

- **Smooth**: Changes the selected stroke or control point from a linear to a smooth curve.

- **Linear**: Changes the selected stroke or control point from a smooth curve to linear.

- **Select All**: Selects all the control points on the polyline.

- **Keys**: Shows or hides the control points along the polyline.

- **Handles**: Shows or hides the Bézier handles along the polyline.

- **Shape**: Places a reshape rectangle around the selected polyline control points. Using the reshape rectangle, you can deform groups of polyline control points or entire shapes much easier than modifying each point.

- **Delete**: Deletes the selected control point(s).

- **Reduce**: Opens a Freehand precision window that can be used to reduce the number of control points on a polyline. This can make the paint stroke easier to modify, especially if it has been created using the Draw tool.

- **Publish**: You can use the Publish menu to either publish control points or the path. Publishing is a form of parameter linking. It makes the selected item available for use by other controls, or to attach a control point to a tracker.

- **Follow Points**: Allows a selected point to follow the path of a published point. The point follows the published point using an offset position.

- **Roto Assist**: Enable the Roto Assist button when you begin painting with the Polyline Stroke tool. The polyline points snap to the closest edge as you click to add points to the shape. A cyan outline indicates the points that have snapped to an edge. There are three main Roto Assist options selectable through the drop-down menu:
  - **Multiple Points**: When enabled, a single click on a high-contrast edge will add multiple points to define the entire edge, instead of having to add each point individually. This is a one time only click. The second click reverts to single point edge detection.
  - **Distance 8**: Opens a dialog where you can set the pixel range within which searching for an edge will take place.
  - **Reset**: Used for resetting the snap attribute of all snapped points. After resetting, the points will become unavailable for tracking.
Inspector

The Paint Controls tab

Controls Tab

Not all of the controls described here appear in all modes. Some controls are useful only in a specific Paint mode and do not appear when they are not applicable. The Controls tab is used to configure your paint settings before painting. Once a paint stroke is created, except for the Multistroke and Clone Multistroke, you can select the stroke in the viewer and update the controls.

Brush Controls

Brush Shape

The brush shape buttons select the brush tip shape. Except for the single pixel shape, you can modify the size of the brush shape in the viewer by holding down the Command or Ctrl key while dragging the mouse.

— **Soft Brush**: The Soft Brush type is a circular brush tip with soft edges.
— **Circular Brush**: A Circular Brush is a brush tip shape with hard edges.
— **Image Brush**: The Image Brush allows images from any node in the node tree, or from a file system, to be used as a brush tip.
— **Single Pixel Brush**: The Single Pixel Brush is perfect for fine detail work, creating a brush tip precisely one pixel in size. No anti-aliasing is applied to the single pixel brush.
— **Square Brush**: A Square Brush is a brush tip with hard edges.

Vary Size

Vary size settings change the stroke size based on speed or a pressure-sensitive pen and tablet.

— **Constant**: The brush tip remains a constant size over the stroke.
— **With Pressure**: The stroke size varies with the actual applied pressure.
— **With Velocity**: The stroke size varies with the speed of painting. The faster the stroke, the thinner it is.
Vary Opacity

Vary opacity settings change the stroke opacity based on speed or a pressure-sensitive pen and tablet.

— **Constant**: The brush tip remains at a constant transparency setting over the entire stroke.
— **With Pressure**: The stroke transparency varies with the applied pressure.
— **With Velocity**: The stroke transparency varies with the speed of painting. The faster the stroke, the more transparent it is.

Softness

Use this control to increase or decrease the Softness of a soft brush.

Image Source

When using the Image Source brush type, select between three possible source brush images.

— **Node**: The image source is derived from the output of a node in the node tree. Drag the node into the Inspector’s Source node input field to set the source.
— **Clip**: The image source is derived from an image or sequence on disk. Any file supported by Fusion’s Loader or MediaIn node can be used.
— **Brush**: Select an image to use as a brush from the menu. Images located in the Fusion > Brushes directory are used to populate the menu.

Color Space

When the Fill tool is selected, a Color Space menu selects the color space when sampling colors around the Fill tool center for inclusion in the fill range.

Channel

When the Fill tool is selected, a Channel menu selects which color channel is used in the fill paint. For example, with alpha selected, the fill occurs on contiguous pixels of the alpha channel.

Apply Controls

Apply Mode

The Apply Modes are buttons that change a brush’s painting functionality.

— **Color**: The Color Apply Mode paints simple colored strokes. When used in conjunction with an image brush, it can also be used to tint the image.
— **Clone**: The Clone Apply Mode copies an area from the same image using adjustable positions and time offsets. This mode can also copy portions of one image into another image. Any image from the node tree can be used as the source image.
— **Emboss**: The Emboss Apply Mode embosses the portions of the image covered by the brush stroke.
— **Erase**: Erase reveals the underlying image through all other strokes, effectively erasing portions of the strokes beneath it without actually destroying the strokes.
— **Merge**: This Apply Mode effectively merges the brush onto the image. This mode behaves in much the same way as the Color Apply Mode but has no color controls. It is best suited for use with the image brush type.
— **Smear**: Smear the image using the direction and strength of the brushstroke as a guide.
— **Stamp**: Stamps the brush onto the image, completely ignoring any alpha channel or transparency information. This mode is best suited for applying decals to the target image.
— **Wire**: This Wire Removal Mode is used to remove wires, rigging, and other small elements in the frame by sampling adjacent pixels and draw them in toward the stroke.

**Stroke Controls**

The stroke controls contain parameters that adjust the entire stroke of paint as well as control it over time.

— **Size**: This control adjusts the size of the brush when the brush type is set to either Soft Brush or Circle. The diameter of the brush is drawn in the viewer as a small circle surrounding the mouse pointer. The size can also be adjusted interactively in the viewer by holding the Command or Ctrl key while dragging the mouse pointer.

— **Spacing**: The Spacing slider determines the distance between dabs (samples used to draw a continuous stroke along the underlying vector shape). Increasing this value increases the density of the stroke, whereas decreasing this value causes the stroke to assume the appearance of a dotted line.

— **Stroke Animation**: The Stroke Animation menu provides several pre-built animation effects that can be applied to a paint stroke. This menu appears only for vector strokes like Stroke and Polyline Stroke.

  — **All Frames**: This default displays the stroke for all frames of the image connected to the orange background input of the Paint node.

  — **Limited Duration**: This exists on the number of frames specified by the Duration slider.

  — **Write On**: When Write On is selected, an animation spline is added to the paint stroke that precisely duplicates the timing of the paint stroke’s creation. The stroke is written on the image exactly as it was drawn. To adjust the timing of the Write On effect, switch to the Spline Editor and use the Time Stretcher node to adjust the overall length of the animation spline. To smooth or manually adjust the motion, try reducing the points in the animation spline.

  — **Write Off**: Write Off performs the reverse of Write On, drawing the stroke starting from the end and working backward to the start of the stroke.

  — **Write On Then Off**: This menu option applies a Write On and then a Write Off animation mode to the stroke.

— **Trail**: Selecting the Trail option from the menu causes both the start and end points of the stroke to be animated simultaneously, offset from each other by the amount specified in the Duration control. This has the effect of creating a painted segment that follows the stroke path. As with the Write On and Write Off effects, this starts on the current frame when the animation mode is selected. The timing of the animation can be adjusted manually using the Spline or Keyframes Editors.

— **Duration**: Duration sets the duration of each stroke in frames. This control is present only for Multistroke and Clone Multistroke, or when the stroke animation mode is set to Limited Duration. It is most commonly employed for frame-by-frame rotoscoping through a scene. Each Vector stroke applied to a scene has a duration in the Keyframes Editor that can be trimmed independently from one stroke to the next. The duration can be set to 0.5, which allows each stroke to last for a single field only when the node tree is processing in Fields mode.
— **Write On and Write Off:** This range slider appears when the Stroke Animation is set to one of the Write On and Write Off methods. The range represents the beginning and end points of the stroke. Increase the Start value from 0.0 to 1.0 to erase the stroke, or increase the End value from 0.0 to 1.0 to draw the stroke on the screen. This control can be animated to good effect. It works most effectively when automatically animated through the use of the Write On and Write Off modes of the Stroke Animation menu.

— **Make Editable:** This button appears only for Vector strokes. Clicking on Make Editable turns the current stroke into a polyline spline so that the shape can be adjusted or animated.

## Paint Node Modifiers

Every paint stroke created in the viewer creates an associated modifier stroke. These modifier strokes are represented as a list of paint stroke operations in the Modifiers tab of the Inspector. Each stroke you create can be modified or deleted, or applied in a different order using the modifier stack.

**NOTE:** The MultiStroke tools are built for speed and can contain many strokes internally without creating a huge list stack in the modifiers.

Each Paint modifier stroke contains Brush controls, Apply controls, and Stroke controls identical to those found in the main Controls tab of the Inspector.

## Keyboard Shortcuts

Keyboard shortcuts allow you to adjust painting styles and color without having to navigate menus.

**While painting:**

- Hold Command or Ctrl while left-dragging to change brush size.
- Hold Option or Alt while clicking to pick a color in the viewer.

**While cloning:**

- Option-click or Alt-click to set the clone source position. Strokes start cloning from the selected location.
- Hold O to temporarily enable a 50% transparent overlay of the clone source (% can be changed with pref Tweaks.CloneOverlayBlend).
- Press P to toggle an opaque overlay of the clone source.
**While overlay is showing:**
Arrow keys change the clone source position; you can also drag crosshairs and adjust angle control or size sliders.
Option + Left/Right or Alt + Left/Right Arrow keys change the clone source angle.
Option + Up/Down or Alt + Up/Down Arrow keys change the clone source size.
Shift + Command or Shift + Ctrl can be used with the above for greater or lesser adjustments. Left and right square brackets, [ and ], change the clone source Time Offset (this requires a specific Clone Source node to be set in the Source Node field).

**Copy Rect/Ellipse:**
Shift + drag out the source to constrain the shape.

**With a single stroke selected (not available on multi or polyline strokes):**
Press X or Y to flip the stroke.

**Paint Groups:**
Command + drag or Ctrl + drag to change the position of a group’s crosshair, without changing the position of the group.
Chapter 112

Particle Nodes

This chapter details the Particle nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Particle Nodes

The Particle nodes are used to generate a large number of duplicated objects that automatically animate. They are used to create elements like falling rain, fireworks, smoke, pixie dust, and much more. There are endless possibilities. Particles in Fusion consist of a set of nodes that are strung together in a chain for generating, modifying, and rendering particles in a 2D or 3D scene.

To begin, every particle system you create must contain two fundamental nodes:

— **pEmitter**: Used to generate the particles and control their basic look, motion, and behavior.
— **pRender**: Used to render the output of the pEmitter into a 2D or 3D scene. When creating particles, you only ever view the pRender node.

The remaining particle nodes modify the pEmitter results to simulate natural phenomena like gravity, flocking, and bounce. The names of particle nodes all begin with a lowercase p to differentiate them from non-particle nodes. They can be found in the particles category in the Effects Library.

**pAvoid [pAv]**

The pAvoid node

**pAvoid Node Introduction**

The pAvoid node is used to create a region or area within the image that affected particles attempt to avoid entering and crossing.

It has two primary controls. The first determines the distance from the region a particle should be before it begins to move away from the region. The second determines how strongly the particle moves away from the region.

A pAvoid node creates a “desire” in a particle to move away from a specific region. If the velocity of the particle is stronger than the combined distance and strength of the pAvoid region, the particle’s desire to avoid the region does not overcome its momentum and the particle crosses that region regardless.
**Inputs**

The pAvoid node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input:** The orange input takes the output of other particle nodes.
- **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area particles avoid.

**Basic Node Setup**

The pAvoid node is placed in between the pEmitter and pRender. A Shape 3D node is used to create the region the particles will avoid.

![A pAvoid node using a Shape 3D node as the region to avoid](image)

**Inspector**

The pAvoid controls

**Randomize**

The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Distance**

Determines the distance from the region a particle should be before it begins to move away from the region.
**Strength**
Determine how strongly the particle moves away from the region. Negative values make the particles move toward the region instead.

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

**pBounce [pBn]**

The pBounce tool is used to create a region from which affected particles will bounce off when they come into contact.

**Inputs**
The pBounce node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green or magenta bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input:** The orange input takes the output of other particle nodes.
- **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area particles bounce off.

**Basic Node Setup**
The pBounce node is placed in between the pEmitter and pRender. A Shape 3D node is used to create the region the particles bounce off.
A pBounce node using a Shape 3D node as the region on which particles bounce off

**Inspector**

The pBounce controls

**Randomize**

The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result.

Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Elasticity**

Elasticity affects the strength of a bounce, or how much velocity the particle will have remaining after impacting upon the Bounce region. A value of 1.0 will cause the particle to possess the same velocity after the bounce as it had entering the bounce. A value of 0.1 will cause the particle to lose 90% of its velocity upon bouncing off of the region.

The range of this control is 0.0 to 1.0 by default, but greater values can be entered manually. This will cause the particles to gain momentum after an impact, rather than lose it. Negative values will be accepted but do not produce a useful result.

**Variance**

By default, particles that strike the Bounce region will reflect evenly off the edge of the Bounce region, according to the vector or angle of the region. Increasing the Variance above 0.0 will introduce a degree of variation to that angle of reflection. This can be used to simulate the effect of a rougher surface.
Spin
By default, particles that strike the region will not have their angle or orientation affected in any way. Increasing or decreasing the Spin value will cause the Bounce region to impart a spin to the particle based on the angle of collision, or to modify any existing spin on the particle. Positive values will impart a forward spin, and negative values impart a backward spin. The larger the value, the faster the spin applied to the particle will be.

Roughness
This slider varies the bounce off the surface to slightly randomize particle direction.

Surface Motion
This slider makes the bounce surface behave as if it had motion, thus affecting the particles.

Surface Motion Direction
This thumbwheel control sets the angle relative to the bounce surface.

Common Controls
Conditions, Style, Region, and Settings Tabs
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

pChangeStyle [pCS]
The pChange Style node

pChange Style Node Introduction
The pChange Style node provides a mechanism for changing the appearance or style of particles that interact with a defined region. The primary controls mirror those found in the Style tab of the pEmitter node. Particles that intersect or enter the defined region change based on the parameters of this node.

Except for the pCustom node, this is the only node that modifies the particles’ appearance rather than its motion. It is often used to trigger a change in the appearance in response to some event, such as striking a barrier.

Inputs
The pChange Style node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green or magenta bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.
— **Input:** The orange input takes the output of other particle nodes.
— **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the custom particle node takes effect.

## Basic Node Setup

Opposite of what you may think, to create a change in style that appears to be caused by some physical event, the pChange Style node should be placed before the node that creates the event. For example, below, the particles generated by the Emitter node change style after bouncing off a pBounce. Both the pChange Style and pBounce use the same Shape 3D node as the region. The pChange Style must be placed before the pBounce. If the pChange Style node is placed after the pBounce, the particles bounce off the region before the pChange Style calculates its effect. The particle will never get to intersect with the pChange Style node’s region, and so the style never changes.

![A pChange Style node placed before the pBounce node](image)

![The pChange Style controls](image)
Randomize
The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

Change Sets
This option allows the user to change the particle’s Set to become influenced by forces other than the original particle. See “The Common Controls” in this chapter to learn more about Sets.

Style
This option allows the user to change the particle’s Style and thus the look. See “The Common Controls” in this chapter to learn more about Styles.

Common Controls
Conditions, Style, Region, and Settings Tabs
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

pCustom [pCu]

pCustom Node Introduction
The pCustom node is used to create custom expressions that affect the properties of particles. This node is similar to the Custom node, except the calculations affect particles rather than pixels.

Inputs
The pCustom node has three inputs. Like most particle nodes, this orange input accepts only other particle nodes. The green and magenta inputs are 2D image inputs for custom image calculations. Optionally, there are teal or white bitmap or mesh inputs, which appear on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

  — **Input**: The orange input takes the output of other particle nodes.
  — **Image 1 and 2**: The green and magenta image inputs accept 2D images that are used for per pixel calculations and compositing functions.
  — **Region**: The teal or white region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the custom particle node takes effect.
Basic Node Setup

The pCustom node is placed in between the pEmitter and pRender. A Shape 3D node is used to create the region where the Custom particle event occurs.

Inspector

All the same operators, functions, and conditional statements described for the Custom node apply to the pCustom node as well, including Pixel-read functions for the two image inputs (e.g., get1w(x,y), getz2b(x,y), and so on).

Number 1–8

Numbers are variables with a dial control that can be animated or connected to modifiers exactly as any other control might. The numbers can be used in equations on particles at current time: n1, n2, n3, n4, … or at any time: n1_at(float t), n2_at(float t), n3_at(float t), n4_at(float t), where t is the time you want. The values of these controls are available to expressions in the Setup and Intermediate tabs.
pCustom Position tab

**Position 1–8**

These eight point controls include 3D X, Y, Z position controls. They are normal positional controls and can be animated or connected to modifiers as any other node might. They are available to expressions entered in the Setup, Intermediate, and Channels tabs.

pCustom Setup tab
**Setup 1–8**

Up to eight separate expressions can be calculated in the Setup tab of the pCustom node. The Setup expressions are evaluated once per frame, before any other calculations are performed. The results are then made available to the other expressions in the node as variables s1, s2, s3, and s4.

Think of them as global setup scripts that can be referenced by the intermediate and channel scripts.

---

**Inter 1–8**

An additional eight expressions can be calculated in the Intermediate tab. The Intermediate expressions are evaluated once per frame, after the Setup expressions are evaluated. Results are available as variables i1, i2, i3, i4, i5, i6, i7, i8, which can be referenced by channel scripts.

**Particle**

Particle position, velocity, rotation, and other controls are available in the Particle tab.

The following particle properties are exposed to the pCustom control:

Common Controls

**Conditions, Style, Region, and Settings Tabs**

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.
The pCustom Force node

The pCustom Force node allows you to change the forces applied to a particle system or subset. This node is one of the most complex and the most powerful node in Fusion. If you are experienced with scripting or C++ programming, you should find the structure and terminology used by the Custom Force node to be familiar.

The forces on a particle within a system can have their positions and rotations affected by forces. The position in XYZ and the Torque, which is the spin of the particle, are controlled by independent custom equations. The Custom Force node is used to create custom expressions and filters to modify the behavior. In addition to providing three image inputs, this node will allow for the connection of up to eight numeric inputs and as many as four XY position values from other controls and parameters in the node tree.

Inputs

The pCustom Force node has three inputs. Like most particle nodes, this orange input accepts only other particle nodes. A green and magenta are 2D image inputs for custom image calculations. Optionally there are teal or white bitmap or mesh inputs, which appear on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

— **Input:** The orange input takes the output of other particle nodes.
— **Image 1 and 2:** The green and magenta image inputs accept 2D images that are used for per-pixel calculations and compositing functions.
— **Region:** The teal or white region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the pCustom Force takes effect.

Basic Node Setup

The pCustom Force node is inserted between a pEmitter and pRender node to serve as a catalyst for particles using advanced C++ and scripting.

A pCustom Force is applied to the particles generated by the pEmitter.
Inspector

The pCustom Force controls

The tabs and controls located in the Inspector are similar to the controls found in the pCustom node. Refer to the pCustom node in this chapter for more information.

Common Controls

Conditions, Style, Region, and Settings Tabs

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

pDirectionalForce [pDF]

The pDirectional Force node

pDirectional Force Node Introduction

This node applies a unidirectional force that pulls the affected particles in a specified direction. Its primary controls affect the strength of the force, and the angle of the force’s pull along the X, Y, and Z axis.

Since the most common use of this node is to simulate gravity, the default direction of the pull is down along the Y axis (-90 degrees), and the default behavior is to ignore regions and affect all particles.
**Inputs**

The pDirectional Force node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green or magenta bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input:** The orange input takes the output of other particle nodes.
- **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the directional force takes effect.

**Basic Node Setup**

The pDirectional Force node is placed in between the pEmitter and pRender and is often used to create gravity.

![A pDirectional Force node placed between the pEmitter and pRender nodes](image)

**Inspector**

The pDirectional Force controls

**Randomize**

The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to select a new seed value randomly, or adjust the slider to select a new seed value manually.
**Strength**
Determines the power of the force. Positive values will move the particles in the direction set by the controls; negative values will move the particles in the opposite direction.

**Direction**
Determines the direction in X/Y space.

**Direction Z**
Determines the direction in Z space.

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

---

**pEmitter [pEm]**

The pEmitter node

---

**pEmitter Node Introduction**
The pEmitter node is the main source of particles (pImage Emitter is another) and will usually be the first node used in any new particle system. This node contains controls for setting the initial position, orientation, and motion of the particles, as well as controls for the visual style of each particle.

Like all other Particle nodes (with the exception of the pRender node), the pEmitter produces a particle set, not a visible image, and therefore cannot be displayed directly in a viewer. To view the output of a particle system, add a pRender node after the pEmitter.

**Inputs**
By default, the pEmitter node has no inputs at all. You can enable an image input by selecting Bitmap from the Style menu in the Style tab. Also, two region inputs, one for bitmap and one for mesh, appear on the node when you set the Region menu in the Region tab to either Bitmap or Mesh. The colors of these inputs change depending on the order in which they are enabled.

- **Style Bitmap Input**: This image input accepts a 2D image to use as the particles’ image. Since this image duplicates into potentially thousands of particles, it is best to keep these images small and square—for instance, 256 x 256 pixels.
- **Region**: The region inputs take a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the particles are emitted.
Basic Node Setup

The pEmitter node starts the branch of a particle system that always ends with a pRender node. The pEmitter can feed directly into a pRender node to feed other particle nodes.

A pEmitter node connected to a pRender node is a typical setup for more particle systems.

Inspector

The pEmitter inspector is divided into four main tabs and a common settings tab. The controls tab is the first tab displayed and it contains settings that affect the general setup of the particle cells emitted by the node. These settings do not directly affect the appearance of the cells or shape of the emitter region. They modify fundamental behaviors like quantity, duration, speed, and rotation of the particle cells.

The pEmitter controls
Randomize and Random Seed
The Random Seed slider is used to seed all the variance and random number generators used by the node when creating the particle system. Two pEmitter nodes with exactly the same settings for all controls and the same random seed will generate exactly the same particle system. Changing the random seed will cause variation between the nodes. Click the Randomize button to automatically set a randomly chosen value for the Random Seed.

Number
This control is used to set the amount of new particles generated on each frame. A value of 1 would cause one new particle to be generated each frame. By frame 10, there would be a total of 10 particles in existence (unless Particle Lifespan was set to fewer than 10 frames).

Animate this parameter to specify the number of particles generated in total. For example, if only 25 particles in total are desired, animate the control to produce five particles on frame 0–4, then set a key on frame five to generate zero particles for the remainder of the project.

Number Variance
This modifies the amount of particles generated for each frame, as specified by the Number control. For example, if Number is set to 10.0 and Number Variance is set to 2.0, the emitter will produce anywhere from 9–11 particles per frame. If the value of Number Variance is more than twice as large as the value of Number, it is possible that no particles will be generated for a given frame.

Lifespan
This control determines how long a particle will exist before it disappears or ‘dies.’ The default value of this control is 100 frames, although this can be set to any value. The timing of many other particle controls is relative to the Lifespan of the particle. For example, the size of a particle can be set to increase over the last 80% of its life, using the Size Over Life graph in the Style tab of the pEmitter.

Lifespan Variance
Like Number Variance, the Lifespan Variance control allows the Lifespan of particles produced to be modified. If Particle Lifespan was set to 100 frames and the Lifespan Variance to 20 frames, particles generated by the emitter would have a lifespan of 90–110 frames.

Color
This provides the ability to specify from where the color of each particle is derived. The default setting is Use Style Color, which will provide the color from each particle according to the settings in the Style tab of the pEmitter node.

The alternate setting is Use Color From Region, which overrides the color settings from the Style tab and uses the color of the underlying bitmap region.

The Use Color From Region option only makes sense when the pEmitter region is set to use a bitmap produced by another node in the composition. Particles generated in a region other than a bitmap region will be rendered as white when the Use Color From Region option is selected.

Position Variance
This control determines whether or not particles can be ‘born’ outside the boundaries of the pEmitter region. By default, the value is set to zero, which will restrict the creation area for new particles to the exact boundaries of the defined region. Increasing this control’s value above 0.0 will allow the particle to
be born slightly outside the boundaries of that region. The higher the value, the ‘softer’ the region’s edge will become.

**Temporal Distribution**

In general, an effect is processed per frame, based on the comp frame rate. However, processing some particles only at the exact frame boundaries can cause pulsing. To make the behavior subtly more realistic, the particles can be birthed in subframe increments.

The default, At The Same Time setting renders on frame boundaries, where as the other two settings take advantage of sub frame rendering. Randomly Distributed randomizes birth times +/- around the frame number, eg birth 10 particles at random sub times 24.1 24.85, 24.21, 24.37 etc. one particle at a time. Evenly Distributed births particles at regular sub times, eg 10 particles, birth 1 at at time at 24.0, 24.1, 24.2, 24.3, 24.4, 24.5 ... 24.8, 24.9.

These settings are influenced by the Sub Frame Accuracy setting in the pRender node. The Sub Frame Accuracy slider controls how many in-between frames are calculated between each frame. The higher the value the more accurate the particle calculation but the longer the render times.

**Velocity**

The controls in the Velocity section determine the speed and direction of the particle cells as the are generated from the emitter region.

**Velocity and Velocity Variance**

These determine the initial speed or velocity of new particles. By default, the particle has no velocity and will not move from its point of origin unless acted upon by outside forces. A velocity setting of 10.0 would cause the particle to cross the entire width of the image in one step so a velocity of 1.0 would cause the particle to cross the width of the image over 10 frames.

Velocity Variance modifies the velocity of each particle at birth, in the same manner described in Lifespan Variance and Number Variance above.

**Inherit**

Inherit Velocity passes the emitter region’s velocity on to the particles. This slider has a wide range that includes negative and positive values. A negative value causes the particles to move in the opposite direction, a value of 1 will cause the particles to move with a velocity that matches the emitter region’s velocity, and a value of 2 causes the particles to move ahead of the emitter region.

**Angle and Angle Variance**

This determines the angle at which particles with velocity applied will be heading at their birth.

**Angle Z and Angle Z Variance**

This is as above, except this control determines the angle of the particles along the Z space axis (toward or away from the camera).
Rotation
Rotation controls are used to set the orientation of particle cells and animating that orientation over time.

Rotation Mode
This menu control provides two options to help determine the orientation of the particles emitted. When the particles are spherical, the effect of this control will be unnoticeable.

- **Absolute Rotation:** The particles will be oriented as specified by the Rotation controls, regardless of velocity and heading.
- **Rotation Relative To Motion:** The particles will be oriented in the same direction as the particle is moving. The Rotation controls can now be used to rotate the particle’s orientation away from its heading.

Rotation XYZ and Rotation XYZ Variance
These controls allow for Rotation of the individual particles. This can be particularly useful when dealing with a bitmap particle type, as the incoming bitmap may not be oriented in the desired direction.

Rotation XYZ Variance can be used to randomly vary the rotation by a specified amount around the center of the Rotation XYZ value to avoid having every particle oriented in the exact same direction.

Spin
Spin controls are auto animated controls that change the orientation of particle cells over time.

Spin XYZ and Spin Variance
These provide a spin to be applied to each particle at birth. The particles will rotate \( x \) degrees each frame, as determined by the value of Spin XYZ.

The Spin XYZ variances will vary the amount of rotation applied to each frame in the manner described by Number Variance and Lifespan Variance documented above.

Sets Tab
This tab contains settings that affect the physics of the particles emitted by the node. These settings do not directly affect the appearance of the particles. Instead, they modify behavior like velocity, spin, quantity, and lifespan.

The pEmitter Sets tab
Set 1–32

To assign the particles created by a pEmitter to a given set, simply select the checkbox of the set number you want to assign. A single pEmitter node can be assigned to one or multiple sets. Once they are assigned in the pEmitter, you can enable sets in other particle nodes so they only affect particles from specific pEmitters.

**Style Tab**

The Style tab provides controls that affect the appearance of the particles. For detailed information about the style Tab, see the “The Common Controls” section at the end of this chapter.

**Region Tab**

The Region tab controls the shape, size, and location of the area that emits the particle cells. This is often called the Emitter. Only one emitter region can be set for a single pEmitter node. If the pRender is set to 2D, then the emitter region will produce particles along a flat plane in Z Space. 3D emitter regions possess depth and can produce particles inside a user-defined, three-dimensional region. For more detail on the Region tab, see “The Common Controls” section at the end of this chapter.

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.
pFlock [pFl]

The pFlock node

pFlock Node Introduction

The pFlock node can be used to simulate the behavior of organic systems, such as a flock of birds or a colony of ants. Its use can make an otherwise mindless particle system appear to be motivated, or acting under the direction of intelligence.

The pFlock node works through two basic principles. Each particle attempts to stay close to other particles and each particle attempts to maintain a minimum distance from other particles.

The strength of these “desires” produces the seemingly motivated behavior perceived by the viewer.

Inputs

The pFlock node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green or magenta bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

— **Input:** The orange background input takes the output of other particle nodes.
— **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the flocking takes effect.

Basic Node Setup

When combined with pFollow, the pFlock node can produce natural swarming behaviors that change direction.

A pFlock node applying more herd-type mentality to particles
Inspector

The pFlock controls

**Randomize**

The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Flock Number**

The value of this control represents the number of other particles that the affected particle will attempt to follow. The higher the value, the more visible “clumping” will appear in the particle system and the larger the groups of particles will appear.

**Follow Strength**

This value represents the strength of each particle’s desire to follow other particles. Higher values will cause the particle to appear to expend more energy and effort to follow other particles. Lower values increase the likelihood that a given particle will break away from the pack.

**Attract Strength**

This value represents the strength of attraction between particles. When a particle moves farther from other particles than the Maximum Space defined in the pFlock node, it will attempt to move closer to other particles. Higher values cause the particle to maintain its spacing energetically, resolving conflicts in spacing more rapidly.
**Repel Strength**
This value represents the force applied to particles that get closer together than the distance defined by the Minimum Space control of the pFlock node. Higher values will cause particles to move away from neighboring particles more rapidly, shooting away from the pack.

**Minimum/Maximum Space**
This range control represents the distance each particle attempts to maintain between it and other particles. Particles will attempt to get no closer or farther than the space defined by the Minimum/Maximum values of this range control. Smaller ranges will give the appearance of more organized motion. Larger ranges will be perceived as disorganized and chaotic.

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

**pFollow [pFo]**

*The pFollow node*

**pFollow Node Introduction**
Inserting the pFollow node into a particle branch causes the particles to spring back and forth toward a follow object. The follow object can be positioned in 3D or animated to create a new motion path for the particles.

**Inputs**
The pFollow node has a single orange input by default. Like most particle nodes, this orange background input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input:** The orange input takes the output of other particle nodes.
- **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where particles will follow the position point.
Basic Node Setup
When combined with pFlock, the pFollow node can produce natural swarming behaviors that change direction.

A pFollow node introduces a follow object that influences the particles’ motion.

Inspector

The pFollow Controls tab

Random Seed
The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

Position XYZ
The position controls are used to create the new path by positioning the follow object. Moving the XYZ parameters displays the onscreen position of the follow object. Animating these parameters creates the new path the particles will be influenced by.

Spring
The Spring setting causes the particles to move back and forth along the path. The spread of the spring motion increases over the life of the particles depending on the distance between the particles and the follow object. Higher spring settings increase the elasticity, while lower settings decrease elasticity.

Dampen
This value attenuates the spring action. A lower setting offers less resistance to the back and forth spring action. A higher setting applies more resistance.
Common Controls

Conditions, Style, Region, and Settings Tabs

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

**pFriction [pFr]**

The pFriction node applies resistance to the motion of a particle, slowing the particle’s motion through a defined region. This node produces two types of Friction. One type reduces the velocity of any particle intersecting/crossing the defined region, and one reduces or eliminates spin and rotation.

**Inputs**

The pFriction node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green or magenta bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input**: The orange input takes the output of other particle nodes.
- **Region**: The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the friction occurs.

**Basic Node Setup**

The pFriction node is placed in between the pEmitter and pRender. A Shape 3D node is used to create the region the particles bounce off.

A pFriction node using a Shape 3D node as the region where friction is introduced to the particles.
Inspector

Random Seed
The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

Velocity Friction
This value represents the Friction force applied to the particle's Velocity. The larger the value, the greater the friction, thus slowing down the particle.

Spin Friction
This value represents the Friction force applied to the particle's Rotation or Spin. The larger the value, the greater the friction, thus slowing down the rotation of the particle.

Common Controls
Conditions, Style, Region, and Settings Tabs
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

pGradientForce [pGF]

pGradient Force Node Introduction
The particles are affected by a force generated by the gradients in the alpha values of the input image. Particles will accelerate along the gradient, moving from white to black (high values to low values).
This node can be used to give particles the appearance of moving downhill or following the contour of a provided shape.

**Inputs**

The pGradient Force node accepts two inputs: the default orange input from a particle node and one from a bitmap image with an alpha channel gradient. A magenta or teal bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input:** The orange input takes the output of other particle nodes.
- **Input:** The green input takes the 2D image that contains the alpha channel gradient.
- **Region:** The magenta or teal region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the gradient force occurs.

**Basic Node Setup**

The pGradient Force node is placed in between the pEmitter and pRender nodes. A Fast Noise node is used to create the alpha gradient used to modify the velocity of the particles.

![Diagram of node setup](image)

A pGradient Force node using a Fast Noise node as the gradient to modify the particles’ motion

**Inspector**

The pGradient Force controls

**Randomize**

The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result.

Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.
**Strength**

Gradient Force has only one specific control, which affects the strength of the force and acceleration applied to the particles. Negative values on this control will cause the Gradient Force to be applied from black to white (low values to high values).

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

**pImage Emitter [pLE]**

The pImage Emitter node takes an input image and treats each pixel of the image as if it were a particle. The main differences between the pImage Emitter and the normal pEmitter is that instead of emitting particles randomly within a given region, this node emits pixels in a regular 2D grid with colors based on the input image.

**Inputs**

The pImage Emitter node has three inputs. Like most particle nodes, the orange input accepts only other particle nodes. Green and magenta inputs are 2D image inputs for custom image calculations. Optionally, there are teal or white bitmap or mesh inputs, which appear on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input**: Unlike most other particle nodes, the orange input on the pImage Emitter accepts a 2D image used as the emitter of the particles. If a region is defined for the emitter, this input is used to define the color of the particles.

- **Style Bitmap Input**: This image input accepts a 2D image to use as the particles’ image. Since this image duplicates into potentially thousands of particles, it is best to keep these images small and square—for instance, 256 x 256 pixels.

- **Region**: The teal or white region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the particles are emitted.
Basic Node Setup

The pImage Emitter node is placed at the start of a particle branch, replacing the location of a pEmitter node. Below, a MediaIn node is used to emit particles using the colors from the clip.

A pImage Emitter node emits particles based on an image connected to the orange input.

Inspector

The pImage Emitter controls
The great majority of controls in this node are identical to those found in the pEmitter, and those controls are documented in that previous section. Below are the descriptions of the controls unique to the pImage Emitter node.

**X and Y Density**

The X and Y Density sliders are used to set the mapping of particles to pixels for each axis. They control the density of the sampling grid. A value of 1.0 for either slider indicates 1 sample per pixel. Smaller values will produce a looser, more pointillistic distribution of particles, while values above 1.0 will create multiple particles per pixel in the image.

**Alpha Threshold**

The Alpha Threshold is used for limiting particle generation so that pixels with semitransparent alpha values will not produce particles. This can be used to harden the edges of an otherwise soft alpha channel. The higher the threshold value, the more opaque a pixel must be before it will generate a particle. Note that the default threshold of 0.0 will create particles for every pixel, regardless of alpha, although many may be transparent and invisible.

**Lock Particle Color to Initial Frame**

Select this checkbox to force the particles to keep the color with which they were born throughout the life of the particle. If this is off, and the input image changes on successive frames, the particles will also change color to match the image. This allows video playback on a grid of particles.

**Create Particles Every Frame**

Enabling this creates a whole new set of particles every frame, instead of just one set on the frame. This can lead to very large particle systems but allows some interesting effects—for example, if the particles are given some initial velocity or if emitting from an animated source. Try a small velocity, an Angle Z of -90, and a seething Fast Noise as a source to get smoothly varying clouds of particles that you could fly through. Note that if this checkbox is left off, only one set of particles is ever created, and thus animating any of the emitter’s other controls will have no effect.

**X/Y/Z Pivot**

These controls allow you to position the grid of emitted particles.

**Use Z Channel for Particle Z**

If the input image used to generate the particles has a Z depth channel, that channel can be used to determine the initial position of the particle in Z space. This can have an interesting hollow shell effect when used in conjunction with camera rotation in the pRender node.

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.
Sets Tab

![Image of pImage Emitter Sets tab]

The pImage Emitter Sets tab

**NOTE:** Pixels with a black (transparent) alpha channel will still generate invisible particles, unless you raise the Alpha Threshold above 0.0. This can slow down rendering significantly. An Alpha Threshold value of $1/255 = 0.004$ is good for eliminating all fully transparent pixels.

The pixels are emitted in a fixed-size 2D grid on the XY plane, centered on the Pivot position. Changing the Region from the default of All allows you to restrict particle creation to more limited areas. If you need to change the size of this grid, use a Transform 3D node after the pRender.

Remember that the various emitter controls apply only to particles when they are emitted. That is, they set the initial state of the particle and do not affect it for the rest of its lifespan. Since pImageEmitter (by default) emits particles only on the first frame, animating these controls will have no effect. However, if the Create Particles Every Frame checkbox is turned on, new particles will be emitted each frame and will use the specified initial settings for that frame.
pKill [pKl]

The pKill node

pKill Node Introduction

The Kill node is used to destroy (kill) any particle that crosses or intersects its region. It has no specific controls, as it has only one possible affect on a particle. The controls found in the Region tab are normally used to limit this node by restricting the effect to particles that fall within a certain region, age, set, or by reducing the probability of the node applying to a given particle.

Inputs

The pKill node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

— **Input:** The orange input takes the output of other particle nodes.
— **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area particles are killed.

Basic Node Setup

The pKill node is placed in between the pEmitter and pRender nodes. A Shape 3D node is used to create the region where the particles die.

Inspection

This node only contains common controls in the Conditions and Regions tabs. The Conditions and Regions controls are used to define the location, age, and set of particles that are killed.
Common Controls

Conditions, Style, Region, and Settings Tabs

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

**pMerge [pMg]**

The pMerge node

**pMerge Node Introduction**

This node has no controls whatsoever. It serves to combine particles from two streams. Any nodes downstream of the pMerge node will treat the two streams as one.

The combined particles will preserve any sets assigned to them when they were created, making it possible for nodes downstream of the pMerge to isolate specific particles when necessary.

**Inputs**

The pMerge node has two identical inputs, one orange and one green. These two inputs accept only other particle nodes.

- **Particle 1 and 2 Input**: The two inputs accept two streams of particles and merge them.

**Basic Node Setup**

The pMerge node connects two pEmitter nodes. The output of the pMerge can go on to feed other particle nodes or to a pRender.

A pMerge node combining two pEmitter nodes.
pPoint Force [pPF]

The pPoint Force node

pPoint Force Node Introduction

This node applies a force to the particles that emanate from a single point in 3D space. The pPoint Force can either attract or repel particles within its sphere of influence. There are four controls specific to the pPoint Force node.

Inputs

The pPoint Force node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input**: The orange input takes the output of other particle nodes.
- **Region**: The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the point force affects the particles.

Basic Node Setup

The pPoint Force node is inserted between a pEmitter and a pRender node.

The pPoint Force node positions a tangent force that particles are attracted to or repelled from.
Inspector

The pPoint Force controls

**Randomize**
The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Strength**
This parameter sets the Strength of the force emitted by the node. Positive values represent attractive forces; negative values represent repellent forces.

**Power**
This determines the degree to which the Strength of the force falls off over distance. A value of zero causes no falloff of strength. Higher values will impose an ever-sharper falloff in strength of the force with distance.

**Limit Force**
The Limit Force control is used to counterbalance potential problems with temporal sub-sampling. Because the position of a particle is sampled only once a frame (unless sub-sampling is increased in the pRender node), it is possible that a particle can overshoot the Point Force’s position and end up getting thrown off in the opposite direction. Increasing the value of this control reduces the likelihood that this will happen.

**X, Y, Z Center Position**
These controls are used to represent the X, Y, and Z coordinates of the point force in 3D space.

**Common Controls**
**Conditions, Style, Region, and Settings Tabs**
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.
pRender \([pRn]\)

The pRender node

pRender Node Introduction

The pRender node converts the particle system to either an image or geometry. The default is a 3D particle system, which must be connected to a Renderer 3D to produce an image. This allows the particles to be integrated with other elements in a 3D scene before they are rendered.

Inputs

The pRender node has one orange input, a green camera input, and a blue effects mask input. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

---

- **Input:** The orange input takes the output of other particle nodes.
- **Camera Input:** The optional green camera input accepts a camera node directly or a 3D scene with a camera connected that is used to frame the particles during rendering.
- **Effect Mask:** The optional blue input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input for 2D particles crops the output of the particles so they are seen only within the mask.

Basic Node Setup

The pRender node is always placed at the end of a particle branch. If the pRender is set to 2D, then the output connects to other 2D nodes like a Merge node. If the pRender is set to 3D, the output connects to a 3D node like a Merge 3D.

All particle branches end with a pRender node.
Output Mode (2D/3D)

While the pRender defaults to 3D output, it can be made to render a 2D image instead. This is done with the 3D and 2D buttons on the Output Mode control. If the pRender is not connected to a 3D-only or 2D-only node, you can also switch it by selecting View > 2D Viewer from the viewer’s pop-up menu.

In 3D mode, the only controls in the pRender node that have any effect at all are Restart, Pre-Roll and Automatic Pre-Roll, Sub-Frame Calculation Accuracy, and Pre-Generate frames. The remaining controls affect 2D particle renders only. The pRender node also has a Camera input on the node tree that allows the connection of a Camera 3D node. This can be used in both 2D and 3D modes to allow control of the viewpoint used to render an output image.

Render and the Viewers

When the pRender node is selected in a node tree, all the onscreen controls from Particle nodes connected to it are presented in the viewers. This provides a fast, easy-to-modify overview of the forces applied to the particle system as a whole.

Pre-Roll Options

Particle nodes generally need to know the position of each particle on the last frame before they can calculate the effect of the forces applied to them on the current frame. This makes changing current time manually by anything but single frame intervals likely to produce an inaccurate image.
The controls here are used to help accommodate this by providing methods of calculating the intervening frames.

**Restart**
This control also works in 3D. Clicking on the Restart button will restart the particle system at the current frame, removing any particles created up to that point and starting the particle system from scratch at the current frame.

**Pre-Roll**
This control also works in 3D. Clicking on this button causes the particle system to recalculate, starting from the beginning of the render range up to the current frame. It does not render the image produced. It only calculates the position of each particle. This provides a relatively quick mechanism to ensure that the particles displayed in the views are correctly positioned.

If the pRender node is displayed when the Pre-Roll button is selected, the progress of the pre-roll is shown in the viewer, with each particle shown as point style only.

**Automatic Pre-Roll**
Selecting the Automatic Pre-Roll checkbox causes the particle system to automatically pre-roll the particles to the current frame whenever the current frame changes. This prevents the need to manually select the Pre-Roll button whenever advancing through time in jumps larger than a single frame. The progress of the particle system during an Automatic Pre-Roll is not displayed to the viewers to prevent distracting visual disruptions.

**About Pre-Roll**
Pre-Roll is necessary because the state of a particle system is entirely dependent on the last known position of the particles. If the current time were changed to a frame where the last frame particle state is unknown, the display of the particle is calculated on the last known position, producing inaccurate results.

To demonstrate:

1. Add a pEmitter and a pRender node to the composition.
2. View the pRender in one of the viewers.
3. Set the Velocity of the particles to 0.1.
4. Place the pEmitter on the left edge of the screen.
5. Set the Current Frame to 0.
6. Set a Render Range from 0–100 and press the Play button.
7. Observe how the particle system behaves.
8. Stop the playback and return the current time to frame 0.
9. In the pRender node, disable the Automatic Pre-Roll option.
10. Use the current time number field to jump to frame 10, and then to frames 60 and 90.

Notice how the particle system only adds to the particles it has already created and does not try to create the particles that would have been emitted in the intervening frames. Try selecting the Pre-Roll button in the pRender node. Now the particle system state is represented correctly.
For simple, fast-rendering particle systems, it is recommended to leave the Automatic Pre-Roll option on. For slower particle systems with long time ranges, it may be desirable to only Pre-Roll manually, as required.

— **Only Render in Hi-Q**

Selecting this checkbox causes the style of the particles to be overridden when the Hi-Q checkbox is deselected, producing only fast rendering Point-style particles. This is useful when working with a large quantity of slow Image-based or Blob-style particles. To see the particles as they would appear in a final render, simply enable the Hi-Q checkbox.

— **View**

This drop-down list provides options to determine the position of the camera view in a 3D particle system. The default option of Scene (Perspective) will render the particle system from the perspective of a virtual camera, the position of which can be modified using the controls in the Scene tab. The other options provide orthographic views of the front, top, and side of the particle system.

It is important to realize that the position of the onscreen controls for Particle nodes is unaffected by this control. In 2D mode, the onscreen controls are always drawn as if the viewer were showing the front orthographic view. (3D mode gets the position of controls right at all times.)

The View setting is ignored if a Camera 3D node is connected to the pRender node’s Camera input on the node tree, or if the pRender is in 3D mode.

### Conditions

**Blur, Glow, and Blur Blend**

When generating 2D particles, these sliders apply a Gaussian blur, glows, and blur blending to the image as it is rendered, which can be used to soften the particles and blend them. The result is no different than adding a Blur after the pRender node in the node tree.

**Sub-Frame Calculation Accuracy**

This determines the number of sub-samples taken between frames when calculating the particle system. Higher values increase the accuracy of the calculation but also increase the amount of time to render the particle system.

**Pre-Generate Frames**

This control is used to cause the particle system to pre-generate a set number of frames before its first valid frame. This is used to give a particle system an initial state from which to start.

A good example of when this might be useful is in a shot where particles are used to create the smoke rising from a chimney. Set Pre-Generate Frames to a number high enough to ensure that the smoke is already present in the scene before the render begins, rather than having it just starting to emerge from the emitter for the first few frames.

**Kill Particles That Leave the View**

Selecting this checkbox control automatically destroys any particles that leave the visible boundaries of the image. This can help to speed render times. Particles destroyed in this fashion never return, regardless of any external forces acting upon them.
**Generate Z Buffer**
Selecting this checkbox causes the pRender node to produce a Z Buffer channel in the image. The depth of each particle is represented in the Z Buffer. This channel can then be used for additional depth operations like Depth Blur, Depth Fog, and Downstream Z Merging.

Enabling this option is likely to increase the render times for the particle system dramatically.

**Depth Merge Particles**
Enabling this option causes the particles to be merged using Depth Merge techniques, rather than layer-based techniques.

**Scene Tab**

The pRender Scene tab

**Z Clip**
The Z Clip control is used to set a clipping plane in front of the camera. Particles that cross this plane are clipped, preventing them from impacting on the virtual lens of the camera and dominating the scene.

**Grid Tab**
These controls do not apply to 3D particles.

The grid is a helpful, non-rendering display guide used to orient the 2D particles in 3D space. The grid is never seen in renders, just like a center crosshair is never seen in a render. The width, depth, number of lines, and grid color can be set using the controls found in this tab.
These controls cannot be animated.

The pRender Grid tab

**Image Tab**

The controls in this tab are used to set the resolution, color depth, and pixel aspect of the rendered image produced by the node.

The pRender Image tab
**Process Mode**

Use this menu control to select the Fields Processing mode used by Fusion to render changes to the image. The default option is determined by the Has Fields checkbox control in the Frame Format preferences.

**Use Frame Format Settings**

When this checkbox is selected, the width, height, and pixel aspect of the rendered images by the node will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

**Width/Height**

This pair of controls is used to set the Width and Height dimensions of the image to be rendered by the node.

**Pixel Aspect**

This control is used to specify the Pixel Aspect ratio of the rendered particles. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor), and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).

**NOTE:** Right-click on the Width, Height, or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height, and pixel aspect to the values for that format, accordingly.

**Depth**

The Depth menu is used to set the pixel color depth of the particles. 32-bit pixels require 4X the memory of 8-bit pixels but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0…1 range, for representing colors that are brighter than white or darker than black.

**Source Color Space**

You can use the Source Color Space menu to set the Color Space of the footage to help achieve a linear workflow. Unlike the Gamut tool, this doesn’t perform any actual color space conversion, but rather adds the source space data into the metadata, if that metadata doesn’t exist. The metadata can then be used downstream by a Gamut tool with the From Image option, or in a Saver, if explicit output spaces are defined there. There are two options to choose from:

- **Auto:** Automatically reads and passes on the metadata that may be in the image.
- **Space:** Displays a Color Space Type menu where you can choose the correct color space of the image.

**Source Gamma Space**

Using the Curve type menu, you can set the Gamma Space of the footage and choose to remove it by way of the Remove Curve checkbox when working in a linear workflow. There are three choices in the Curve type menu:
— **Auto:** Automatically reads and passes on the metadata that may be in the image.
— **Space:** Displays a Gamma Space Type menu where you can choose the correct gamma curve of the image.
— **Log:** Brings up the Log/Lin settings, similar to the Cineon tool. For more information, see Chapter 38, “Film Nodes,” in the Fusion Reference Manual or Chapter 98 in the DaVinci Resolve Reference Manual.

**Remove Curve**
Depending on the selected Gamma Space or on the Gamma Space found in Auto mode, the Gamma Curve is removed from, or a log-lin conversion is performed on, the material, effectively converting it to a linear output space.

**Motion Blur**
As with other 2D nodes in Fusion, Motion Blur is enabled from within the Settings tab. You may set Quality, Shutter Angle, Sample Center, and Bias, and Blur will be applied to all moving particles.

**NOTE:** Motion Blur on 3D mode particles (rendered with a Renderer 3D) also requires that identical motion blur settings are applied to the Renderer 3D node.

---

**pSpawn [pSp]**

The pSpawn node

---

**pSpawn Node Introduction**
The pSpawn node makes each affected particle act as an emitter that can produce one or more particles of its own. The original particle continues until the end of its lifespan, and each of the particles it emits becomes wholly independent with a lifespan and properties of its own.

As long as a particle falls under the effect of the pSpawn node, it will continue to generate particles. It is important to restrict the effect of the node with limiters like Start and End Age, Probability, Sets and Regions, and by animating the parameters of the emitter so that the node is operative only when required.

**Inputs**
By default, the pSpawn node has a single orange input. Like most particle nodes, this orange input accepts only other particle nodes. You can enable an image input by selecting Bitmap from the Style menu in the Style tab. Also, two region inputs, one for bitmap and one for mesh, appear on the node.
when you set the Region menu in the Region tab to either Bitmap or Mesh. The colors of these inputs change depending on the order they are enabled.

- **Input:** The orange input accepts the output of other particle nodes.
- **Style Bitmap Input:** This image input accepts a 2D image to use as the particles’ image. Since this image duplicates into potentially thousands of particles, it is best to keep these images small and square—for instance, 256 x 256 pixels.
- **Region:** The region inputs take a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the particles are emitted.

**Basic Node Setup**

The pSpawn node is placed between the pEmitter and pRender nodes. Using the Age parameter in the pSpawn’s Conditions tab, you can spawn new particles as the old ones die off. This is one way to have a trail of particles shoot up in the air like a rocket and burst into sparkling fireworks.

A pSpawn node used to generate new particles at specific points in the old particles’ life

**Inspector**

The pSpawn node has a large number of controls, most of which exactly duplicate those found within the pEmitter node. There are a few controls that are unique to the pSpawn node, and their effects are described below.
Affect Spawned Particles
Selecting this checkbox causes particles created by spawning to also become affected by the pSpawn node on subsequent frames. This can exponentially increase the number of particles in the system, driving render times up to an unreasonable degree. Use this checkbox cautiously.

Velocity Transfer
This control determines how much velocity of the source particle is transferred to the particles it spawns. The default value of 1.0 causes each new particle to adopt 100 percent of the velocity and direction from its source particle. Lower values will transfer less of the original motion to the new particle.

Common Controls
Conditions, Style, Region, and Settings Tabs
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.

pTangent Force [pTF]

The pTangent Force node

pTangent Force Node Introduction
This node is used to apply a tangential force to the particles—a force that is applied perpendicularly to the vector between the pTangent Force’s region and the particle it is affecting.

Inputs
The pTangent Force node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

— **Input:** The orange input takes the output of other particle nodes.
— **Region:** The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area where the tangent force effects the particles.
Basic Node Setup
The pTangent Force node is inserted between a pEmitter and a pRender node.

The pTangent Force node positions a tangent force that particles maneuver around.

Inspector

The pTangent Force controls

The controls for this node are used to position the offset in 3D space and to determine the strength of the tangential force along each axis independently.

Randomize
The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result.

Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

X, Y, Z Center Position
These controls are used to represent the X, Y, and Z coordinates of the Tangent force in 3D space.

X, Y, Z Center Strength
These controls are used to determine the Strength of the Tangent force in 3D space.

Common Controls

Conditions, Style, Region, and Settings Tabs
The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.
pTurbulence [pTr]

The pTurbulence node

pTurbulence Node Introduction

The pTurbulence node imposes a frequency-based chaos on the position of each particle, causing the motion to become unpredictable and uneven. The controls for this node affect the strength and density of the Turbulence along each axis.

Inputs

The pTurbulence node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input**: The orange input takes the output of other particle nodes.
- **Region**: The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area of turbulence.

Basic Node Setup

The pTurbulence node is inserted between a pEmitter and a pRender node.

The pTurbulence node disturbs the rigid flow of particles for a more natural motion.
Inspector

The pTurbulence controls

Randomize

The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

X, Y, and Z Strength

The Strength control affects the amount of chaotic motion imparted to particles.

Strength Over Life

This mini Spline Editor control can be used to control the amount of turbulence applied to a particle according to its age. For example, a fire particle may originally have very little turbulence applied at the start of its life, and as it ages, the turbulence increases.

Density

Use this control to adjust the density in the turbulence field. Lower values causes more particle cells to be affected similarly, almost as if “waves” of the turbulence field run through the particles, affecting groups of cells at the same time. Higher values add finer variations to more individual particle cells causing more of a spread in the turbulence field.

Common Controls

Conditions, Style, Region, and Settings Tabs

The Conditions, Style, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in “The Common Controls” section at the end of this chapter.
pVortex [pVt]

The pVortex node applies a rotational force to each particle, causing them to be drawn toward the source of the Vortex. In addition to the Common Particle Controls, the pVortex node also has the following controls.

**Inputs**

The pVortex node has a single orange input by default. Like most particle nodes, this orange input accepts only other particle nodes. A green bitmap or mesh input appears on the node when you set the Region menu in the Region tab to either Bitmap or Mesh.

- **Input**: The orange input takes the output of other particle nodes.
- **Region**: The green or magenta region input takes a 2D image or a 3D mesh depending on whether you set the Region menu to Bitmap or Mesh. The color of the input is determined by whichever is selected first in the menu. The 3D mesh or a selectable channel from the bitmap defines the area of the vortex.

**Basic Node Setup**

The pVortex node is placed in between the pEmitter and pRender nodes.

A pVortex node creates a spiraling motion for particles that fall within its pull.
Inspector

The pVortex controls

**Randomize**
The Random Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Strength**
This control determines the Strength of the Vortex Force applied to each particle.

**Power**
This control determines the degree to which the Strength of the Vortex Force falls off with distance.

**X, Y, and Z Offset**
Use these sliders to set the amount by which the vortex Offsets the affected particles.

**Size**
This is used to set the Size of the Vortex Force.

**Angle X and Y**
These sliders control the amount of rotational force applied by the Vortex along the X and Y axes.

**Common Controls**

**Conditions, Style, Region, and Settings Tabs**
The Conditions, Region, and Settings tabs are common to all Particle nodes, so their descriptions can be found in the following “The Common Controls” section.
The Common Controls

Particle nodes share a number of identical controls in the inspector. This section describes the Style, Conditions, Region, and Settings tabs that are common among particle nodes.

Inspector

The pEmitter Style tab

Style Tab

The Style Tab is common to the pEmitter, pSpawn, pChangeStyle, and pImage Emitter. It controls the appearance of the particles using general controls like type, size, and color.

Style

The Style menu provides access to the various types of particles supported by the Particle Suite. Each style has its specific controls, as well as controls it will share with other styles.

— **Point**: This option produces particles precisely one pixel in size. Controls that are specific to Point Style are Apply Mode and Sub Pixel Rendered.

— **Apply Mode**: This menu applies only to 2D particles. 3D particle systems are not affected. It includes Apply modes for Add and Merge. Add combines overlapping particles by adding together the color values of each particle. Merge uses a simple over operation to combine overlapping particles.

— **Sub Pixel Rendered**: This checkbox determines whether the point particles are rendered with Sub Pixel precision, which provides smoother-looking motion but blurrier particles that take slightly longer to render.

— **Bitmap**: This style produces particle cells based on an image file or another node in the Node editor. When this option is selected an orange image input appears on the node in the node editor. There are several controls for affecting the appearance and animation. In addition to the controls in the Style section, a Merge section is displayed at the bottom of the inspector when Bitmap is selected as the Style. The Merge section includes controls for additive or subtractive merges when the particle cells overlap.

— **Animate Over Time**: This menu includes three options for determining how movie files play when they are used as particle cell bitmaps. The Over Time setting plays the movie file sequentially. For instance, when the comp is on frame 2, frame 2 of the movie file is displayed, when the comp is on frame 3, frame 3 of the movie files is displayed and so on. If a particle cell is not generated until frame 50, it begins with frame 50 of the movie file. This causes all particle...
cells to use the same image on any give frame of the comp. The Particle Age setting causes each particle cell to begin with the first frame of the movie file, regardless of when the particle cell is generated. The Particle Birth Time setting causes each particle to begin with the frame that coincides with the frame of the particle cell birth time. For instance, if the particle is generated on frame 25, then it uses frame 25 of the movie file for the entire comp. Unlike the other two options, the Particle Birth Time setting holds the same frame for the duration of the comp.

- **Time Offset:** This dial is used to slip or offset the starting frame used from the movie file. For instance, setting it to 10 will cause the movie file to start at frame 10 instead of frame 1.

- **Time Scale:** This slider is a multiplier on the frame. Instead of using an offset, it changes the starting frame by multiplying the frame by the value selected with the slider. For instance, if a value of 2 is selected then when the playhead reaches frame 2, the movie files displays frame 4 (2x2=4) and when the playhead reaches frame 8, the movie file displays frame 16 (8x2=16).

- **Gain:** The gain slider is a multiplier of the pixel value. It is used to apply a correction to the overall Gain of the Bitmap. Let’s say you have a bitmap particle cell that contains a pixel value of R0.5 G0.5 B0.4 and you add a Gain of 1.2, you end up with a pixel value of R0.6 G0.6, B0.48 (i.e., 0.4 * 1.2 = 0.48) while leaving black pixels unaffected. Higher values produce a brighter image, whereas lower values reduce both the brightness and the transparency of the image.

- **Style Bitmap:** This control appears when the Bitmap style is selected, along with an orange Style Bitmap input on the node’s icon in the Node view. Connect a 2D node to this input to provide images to be used for the particles. You can do this on the Node view, or you may drag and drop the image source node onto the Style Bitmap control from the Node Editor or Timeline, or right-click on the control and select the desired source from the Connect To menu.

- **Blob:** This option produces large, soft spherical particles, with controls for Color, Size, Fade timing, Merge method, and Noise.

- **Noise:** This slider only applies to 2D Blob particles. The noise slider is used to introduce a computer generated Perlin noise pattern into the blob particles in order to give the blobs more texture. A setting of 0 introduces no noise to the Blob particles and a setting of 1 introduces the maximum amount of noise.

- **Brush:** This styles produces particle cells based on any image file located in the brushes directory. There are numerous controls for affecting the appearance and animation.

  - **Gain:** The gain slider is a multiplier of the pixel value. It is used to apply a correction to the overall Gain of the image that is used as the Brush. Let’s say you have a brush particle cell that contains a pixel value of R0.5 G0.5 B0.4 and you add a Gain of 1.2, you end up with a pixel value of R0.6 G0.6, B0.48 (i.e., 0.4 * 1.2 = 0.48) while leaving black pixels unaffected. Higher values produce a brighter image, whereas lower values reduce both the brightness and the transparency of the image.

  - **Brush:** This menu shows the names of any image files stored in the Brushes directory. The default is the Brushes subdirectory within Fusion’s install folder. The location of the Brushes directory is defined in the Preferences dialog, under Path Maps. The location of the Brushes directory is defined in the Preferences dialog, under Path Maps.

  - **Use Aspect From:** The Use Aspect From menu includes three settings for the aspect ratio of the brush image. You can choose image format to use the brush image’s native aspect ration. Choose Frame Format to use the aspect ratio set in the Frame Format Setting in the Fusion Preferences, or choose Custom to enter your own Pixel X and Y dimensions.
— **Line:** This style produces straight line-type particles with optional “falloff.” The Size to Velocity control described below (under Size Controls) is often useful with this Line type. The Fade control adjusts the amount of falloff over the length of the line.

— **Point Cluster:** This style produces small clusters of single-pixel particles. Point Clusters are similar to the Point style; however, they are more efficient when a large quantity of particles is required. This style shares parameters with the Point style. Additional controls specific to Point Cluster style are Number of Points and Number Variance.

— **Sub Pixel Rendered:** This checkbox determines whether the point particles are rendered with Sub Pixel precision, which provides smoother-looking motion but blurrier particles that take slightly longer to render.

— **Number of Points and Variance:** The value of this control determines how many points are in each Point Cluster.

### Color Controls

The Color Controls select the color and Alpha values of the particles generated by the emitter.

#### Color Variance

These range controls provide a means of expanding the colors produced by the pEmitter. Setting the Red variance range at -0.2 to +0.2 will produce colors that vary 20% on either side of the red channel, for a total variance of 40%. If the pEmitter is set to produce R0.5, G0.5, B0.5 (pure gray), the variance shown above will produce points with a color range between R0.3, G0.5, B0.5, and R0.7, G0.5, B0.5.

To visualize color space as values between 0-256 or as 0-65535, change the values used by Fusion using the Show Color As option provided in the General tab within the Preferences dialog.

#### Lock Color Variance

This checkbox locks the color variance of the particles. Unlocking this allows the color variance to be applied differently to each color channel, giving rise to a broader range of colors.

![Particles Color Over Life controls](image)

### Color Over Life

This standard gradient control allows for the selection of a range of color values to which the particle will adhere over its lifetime.
The left point of the gradient represents the particle color at birth. The right point shows the color of the particle at the end of its lifespan.

Additional points can be added to the gradient control to cause the particle color to shift throughout its life.

This type of control can be useful for fire-type effects (for example, the flame may start blue, turn orange, and end a darker red). The gradient itself can be animated over time by right-clicking on the control and selecting Animate from the contextual menu. All points on the gradient will be controlled by a single Color Over Life spline, which controls the speed at which the gradient itself changes. You may also use the From Image modifier, which produces a gradient from the range of colors in an image along a line between two points.

![Particles Size and Fade controls](image)

**Size Controls**

The majority of the Size Controls are self-explanatory. The Size and Size Variance controls are used to determine the size and degree of size variation for each particle. It is worth noting that the Point style does not have size controls (each point is a single pixel in size, and there is no additional control).

When a Bitmap Particle style is used, a value of 1.0 indicates that each particle should be the same size as the input bitmap. A value of 2.0 will scale the particle up in size by 200%. For the best quality particles, always try to make the input bitmap as big, or bigger, than the largest particle produced by the system.

For the Point Cluster style, the size control adjusts the density of the cluster, or how close together each particle will get.

There are additional size controls that can be used to adjust further the size of particles based on velocity and depth.

**Size to Velocity**

This increases the size of each particle relative to the velocity or speed of the particle. The velocity of the particle is added to the size, scaled by the value of this control.

1.0 on this control, such as for a particle traveling at 0.1, will add another 0.1 to the size (velocity * size to velocity + size = new size). This is most useful for Line styles, but the control can be used to adjust the size of any style.
Size Z Scale
This control measures the degree to which the size of each particle changes according to its Z position. The effect is to exaggerate or reduce the impact of perspective. The default value is 1.0, which provides a relatively realistic perspective effect.

Objects on the focal plane (Z = 0.0) will be actual-sized. Objects farther along Z will become smaller. Objects closer along Z will get larger.

A value of 2.0 will exaggerate the effect dramatically, whereas a value of 0.0 will cancel the effects of perspective entirely.

Size Over Life
This spline control determines the size of a particle throughout its lifespan. The vertical scale represents a percentage of the value defined by the Size control, from 0 to 200%. The horizontal scale represents a percentage of the particle’s lifespan (0 to 100%).

This graph supports all the features available to a standard spline editor. These features can be accessed by right-clicking on the graph. It is also possible to view and edit the graph spline in the larger Spline Editor.

Fade Controls
This simple range slider provides a mechanism for fading a particle at the start and end of its lifetime. Increasing the Fade In value will cause the particle to fade in at the start of its life. Decreasing the Fade Out value will cause the particle to fade out at the end of its life.

This control’s values represent a percentage of the particle’s overall life, therefore, setting the Fade In to 0.1 would cause the particle to fade in over the first 10% of its total lifespan. For example, a particle with a life of 100 frames would fade in from frame 0…10.

Merge Controls
This set of particle controls affects the way individual particles are merged together. The Subtractive/Additive slider works as documented in the standard Merge node. The Burn-In control will cause the particles to overexpose, or “blow out,” when they are combined.

None of the Merge controls will have any effect on a 3D particle system.

Particles Blur controls
Blur Controls

This set of particle controls can be used to apply a Blur to the individual particles. Blurring can be applied globally, by age, or by Z depth position.

None of the Blur controls will have any effect on a 3D particle system.

Blur (2D) and Blur Variance (2D)

These controls apply blur to each particle. Unlike the Blur in the pRender node, this is applied to each particle independently before the particles are merged together. The Blur Variance slider modifies the amount of blur applied to each particle.

Blur Over Life

This spline graph controls the amount of blur that is applied to the particle over its life. The vertical scale represents a percentage of the value defined by the Blur control. The horizontal scale represents a percentage of the particle’s lifespan.

This graph supports all of the features available to a standard Spline Editor. These features can be accessed by right-clicking on the graph. It is also possible to view and edit the spline in the larger Spline editor.

Z Blur (DoF) (2D) and DoF Focus

This slider control applies blur to each particle based on its position along the Z axis.

The DoF Focus range control is used to determine what area of the image remains in focus. Lower values along Z are closer to the camera. Higher values are farther away. Particles within the range will remain in focus. Particles outside that range will have the blur defined by the Z Blur control applied to them.

Conditions

Conditions Tab

The Conditions tab limits the particles that are affected by the node’s behavior. You can limit the particle using probability or more specifically using sets.

Probability

The Probability slider determines the percentage of chance that the node affects any given particle.

The default value of 1.0 affects all particles. A setting of 0.6 would mean that each particle has a 60 percent chance of being affected by the control.
Probability is calculated for each particle on each frame. For example, a particle that is not affected by a force on one frame has the same chance of being affected on the next frame.

**Start/End Age**

This range control can be used to restrict the effect of the node to a specified percentage of the particle lifespan.

For example, to restrict the effect of a node to the last 20 percent of a particle’s life, set the Start value to 0.8, and the End value remains at 1.0. The node on frames 80 through 100 only affects a particle with a lifespan of 100 frames.

**Set Mode Menu**

The Set Mode menu drives how the particle node influences the active particle sets. There are three options from this menu:

- **Ignore Sets**: The particle node disregards the state of the Set checkboxes and applies to all nodes.
- **Affect Specified Sets**: The particle node applies its behavior to the active Set checkboxes only.
- **Ignore Specified Sets**: The particle node applies its behavior to the inactive Set checkboxes only.

**Set #**

The state of a Set # checkbox determines if the Particle node’s effect will be applied to the particles in the set. It allows you to limit the effects of some nodes to a subset of particles.

Sets are assigned by the nodes that create particles. These include the pEmitter, pImage Emitter, pChangeStyle, and the pSpawn nodes.

**Region Tab**

The Region tab is used to restrict the node’s effect to a geometric region or plane, and to determine the area where particles are created if it’s a pEmitter node or where the behavior of a node has influence.

The Region tab is common to almost all particle nodes. In the pEmitter node Emitter Regions are used to determine the area where particles are created. In most other tools it is used to restrict the tool’s effect to a geometric region or plane. There are seven types of regions, each with its own controls. Only one emitter region can be set for a single pEmitter node. If the pRender is set to 2D, then the emitter region will produce particles along a flat plane in Z Space. 3D emitter regions possess depth and can produce particles inside a user-defined, three-dimensional region.
Region Mode Menu

The Region Mode menu includes seven types of regions to define the area, each with its controls.

- **All**: In 2D, the particles will be created anywhere within the boundaries of the image. In 3D, this region describes a cube 1.0 x 1.0 x 1.0 units in size.

- **Bézier**: Bézier mode uses a user-created polyline to determine the region where particles are created. The Bézier mode works in both 2D and 3D modes; however, the Bézier polyline region can only be created in 2D.
  To animate the shape of the polyline over time or to connect it to another polyline, right-click the Shape animation label at the bottom of the inspector and select the appropriate option from the drop-down menu.

- **Bitmap**: A Bitmap source from one of the other nodes in the composition will be used as the region where particles are born.

- **Cube**: A full 3D Cube is used to determine the region within which particles are created. The height, width, depth, and XYZ positions can all be determined by the user and be animated over time.

- **Line**: A simple line control determines where particles are created. The line is composed of two end-points, which can be connected to Paths or Trackers, as necessary. This type of emitter region includes X, Y, and Z position controls for the start and end of the line.

- **Mesh**: Any 3D Mesh can be used as a region. In Mesh mode, the region can also be restricted by the Object ID using the ObjectID slider. See below for a more in-depth explanation of how mesh regions work.

- **Rectangle**: The Rectangle region type is like the Cube type, except that this region has no depth in Z space. Unlike other 2D emitter regions, this region can be positioned and rotated in Z space.

- **Sphere**: This is a spherical 3D emitter region with Size and Center Z controls. Sphere (3D) is the default region type for a new pEmitter node.

Mesh Regions

**Region Type**

The Region Type drop-down menu allows you to choose whether the region will include the inner volume or just the surface. For example, with a pEmitter mesh region, this determines if the particles emit from the surface or the full volume.

**Winding Rule and Winding Ray Direction**

The Winding Rule and Winding Ray Direction parameters determine how the mesh region handles particle creation with meshes that are not closed, as is common in many meshes imported from external applications. This scenario is common with imported mesh geometry, and even geometry that appears closed will frequently appear to “leak” thanks to improperly welded vertices.

To determine if a particle is in the interior of an object, a ray is cast from infinity through that particle and then out to -infinity. The Winding Ray Direction determines which direction this ray is cast in. Each time a surface is pierced by the ray, it is recorded and added onto a total to generate a winding number. Going against a surfaces normal counts as +1, and going with the normal counts as -1.

The Winding Rule is then used to determine what is inside/outside. For example, setting the Winding Rule to Odd means that only particles with odd values for the winding number are kept when creating the particles. The exact same approach is used to ensure that polylines that intersect themselves are closed properly.
For example, the following node tree and image show two image planes being used as a mesh region for particle creation.

By setting the region’s Winding Ray Direction to the Z (blue) axis, this mesh can then be treated as a closed volume for purposes of particle creation, as pictured below.

**Limit By ObjectID**

Selecting this checkbox allows the Object ID slider to select the ObjectID used as part of the region.
**Style Tab**

The Style tab exists in the pEmitter, pSpawn, pChangeStyle, and pImage Emitter. It controls the appearance of the particles, allowing the look of the particles to be designed and animated over time.

**Style**

The Style menu provides access to the various types of particles supported by the Particle Suite. Each style has its specific controls, as well as controls it will share with other styles.

— **Point Style:** This option produces particles precisely one pixel in size. Controls that are specific to Point style are Apply Mode and Sub Pixel Rendered.

— **Bitmap Style and Brush Style:** Both the Bitmap and Brush styles produce particles based on an image file. The Bitmap style relies on the image from another node in the node tree, and the Brush style uses image files in the Brushes directory. They both have numerous controls for affecting their appearance and animation, described below.

— **Blob Style:** This option produces large, soft spherical particles, with controls for Color, Size, Fade timing, Merge method, and Noise.

— **Line Style:** This style produces straight line-type particles with optional “falloff.” The Size to Velocity control described below (under Size Controls) is often useful with this Line type. The Fade control adjusts the amount of falloff over the length of the line.

— **Point Cluster Style:** This style produces small clusters of single-pixel particles. Point Clusters are similar to the Point style; however, they are more efficient when a large quantity of particles is required. This style shares parameters with the Point style. Additional controls specific to Point Cluster style are Number of Points and Number Variance.

**Style Options**

The following options appear only on some of the styles, as indicated below.

**Apply Mode (Point and Point Cluster)**

This control applies only to 2D particles; 3D particle systems are not affected.

— **Add:** Overlapping particles are combined by adding together the color values of each particle.

— **Merge:** Overlapping particles are merged.

**Sub Pixel Rendered (Point and Point Cluster)**

This checkbox determines whether the point particles are rendered with Sub Pixel precision, which provides smoother-looking motion but blurrier particles that take slightly longer to render.

**Number of Points and Variance (Point Cluster)**

The value of this control determines how many points are in each Point Cluster.

**Animate (Bitmap Style)**

If the Bitmap source is a movie file or image sequence, this menu determines which frame is grabbed from the source and applied to newly-created particles.
— **Over Time:** All particles use the image produced by the Style Bitmap node at the current time, and change to each successive image together in step, as time increases. A particle created at frame 1 will contain the image at frame 1 of the Style Bitmap. At frame 2, the original particle will use the image from frame 2, and so will any new particles. All created particles will share the same bitmap image from their source at all times.

— **Particle Age:** Each particle animates through the sequence of images provided by the Style Bitmap node, independently of other particles. In other words, an individual particle’s appearance is taken from the Style Bitmap node at successive times, indexed by its age.

— **Particle Birth Time:** New particles take the image from the Style Bitmap node at the current time and keep it unchanged until the end of the particle’s lifespan. Thus, particles generated on a given frame will all have the same appearance and will stay that way.

**Time Offset (Bitmap Style)**
This control allows the Bitmap source frame to be offset in time from the current frame.

**Time Scale (Bitmap Style)**
This control scales the time range of the source bitmap images by a specified amount. For example, a scale of 2 will cause the particle created at frame 1 to be read from the bitmap source at frame 2.

**Gain (Bitmap and Brush Style)**
This control applies a gain correction to the image used as the bitmap. Higher values produce a brighter image, whereas lower values reduce both the brightness and the transparency of the image.

**Style Bitmap (Bitmap Style)**
This control appears when the Bitmap style is selected, along with an orange Style Bitmap input on the node’s icon in the Node view. Connect a 2D node to this input to provide images to be used for the particles. You can do this on the Node view, or you may drag and drop the image source node onto the Style Bitmap control from the Node Editor or Timeline, or right-click on the control and select the desired source from the Connect To menu.

**Brush (Brush Style)**
This menu shows the names of any image files stored in the Brushes directory. The location of the Brushes directory is defined in the Preferences dialog, under Path Maps. The default is the Brushes subdirectory within Fusion’s install folder. If no images are in this directory, the only option in the menu will be None, and no particles will be rendered.

**Noise (Blob Style)**
Increasing this control’s value will introduce grain-type noise to the blobby particle.

**Fade (Line Style)**
The Fade control adjusts the falloff over the line particle’s length.

The default value of 1.0 causes the line to fade out completely by the end of the length.
**Color Controls**

The Color Controls select the color and Alpha values of the particles generated by the emitter.

**Color Variance**

These range controls provide a means of expanding the colors produced by the pEmitter. Setting the Red variance range at -0.2 to +0.2 will produce colors that vary 20% on either side of the red channel, for a total variance of 40%. If the pEmitter is set to produce R0.5, G0.5, B0.5 (pure gray), the variance shown above will produce points with a color range between R0.3, G0.5, B0.5, and R0.7, G0.5, B0.5.

To visualize color space as values between 0-256 or as 0-65535, change the values used by Fusion using the Show Color As option provided in the General tab within the Preferences dialog.

**Lock Color Variance**

This checkbox locks the color variance of the particles. Unlocking this allows the color variance to be applied differently to each color channel, giving rise to a broader range of colors.

![Particles Color Over Life controls](image)

**Color Over Life**

This standard gradient control allows for the selection of a range of color values to which the particle will adhere over its lifetime.

The left point of the gradient represents the particle color at birth. The right point shows the color of the particle at the end of its lifespan.

Additional points can be added to the gradient control to cause the particle color to shift throughout its life.

This type of control can be useful for fire-type effects (for example, the flame may start blue, turn orange and end a darker red). The gradient itself can be animated over time by right-clicking on the control and selecting Animate from the contextual menu. All points on the gradient will be controlled by a single Color Over Life spline, which controls the speed at which the gradient itself changes. You may also use the From Image modifier, which produces a gradient from the range of colors in an image along a line between two points.
Chapter 113

Position Nodes

This chapter details the Position nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Z to World Pos [Z2W] 2460
The Common Controls 2463
Volume Fog [VLF]

Volume Fog Node Introduction

The Volume Fog node is used to create sophisticated volumetric fog on images containing XYZ Position channels.

As opposed to 3D-rendered volumetric fog, it works on 2D images and delivers much faster results and interactive feedback when setting up the fog. See the “WPP Concept” section at the end of this chapter for further explanation of how this technology works and to learn about the required imagery.

Basic Node Setup

The Volume Fog node takes an image input; in the example below, it is a Renderer 3D with World Position enabled in the output channels. Another input is the 3D scene, which contains the camera. A Fast Noise node generates the fog texture.

Inputs

The following inputs appear on the Volume Fog node in the Node Editor.

- **Image**: The orange input accepts the primary image where the fog will be applied. This image contains a World Position Pass in the XYZ Position channels.

- **Fog Image**: The green Fog image input is for creating volumetric fog with varying depth and extent; a 2D image can be connected here. A good starting point is to use a Fast Noise at a small resolution of 256 x 256 pixels.

- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the fog to certain areas.

- **Scene Input**: The magenta scene input accepts a 3D scene containing a 3D Camera.
Inspector

The Volume Fog Shape tab

Shape Tab

The Shape tab defines the size and location of the fog volume. You can either use the Pick buttons to select the location and orientation in the viewer or use the Translation, Rotation, and Scale controls.

Shape

This menu switches between a basic spherical or rectangular volume to be placed in your image. These volumes can then be further refined using the Fog image and effect mask.

Pick

Drag the Pick button into the viewer to select the XYZ coordinates from any 3D scene or 2D image containing XYZ values, such as a rendered World Pass, to position the center of the Volume object. When picking from a 2D image, make sure it’s rendered in 32-bit float to get full precision.

X, Y, Z Offset

These controls can be used to position the center of the fog volume manually or can be animated or connected to other controls in Fusion.

Rotation Pick

Drag the Pick button into the viewer to select the rotational values from any 3D Scene or 2D image containing those values, like an XYZ-Normal-Pass, to reorient the fog volume.

When picking from a 2D image, like an XYZ Normal pass, make sure it’s rendered in 32-bit float to get full precision and accurate rotational values.

X, Y, Z Rotation

Use these controls to rotate the fog volume around its center.
X, Y, Z Scale
Scale the fog volume in any direction from its center to refine further the overall Size value specified below.

Size
The overall size of the fog volume created.

Soft Edge
Controls how much the fog volume is faded toward the center from its perimeter to achieve a softer look.

The Volume Fog Color tab

Color Tab
The Color tab controls the detail and color of the fog.

Adaptive Samples
Volumes images consist of multiple layers, so there may be 64 layers in a volume. This checkbox adjusts the rendering algorithm for how to best blend those layers.

Dither: Applies a form of noise to improve the blending and hide visible layer differences.

Samples
Determines how many times a “ray” shot into the volume will be evaluated before the final image is created. Not unlike raytracing, higher values lead to more detail inside the volume but also increase render times.
**Z Slices**
The higher the Z Slices value, the more images from the connected Fog image sequence will be used to form the depth of the volume.

You can, for example, use a Fast Noise with a high Seethe Rate to create such a sequence of images. Be careful with the resolution of the images. Higher resolutions can require a large amount of memory. As a rule of thumb, a resolution of 256 x 256 pixels with 256 Z Slices (i.e., forming a 256 x 256 x 256 cubic volume, which will use up to 256 MB for full color 32-bit float data) should give you a good starting point.

**First Slice Time**
Determines which frame of the Global Range is used to deliver the first slice from the connected fog image sequence.

Make sure that both Global In and Global Out, as well as the valid range of your source node, fall within the range of First Slice Time + Z Slices.

**Color**
Allows you to modify the color of the fog generated. This will multiply over any color provided by the connected Fog image.

**Gain**
Increases or decreases the intensity of the fog. More Gain will lead to a stronger glow and less transparency in the fog. Lower values let the fog appear less dense.

**Subtractive/Additive Slider**
Similar to the Merge node, this value controls whether the fog is composed onto the image in Additive or Subtractive mode, leading to a brighter or dimmer appearance of the fog.

**Fog Only**
This option outputs the generated fog on a black background, which then can be composited manually or used as a mask on a Color Corrector for further refinement.

---

**Noise Tab**
The Noise tab controls the shape and pattern of the noise added to the fog.
**Detail**
Increase the value of this slider to produce a greater level of detail in the noise result. Larger values add more layers of increasingly detailed noise without affecting the overall pattern. High values take longer to render but can produce a more natural result.

**Gain**
This control increases or decreases the brightest parts of the noise map.

**Brightness**
This control adjusts the overall brightness of the noise map, before any gradient color mapping is applied. In Gradient mode, this produces a similar effect to the Offset control.

**Translation**
Use the Translation coordinate control to pan and move the noise pattern.

**Noise Rotation**
Use the Rotation controls to orient the noise pattern in 3D.

**Seethe**
Adjust this thumbwheel control to interpolate the noise map against a different noise map. This will cause a crawling shift in the noise, like it was drifting or flowing. This control must be animated to affect the noise over time.

**Discontinuous**
Normally, the Noise function interpolates between values to create a smooth, continuous gradient of results. Enable this checkbox to create hard discontinuity lines along some of the noise contours. The result will be a dramatically different effect.

**Inverted**
Select this checkbox to invert the noise, creating a negative image of the original pattern. This is most effective when Discontinuous is also enabled.

The Volume Fog Camera tab

**Camera Tab**
For a perfect evaluation of a fog volume, a camera or 3D scene can be connected to the Scene input of the node.
**Camera**

If multiple cameras are available in the connected Scene input, this menu allows the selection of the correct camera needed to evaluate the fog volume. Instead of connecting a camera, position values can be provided manually or by connecting the XYZ values to other controls.

**Translation Pick**

Drag the Pick button into the viewer to select XYZ coordinates from any 3D scene or 2D image containing XYZ values, like a rendered World Pass, to define the center of the camera. When picking from a 2D image, make sure it's rendered in 32-bit float to get full precision.

**X, Y, Z Offset**

These controls can be used to define the center of the camera manually or can be animated or connected to other controls in Fusion.

---

The Volume Fog Light tab

**Light Tab**

To utilize the controls in the Light tab, you must have actual lights in your 3D scene. Connect that scene, including Camera and Lights, to the 3D input of the node.

**Do Lighting**

Enables or disables lighting calculations. Keep in mind that when not using OpenCL (i.e., rendering on the CPU), these calculations may become a bit slow.

**Do In-Scattering**

Enables or disables light-scattering calculations. The volume will still be lit according to the state of the Do Lighting checkbox, but scattering will not be performed.
**Light Samples**
Determines how accurate the lighting is calculated. Higher values mean more accurate calculation at the expense of longer render times.

**Density**
This is similar to scattering in that it makes the fog appear thicker. With a high amount of scattering, though, the light will be scattered out of the volume before it has had much chance to travel through the fog, meaning it won’t pick up a lot of the transmission color. With a high density instead, the fog still appears thicker, but the light gets a chance to be transmitted, thus picking up the transmission color before it gets scattered out. Scattering is affected by the light direction when Asymmetry is not 0.0. Density is not affected by light direction at all.

**Scattering**
Determines how much of the light bouncing around in the volume ends up scattering the light out of the fog. If the light scatters more, or more accurately, then there’s a higher probability of the light being scattered out of the volume, hence less light is left to continue through the fog. This option can make the fog seem denser.

**Asymmetry**
Determines in what direction the light is scattered. A value of 0 produces uniform, or isotropic, scattering, meaning all directions have equal probability. A value greater than 0 causes “forward scattering,” meaning the light is scattered more into the direction of the light rays. This is similar to what happens with water droplets in clouds. A value smaller than 0 produces “back scattering,” where the light is more scattered back toward the original light source.

**Transmission**
Defines the color that is transmitted through the fog. The light that doesn’t get scattered out will tend toward this color. It is a multiplier, though, so if you have a red light, but blue transmission, you won’t see any blue.

**Reflection**
Changes the intensity of the light that is scattered out. Reflection can be used to modify the overall color before Emission is added. This will be combined with the color channels of the volume texture and then used to scale the values. The color options and the color channels of the volume texture are multiplied together, so if the volume texture were red, setting the Reflection color options to blue would not make the result blue. In such a case, they will multiply together to produce black.

**Emission**
This adds a bit of “glowing” to the fog, adding energy/light back into the calculation. If there are no lights in the scene, and the fog emission is set to be 1.0, the results are similar to no lighting, like turning off the Do Lighting option. Glowing can also be done while producing a different kind of look, by having a Transmission greater than 1. This, however, would never happen in the real world.

**Common Controls**

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Position nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Examples

In these examples, we are looking at a volume from the outside. On the left, you see how the Volume Fog looks with straight accumulation. That means the Do Lighting option is turned off.

On the right, you see the same volume with lighting/scattering turned on, and a single point light.

Here, we have a slightly more complex Volume.

On the left with straight accumulation; in the middle with lighting, scattering, and a single point light; and on the right, the light in the scene has been moved, which also influences the look of the volume.
Volume Mask [VLM]

The Volume Mask node

Volume Mask Node Introduction

The Volume Mask node is used to create volumetric masks from images containing XYZ Position channels.

This can, for example, be used to isolate objects for color correction without the need to track or rotoscope the scene. See the “WPP Concept” section later in this chapter for further explanation on how this technology works and to learn about the required imagery.

Inputs

The following three inputs appear on the Volume Mask node in the Node Editor:

— **Image**: The orange image input accepts a 2D image containing a World Position Pass in the XYZ Position channels.
— **Mask Image**: An image can be connected to the green mask image input for refining the mask.
— **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the volume mask to certain areas.

Basic Node Setup

Below, a MediaIn labeled RGBA contains the main rendered image from a 3D scene. A World Position Pass from a 3D-rendered scene is labeled WPP_PASS. The Channel Booleans node is used to map the X position pass to the red channel, Y to the green channel, and Z to the blue channel. The Volume Mask tool extracts the 3D position information from the World Position Pass to place a mask in 3D space. The mask is then used as an effect mask on a color corrector to selectively color correct objects in a 3D scene.
Inspector

The Volume Mask Shape tab

Shape Tab

The Shape tab defines the size and location of the Volume Mask. You can either use the Pick buttons to select the location and orientation in the viewer or use the Translation, Rotation, and Scale controls.

Shape

This menu switches between a spherical or rectangular mask to be placed in your image. The mask can be further refined using the mask image input.

Translation Pick

Drag the Pick button into the viewer to select XYZ coordinates from any 3D scene or 2D image containing XYZ values, like a rendered World Pass, to position the center of the Volume Mask. When picking from a 2D image, make sure it’s rendered in 32-bit float to get full precision.

X, Y, Z Offset

These controls can be used to position the center of the mask manually or can be animated or connected to other controls in Fusion.

Rotation Pick

Drag the Pick button into the viewer to select rotational values from any 3D scene or 2D image containing those values, like an XYZ Normal pass, to reorient the mask.

When picking from a 2D image, like an XYZ Normal pass, make sure it’s rendered in 32-bit float, and use World Space coordinates to get full precision and the correct rotational values.

X, Y, Z Rotation

Use these controls to rotate the mask around its center.
X, Y, Z Scale
Scale the mask in any direction from its center to further refine the overall Size value specified below.

Size
The overall size, in X, Y, and Z, of the mask created.

Soft Edge
Controls how much the Volume is faded toward the center from its perimeter to achieve a softer look.

The Volume Mask Color tab

Color Tab
The Color tab controls the color and blending of the mask image.

Color
Allows you to modify the color of the generated Volume Mask. This will add to any color provided by the connected mask image.

Subtractive/Additive Slider
Similar to the Merge node, this value controls whether the mask is composed onto the image in Additive or Subtractive mode, leading to a brighter or dimmer appearance of the mask.

Mask Only
Outputs the generated mask on a black background, which then can be used as a mask on a Color Corrector for further refinement.
The Volume Mask Camera tab

**Camera Tab**

For a perfect evaluation of a Volume, a camera or 3D scene can be connected to the Scene input of the node.

**Camera**

If multiple cameras are available in the connected Scene input, this drop-down menu allows you to choose the correct camera needed to evaluate the Volume.

Instead of connecting a camera, position values can also be provided manually or by connecting the XYZ values to other controls.

**Translation Pick**

Drag the Pick button into the viewer to select XYZ coordinates from any 3D scene or 2D image containing XYZ values, like a rendered World Pass, to define the center of the camera.

When picking from a 2D image, make sure it’s rendered in 32-bit float to get full precision.

**X, Y, Z Offset**

These controls can be used to define the center of the camera manually or can be animated or connected to other controls in Fusion.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Position nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Z to World Pos [Z2W]

The Z to World Position node

Z to World Pos Node Introduction

The Z to World Pos node is used to either generate a World Position Pass from a Z channel and a 3D Camera or a Z channel from a World Position Pass and a 3D Camera.

Creating a World Position Pass from Z-depth can be useful when your 3D application is not capable of creating a WPP.

It can also be used when a 3D-tracking software outputs a per-pixel Z-depth together with the 3D Camera. Thus, the Volume Mask and Volume Fog could be applied to real-world scenes. The quality of the resulting WPP depends mainly on the quality of the incoming Z channel.

See the “WPP Concept” section for further explanation on how this technology works and to learn about the required imagery.

Inputs

The following inputs appear on the node tile in the Node Editor:

- **Image**: The orange image input accepts an image containing a World Position Pass or a Z-depth pass, depending on the desired operation.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the World Position Pass to certain areas.
- **Scene Input**: The magenta scene input accepts a 3D scene input containing a 3D Camera.

Basic Node Setup

Below, a MediaIn labeled RGBA contains the main rendered image from a 3D scene. A Z-depth pass from a 3D-rendered scene is labeled Z_PASS. The Channel Booleans node is used to map the Aux Z channel into either the red, green, or blue channel. The Z to World Position node is placed after the Channel Booleans node, and an imported 3D camera that matches the RGBA image is connected to the 3D camera input on the Z to World Position node. A Channel Booleans node is placed after the Z to World Position node, which can remap the X, Y, and Z positions for use in other nodes.
A Z to World Position node creates a World Position Pass from a Z-depth pass

**Inspector**

The Z to World Position Controls tab

**Controls Tab**

The Controls tab determines whether you are creating a World Position Pass or a Z channel. If there is more than one camera in the connected scene, this tab also selects the camera to use for the calculation.

**Mode**

This menu switches between creating a Z channel from a World Position Pass or vice versa.

**Camera**

If multiple cameras are available in the connected Scene input, this drop-down menu allows you to choose the correct camera needed to evaluate the image.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Position nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**WPP Concept**

The Position nodes in Fusion offer an entirely new way of working with masks and Volumetrics for footage containing XYZ Position channels. Z to World offers the option to create those channels out of a Z channel and 3D Camera information. For this overview, we refer to the World Position Pass as WPP.
What Is a WPP?

The WPP interprets each pixel’s XYZ position in 3D space as an RGB color value.

For instance, if a pixel sits at 0/0/0, the resulting pixel has an RGB value of 0/0/0 and thus will be black. If the pixel sits at 1/0/0 in the 3D scene, the resulting pixel is entirely red. Of course, if the coordinates of the pixel are something like -60/75/123, WPP interprets those values as RGB color values as well.

Due to the potentially enormous size of a 3D scene, the WPP channel should always be rendered in 32-bit floating point to provide the accuracy needed. The image below shows a 3D rendering of a scene with its center sitting at 0/0/0 in 3D Space and the related WPP. For better visibility, the WPP is normalized in this example.

![Image of 3D rendering with WPP channel]

Different Coordinate Spaces

Rendering WPPs can occur in different Coordinate Spaces. These include World Space, Eye Space, and Object Space. The image below depicts how those different spaces look, although the nodes in Fusion require the WPP rendering to occur in World Space.

![Image of different coordinate spaces]

The Scene Input

The nodes offer a Scene input, which can either be a 3D camera or a 3D scene containing a camera. While the camera is vital for the Z to World node, Volume Mask and Volume Fog can generate their output without any camera attached or with the camera position set to 0/0/0.

However, connecting a camera that lines up with the original camera the WPP has been rendered from, or setting the camera’s position manually, dramatically improves the accuracy and look of the resulting fog or mask.
The “Invisible Sphere”

The example scene shown so far has an empty background, meaning there is nothing in the scene apart from the ground plane and the cubes.

If applying fog to a scene like that, which is larger than the ground plane, the result will look similar to the “w/o Sphere” example shown below because, with no WPP information outside the ground plane, the resulting value is 0/0/0, and the fog fills that area as well.

To get around that, you can add an invisible bounding sphere to your scene to create “dummy” WPP values to help the Fog node to create the correct volume as shown in the “with Sphere” example below.

---

The Common Controls

Nodes that handle Position operations share several identical controls in the Inspector. This section describes controls that are common among Position nodes.

**Inspector**

- **Settings**
  - Blend: 1.0
  - Process when Blend is 0.0
  - Apply Mask Inverted
  - Multiply by Mask
  - Use Object
  - Use Material
  - Motion Blur
  - Use GPU: Auto
- **Comments**
- **Frame Render script**
- **Start Render Script**
- **End Render Script**
Settings Tab
The Settings tab in the Inspector can be found on every tool in the Position category. The controls are consistent and work the same way for each tool.

Blend
The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this will cause the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0
The tool is processed even when the input value is zero. This can be useful if the node is scripted to trigger a task, but the node’s value is set to 0.0.

Red/Green/Blue/Alpha Channel Selector
These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur will first be applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this will generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

Apply Mask Inverted
Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

Multiply by Mask
Selecting this option will cause the RGB values of the masked image to be multiplied by the mask channel’s values. This will cause all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

Use Object/Use Material (Checkboxes)
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels will be used if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

Correct Edges
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Object ID/Material ID (Sliders)

Use these sliders to select which ID will be used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the viewer. The image or sequence must have been rendered from a 3D software package with those channels included.

Motion Blur

- **Motion Blur**: This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.
- **Quality**: Quality determines the number of samples used to create the blur. A quality setting of 2 will cause Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.
- **Shutter Angle**: Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one full frame exposure. Higher values are possible and can be used to create interesting effects.
- **Center Bias**: Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.
- **Sample Spread**: Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

Use GPU

The Use GPU menu has three settings. Setting the menu to Disable turns off GPU hardware-accelerated rendering. Enabled uses the GPU hardware for rendering the node. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.

Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 114

Resolve Connect

This chapter details the single node found in the Resolve Connect category, available only in standalone Fusion Studio.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Contents

External Matte Saver [EMS] 2467
External Matte Saver [EMS]

The External Matte Saver node

NOTE: The Resolve Connect category and External Matte Saver node are available only in Fusion Studio.

External Matte Saver Node Introduction

The External Matte Saver node renders multiple mattes into multiple channels of an EXR file. This file is intended to import into DaVinci Resolve’s Color page as an efficient way to deliver multiple mattes for color grading. To perform the same operation with a traditional Saver node, a Channel Boolean is needed to place each matte into a channel, and then name that channel in the Saver. It requires a bit more of a set up. This node streamlines the process by providing multiple inputs and naming the channel based on the node.

Inputs

By default, the node provides a single input for a 2D image you want to save as a matte.

— **Input:** Although initially there is only a single orange input for a matte to connect, the Inspector provides an Add button for adding additional inputs. Each input uses a new color, but all accept 2D RGBA images.

Basic Node Setup

The External Matte Saver node can be placed at the end of any node tree branch for saving mattes. Below, it is connected to the Delta Keyer as well as three other mattes. Each matte beyond the initial one is connected by clicking the Add button in the Inspector first, and then a new input is provided on the node.
An External Matte Saver node added as a separate branch in a node tree to render the mattes

**Inspector**

The External Matte Saver Controls tab

**Controls Tab**

The Controls tab is used to name the saved file and determine where on your hard drive the file is stored.

**Filename**

Enter the name you want to use for the EXR file in the Filename field. At the end of the name, append the .exr extension to ensure that the file is saved as an EXR file.

**Browse**

Clicking the Browse button opens a standard file browser window where you can select the location to save the file.

**Mattes Tab**

The Mattes tab is where you set up the number of mattes saved in the file, the name for each channel, and the RGBA channels saved from each input.
**Channels menu**
The Channels menu allows you to select which channels are saved in the matte. You can choose the alpha channel, the RGB channels, or the RGBA channels.

**Channels Name**
The Channels Name field allows you to customize the name of the matte channel you are saving. This name is displayed in DaVinci Resolve’s Color page.

**Node Name**
The Node Name field displays the source of the matte. This is automatically populated when you connect a node to the input.

**Add**
Clicking the Add button adds an input on the node and another set of fields for you to configure and name the new matte channel.

The External Matte Saver Settings tab

**Settings Tab**
The Settings Tab in the Inspector is similar to settings found in the Saver tool. The controls are consistent and work the same way as the Settings in other tools.
Blend
The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this causes the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0
The tool is processed even when the input value is zero. This can be useful if processing of this node is scripted to trigger another task, but the value of the node is set to 0.0.

Red/Green/Blue/Alpha Channel Selector
These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur is first applied to the image, and then the red channel from the original input is copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

Apply Mask Inverted
Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

Multiply by Mask
Selecting this option causes the RGB values of the masked image to be multiplied by the mask channel’s values. This causes all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

Use Object/Use Material (Checkboxes)
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels are used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

Correct Edges
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Object ID/Material ID (Sliders)
Use these sliders to select which ID is used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the viewer. The image or sequence must have been rendered from a 3D software package with those channels included.
Motion Blur

— **Motion Blur:** This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.

— **Quality:** Quality determines the number of samples used to create the blur. A quality setting of 2 causes Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.

— **Shutter Angle:** Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one full frame exposure. Higher values are possible and can be used to create interesting effects.

— **Center Bias:** Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.

— **Sample Spread:** Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 115

Shape Nodes

This chapter details the Shape nodes available in Fusion.

Contents

sBoolean 2473
sDuplicate 2476
sEllipse 2478
sExpand 2481
sGrid 2483
sJitter 2484
sMerge 2486
sNGon 2487
sOutline 2490
sRectangle 2492
sRender 2495
sStar 2498
sTransform 2501
Common Controls 2503
sBoolean

The sBoolean node combines or excludes overlapping areas of two shapes based on a menu of boolean operations.

Like almost all shape nodes, you can only view the sBoolean node's results through a sRender node.

**External Inputs**

The following inputs appear on the node's tile in the Node Editor. Except when using the subtract boolean operation, which shape you connect into which input does not matter.

- **Input1:** [orange, required] This input accepts the output of another shape node. This input is used as the base shape when the subtract boolean operation is chosen.
- **Input2:** [green, optional] This input accepts the output of another shape node. This input is used to cut the base shape hole when the subtract boolean operation is chosen.

**Basic Node Setup**

The sBoolean node is used to combine two shape nodes. The output of the sBoolean can then be output to another shape node or a sRender node for viewing.

**Inspector**

The sBoolean Controls tab
Controls

The Controls tab is primarily used to select the boolean operation that determines how the two shapes are combined.

Operation

The operation menu includes four boolean operations:

— **Intersection**: Sometimes called an AND operation, this setting will only show areas where the two shapes overlap. The result is only where input 1 AND input 2 overlap.

  Star and ellipse shapes with an sBoolean node set to intersection

— **Union**: Sometimes called an OR operation, this setting will only show areas where either of the two shapes exists. The result is where either input 1 OR input 2 exists. The Union setting is similar to the result of the sMerge node.

  Star and ellipse shapes with an sBoolean node set to union

— **Subtract**: Sometimes called a NOT operation, this setting outputs the shape of input 1 but eliminates the areas where input 2 overlaps. The result is input 1 minus input 2.

  Star and ellipse shapes with an sBoolean node set to subtract
— **Xor:** Sometimes called an AND NOT operation, this setting outputs the shape of input 1 or input 2 but eliminates the areas where they overlap. The result is (input 1 minus input 2) + (input 2 minus input 1).

![Star and ellipse shapes with an sBoolean node set to xor](image)

**Style Mode**

The Style mode menu only includes one option. The Replace setting replaces the color and alpha level of the incoming shapes with the color set in the Style tab.

**Style Tab**

![The sBoolean Style tab](image)

**Style**

Any color assigned to the individual shape nodes is replaced by the color set using the Style tab controls.

**Color**

The color controls determine the color of the output shape from the sBoolean node. To choose a shape color, you can click the color disclosure arrow, use the color swatch, or drag the eyedropper into the viewer to select a color from an image. The RGBA sliders or number fields can be used to enter each color channel’s value or the strength of the alpha channel.
Allow Combining

When this checkbox is enabled, the alpha channel value is maintained even when passing through other nodes downstream that may cause the shape to overlap with copies of itself. When disabled, the alpha channel value may increase when the shape overlaps itself.

For instance, if an ellipse’s alpha channel is set to .5, enabling the Allow Combining checkbox maintains that value even if the shape passes through a duplicate or grid node that causes the shape to overlap. Disabling the checkbox causes the alpha channel values to be compounded at each overlapping area. When using the sBoolean node, the individual shape node checkboxes are ignored, and the sBoolean node’s checkbox determines the alpha channel’s behavior.

Common Controls

Settings tab

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sDuplicate

The sDuplicate node creates copies of the input shape, offsetting each copy’s position, size, and rotation. Like almost all shape nodes, you can only view the sDuplicate node’s results through a sRender node.

External Inputs

The following input appears on the node’s tile in the Node Editor:

— **Input1**: [orange, required] This input accepts the output of another Shape node. The shape connected to this input is copied and offset based on the controls in the Inspector.
Basic Node Setup

The sDuplicate node takes a single input that is most often from a single or compound shape from a sMerge or sBoolean node. The sDuplicate node creates copies of the incoming shape and offsets them to create a pattern. The output of the sDuplicate can then be output to another shape node or to a sRender node for viewing or compositing into the greater node tree.

An sEllipse shape connected to an sDuplicate and then output to an sRender for viewing and combining with other elements

Inspector

The sDuplicate Controls tab

Controls

The Controls tab is used to determine the number of copies and set their position, size, and rotation offset.

Copies

This slider determines the number of copies created by the node. The number does not include the original shape, so entering a value of five will produce five copies plus the original.

X and Y Offset

These sliders set the X and Y distance between each of the copies. Each copy is offset from the previous copy by the value entered in the X and Y number fields. The copies all start at 0, the center of the original shape, and are offset from there. Using Fusion’s normalized coordinate system, entering X Offset at 0.5 would move each copy half the frame’s width to the right. Entering -1.0 would move each copy to the left by the width of the frame.

X and Y Size

Sets the X and Y size offset based on the previous shape size. For instance, an X and Y value of 1.0 creates copies identical in size to the original but. Entering a value of X and Y of 0.5 will cause each copy to be half the size of the copy before it.
**Axis Mode**

The Axis mode menu provides four options for determining how each copy determines its rotational pivot point.

- **Absolute**: Allows you to set an X and Y position for the axis of rotation based on the original shape’s location. The axis of rotation is then copied and offset with each duplicated shape.
- **Origin Relative**: Each copy uses its center point as its axis of rotation.
- **Origin Absolute**: Each copy uses the center of the original shape as its axis of rotation.
- **Progressive**: Compounds each shape copy by progressively transforming each copy based on the previous shape’s position, rotation, and scale.

**X and Y Pivot**

The X and Y pivot controls are displayed when the Axis mode is set to Absolute. You can use these position controls to place the axis of rotation.

**Rotation**

Determines an offset rotation applied to each copy. The rotation is calculated from the offset rotation of the previous copy. To rotate all copies identically, use the Angle parameter on the original shape or use a sTransform node.

**Common Controls**

**Settings tab**

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**sEllipse**

The sEllipse node

The sEllipse node is used to create circular shapes. Like almost all shape nodes, you can only view the sEllipse node’s results through a sRender node.

**External Inputs**

This node generates shapes and does not have any inputs.
Basic Node Setup

The sEllipse node is a shape generator, meaning it generates a shape and therefore has no input. The output of the sEllipse can go into a sRender for viewing and further compositing or, more likely, connect to another shape node like sGrid or sDuplicate.

An sEllipse node connecting to an sGrid node, and then viewed using an sRender node

Inspector

The sEllipse Controls tab

Controls

The Controls tab is used to define the elliptical shape characteristics, including fill, border, size, and position.

Solid

When enabled, the Solid checkbox fills the elliptical shape with the color defined in the Style tab. When disabled, an outline created by the Border Width control is displayed, and the center is made transparent.

Border Width

This parameter expands or contracts the border around the shape. Although it can be used when the Solid checkbox is enabled, it is primarily used to determine the outline thickness when the checkbox is disabled.

Cap style

When the Solid checkbox is disabled, three cap style options are displayed. The cap styles can create lines with flat, rounded, or squared ends. Flat caps have flat, squared ends, while rounded caps have semi-circular ends. Squared caps have projecting ends that extend half the line width beyond the end of the line.

The caps are not visible unless the length is below 1.0.
Position
The position parameter is only displayed when the Solid checkbox is disabled. It allows you to position the starting point of the shape. When used in conjunction with the length parameter, it positions the gap in the ellipse outline.

Length
The length parameter is only displayed when the Solid checkbox is disabled. A length of 1.0 is a closed shape. Setting the length below 1.0 creates an opening or gap in the outline. Keyframing the length parameters allows you to create write-on style animations.

X and Y Offset
These parameters are used to position the shape left, right, up, and down in the frame. The shape starts in the center of the frame, and the parameters are used to offset the position. The offset coordinates are normalized based on the width of the frame. An X offset of 0.0 is centered, and a value of 0.5 places the center of the shape directly on the right edge of the frame.

Width/Height
The width and height determine the vertical and horizontal size of the ellipse. If the values are identical, then you have a perfect circle.

Angle
The angle rotates the shape, which on a perfect circle doesn’t change the image all that much, but if you create an oval or an outline with a short length, you can rotate the shape based on the center axis.

Style Tab

![The sEllipse Style tab](image)

The sEllipse Style tab

Style
The Style tab is used to assign a color to the shape and control its transparency.

Color
The color controls determine the color of the fill and border. To choose a shape color, you can click the color disclosure arrow, use the color swatch, or drag the eyedropper into the viewer to select a color.
from an image. The RGBA sliders or number fields can be used to enter each color channel’s value or the strength of the alpha channel.

**Allow Combining**

When this checkbox is enabled, the alpha channel value is maintained even when passing through other nodes downstream that may cause the shape to overlap with copies of itself. When disabled, the alpha channel value may increase when the shape overlaps itself.

For instance, if an ellipse’s alpha channel is set to .5, enabling the Allow Combining checkbox maintains that value even if the shape passes through a Duplicate or Grid node that causes the shape to overlap. Disabling the checkbox causes the alpha channel values to be compounded at each overlapping area.

![Allow Combining Enabled](left), Allow Combining Disabled (right)

**Common Controls**

**Settings tab**

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**sExpand**

The sExpand node is used to dilate or erode shapes. Like almost all Shape nodes, you can only view the sExpand node’s results through a sRender node.

**External Inputs**

The following input appears on the node’s tile in the Node Editor.

— **Input1**: [orange, required] This input accepts the output of another shape node. This shape or compound shape connected to this input is either eroded or dilated.
Basic Node Setup

The sExpand node takes a single input that is most often from a compound shape. However, it can be used on single shapes like sStars and sNgons. The output of the sExpand can then be output to another shape node or to a sRender node for viewing or compositing into the greater node tree.

Inspector

The sExpand Controls tab

Controls

The Controls tab includes all of the parameters for the sExpand node.

Amount

A positive value dilates the shape while a negative value erodes it.

Border Style

The border style controls how the expanded or contracted shapes join at the corners. There are four styles provided as options. Bevel squares off the corners. Round creates rounded corners. Miter and Miter Clip maintain pointed edges, until a certain threshold. The Threshold is set by the Miter limit slider.

Miter Limit

The Miter parameter is only displayed when the Miter or Miter Clip border style is selected. The miter limit determines when the pointed edges become beveled based on the shape's thickness.

Common Controls

Settings tab

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
sGrid

The sGrid node replicates the shape on an X and Y grid and adds the ability to offset the rows and columns. Like almost all Shape nodes, you can only view the sGrid node’s results through a sRender node.

External Inputs

The following input appears on the node’s tile in the Node Editor.

— **Input1**: [orange, required] This input accepts the output of another Shape node. The shape connected to this input is replicated on a custom grid.

Basic Node Setup

The sGrid node takes a single input from a single or compound shape from an sMerge or sBoolean node. The sGrid node places the incoming shape on a grid of rows and columns. The output of the sGrid can then be output to another Shape node or a sRender node for viewing or compositing into the greater node tree.

Inspector

The sGrid Controls tab

Controls

The Controls tab is used to determine the number of grid cells and their offset position.
Grid Cells X and Y
These parameters set the number of cells on the grid, both horizontally and vertically. For instance, entering 5 in the X and Y number field creates five rows of the shape and five columns.

X and Y Offset
Sets the X and Y distance between the rows and columns. An offset value of 0.0 will have all the rows and columns on top of each other. Entering X Offset at 1.0 would spread the columns the width to the frame.

Common Controls
Settings tab
The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sJitter
The sJitter node is most often used to randomly position an array of shapes generated from a sGrid or sDuplicate node. However, it includes an auto-animating random mode that can be used to distort and randomly jitter single shapes.

Like almost all Shape nodes, you can only view the sJitter node’s results through a sRender node.

External Inputs
The following input appears on the node’s tile in the Node Editor.

— Input: [orange, required] This input accepts the output of another Shape node. The shape connected to this input is offset, distorted, and animated based on the sJitter node settings.

Basic Node Setup
The sJitter node takes an array of shapes from a sGrid or sDuplicate node and randomly changes their position, size, and rotation. The output of the sExpand can then be output to another Shape node or to a sRender node for viewing or compositing into the greater node tree.

An array of shapes created by the sGrid node input into an sJitter node to randomly offset or scale the shapes
Inspector

The Controls tab offers range sliders that determine the variation amount for offset, size, and rotation. The Point Jitter parameters are used to offset the invisible points that create the vector shapes.

**Jitter Mode**

The Jitter Mode menu allows you to choose between static position and size offsets or enabling an auto-animation mode. Leaving the default Fixed selection allows you to offset a grid of shapes, animating with keyframes or modifiers if needed. The Random menu selection auto-animates the parameters based on the range you define using the range sliders. If all the range sliders are left in the default position, no random animation is created. Increasing the range on any given parameter will randomly animate that parameter between the range slider values.

**Shape X and Y Offset**

These parameters set the horizontal and vertical offset from the shape array’s original position. This is done randomly, so not all shapes in the array will offset by the same amount.

**Shape X and Y Size**

These parameters set the horizontal and vertical scaling for each shape in an array. The left range value decreases the scale, and the right range value increases the scale. This is done randomly, so not all shapes in the array will scale by the same amount.

**Shape Rotate**

This parameter rotates each shape in an array.

**Point Jitter**

The X and Y Point Jitter parameters use the vector control points to distort the shape. This can be used to give a distressed appearance to ellipses or wobbly animation to other shapes.
Common Controls

Settings tab

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sMerge

The sMerge node combines shapes similar to a standard Merge node, except the sMerge node can accept more than two shape inputs.

Like almost all Shape nodes, you can only view the sMerge node’s results through a sRender node.

External Inputs

The node displays only two inputs first, but as each shape node is connected, a new input appears on the node, assuring there is always one free to add a new shape into the composite.

— Input[#]: These multi-colored inputs are used to connect multiple Shape node. There is no limit to the number of inputs this node can accept. The node dynamically adds more inputs as needed, ensuring that there is always at least one input available.

Basic Node Setup

The sMerge node is used to combine two Shape nodes. In terms of layering, each subsequent input is placed over the previous input. For instance, the first shape connected to the orange input is the bottom-most shape, the green input is layered over it, and if a third shape is connected to the pink input, that is the topmost layer.

Three shapes are combined in an sMerge node, then output to an sRender for viewing and further processing.
Inspector

The only control for the sMerge node is the Override Axis checkbox, which overrides the shape's axis.

Common Controls
Settings tab
The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sNGon

The sNGon node is used to create multi-sided shapes like triangles, pentagons, and octagons. Like almost all Shape nodes, you can only view the sNGon node's results through a sRender node.

External Inputs
This node generates shapes and does not have any inputs.

Basic Node Setup
The sNGon node is a shape generator, meaning it generates a shape and therefore has no inputs. The output of the sNGon can go into a sRender for viewing and further compositing or, more likely, connect to another Shape node like sGrid or sDuplicate.
Controls
The Controls tab is used to define multi-sided shape characteristics, including fill, border, size, and position.

Solid
When enabled, the Solid checkbox fills the NGon shape with the color defined in the Style tab. When disabled, an outline created by the Border Width control is displayed, and the center is made transparent.

Border Width
This parameter expands or contracts the border around the shape. Although it can be used when the Solid checkbox is enabled, it is primarily used to determine the outline thickness when the checkbox is disabled.

Border Style
The Border Style parameter controls how the sides of the NGon join at the corners. There are three styles provided as options. Bevel squares off the corners. Round creates rounded corners. Miter maintains pointed corners.

Cap style
When the Solid checkbox is disabled, three cap style options are displayed. The cap styles can create lines with flat, rounded, or squared ends. Flat caps have flat, squared ends, while rounded caps have semi-circular ends. Squared caps have projecting ends that extend half the line width beyond the end of the line.

The caps are not visible unless the length is below 1.0.

Position
The Position parameter is only displayed when the Solid checkbox is disabled. It allows you to position the starting point of the shape. When used in conjunction with the Length parameter, it positions the gap in the outline.
Length
The Length parameter is only displayed when the Solid checkbox is disabled. A length of 1.0 is a closed shape. Setting the length below 1.0 creates an opening or gap in the outline. Keyframing the Length parameters allows you to create write-on style animations.

X and Y Offset
These parameters are used to position the shape left, right, up, and down in the frame. The shape starts in the center of the frame, and the parameters are used to offset the position. The offset coordinates are normalized based on the width of the frame. So, an X offset of 0.0 is centered and a value of 0.5 places the center of the shape directly on the right edge of the frame.

Width/Height
The Width and Height parameters determine the vertical and horizontal size of the ellipse. If the values are identical, then all sides are of equal length.

Angle
The Angle parameter rotates the shape based on the center axis.

Style Tab
The sNGon Style tab

Style
The Style tab is used to assign a color to the shape and control its transparency.

Color
The Color controls determine the color of the fill and border. To choose a shape color, you can click the color disclosure arrow, use the color swatch, or drag the eyedropper into the viewer to select a color from an image. The RGBA sliders or number fields can be used to enter each color channel’s value or the strength of the alpha channel.

Allow Combining
When this checkbox is enabled, the alpha channel value is maintained even when passing through other nodes downstream that may cause the shape to overlap with copies of itself. When disabled, the alpha channel value may increase when the shape overlaps itself.
For instance, if a NGon alpha channel is set to .5, enabling the Allow Combining checkbox maintains that value even if the shape passes through a duplicate or grid node that causes the shape to overlap. Disabling the checkbox causes the alpha channel values to be compounded at each overlapping area.

![Allow Combining Enabled (left), Allow Combining Disabled (right)]

**Settings tab**

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

### sOutline

The sOutline node is used to create outlines from merged or boolean compound shapes. The individual shapes retain their own style, color, size, position, and other characteristics. The only difference is the border thickness, border style, position, and length are applied to all incoming shapes uniformly in the sOutline node.

Like almost all shape nodes, you can only view the sOutline node’s results through a sRender node.

**External Inputs**

The following input appears on the node’s tile in the Node Editor:

- **Input1**: [orange, required] This input accepts the another shape node’s output, but more likely a compound shape from a sMerge or sBoolean. An outline is created from the compound shape connected to this input.

**Basic Node Setup**

The sOutline node takes a single input that is most often from a compound shape, however, it can sometimes be useful on single shapes to create double outlines. The output of the sOutline can then be output to another Shape node or to a sRender node for viewing or compositing into the greater node tree.
A compound shape from an sBoolean node is connected to an sOutline for creating a complex outlined shape.

**Inspector**

The sOutline Controls tab

**Controls**

The Controls tab is used to define the outline thickness, border and cap style, position, and length that is applied to the compound shape connected to the input.

**Thickness**

This parameter controls the width of the outline.

**Border Style**

The Border Style parameter controls how the outline joins at the corners. There are three styles provided as options. Bevel squares off the corners. Round creates rounded corners. Miter maintains pointed corners.

**Cap style**

Three Cap Style options are used to create lines with flat, rounded, or squared ends. Flat caps have flat, squared ends, while rounded caps have semi-circular ends. Squared caps have projecting ends that extend half the line width beyond the end of the line.

The caps are not visible unless the length is below 1.0.

**Position**

The Position parameter allows you to position the starting point of the shape. When used in conjunction with the Length parameter, it positions the gap in the outline.

**Length**

The Length parameter controls the end position of the outline. A length of 1.0 is a closed shape. Setting the length below 1.0 creates an opening or gap in the outline. Keyframing the Length parameters allows you to create write-on style animations.
Common Controls

Settings tab

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sRectangle

The sRectangle node is used to create rectangular shapes. Like almost all shape nodes, you can only view the sRectangle node’s results through a sRender node.

External Inputs

This node generates shapes and does not have any inputs.

Basic Node Setup

The sRectangle node is a shape generator, meaning it generates a shape and therefore has no inputs. The output of the sRectangle can go into a sRender for viewing and further compositing or, more likely, connect to another Shape node like sGrid or sDuplicate.

Inspector

The sRectangle Controls tab
Controls
The Controls tab is used to define the rectangle characteristics, including fill, border, size, and position.

Solid
When enabled, the Solid checkbox fills the rectangle shape with the color defined in the Style tab. When disabled, an outline created by the Border Width control is displayed, and the center is made transparent.

Border Width
This parameter expands or contracts the border around the shape. Although it can be used when the Solid checkbox is enabled, it is primarily used to determine the outline thickness when the checkbox is disabled.

Border Style
The Border Style parameter controls how the sides of the rectangle join at the corners. There are three styles provided as options. Bevel squares off the corners. Round creates rounded corners. Miter maintains pointed corners.

Cap style
When the Solid checkbox is disabled, three Cap Style options are displayed. The cap styles can create lines with flat, rounded or squared ends. Flat caps have flat, squared ends, while rounded caps have semi-circular ends. Squared caps have projecting ends that extend half the line width beyond the end of the line.

The caps are not visible unless the length is below 1.0.

Position
The Position parameter is only displayed when the Solid checkbox is disabled. It allows you to position the starting point of the shape. When used in conjunction with the Length parameter, it positions the gap in the outline.

Length
The Length parameter is only displayed when the Solid checkbox is disabled. A length of 1.0 is a closed shape. Setting the length below 1.0 creates an opening or gap in the outline. Keyframing the Length parameters allows you to create write-on style animations.

X and Y Offset
These parameters are used to position the shape left, right, up, and down in the frame. The shape starts in the center of the frame, and the parameters are used to offset the position. The offset coordinates are normalized based on the width of the frame. So an X offset of 0.0 is centered and a value of 0.5 places the center of the shape directly on the right edge of the frame.

Width/Height
The Width and Height parameters determine the vertical and horizontal size of the rectangle. If the values are identical, then you have a square.

Corner Radius
This parameter determines if the corners of the rectangle are sharp or rounded. A value of 0.0 produces sharp corners, while a value of 1.0 will create a circle from a staring square shape or a pill shape from a rectangle.
Angle

The Angle parameter rotates the shape based on the center axis.

Style Tab

The sRectangle Style tab

Style

The Style tab is used to assign color to the shape and control its transparency.

Color

The Color parameter controls determine the color of the fill and border from the sRectangle node. To choose a shape color, you can click the color disclosure arrow and use the color swatch, or drag the eye dropper into the viewer to select a color from an image. The RGBA sliders or number fields can be used to enter the value of each color channel or the strength of the alpha channel.

Allow Combining

When this checkbox is enabled, the alpha channel value is maintained even when passing through other nodes downstream that may cause the shape to overlap with copies of itself. When disabled, the alpha channel value may increase when the shape overlaps itself. For instance, if a rectangle alpha channel is set to .5, enabling the Allow Combining checkbox maintains that value even if the shape passes through a duplicate or grid node that causes the shape and alpha channel to overlap. Disabling the checkbox causes the alpha channel values to be compounded at each overlapping area.
Common Controls

Settings tab

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sRender

The sRender node

The sRender node converts the vector shapes to an image. The output of the sRender allows the vector shapes to be integrated with other elements in a composite.

Inputs

There is one input on the Background node for an Effect Mask input.

— **Input1** ([orange, required]) This input accepts the output of your final shape node. A rendered bitmap image is created from the sRender node for composting into the rest of your comp.

— **Effect Mask**: The optional blue effect mask input accepts a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the displayed area to only those pixels within the mask.

Basic Node Setup

The sRender node is always placed at the end of a string of Shape nodes. The output connects to other 2D nodes like a Soft Glow node.

Multiple Shape nodes connected to the sRender node and then processed and composited with a title
Inspector

The sRender Image tab

The controls in this tab are used to set the resolution, color depth, and pixel aspect of the image produced by the sRender node.

Process Mode
Use this menu control to select the Fields Processing mode used by Fusion to render the resulting image. The default Full Frames option is appropriate for progressive formats.

Width/Height
This pair of controls are used to set the Width and Height dimensions of the image to be created by the sRender node.

Pixel Aspect
This control is used to specify the Pixel Aspect ratio of the created images. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor), and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).

**NOTE:** Right-click on the Width, Height, or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height, and pixel aspect to the values for that format, accordingly.

Auto Resolution
When this checkbox is selected, the width, height, and pixel aspect of the image created by the node will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.
**Depth**

The Depth button array is used to set the pixel color depth of the image created by the Creator node. 32-bit pixels require 4X the memory of 8-bit pixels but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

**Source Color Space**

You can use the Source Color Space menu to set the Color Space of the footage to help achieve a linear workflow. Unlike the Gamut tool, this doesn’t perform any actual color space conversion, but rather adds the source space data into the metadata, if that metadata doesn’t exist. The metadata can then be used downstream by a Gamut tool with the From Image option, or in a Saver, if explicit output spaces are defined there. There are two options to choose from:

- **Auto**: Automatically reads and passes on the metadata that may be in the image.
- **Space**: Displays a Color Space Type menu where you can choose the correct color space of the image.

**Source Gamma Space**

Using the Curve Type menu, you can set the Gamma Space of the footage and choose to remove it by way of the Remove Curve check box when working in a linear workflow. There are three choices in the Curve Type menu:

- **Auto**: Automatically reads and passes on the metadata that may be in the image.
- **Space**: Displays a Gamma Space Type menu where you can choose the correct gamma curve of the image.
- **Log**: Brings up the Log/Lin settings, similar to the Cineon tool. For more information, see Chapter 38, “Film Nodes,” in the Fusion Reference Manual or Chapter 98 in the DaVinci Resolve Reference Manual.

**Remove Curve**

Depending on the selected Gamma Space or on the Gamma Space found in Auto mode, the Gamma Curve is removed from, or a log-lin conversion is performed on, the material, effectively converting it to a linear output space.

**Common Controls**

**Settings tab**

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
sStar

The sStar node is used to create multi-point star shapes. Like almost all Shape nodes, you can only view the sStar node’s results through a sRender node.

External Inputs

This node generates shapes and does not have any inputs.

Basic Node Setup

The sStar node is a shape generator, meaning it generates a shape and therefore has no inputs. The output of the sStar can go into a sRender for viewing and further compositing or, more likely, connect to another shape node like sGrid or sDuplicate.

Inspector

The sStar Controls tab

Controls

The Controls tab is used to define the star shape’s characteristics, including number of points, depth, fill, border, size, and position.
Points
This slider determines the number of points or arms on the star.

Depth
The depth slider controls the inner radius or width of the arms. A depth of 0.001 makes hair-thin arms, while a depth of 1.0 makes a faceted circle.

Solid
When enabled, the Solid checkbox fills the star shape with the color defined in the Style tab. When disabled, an outline created by the Border Width control is displayed, and the center is made transparent.

Border Width
This parameter expands or contracts the border around the shape. Although it can be used when the Solid checkbox is enabled, it is primarily used to determine the outline thickness when the checkbox is disabled.

Border Style
The Border Style parameter controls how the sides of the star join at the corners. There are three styles provided as options. Bevel squares off the corners. Round creates rounded corners. Miter maintains pointed corners.

Cap style
When the Solid checkbox is disabled, three cap style options are displayed. The cap styles can create lines with flat, rounded or squared ends. Flat caps have flat, squared ends while rounded caps have semi-circular ends. Squared caps have projecting ends that extend half the line width beyond the end of the line.

The caps are not visible unless the length is below 1.0.

Position
The Position parameter is only displayed when the Solid checkbox is disabled. It allows you to position the starting point of the shape. When used in conjunction with the length parameter, it positions the gap in the outline.

Length
The Length parameter is only displayed when the Solid checkbox is disabled. A length of 1.0 is a closed shape. Setting the length below 1.0 creates an opening or gap in the outline. Keyframing the Length parameters allows you to create write-on style animations.

X and Y Offset
These parameters are used to position the shape left, right, up, and down in the frame. The shape starts in the center of the frame, and the parameters are used to offset the position. The offset coordinates are normalized based on the width of the frame. So an X offset of 0.0 is centered and a value of 0.5 places the center of the shape directly on the right edge of the frame.

Width/Height
The Width and Height parameters determine the vertical and horizontal size of the star. If the values are identical, then all arms of the star are of equal length.
Angle

The Angle parameter rotates the shape based on the center axis.

Style Tab

The sStar Style tab

Style

The Style tab is used to assign color to the shape and control its transparency.

Color

The Color controls determine the color of the fill and border from the sStar node. To choose a shape color, you can click the color disclosure arrow and use the color swatch, or drag the eye dropper into the viewer to select a color from an image. The RGBA sliders or number fields can be used to enter the value of each color channel or the strength of the alpha channel.

Allow Combining

When this checkbox is enabled, the alpha channel value is maintained even when passing through other nodes downstream that may cause the shape to overlap with copies of itself. When disabled, the alpha channel value may increase when the shape overlaps itself. For instance, if a star alpha channel is set to .5, enabling the Allow Combining checkbox maintains that value even if the shape passes through a duplicate or grid node that causes the shape and alpha channel to overlap. Disabling the checkbox causes the alpha channel values to be compounded at each overlapping area.

Allow Combining Enabled (left), Allow Combining Disabled (right)
Common Controls

Settings tab
The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

sTransform

The sTransform node is used to add an additional set of transform controls to the existing controls that are contained in Shape nodes. These additional transforms can be used to create hierarchical animations. For instance, you can use a sStar’s built-in Angle control to spin the star around. The star can then be output to an sTransform node. The rotation control in the sTransform can be used to orbit the star around the frame.

Like almost all Shape nodes, you can only view the sStar node’s results through a sRender node.

External Inputs
The following input appears on the node’s tile in the Node Editor:

— **Input1**: [orange, required] This input accepts the output of another Shape node. The shape connected to this input is moved, scaled, and rotated based on the sTransform settings.

Basic Node Setup
The sTransform node takes the input from another Shape node and adds another set of transforms or hierarchical animation. The output of the sTransform can go into a sRender for viewing and further compositing.

An sStar node connecting to an sTransform node, and then viewed using an sRender node
Inspector

The sTransform Controls tab

Controls

The Controls tab is used to define the add a set of transform controls to the incoming shape.

X and Y Offset

These parameters are used to position the shape left, right, up, and down in the frame. The shape starts in the center of the frame, and the parameters are used to offset the position. The offset coordinates are normalized based on the width of the frame. So an X offset of 0.0 is centered and a value of 0.5 places the center of the shape directly on the right edge of the frame.

X and Y Size

The X and Y Size determine the vertical and horizontal scaling of the incoming shape. If the values are different then the shape will be skewed from its original design.

Rotation

The dial rotates the shape based on the pivot controls.

X and Y Pivot

These parameters position the axis of rotation for the incoming shape. The pivot point is visible in the viewer as a red X. The X can be dragged in the viewer for positioning.

Transform Axis

Check this box to apply the transform to the shape’s axis.

Common Controls

Settings tab

The Settings tab in the Inspector is common to all Shape nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Common Controls

Nodes that handle Shape operations share a number of identical controls in the Inspector. This section describes controls that are common amongst Shape nodes.

Settings Tab

The Settings tab in the Inspector can be found on every Shape node. Most of the controls listed here are only found in the sRender node but a few are common to all Shape nodes.

Blend (sRender only)

The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming. Normally, this causes the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0 (sRender only)

The tool is processed even when the input value is zero. This can be useful if processing of this node is scripted to trigger another task but the value of the node is set to 0.0.

Red/Green/Blue/Alpha Channel Selector (sRender only)

These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the red button on a Blur tool is deselected, the blur is first applied to the image, then the red channel from the original input is copied back over the red channel of the result.

There are some exceptions, such as tools where deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Control tabs are identical.

Apply Mask Inverted (sRender only)

Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

Multiply By Mask (sRender only)

Selecting this option causes the RGB values of the masked image to be multiplied by the mask channel’s values. This causes all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

Motion Blur (sRender only)

— **Motion Blur:** This toggles the rendering of motion blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.

— **Quality:** Quality determines the number of samples used to create the blur. A quality setting of 2 causes Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.

— **Shutter Angle:** Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one whole frame exposure. Higher values are possible and can be used to create interesting effects.
— **Center Bias**: Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.
— **Sample Spread**: Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

**Use GPU (sRender only)**

The user GPU menu has three settings. Setting the menu to Disable turns off hard accelerated rendering using the graphics card in your computer. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.

**Hide Incoming Connections**

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the empty field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree the line will reappear.

**Comments**

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower left corner of the node when the full tile is displayed or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

**Scripts**

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more information on scripting nodes, see the Fusion scripting documentation.
This chapter details the Stereo nodes available in Fusion. Stereoscopic nodes are available only in Fusion Studio and DaVinci Resolve Studio.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Anaglyph [Ana]

The Anaglyph node

NOTE: The Anaglyph node is available only in Fusion Studio and DaVinci Resolve Studio.

Anaglyph Node Introduction

The Anaglyph node is used to create stereoscopic images by combining separate left eye and right eye images. It is most commonly used at the end of a stereoscopic workflow to display or deliver the final result.

Inputs

The three inputs on the Anaglyph node are the left eye input, right eye input, and effect mask.

— **Left Eye Input**: The orange input is used to connect the 2D image representing the left eye in the stereo comp.
— **Right Eye Input**: The green input is used to connect the 2D image representing the right eye in the stereo comp.
— **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the stereoscopic creation to only those pixels within the mask.

Basic Node Setup

The Anaglyph node is usually placed at the end of a stereoscopic node tree to display the final result.

When using separate images for the left and right eye, the left eye image is connected to the orange input, and the right eye image is connected to the green input of the node. When using either horizontally or vertically stacked images containing both left eye and right eye information, these only connect to the orange input.
Inspector

The Anaglyph Controls tab

Controls Tab

Using the parameters in the Controls tab, the separate images are combined to create a stereoscopic output.

Color Type Menu

The Color Type menu allows you to choose between different color encodings to fit your preferred display device. To match your stereo glasses, you can choose between Red/Cyan, Red/Green, Red/Blue, Amber/Blue, and Green/Magenta encoding; Red/Cyan is the most commonly used.

Method

In addition to the color used for encoding the image, you can also choose five different methods from the Method menu: Monochrome, Half-color, Color, Optimized, and Dubois. These methods are described below.
— **Monochrome**: Assuming you are using a Red/Cyan Color Type, the left eye contains the luminance of the left image and is placed in the output of the red channel. The right eye contains the luminance of the right image and is placed in the output green and blue channels.

— **Half-Color**: Assuming you are using a Red/Cyan Color Type, the left eye contains the luminance of the left image and is placed in the output of the red channel. The right eye contains the color channels from the right image that match the glasses' color for that eye.

— **Color**: The left eye contains the color channels from the left image that match the glasses' color for that eye. The right eye contains the color channels from the right image that match the glasses' color for that eye.

— **Optimized**: Used with red/cyan glasses, for example, the resulting brightness of what shows through the left eye is substantially less than the brightness of the right eye. Using typical ITU-R 601 ratios for luminance as a guide, the red eye would give 0.299 brightness, while the cyan eye would give $0.587 + 0.114 = 0.701$ brightness—over twice as bright. The difference in brightness between the eyes can produce what are referred to as retinal rivalry or binocular rivalry, which can destroy the stereo effect. The Optimized method generates the right eye in the same fashion as the Color method. The left eye also uses the green and blue channels but in combination with increased brightness that reduces retinal rivalry. Since it uses the same two channels from each of the source images, it doesn't reproduce the remaining one. For example, $1.05 \times$ the green and $0.45 \times$ the blue channels of the left image is placed in the red output channel, and the green and blue channels of the right image are placed in the output green and blue channels. Red from both the left and right images is not used.
— **Dubois**: Images with fairly saturated colors can produce retinal rivalry with the Half-color, Color, and Optimized methods because the color is visible in only one eye. For example, with red/cyan glasses, a saturated green object looks black in the red eye, and green in the cyan eye. The Dubois method uses the spectral characteristics of (specifically) red/cyan glasses and CRT (Trinitron) phosphors to produce a better anaglyph and in the end, tends to reduce retinal rivalry caused by such color differences in each eye. It also tends to reduce ghosting produced when one eye ‘leaks’ into the other eye. The particular calculated matrix in Fusion is designed for red/cyan glasses and isn’t available for other glasses types. Since it is also derived from CRT color primaries, it may not give the best results with a common LCD (though it’ll still likely produce less retinal rivalry and ghosting than the other methods).

**Swap Eyes**

Allows you to swap the left and right eye inputs easily.

**Horiz Stack**

Takes an image that contains both left and right eye information stacked horizontally. These images are often referred to as “crosseyed” or “straight stereo” images. You only need to connect that one image to the orange input of the node. It then creates an image half the width of the original input, using the left half of the original image for the left eye and the right half of the original image for the right eye. Color encoding takes place using the specified color type and method.

**Vert Stack**

Takes an image that contains both left and right eye information stacked vertically. You only need to connect that one image to the orange input of the node. It then creates an image half the height of the original input, using the bottom half of the original image for the left eye and the top half of the original image for the right eye. Color encoding takes place using the specified color type and method.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Combiner [Com]

The Combiner node is available only in Fusion Studio and DaVinci Resolve Studio.

Combiner Node Introduction

The Combiner node takes two stereoscopic inputs and creates so-called “stacked images” with the left and right eye, either side by side or on top of each other. Stereoscopic nodes are available only in Fusion Studio and DaVinci Resolve Studio.

Inputs

The two inputs on the Combiner node are used to connect the two images that get combined in a stacked stereo image.

— **Image 1 Input:** The orange input is used to connect the 2D image representing the left eye in the stereo comp.

— **Image 2 Input:** The green input is used to connect the 2D image representing the right eye in the stereo comp.

Basic Node Setup

Below, a left eye image and right eye image are connected to the Combiner node to create a single stacked stereo image. It can be more efficient to render out the stacked stereo images as EXR files than to generate the disparity on-the-fly.

![Combiner Node Setup Diagram](image)

Left and right eye images are connected into a Combiner node to generate a stacked stereo image.
Controls Tab
To stack the images, the left eye image is connected to the orange input, and the right eye image is connected to the green input of the node.

Combine
The Combine menu provides three options for how the two images are made into a stacked stereo image.

— **None**: No operation will take place. The output image is identical to the left eye input.

— **Horiz**: Both images will be stacked horizontally, or side-by-side, with the image connected to the left eye input on the left. This will result in an output image double the width of the input image.

— **Vert**: Both images will be stacked vertically, or on top of each other, with the image connected to the left eye input on the bottom. This will result in an output image double the height of the input image.

Swap Eyes
Allows you to easily swap the left and right eye input.

Add Metadata
Metadata is carried along with the images and can be added to the existing metadata using this checkbox. To view Metadata, use the viewer’s SubView menu set to Metadata.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
**Disparity [Dis]**

The Disparity node

**NOTE:** The Disparity node is available only in Fusion Studio and DaVinci Resolve Studio.

**Disparity Node Introduction**

Disparity generates the left/right shift between the frames in a stereo pair. It also generates the vertical disparity between the left/right images, which is usually a lot smaller than the horizontal disparity and ideally should be 0 to minimize viewing discomfort. When viewing the output of the Disparity node in the views, the human eye can distinguish quality/detail in the Disparity map better by looking at either the grayscale X disparity or Y disparity rather than looking at the combined XY disparity as a Red/Green color image.

The generated disparity is stored in the output image’s Disparity aux channel, where the left image contains the left > right disparity, and the right image contains the right > left disparity. Because disparity works based on matching regions in the left eye to regions in the right eye by comparing colors and gradients of colors, colors in the two eyes must be as similar as possible. Thus, it is a good idea to color correct ahead of time. It is also a good idea to crop away any black borders around the frames, as this confuses the disparity tracking (and also causes problems if you are using the Color Corrector’s histogram match ability to do the color matching).

In Stack mode, left and right outputs deliver the same image. If the left and right images have a global vertical offset larger than a few pixels, it can help the disparity tracking algorithm if you vertically align features in the left/right eyes ahead of time using a Transform node. Small details tend to get lost in the tracking process when you have a large vertical offset between left/right eyes.

Consider using a SmoothMotion node to smooth your disparity channel. This can help reduce time-dependent flickering when warping an eye. Also, think about whether you want to remove lens distortion before computing disparity. If you do not, your Disparity map becomes a combined Disparity and Lens Distortion map. This can have advantages and disadvantages.

One disadvantage is that if you then do a vertical alignment, you are also removing lens distortion effects. When trying to reduce the computation time, start first with adjusting the Proxy and Number of Iterations sliders.

The Disparity node does not support RoI or DoD.
**Inputs**

The two inputs on the Disparity node are used to connect the left and right images.

- **Left Input:** The orange input is used to connect either the left eye image or the stacked image.
- **Right Input:** The green input is used to connect the right eye image. This input is available only when the Stack Mode menu is set to Separate.

**Outputs**

Unlike most nodes in Fusion, Disparity has two outputs for the left and right eye.

Left Output: This holds the left eye image with a new disparity channel, or a Stacked Mode image with a new disparity channel.

Right Output: This holds the right eye image with a new disparity channel. This output is visible only if Stack Mode is set to Separate.

**Basic Node Setup**

Below, a left eye image and right eye image are connected to the Disparity node. The Disparity node then outputs each eye to Saver nodes. It can be more efficient to render out the stereo images as EXR files than to generate the disparity on-the-fly.

![Left and right eye images are connected into a Disparity node to generate and render out a stereo image](image)

**Inspector**

The Disparity Controls tab

---

Chapter 116 Stereo Nodes 2513
**Proxy (for Tracking)**

The input images are resized down by the proxy scale, tracked to produce the disparity, and then the resulting disparities are scaled back up. This option is purely to speed up the calculation of the disparity, which can be slow. The computational time is roughly proportional to the number of pixels in the image. This means a proxy scale of 2 gives a 4x speedup, and a proxy scale of 3 gives a 9x speedup. In general, 1:1 proxy will give the most detailed flow, but keep in mind that this is highly dependent on the amount of noise and film grain. If noise is present in large quantities, it can completely obliterate any gains moving from 2:1 to 1:1 proxy. In some situations, it can even make things worse. You can think of the Proxy setting as acting as a simplistic low-pass filter for removing noise/grain.

**Advanced**

The Advanced settings section has parameter controls to tune the Disparity map calculations. The default settings have been chosen to be the best default values from experimentation with many different shots and should serve as a good standard. In most cases, tweaking of the Advanced settings is not needed.

**Smoothness**

This controls the smoothness of the disparity. Higher values help deal with noise, while lower values bring out more detail.

**Edges**

This slider is another control for smoothness but applies it based on the color channel. It tends to have the effect of determining how edges in the disparity follow edges in the color images. When it is set to a lower value, the disparity becomes smoother and tends to overshoot edges. When it is set to a higher value, edges in the disparity align more tightly with the edges in the color images, and details from the color channels start to slip into the disparity, which is not usually desirable.

As a rough guideline, if you are using the disparity to produce a Z channel for post effects like depth of field, experiment with higher values, but if you are using the disparity to do interpolation, you might want to keep the values lower.

In general, if the Edges slider is set is too high, there can be problems with streaked out edges when the disparity is used for interpolation.

**Match Weight**

This controls how matching is done between neighboring pixels in the left image and neighboring pixels in the right image. When a lower value is used, large structural color features are matched. When higher values are used, small sharp variations in the color are matched. Typically, a good value for this slider is in the [0.7, 0.9] range. Setting this option higher tends to improve the matching results in the presence of differences due to smoothly varying shadows or local lighting variations between the left and right images. You should still color match the initial images so they are as similar as possible; this option tends to help with local variations (e.g., lighting differences due to light passing through a mirror rig).

**Mismatch Penalty**

This controls how the penalty for mismatched regions grows as they become more dissimilar. The slider provides a choice between a balance of Quadratic (lower values) and Linear (higher values) penalties. Lower value Quadratic settings strongly penalize large dissimilarities, while higher value Linear settings are more robust to dissimilar matches. Moving this slider toward lower tends to give a disparity with more small random variations in it, while higher values produce smoother, more visually pleasing results.
**Warp Count**
Turning down the Warp Count makes the disparity computations faster. In particular, the computational time depends linearly upon this option. To understand what this option does, you need to understand that the Disparity algorithm progressively warps the left image until it matches with the right image. After some point, convergence is reached, and additional warps are just a waste of computational time. The default value in Fusion is set high enough that convergence should always be reached. You can tweak this value to speed up the computations, but it is good to watch how the disparity is degrading in quality at the same time.

**Iteration Count**
Turning down the Iteration Count makes the disparity computations faster. In particular, the computational time depends linearly upon this option. Just like adjusting Warp Count, at some point adjusting this option higher will yield diminishing returns and will not produce significantly better results. By default, this value is set to something that should converge for all possible shots and can be tweaked lower fairly often without reducing the disparity’s quality.

**Filtering**
This menu determines the filtering operations used during flow generation. Catmull-Rom filtering will produce better results, but at the same time, it increases the computation time steeply.

**Stack Mode**
This menu determines how the input images are stacked.

When set to Separate, the Right Input and Output will appear, and separate left and right images must be connected.

**Swap Eyes**
Enabling this checkbox causes the left and right images to swap.

**Common Controls**

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

### Disparity To Z [D2Z]

![The DisparityToZ node](image_url)

**NOTE:** The Disparity to Z node is available only in Fusion Studio and DaVinci Resolve Studio.
Disparity to Z Node Introduction

Disparity To Z takes a 3D camera and an image containing a disparity channel as inputs, and outputs the same image but with a newly computed Z channel.

Optionally, this node can output Z into the RGB channels. Ideally, either a stereo Camera 3D or a tracked stereo camera is connected into Disparity To Z. However, if no camera is connected, the node provides artistic controls for determining a Z channel. The depth created by this node can be used for post effects like fogging or depth of field (DoF).

The Z values produced become more incorrect the larger (negative) they get. The reason is that disparity approaches a constant value as Z approaches -infinity. So Z = -1000 and Z = -10000 and Z = -100000 may map to D=142.4563 and D=142.4712 and D=142.4713. As you can see, there is only 0.0001 in D to distinguish between 10,000 and 100,000 in Z. The maps produced by disparity are not accurate enough to make distinctions like this.

Inputs

The three inputs on the Disparity To Z node are used to connect the left and right images and a camera node.

— **Left Input**: The orange input is used to connect either the left eye image or the stack image.
— **Right Input**: The green input is used to connect the right eye image. This input is available only when the Stack Mode menu is set to Separate.
— **Stereo Camera**: The magenta input is used to connect a stereo camera node.

Outputs

Unlike most nodes in Fusion, Disparity To Z has two outputs for the left and right eye.

— **Left Output**: This holds the left eye image with a new Z channel, or a Stacked Mode image with a new disparity channel.
— **Right Output**: This holds the right eye image with a new Z channel. This output is visible only if Stack Mode is set to Separate.

Basic Node Setup

Disparity To Z takes a 3D camera and stereo images containing a disparity channel as inputs. The output is an image with a newly computed Z channel.
Inspector

The Disparity To Z Controls tab

Controls Tab

In addition to outputting Z values in the Z channel, this tab promotes the color channels to float32 and outputs the Z values into the color channels as \( \{z, z, z, 1\} \). This option is useful to get a quick look at the Z channel.

**NOTE:** Z values are negative, becoming more negative the further you are from the camera. The viewers only show 0.0 to 1.0 color, so to visualize other data it has to be converted via a normalization method to fit in a display 0-1 range. To do this, right-click in the viewer and choose Options > Show Full Color Range.

Output Z to RGB

Rather than keeping the Z values within the associated aux channel only, they will be copied into the RGB channels for further modification with any of Fusion’s nodes.

Refine Z

The Enable checkbox refines the depth map based upon the RGB channels. The refinement causes edges in the flow to align more closely with edges in the color channels. The downside is that unwanted details in the color channels start to show up in the flow. You may want to experiment with using this option to soften out harsh edges for Z-channel post effects like depth of field or fogging.

HiQ Only

Activating this checkbox causes the Refine Z option to process only when rendering is set to High Quality. You can ensure High Quality is enabled by right-clicking to the left or right of the transport controls in the main toolbar.

Strength

Increasing this slider does two things. It smooths out the depth in constant color regions and moves edges in the Z channel to correlate with edges in the RGB channels.

Increasing the refinement has the undesirable effect of causing texture in the color channel to show up in the Z channel. You will want to find a balance between the two.

Radius

This is the radius of the smoothing algorithm.
Stack Mode
This menu determines how the input images are stacked.

When set to Separate, the Right Input and Output will appear, and separate left and right images must be connected.

Swap Eyes
Enabling this checkbox causes left and right images to be swapped.

![Image of Disparity To Z Camera tab]

The Disparity To Z Camera tab

Camera Tab
If you need correct real-world Z values because you are trying to match some effect to an existing scene, you should use the External Camera options to get precise Z values back. If any Z-buffer will suffice and you are not that particular about the exact details of how it is offset and scaled, or if there is no camera available, the Artistic option might be helpful.

— **External Mode:** An input is available on the node to connect an existing stereo Camera 3D. This can either be a single stereo Camera 3D (i.e., its eye separation is set to non-zero), or a pair of (tracked) Camera 3Ds connected via the Camera 3D > Stereo > Right Camera input.

— **Artistic Mode:** If you do not have a camera, you can adjust these controls to produce an “artistic” Z channel whose values will not be physically correct but will still be useful. To reconstruct the Disparity > Z Curve, pick (D, Z) values for a point in the foreground and a point in the background.

**TIP:** If artistic mode is a little too “artistic” for you and you want more physically-based parameters to adjust (e.g., convergence and eye separation), create a dummy Camera 3D, connect it into the Disparity To Z > Camera input, and then fiddle with the Camera 3D’s controls.

Foreground Disparity (Pick from Left Eye)
When the camera Mode is set to Artistic, a Foreground Disparity slider is available. This is the disparity for the closest foreground object. It will get mapped to the depth value specified by the Foreground Depth control. Any objects with disparity outside of the range [ForegroundDisparity, BackgroundDisparity] will have their disparity values clipped to this range leading to flat areas in the Z channel, so make sure that you pick values that enclose the actual disparity range.

Background Disparity (Pick from Left Eye)
When the camera Mode is set to Artistic, a Background Disparity is available. This is the disparity for the furthest background object. It will get mapped to the depth value specified by the Background Depth control. One way to think of this input is as the upper limit to disparity values for objects at -infinity. This value should be for the left eye. The corresponding value in the right eye will be the same in magnitude but negative.
**Foreground Depth**
This is the depth to which Foreground Disparity will be mapped. Think of this as the depth of the nearest object. Note that values here are positive depth.

**Background Depth**
This is the depth to which Background Disparity will be mapped. Think of this as the depth of the most distant object.

**Falloff**
Falloff controls the shape of the depth curve between the requested foreground and background depths. When set to Hyperbolic, the disparity-depth curve behaves roughly like depth = constant / disparity. When set to Linear, the curve behaves like depth = constant * disparity. Hyperbolic tends to emphasize Z features in the foreground, while linear gives foreground/background features in the Z channel equal weighting.

Unless there’s a specific reason, choose Hyperbolic, as it is more physically accurate, while Linear does not correspond to nature and is purely for artistic effect.

**Common Controls**

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**Global Align [GA]**

The GlobalAlign node

---

**NOTE:** The Global Align node is available only in Fusion Studio and DaVinci Resolve Studio.

**Global Align Node Introduction**

As opposed to Stereo Align, this node does not utilize optical flow at all. It’s meant as a fast and convenient way to do simple stereo alignment for both X and Y as well as rotation.

Global Align comes in handy at the beginning of the node chain to visually correct major differences between the left and right eye before calculating Disparity.

Manual correction of large discrepancies between left and right, as well as applying an initial color matching, helps Disparity generate more accurate results.
**Inputs**

The two inputs on the Global Align node are used to connect the left and right images.

- **Left Input:** The orange input is used to connect either the left eye image or the stack image.
- **Right Input:** The green input is used to connect the right eye image. This input is available only when the Stack Mode menu is set to Separate.

**Outputs**

Unlike most nodes in Fusion, Global Align has two outputs for the left and right eye.

- **Left Output:** This outputs the newly aligned left eye image.
- **Right Output:** This outputs the newly aligned right eye image.

**Basic Node Setup**

Global Align is typically placed at the beginning of the node tree. Below it is inserted between the left and right eye images and the Disparity node to visually correct major differences.

![Node Diagram](image)

A Global Align node used to manually correct left and right eye discrepancies

**Inspector**

![Inspector](image)

The Global Align Controls tab
Controls Tab

The Controls tab includes translation and rotation controls to align the stereo images manually.

Translation X and Y

- **Balance**: Determines how the global offset is applied to the stereo footage.
- **None**: No translation is applied.
- **Left Only**: The left eye is shifted, while the right eye remains unaltered.
- **Right Only**: The right eye is shifted, while the left eye remains unaltered.
- **Split Both**: Left and right eyes are shifted in opposite directions.

Snap to Nearest Pixel

While adjusting the X or Y shift dial, this option ensures that the image is shifted in full pixel amounts only to maintain optimum quality. This avoids sub-pixel rendering of the image, which could result in subtle blurring.

Rotation

- **Balance**: Determines how the global rotation is applied to the stereo footage.
- **None**: No rotation is applied.
- **Left Only**: The left eye is rotated, while the right eye remains unaltered.
- **Right Only**: The right eye is rotated, while the left eye remains unaltered.
- **Split Both**: Left and right eyes are rotated in opposite directions.

Angle

This dial adjusts the angle of the rotation. Keep in mind that the result depends on the Balance settings. If only rotating one eye by, for example, 10 degrees, a full 10-degree rotation will be applied to that eye.

When applying rotation in Split mode, one eye will receive a -5 degree and the other eye a +5 degree rotation.

Translation Filter Method

This menu chooses the filter method that delivers the best results depending on the content of your footage.

Visualization

This control allows for different color encodings of the left and right eye to conveniently examine the results of the above controls without needing to add an extra Anaglyph or Combiner node.

Set this to None for final output.

Stack Mode

Determines how the input images are stacked.

When set to Separate, the right input and output will appear, and separate left and right images must be connected.

Swap Eyes

With Stacked Mode, image stereo pairs’ left and right images can be swapped.
Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

New Eye [NE]

The New Eye node

NOTE: The New Eye node is available only in Fusion Studio and DaVinci Resolve Studio.

New Eye Node Introduction

The New Eye node constructs a new image by interpolating between two existing stereo images using the embedded disparity channels. This node can also be used to replace one view with a warped version of the other. In Stack Mode, L and R outputs will output the same image.

You can map the left eye onto the right eye and replace it. This can be helpful when removing errors from certain areas of the frame.

New Eye does not interpolate the aux channels but instead destroys them. In particular, the disparity channels are consumed/destroyed. Add another Disparity node after the New Eye if you want to generate Disparity for the realigned footage.

Inputs

The two inputs on the New Eye node are used to connect the left and right images.

— **Left Input**: The orange input is used to connect either the left eye image or the stack image.
— **Right Input**: The green input is used to connect the right eye image. This input is available only when the Stack Mode menu is set to Separate.

Outputs

Unlike most nodes in Fusion, New Eye has two outputs for the left and right eye.

— **Left Output**: This outputs the left eye image with a new disparity channel, or a Stacked Mode image with a new disparity channel.
— **Right Output**: This outputs the right eye image with a new disparity channel. This output is visible only if Stack Mode is set to Separate.
Basic Node Setup

The New Eye node in the example below constructs a new image by interpolating between the two stereo images using the embedded disparity channels.

A New Eye node creates a new stereo image using embedded disparity.

Inspector

The New Eye Controls tab

Controls Tab

The Controls tab is divided into identical parameters for the left eye and right eye. The parameters are used to select which eye to recreate and the methods used for the interpolation.

Enable

The Enable checkbox allows you to activate the left or right eye independently. The New Eye will replace enabled eye with an interpolated eye. For example, if the left eye is your “master” eye and you are recreating the right eye, you would disable the left eye and enable the right eye.
Lock XY
Locks the X and Y interpolation parameters. When they are unlocked, you can provide separate interpolation factors for using the X and Y disparity. For example, if you are working with the right eye and you have the X Interpolation slider set to 1.0 and the Y Interpolation slider set to -1.0, you will be effectively interpolating the left eye onto the right eye but vertically aligned to the left eye.

XY Interpolation Factor
Interpolation determines where the interpolated frame is positioned, relative to the two source frames: A slider position of -1.0 outputs the frame Left and a slider position of 1.0 outputs the frame Right. A slider position of 0.0 outputs a result that is halfway between Left and Right.

Depth Ordering
The Depth Ordering is used to determine which parts of the image should be rendered on top. When warping images, there is often overlap. When the image overlaps itself, there are two options for which values should be drawn on top.

— Largest Disparity On Top: The larger disparity values will be drawn on top in the overlapping image sections.
— Smallest Disparity On Top: The smaller disparity values will be drawn on top in the overlapping image sections.

Clamp Edges
Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to use Clamp Edges only to correct small gaps around the edges of an interpolated frame.

Softness
Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you have only one checkbox enabled, you can use a larger softness at around 0.03.

Source Frame and Warp Direction
The output of this node is generated by combining up to four different warps. You can choose to use either the color values from the left or right frame in combination with the Forward (left > right) Disparity or the Backward (right > left) Disparity. Sometimes you will want to replace an existing eye. For example, if you want to regenerate the right eye, you would only use left eye warps.

It’s good to experiment with various options to see which gives the best effect. Using both the left and right eyes can help fill in gaps on the left/right side of images. Using both the Forward/Backward Disparity can give a doubling-up effect in places where the disparities disagree with each other.

— Left Forward: Takes the Left frame and uses the Forward Disparity to interpolate the new frame.
— Right Forward: Takes the Right frame and uses the Forward Disparity to interpolate the new frame.
— Left Backward: Takes the Left frame and uses the Back Disparity to interpolate the new frame.
— Right Backward: Takes the Right frame and uses the Back Disparity to interpolate the new frame.
Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Splitter [Spl]

![The Splitter node](image)

NOTE: The Splitter node is available only in Fusion Studio and DaVinci Resolve Studio.

Splitter Node Introduction

The Splitter takes a stacked input image—such as created with the Combiner—and provides two output images: a left eye and a right eye.

Inputs

The two inputs on the Splitter node are used to connect the left and right images.

— **Left Input**: The orange input is used to connect a stacked stereo image.

Outputs

Unlike most nodes in Fusion, the Splitter node has two outputs for the left and right eye.

— **Left Output**: This outputs the left eye image.
— **Right Output**: This outputs the right eye image.

Basic Node Setup

Below, a stacked stereo image is connected to the input on a Splitter where a left and right eye is output.

![A Splitter node creates a left and right image from a stacked stereo image](image)
Inspector

The Splitter Controls tab

Controls Tab
The Controls tab is used to define the type of stacked image connected to the node’s input.

Split
The Split menu contains three options for determining the orientation of the stacked input image.

— None: No operation takes place. The output image on both outputs is identical to the input image.
— Horiz: The node expects a horizontally stacked image. This will result in two output images, each being half the width of the input image.
— Vert: The node expects a vertically stacked image. This will result in two output images, each being half the height of the input image.

Swap Eyes
Allows you to easily swap the left and right eye outputs.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Stereo Align [SA]

The StereoAlign node

NOTE: The Stereo Align node is available only in Fusion Studio and DaVinci Resolve Studio.
Stereo Align Node Introduction

This extremely versatile node for fixing Stereo issues can be used for performing any of the following actions or combinations thereof:

— Vertical alignment of one eye to the other
— Changing the convergence
— Changing the eye separation

By combining these operations in one node, you can execute them using only a single image resampling. In essence, this node can be thought of as applying scales and translation to the disparities and then using the modified disparities to interpolate between the views.

**NOTE:** Changing the eye separation can cause holes to appear, and it may not be possible to fill them since the information needed may not be in either image. Even if the information is there, the disparity may have mismatched the holes. You may need to fill the holes manually. This node modifies only the RGBA channels.

**TIP:** Stereo Align does not interpolate the aux channels but instead destroys them. In particular, the disparity channels are consumed/destroyed. Add another Disparity node after the StereoAlign if you want to generate Disparity for the realigned footage.

**Inputs**

The two inputs on the Stereo Align node are used to connect the left and right images.

— **Left Input:** The orange input is used to connect either the left eye image or the stack image.
— **Right Input:** The green input is used to connect the right eye image. This input is available only when the Stack Mode menu is set to Separate.

**Outputs**

Unlike most nodes in Fusion, Stereo Align has two outputs for the left and right eye.

— **Left Output:** This outputs the left eye image with a new disparity channel, or a Stacked Mode image with a new disparity channel.
— **Right Output:** This outputs the right eye image with a new disparity channel. This output is visible only if Stack Mode is set to Separate.

**Basic Node Setup**

Below, the Stereo Align receives the left and right eye images with disparity. Once the adjustments are made, another Disparity node is added after it to generate disparity for the realigned footage.
A Stereo Align node destroys the disparity channel, so another Disparity node is placed after it.

**Inspector**

The Stereo Align Controls tab

**Controls Tab**

**Vertical Alignment**

This option determines how the vertical alignment is split between two eyes. Usually, the left eye is declared inviolate, and the right eye is aligned to it to avoid resampling artifacts.

When doing per pixel vertical alignment, it may be helpful to roughly pre-align the images by a global Y-shift before disparity computation because the disparity generation algorithm can have problems resolving small objects that move large distances.
Also, be aware that you must be careful about lens distortion because even if two cameras are perfectly vertically aligned, they will still have vertical disparities due to lens distortion. As a best practice, remove the lens distortion before computing the disparity. When a vertical alignment of the right eye is done, you have essentially removed the Y-component of the lens distortion in the right eye, and it will look wrong later when you try to distort it again.

**Apply to**
- **Right:** Only the right eye is adjusted.
- **Left:** Only the left eye is adjusted.
- **Both:** The vertical alignment is split evenly between the left and right eyes.

**Mode**
- **Global:** The eyes are simply translated up or down by the Y-shift to match up.
- **Per Pixel:** The eyes are warped pixel-by-pixel using the disparity to vertically align.

Keep in mind that this can introduce sampling artifacts and edge artifacts.

**Y-shift**
Y-shift is available only when the Mode menu is set to Global. You can either adjust the Y-shift manually to get a match or drag the Sample button into the viewer, which picks from the disparity channel of the left eye. Also remember, if you use this node to modify disparity, you can’t use the Sample button while viewing the node’s output.

**Snap to Whole Pixels**
You can snap the global shift to whole pixels by enabling this option. When enabled, there is no resampling of the image, but rather a simple shift is done so there will be no softening or image degradation.

**Convergence Point**
The Convergence Point section is used as a global X-translation of L/R images.

**Apply to**
This menu determines which eyes are affected by convergence. You can choose to apply the convergence to the left eye, right eye, or split between the two. In most cases, this will be set to Split. If you set the eyes to Split, then the convergence will be shared 50-50 between both eyes. Sharing the convergence between both eyes means you get half the shift in each eye, which in turn means smaller holes and artifacts that need to be fixed later. The tradeoff is that you’ve resampled both eyes rather than keeping one eye as a pure reference master.

**X-shift**
You can either use the slider to adjust the X-shift manually to get a match or use the Sample button to pick from the disparity channels for easy point-to-feature alignment.

**Snap**
You can snap the global shift to whole pixels using this option. In this mode, there is no resampling of the image, but rather a simple shift is done so there will be no softening or image degradation.
**Eye Separation**

Eye Separation changes the distance between the left/right eyes, causing objects in the left/right eyes to converge/diverge further depending on their distance from the camera.

This has the same effect as the Eye Separation option in the Camera 3D node.

**Separation**

This is a scale factor for eye separation.

- When set to 0.0, this leaves the eyes unchanged.
- Setting it to 0.1 increases the shifts of all objects in the scene by a factor of 10% in each eye.
- Setting it to 0.1 will scale the shifts of all objects 10% smaller.

Unlike the Split option for vertical alignment, which splits the alignment effect 50-50 between both eyes, the Both option will apply 100-100 eye separation to both eyes. If you are changing eye separation, it can be a good idea to enable per-pixel vertical alignment, or the results of interpolating from both frames can double up.

**Left/Right Eye Options**

The left and right eye options contain depth ordering and warp direction controls independently for the left and right eye.

**Depth Ordering**

The Depth Ordering is used to determine which parts of the image should be rendered on top. When warping images, there is often overlap. When the image overlaps itself, there are two options for which values should be drawn on top.

- **Largest Disparity On Top:** The larger disparity values will be drawn on top in the overlapping image sections.
- **Smallest Disparity On Top:** The smaller disparity values will be drawn on top in the overlapping image sections.

**Clamp Edges**

Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to use Clamp Edges only to correct small gaps around the edges of an interpolated frame.

**Edge Softness**

Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you have only one checkbox enabled, you can use a larger softness at around 0.03.

**Source Frame and Warp Direction**

The output of this node is generated by combining up to four different warps. You can choose to use either the color values from the left or right frame in combination with the Forward (left > right) Disparity...
or the Backward (right > left) Disparity. Sometimes you will want to replace an existing eye. For example, if you want to regenerate the right eye, you would use only left eye warps.

It’s good to experiment with various options to see which gives the best effect. Using both the left and right eyes can help fill in gaps on the left/right side of images. Using both the Forward/Backward Disparity can give a doubling-up effect in places where the disparities disagree with each other.

— **Left Forward**: Takes the Left frame and uses the Forward Disparity to interpolate the new frame.
— **Right Forward**: Takes the Right frame and uses the Forward Disparity to interpolate the new frame.
— **Left Backward**: Takes the Left frame and uses the Back Disparity to interpolate the new frame.
— **Right Backward**: Takes the Right frame and uses the Back Disparity to interpolate the new frame.

**Stack Mode**

In Stack Mode, L and R outputs will output the same image.

If High Quality is off, the interpolations are done using nearest-neighbor sampling, leading to a more “noisy” result. To ensure High Quality is enabled, right-click under the viewers, near the transport controls, and choose High Quality from the pop-up menu.

**Swap Eyes**

Allows you to easily swap the left and right eye outputs.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**Example**

Different settings for Eye Separation…

…and example settings for Convergence
Z To Disparity [Z2D]

The Z To Disparity node

**NOTE:** The Z To Disparity node is available only in Fusion Studio and DaVinci Resolve Studio.

**Z To Disparity Node Introduction**

Z To Disparity takes a stereo camera and an image containing a Z channel and outputs the same image but with disparity channels in it. This is useful for constructing a Disparity map from CG renders, which will be more accurate than the Disparity map created from the Disparity node.

**Inputs**

The three inputs on the Z To Disparity node are used to connect the left and right images and a camera node.

- **Left Input:** The orange input is used to connect either the left eye image or the stack image.
- **Right Input:** The green input is used to connect the right eye image. This input is available only when the Stack Mode menu is set to Separate.
- **Stereo Camera:** The magenta input is used to connect a stereo perspective camera, which may be either a Camera 3D with eye separation, or a tracked L/R Camera 3D.

**Outputs**

Unlike most nodes in Fusion, Z To Disparity has two outputs for the left and right eye.

- **Left Output:** This outputs the left eye image containing a new disparity channel, or a Stacked Mode image with a new disparity channel.
- **Right Output:** This outputs the right eye image with a new disparity channel. This output is visible only if Stack Mode is set to Separate.

**Basic Node Setup**

Below, a stereo camera and an image containing a Z channel is connected to a Z To Disparity node. The same image is output with disparity channels.
A Z To Disparity node takes an image with a Z channel and creates a disparity channel.

**Inspector**

The Z To Disparity Controls tab

**Controls Tab**

The Controls tab includes settings that refine the conversion algorithm.

**Output Disparity To RGB**

In addition to outputting disparity values into the disparity channel, activating this checkbox causes Z To Disparity to also output the disparity values into the color channels as \([x, y, 0, 1]\).

When activated, this option will automatically promote the RGBA color channels to float32. This option is useful for a quick look to see what the disparity channel looks like.

**Refine Disparity**

This refines the Disparity map based on the RGB channels.

**Strength**

Increasing this slider does two things. It smooths out the depth in constant color regions and moves edges in the Z channel to correlate with edges in the RGB channels. Increasing the refinement has the undesirable effect of causing texture in the color channel to show up in the Z channel. You will want to find a balance between the two.

**Radius**

This is the pixel-radius of the smoothing algorithm.

**Stack Mode**

In Stack Mode, L and R outputs will output the same image.

If HiQ is off, the interpolations are done using nearest-neighbor sampling, leading to a more “noisy” result.
Swap Eyes

This allows you to easily swap the left and right eye outputs.

![The Z To Disparity Camera tab](image)

Camera Tab

The Camera tab includes settings for selecting a camera and setting its conversion point if necessary.

Camera Mode

If you need correct real-world disparity values because you are trying to match some effect to an existing scene, you should use the External setting to get precise disparity values back. When External is selected, a magenta camera input is available on the node to connect an existing stereo Camera 3D node, and use the Camera settings to determine the Disparity settings.

If you just want any disparity and do not particularly care about the exact details of how it is offset and scaled, or if there is no camera available, then the Artistic setting might be helpful.

Camera

If you connect a Merge 3D node that contains multiple cameras to the camera input, the Camera menu allows you to select the camera to use.

![Artistic Camera mode](image)

If you do not have a camera, you can adjust the artistic controls to produce a custom disparity channel whose values will not be physically correct but will be good enough for compositing hacks. There are two controls to adjust:

Convergence Point

This is the Z value of the convergence plane. This corresponds to the negative of the Convergence Distance control that appears in Camera 3D. At this distance, objects in the left and right eyes are at exactly the same position (i.e., have zero disparity).

Objects that are closer appear to pop out of the screen, and objects that are further appear behind the screen.
**Background Disparity (Sample from Left Eye)**

This is the disparity of objects in the distant background. You can think of this as the upper limit to disparity values for objects at infinity. This value should be for the left eye. The corresponding value in the right eye will be the same in magnitude but negative.

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Stereo nodes. These common controls are described in detail in the following "The Common Controls" section.

---

**The Common Controls**

The Common Settings tab can be found on virtually every tool found in Fusion. The following controls are specific settings for Stereo nodes.

**Settings Tab**

![The Common Settings Stereo 3D Settings tab](image)

**Blend**

The Blend control is used to blend between the tool's original image input and the tool's final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this will cause the tool to skip processing entirely, copying the input straight to the output.
**Process When Blend Is 0.0**

The tool is processed even when the input value is zero. This can be useful if the node is scripted to trigger a task, but the node’s value is set to 0.0.

**Red/Green/Blue/Alpha Channel Selector**

These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur will first be applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this will generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

**Apply Mask Inverted**

Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

**Multiply by Mask**

Selecting this option will cause the RGB values of the masked image to be multiplied by the mask channel’s values. This will cause all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

**Use Object/Use Material (Checkboxes)**

Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels will be used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

**Correct Edges**

This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

For more information on the Coverage and Background Color channels, see Chapter 18, “Understanding Image Channels,” in the Fusion Studio Reference Manual or Chapter 78 in the DaVinci Resolve Reference Manual.

**Object ID/Material ID (Sliders)**

Use these sliders to select which ID will be used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the viewer. The image or sequence must have been rendered from a 3D software package with those channels included.
Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 117

Tracker Nodes

This chapter details the Tracker nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

The Common Controls 2584
Tracker Node Introduction

The Tracker is used to detect and follow one or more pixel patterns across frames in moving video. The tracking data can then be used to control the position or values of other nodes in the composition (for example, the center of a Light Rays node). Additionally, trackers can be used to stabilize an image or to apply destabilization to one image based on the motion of another.

Inputs

The Tracker has three inputs:

- **Background**: The orange image input accepts the main 2D image to be tracked.
- **Foreground**: The optional green foreground accepts a 2D image to be merged on top of the background as a corner pin or match move.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the tracking to certain areas.

Basic Node Setup

Tracker nodes can be applied inline with other nodes or as a branch from the clip you want to track. When used inline, an image can be stabilized by connecting it to the orange background input. After the image is tracked, setting the Tracker’s Operation menu to Match Move will apply a stabilization to the connected image.
When used as an offshoot from the node tree, an image can be tracked and then that tracking data is published for use on another node somewhere else in the node tree. The output of the Tracker does not need to connect to another node. The tracking data is published and can be used via the Connect To contextual menu.

A Tracker node branched from the node tree

The Tracker can also work as a replacement for a Merge tool in match-moving setups. Below, the Tracker tracks the image connected to the orange background input and applies the tracking data to the image connected to the foreground input. The same foreground-over-background merge capabilities are available in the Tracker node.

A Tracker node set up to apply a match move to the foreground input

**Tracker Onscreen Controls**

Each pattern in the Tracker has its own set of onscreen controls used to select the pixels in the image to be tracked. These controls are visible in the viewers whenever you select a tracker in the node tree.
Pattern Rectangle
In the viewer, the tracker displays a solid-line red rectangle called the pattern rectangle. Every pixel within the rectangle makes up the pattern used for tracking. You can resize the pattern if necessary by dragging on the rectangle's borders.

A pattern rectangle identifies the area to track.

Search Rectangle
Whenever the mouse moves over the pattern rectangle, a second rectangle with a dashed outline appears. The dashed outline represents the search area, which determines how far away from the current pattern the Tracker looks in the next frame. The search area should always be larger than the pattern, and it should be large enough to encompass the largest frame-to-frame movement in the scene. Faster moving objects require larger search areas, and slower moving objects can get away with smaller search areas. The larger the search area, the longer it takes to track, so try not to make the search area larger than necessary. If the selected Tracker has a custom name, the name of that Tracker is displayed as a label at the bottom right of the search area rectangle.

The search rectangle is the area searched from frame to frame to locate the pattern.

Repositioning the Tracker
The pattern rectangle has a small handle in the upper-left corner. Dragging on the handle repositions the pattern. An enlarged view of the pattern is displayed under your mouse pointer to assist with the precise positioning of the pattern. This thumbnail disappears when the mouse button is released. You can adjust the magnification ratio in the Inspector’s Options tab.

Dragging the handle magnifies the pattern rectangle for precise placement.
TIP: There is no limit to the number of trackers that can be used in one composition, or the number of objects that use the tracking data. There is also no limit to the number of patterns that can be tracked by a single Tracker node. This chapter serves as a reference for the various controls in the Tracker, but we strongly suggest you read the more general information in Chapter 22, “Using the Tracking Node,” in the Fusion Reference Manual or Chapter 82 in the DaVinci Resolve Reference Manual.

The Tracker can be employed in two forms: as a node in the Node Editor or as a modifier attached to a parameter. When used as a node in the Node Editor, the image tracked comes from the input to the Tracker node. When used as a modifier, controls appear in the Modifiers tab for the node with the connected control. Tracker Modifiers can track only one pattern, but the image source can come from anywhere in the composition. Use this technique when tracking a quick position for an element.

Inspector

The Tracker node Trackers tab

Trackers Tab

The Trackers tab contains controls for creating, positioning, and initiating tracking operations. After tracking, offset controls are used to improve the alignment of the image following the track.
Track Buttons
There are four buttons to initiate tracking, and one button in the middle used to stop a track in progress. These buttons can track the current pattern forward or backward in time. Holding the pointer over each button displays a tooltip with the name of each button.

The buttons operate as follows:

— **Track Reverse**: Clicking this button causes all active trackers to begin tracking, starting at the end of the render range and moving backward through time until the beginning of the render range.
— **Track Reverse From Current Time**: Clicking this button causes all active trackers to begin tracking, starting at the current frame and moving backward through time until the beginning of the render range.
— **Stop Tracking**: Clicking this button or pressing ESC stops the tracking process immediately. This button is active only when tracking is in process.
— **Track Forward From Current Time**: Clicking this button causes all active trackers to begin tracking, starting at the current frame and moving forward through time until the end of the render range.
— **Track Forward**: Clicking this button causes all active trackers to begin tracking, starting at the first frame in the render range and moving forward through time until the end of the render range.

Tracking Behavior Controls
The following controls all affect how trackers adapt to changing patterns, how the resulting track path is defined, and how many keyframes are generated.

**Frames Per Path Point**
This slider determines how often the Tracker sets a keyframe on the path. The default is 1, which sets a keyframe on the tracked path at every frame.

Increasing the value causes the tracked path to be less accurate. This may be desirable if the track is returning fluctuating results, but under normal circumstances, leave this control at its default value.

**TIP:** If the project is field rendered, a value of 1 sets a keyframe on every field. Since the Tracker is extremely accurate, this will result in a slight up-and-down jittering due to the position of the fields. For better results when tracking interlaced footage in Field mode, set the Frames Per Path Point slider to a value of 2, which results in one keyframe per frame of your footage.

**Adaptive Mode**
Fusion is capable of reacquiring the tracked pattern, as needed, to help with complex tracks. This menu determines the Adaptive tracking method.

— **None**: When set to None, the tracker searches for the original pattern in each frame.
— **Every Frame**: When set to Every Frame, the tracker reacquires the pattern every frame. This helps the Tracker compensate for gradual changes in profile and lighting over time.
— **Best Match**: When set to Best Match, the tracker compares the original selected pattern to the pattern acquired at each frame. If the variation between the two patterns exceeds the threshold amount defined by the Match Tolerance control, the tracker does not reacquire the pattern on that frame. This helps to avoid Tracker drift caused by transient artifacts that cross the pattern’s path (such as a shadow).

**Path Center**

This menu determines how the Tracker behaves when repositioning a pattern. This menu is particularly useful when a pattern leaves the frame or changes so significantly that it can no longer be tracked.

— **Pattern Center**: When Pattern Center is selected in the menu, the tracked path continues from the center of the new path. This is appropriate when replacing an existing path entirely.

— **Track Center (append)**: When Track Center (append) is selected in the menu, the path tracked by a new pattern will be appended to the existing path. The path created is automatically offset by the required amount. This setting is used to set a new tracking pattern when the original pattern moves out of the frame or gets obscured by other objects. This technique works best if the new pattern is located close to the position of the original pattern to avoid any problems with parallax or lens distortion.

**Tracker List**

A Tracker node can track multiple patterns. Each tracker pattern created in the current Tracker node is managed in the Tracker List.

**Tracker List**

The Tracker List shows the names of all trackers created.

— Each tracker pattern appears in the list by name, next to a small checkbox. Clicking the name of the tracker pattern will select that tracker pattern.

— The controls below the list will change to affect that tracker pattern only. Click a selected tracker pattern once to rename the tracker pattern to something more descriptive.

— Clicking the checkbox changes the state of the tracker.

**Tracker States**

— **Enabled (black checkbox)**: An enabled pattern will re-track each time the track is initiated. Its path data is available for use by other nodes, and the data is available for Stabilization and Corner Positioning.

— **Suspended (white circle)**: A Suspended pattern does not re-track when the track is initiated. The data is locked to prevent additional changes. The data from the path is still available for other nodes, and the data is available for advanced Tracking modes like Stabilization and Corner Positioning.

— **Disabled (clear)**: A Disabled pattern does not create a path when tracking is initialized, and its data is not available to other nodes or for advanced Tracking operations like Stabilization and Corner Positioning.
Three tracking patterns from top to bottom: enabled, suspended, and disabled

Add/Delete Tracker

Use these buttons to add or delete trackers from your Tracker List.

Show

This menu selects what controls are displayed in the Tracker node controls. They do not affect the operation of the tracker; they only affect the lower half of the Inspector interface.

— **Selected Tracker Details:** When Selected Tracker Details is chosen, the controls displayed pertain only to the currently selected tracker. You will have access to the Pattern window and the Offset sliders.

— **All Trackers:** When All Trackers is selected, the pattern window for each of the added tracking patterns is displayed simultaneously below the Tracker List.

Left Pattern Display

The pattern display has two side-by-side image windows and a series of status bars. The window on the left shows the pattern initially selected, while the one on the right shows a real-time display of the current pattern as tracking progresses.

As the onscreen controls move while tracking, the display in the leftmost window updates to show the pattern. As the pattern moves, the vertical bars immediately to the right of the image indicate the clarity and contrast of the image channels.

The best channel or channels get selected for tracking based on clarity. These channels have a gray background in the vertical bar representing that channel. You can use the automatic tracking or override the selection and choose the channel by selecting the button beneath the channel to track.

Tracker pattern display

Under normal circumstances, the channel selected shows in the pattern display. If the selected channel is blue, then a grayscale representation of the blue channel for the pattern appears. The image is represented in color only when you activate the Full Color button.
Override this behavior by selecting the Show Full Color button beneath the pattern display instead of the Show Selected Channel button.

**TIP:** Because Fusion looks for the channel with the highest contrast automatically, you might end up tracking a noisy but high-contrast channel. Before tracking, it’s always a good idea to zoom in to your footage and check the RGB channels individually.

**Right Pattern Display**

The pattern display on the right indicates the actual pattern acquired for tracking. This display is black until tracking the selected pattern for the first time. The pattern display becomes active during tracking, displaying the pattern that Fusion acquires from frame to frame.

As the tracking occurs, the pattern from each frame accumulates into a Flipbook, which can be played back in the pattern window after tracking by using the transport controls at the bottom of the window.

While the track is progressing, the vertical bar immediately to the right of the pattern shows how confident Fusion is that the current pattern matches the initially selected pattern. A green bar indicates a high degree of confidence that the current pattern matches the original, a yellow bar indicates less certainty, and a red bar indicates extreme uncertainty.

After tracking, the pattern display shows a small Flipbook of the track for that pattern to help identify problem frames for the track.

**Tracker Sizes**

In addition to onscreen controls, each tracker has a set of sizing parameters that let you adjust the pattern and search box.

- **Pattern Width and Height:** Use these controls to adjust the width and height of the selected tracker pattern manually. The size of the tracker pattern can also be adjusted in the viewer, which is the normal method, but small adjustments are often easier to accomplish with the precision of manual controls.

- **Search Width and Height:** The search area defines how far Fusion will look in the image from frame to frame to reacquire the pattern during tracking. As with the Pattern Width and Height, the search area can be adjusted in the viewer, but you may want to make small adjustments manually using these controls.

**Tracked Center**

This positional control indicates the position of the tracker’s center. To remove a previously tracked path from a tracker pattern, right-click this parameter and select Remove Path from the contextual menu.

**X and Y Offset**

The Offset controls help to create a track for objects that may not provide very well defined or reliable patterns. The Offset controls permit the tracking of something close to the intended object instead. Use these Offsets to adjust the desired position of the path, while the tracker pattern rectangle is positioned over the actual tracking location.
The Offset can also be adjusted directly in the viewer by activating the Offsets button in the viewer toolbar.

The tracker offset icon in the upper left of the viewer is used to offset the tracking pattern from the intended object.

The Tracker Operation tab

**Operation Tab**

While the Trackers tab controls let you customize how the Tracker node analyzes motion to create motion paths, the Operation tab puts the analyzed motion data to use, performing image transforms of various kinds.

The Tracker node is capable of performing a wide variety of functions, from match moving an object into a moving scene, smoothing out a shaky camera movement, or replacing the content of a sign. Use the options and buttons in the Operation tab to select the function performed by the Tracker node.

**Operation Menu**

The Operation menu contains four functions performed by the Tracker. The remaining controls in this tab fine-tune the result of this selection.

--- **None**: The Tracker performs no additional operation on the image beyond merely locating and tracking the chosen pattern. This is the default mode, used to create a path that will then drive another parameter on another node.
— **Match Move:** When only the orange background input is connected, this mode stabilizes the image. When a foreground image is connected to the green foreground input, the foreground image matches the position, rotation, and scaling based on the tracking patterns. Stabilizing and match move require a minimum of one tracking pattern to determine position, and two or more to determine scaling and rotation.

— **Corner Positioning:** The Corner Positioner mode tracks the four corners of a rectangular object and replaces the contents with a new image. This function requires a minimum of four tracking patterns. If there are not enough tracking patterns, new tracking patterns are added until the total equals four.

— **Perspective Positioning:** This mode is the inverse of the Corner Positioning mode. Rather than replacing the contents of the rectangle, the four trackers are mapped to the four corners of the image. This is generally used to remove perspective from an image. Like the Corner Positioning mode, this mode requires four tracking patterns, which automatically get added if there are fewer patterns.

### Additional Layering Controls

When you choose any operation other than None, a series of additional controls appear.

**Merge**

The Merge control determines what is done (if anything) with the image provided to the green Foreground input of the Tracker. This menu appears when the operation is set to anything other than None.

— **BG Only:** The foreground input is ignored; only the background is affected. This is used primarily when stabilizing the background image.

— **FG Only:** The foreground input is transformed to match the movement in the background, and this transformed image is passed through the Tracker’s output. This Merge technique is used when match moving one layer’s motion to another layer’s motion.

— **FG Over BG:** The foreground image is merged over the background image, using the Merge method described by the Apply Mode control that appears.

— **BG Over FG:** The background is merged over the foreground. This technique is often used when tracking a layer with an Alpha channel so that a more static background can be applied behind it.

### Apply Mode and Operator Menus

This menu provides a variety of options that determine how the two layers should be combined. The options in this menu are identical to those found in the Merge node.

— **Apply Modes:** The Apply Mode setting determines the math used when blending or combining the foreground and background pixels.

  — **Normal:** The Default merge mode uses the foreground’s alpha channel as a mask to determine which pixels are transparent and which are not. When this is active, another menu shows possible operations, including Over, In, Held Out, Atop, and XOR.

  — **Screen:** Screen merges the images based on a multiplication of their color values. The alpha channel is ignored, and layer order becomes irrelevant. The resulting color is always lighter. Screenign with black leaves the color unchanged, whereas screening with white will always produce white. This effect creates a similar look to projecting several film frames onto the same surface. When this is active, another menu shows possible operations, including Over, In, Held Out, Atop, and XOR.
— **Dissolve**: Dissolve mixes two image sequences together. It uses a calculated average of the two images to perform the mixture.

— **Multiply**: Multiplies the values of a color channel. This will give the appearance of darkening the image as the values are scaled from 0 to 1. White has a value of 1, so the result would be the same. Gray has a value of 0.5, so the result would be a darker image or, in other words, an image half as bright.

— **Overlay**: Overlay multiplies or screens the color values of the foreground image, depending on the color values of the background image. Patterns or colors overlay the existing pixels while preserving the highlights and shadows of the color values of the background image. The background image is not replaced but is mixed with the foreground image to reflect the original lightness or darkness of the background image.

— **Soft Light**: Soft Light darkens or lightens the foreground image, depending on the color values of the background image. The effect is similar to shining a diffused spotlight on the image.

— **Hard Light**: Hard Light multiplies or screens the color values of the foreground image, depending on the color values of the background image. The effect is similar to shining a harsh spotlight on the image.

— **Color Dodge**: Color Dodge uses the foreground's color values to brighten the background image. This is similar to the photographic practice of dodging by reducing the exposure of an area of a print.

— **Color Burn**: Color Burn uses the foreground's color values to darken the background image. This is similar to the photographic practice of burning by increasing the exposure of an area of a print.

— **Darken**: Darken looks at the color information in each channel and selects the background or foreground image's color value, whichever is darker, as the result color. Pixels lighter than the merged colors are replaced, and pixels darker than the merged color do not change.

— **Lighten**: Lighten looks at the color information in each channel and selects the background or foreground image's color values, whichever is lighter, as the result color value. Pixels darker than the merged color are replaced, and pixels lighter than the merged color do not change.

— **Difference**: Difference looks at the color information in each channel and subtracts the foreground color values from the background color values or the background from the foreground, depending on which has the greater brightness value. Merging with white inverts the color. Merging with black produces no change.

— **Exclusion**: Exclusion creates an effect similar to but lower in contrast than the Difference mode. Merging with white inverts the base color values. Merging with black produces no change.

— **Hue**: Hue creates a result color with the luminance and saturation of the background color values and the hue of the foreground color values.

— **Saturation**: Saturation creates a result color with the luminance and hue of the base color and the saturation of the blend color.

— **Color**: Color creates a result color with the luminance of the background color value and the hue and saturation of the foreground. This preserves the gray levels in the image and is useful for coloring monochrome images.

— **Luminosity**: Luminosity creates a color with the hue and saturation of the background color and the luminance of the foreground color. This mode creates an inverse effect from that of the Color mode.
Operator Modes: This menu is used to select the Operation Mode of the merge. It determines how the foreground and background are combined to produce a result. This drop-down menu is visible only when the Merge node’s Apply Mode is set to either Normal or Screen.

NOTE: For an excellent description of the math underlying the Operation modes, read “Compositing Digital Images,” Porter, T., and T. Duff, SIGGRAPH 84 proceedings, pages 253-259. Essentially, the math is as described below.

TIP: Some modes not listed in the Operator drop-down menu (Under, In, Held in, Below) are easily obtained by swapping the foreground and background inputs and choosing a corresponding mode.

The formula used to combine pixels in the merge is always fg * x + bg * y. The different operations determine exactly what x and y are, as shown in the description for each mode.

The Operator modes are as follows:

— **Over:** The Over mode adds the foreground layer to the background layer by replacing the pixels in the background with the pixels from the Z wherever the foreground’s alpha channel is greater than 1.

  \[ x = 1, \quad y = 1 - \text{foreground Alpha} \]

— **In:** The In mode multiplies the alpha channel of the background input against the pixels in the foreground. The color channels of the foreground input are ignored. Only pixels from the foreground are seen in the final output. This essentially clips the foreground using the mask from the background.

  \[ x = \text{background Alpha}, \quad y = 0 \]

— **Held Out:** Held Out is essentially the opposite of the In operation. The pixels in the foreground image are multiplied against the inverted alpha channel of the background image. You can accomplish exactly the same result using the In operation and a Matte Control node to invert the matte channel of the background image.

  \[ x = 1 - \text{background Alpha}, \quad y = 0 \]

— **ATop:** ATop places the foreground over the background only where the background has a matte.

  \[ x = \text{background Alpha}, \quad y = 1 - \text{foreground Alpha} \]

— **XOr:** XOr combines the foreground with the background wherever either the foreground or the background have a matte, but never where both have a matte.

  \[ x = 1 - \text{background Alpha}, \quad y = 1 - \text{foreground Alpha} \]
— **Subtractive/Additive**: This slider controls whether Fusion performs an Additive merge, a Subtractive merge, or a blend of both. This slider defaults to Additive merging for most operations, assuming the input images are premultiplied (which is usually the case). If you don’t understand the difference between Additive and Subtractive merging, here’s a quick explanation:

— An Additive merge is necessary when the foreground image is premultiplied, meaning that the pixels in the color channels have been multiplied by the pixels in the alpha channel. The result is that transparent pixels are always black since any number multiplied by 0 always equals 0. This obscures the background (by multiplying with the inverse of the foreground alpha), and then simply adds the pixels from the foreground.

— A Subtractive merge is necessary if the foreground image is not premultiplied. The compositing method is similar to an Additive merge, but the foreground image is first multiplied by its alpha to eliminate any background pixels outside the alpha area.

In most software applications, you will find the Additive/Subtractive option displayed as a simple checkbox. Fusion lets you blend between the Additive and Subtractive versions of the merge operation, which is occasionally useful for dealing with problem composites with edges that are calling attention to themselves as too bright or too dark.

For example, using a Subtractive setting on a premultiplied image may result in darker edges. Using an Additive setting with a non-premultiplied image may result in lightening the edges. By blending between Additive and Subtractive, you can tweak the edge brightness to be just right for your situation.

**Filter Method (Match Move)**

Determines which filter to use to handle image transforms made using the Tracker node. This menu appears only when the Operation Mode is set to Match Move.

— **Box**: This is a simple interpolation resize of the image.

— **Linear**: This uses a simplistic filter, which produces relatively clean and fast results.

— **Quadratic**: This filter produces a nominal result. It offers a good compromise between speed and quality.

— **Cubic**: This produces better results with continuous-tone images but is slower than Bi-Cubic. If the images have fine detail in them, the results may be blurrier than desired.

— **Catmull-Rom**: This produces good results with continuous-tone images that are resized down. It produces sharp results with finely detailed images.

— **Gaussian**: This is very similar in speed and quality to Bi-Cubic.

— **Mitchell**: This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.

— **Lanczos**: This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.

— **Sinc**: This is an advanced filter that produces very sharp, detailed results; however, it may produce visible “ringing” in some situations.

— **Bessel**: This is similar to the Sinc filter but may be slightly faster.
**Edges**
This menu selects how the revealed edges are handled when the image is moved to match position and scaling.

- **Black Edges:** Out-of-frame edges revealed by Stabilization are left black.
- **Wrap:** Portions of the image moved off frame to one side are used to fill edges that are revealed on the opposite side.
- **Duplicate:** The last valid pixel on an edge is repeated to the edge of the frame.
- **Mirror:** Image pixels are mirrored to fill to the edge of the frame.

**Position, Rotation, and Scaling Checkboxes (Match Move)**
The Position, Rotation, and Scaling checkboxes appear only when the mode is set to Match Move. They determine what components of motion that Stabilization will attempt to correct in the image. For example, if only the Position checkbox is selected, no attempt will be made to correct for Rotation and Scaling in the image.

**Flatten Transformation (Match Move)**
This checkbox appears only when the mode is set to Match Move. Like most transformations in Fusion, Stabilization is concatenated with other sequential transformations by default. Selecting this checkbox will flatten the transform, breaking any concatenation taking place and applying the transform immediately.

**Mapping Type**
The Mapping Type control appears only in the Corner Positioning mode. There are two options in the menu:

- **Bi_Linear:** The first method is Bi-Linear, where the foreground image is mapped into the background without any attempt to correct for perspective distortion. This is identical to how previous versions of Fusion operated.
- **Perspective:** The foreground image is mapped into the background taking perspective distortion into account. This is the preferred setting since it maps better to the real world than the older Bi-Linear setting.

**Corner Selector (Corner or Perspective Positioning)**
When the operation of the Tracker is set to either Corner or Perspective Positioning modes, four drop-down menus appear. These options choose which trackers map to each of the four corners of the rectangle. This is useful when a Tracker has more than four patterns selected, and you must choose which patterns the positioners use.

**Rotate Clockwise and Counter-Clockwise Buttons (Corner or Perspective Positioning)**
These controls appear only when the operation of the Tracker is set to either Corner or Perspective Positioning modes. They are used to rotate the foreground image by 90 degrees before it is applied to the background.

**Stabilize Settings**
The Tracker node automatically outputs several steady and unsteady position outputs to which other controls in the Node Editor can be connected. The Stable Position output provides X and Y coordinates to match or reverse motion in a sequence. These controls are available even when the operation is not set to Match Move, since the Stable Position output is always available for connection to other nodes.
**Match Move Settings**

These settings determine how tracking data is correlated with the reference pattern for making transforms.

**Pivot Type**

The Pivot type menu determines how the anchor point for rotation is selected.

- **Tracker Average:** Averages the location based on the tracking points.
- **Selected Tracker:** Provides a menu where one of the current trackers can be selected as the pivot point.
- **Manual:** Displays X and Y position number fields where you can manually position the pivot points.

**Reference**

The Reference mode determines the “snapshot frame” based on the frame where the pattern is first selected. All Stabilization is intended to return the image back to that reference.

- **Select Time:** Lets you select the current frame.
- **Start:** The Snapshot Frame is determined to be the first frame in the tracked path. All Stabilization is intended to return the image back to that reference.
- **Start and End:** The Start and End Reference mode is somewhat different from all other Reference modes. Where the others are intended to take a snapshot frame to which all stabilization returns, immobilizing the image, the Start and End mode is intended to smooth existing motion, without removing it. This mode averages the motion between the Start and End of the path, drawing a straight line between those points.

   When this mode is active, it reveals the Reference Intermediate Points control. Increasing the value of this control increases the number of points in the path used by the Reference, smoothing the motion from a straight line between Start and End without making it wholly linear.

- **End:** The Snapshot Frame is determined to be the last frame in the tracked path. All Stabilization is intended to return the image back to that reference.

**TIP:** By default, the Tracker displays a single displacement path of the tracked data in the Spline Editor. To view X and Y paths of the tracked points in the Spline Editor, go to Preferences > globals > splines.

**Display Options Tab**

The Display Options tab lets you customize the look of onscreen controls in the viewer.

The Tracker Display Options tab
Show Pattern Names
This option defines whether the Tracker’s pattern names will be displayed in the viewer. Switch it off to see the pattern rectangle instead.

Enlarged Pattern on Dragging
This option defines whether there is a magnified thumbnail view when positioning the pattern rectangle.

Enlargement Scale
The zoom factor that is used when positioning the pattern rectangle when the above option is activated.

**TIP:** The outputs of a tracker (seen in the Connect to… menu) can also be used by scripts. They are:

- **SteadyPosition**: Steady Position
- **UnsteadyPosition**: Unsteady Position
- **SteadyAxis**: Steady Axis
- **SteadySize**: Steady Size
- **UnsteadySize**: Unsteady Size
- **SteadyAngle**: Steady Angle
- **UnsteadyAngle**: Unsteady Angle
- **Position1**: Tracker 1 Offset position
- **PerspectivePosition1**: Tracker 1 Perspective Offset position
- **PositionX1**: Tracker 1 Offset X position (3D Space)
- **PositionY1**: Tracker 1 Offset Y position (3D Space)
- **PerspectivePositionX1**: Tracker 1 Perspective Offset X position (3D Space)
- **PerspectivePositionY1**: Tracker 1 Perspective Offset Y position (3D Space)
- **SteadyPosition1**: Tracker 1 Steady Position
- **UnsteadyPosition1**: Tracker 1 Unsteady Position (likewise for the 2nd, 3rd, and so on)

Common Controls

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Tracking nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Planar Tracker Node [PTra]

Planar Tracker Node Introduction

The Planar Tracker node is designed to solve a match-moving problem that commonly comes up during post-production. As an example, live-action footage can often contain a planar surface such as a license plate or a road sign that needs new numbers in the license plate or a new city’s name on the road sign. Often, the problem is that the camera is moving in the shot, so the license plate or road sign is continuously changing perspective. You cannot just merge a new license plate over the existing one without accounting for the perspective distortions. A time-intensive way to solve this problem would be to use a Corner Pin node and manually keyframe the four corners. The Planar Tracker automates this keyframing process and tracks the perspective distortions of a planar surface over time. That tracking data is then applied with those same perspective distortions to a different foreground.

**TIP:** Part of using a Planar Tracker is also knowing when to give up and fall back to using Fusion’s Tracker node or to manual keyframing. Some shots are simply not trackable, or the resulting track suffers from too much jitter or drift. The Planar Tracker is a useful time-saving node in the artist’s toolbox, but while it may track most shots, it is not a 100% solution.

What the Planar Tracker Saves

While the Planar Tracker does save the resulting final track in the composition on disk, it does not save temporary tracking information such as the individual point trackers (compared with the Camera Tracker, which does save the individual point trackers). Some consequences of this include:

- The point trackers no longer appear in the viewer when a comp containing a Planar Tracker node is saved and reloaded.
- Tracking may not be resumed after a comp containing a Planar Tracker node has been saved and reloaded. In particular, this also applies to auto saves. For this reason, it is good to complete all planar tracking within one session.
- The size of composition files is kept reasonable (in some situations, a Planar Tracker can produce hundreds of megabytes of temporary tracking data).
- Saving and loading of compositions is faster and more interactive.
Inputs

The Planar Tracker has four inputs:

- **Background**: The orange background image input accepts a 2D image with the planar surface to be tracked.
- **Corner Pin 1**: The green corner pin 1 input accepts a 2D image to be pinned on top of the background. There may be multiple corner pin inputs, named Corner Pin 1, Corner Pin 2,… etc.
- **Occlusion Mask**: The white occlusion mask input is used to mask out regions that do not need to be tracked. Regions where this mask is white will not be tracked. For example, a person moving in front of and occluding bits of the pattern may be confusing the tracker, and a quickly-created rough rotomask around the person can be used to tell the tracker to ignore the masked-out bits.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the output of the Planar Tracker to certain areas.

Basic Node Setup

A basic Planar Tracker setup consists of just two nodes: a MediaIn connects to the background input and the Planar Tracker can be used as a separate branch from the rest of the node tree. Once the tracking is completed, a Planar Transform node should be generated to use the planar tracking data.

A Planar Tracker can be isolated on its own branch of a node tree.

A Typical Planar Tracker Workflow

The following steps outline the workflow with the Planar Tracker:

1. **Remove lens distortion**: The more lens distortion in the footage, the more the resulting track will slide and wobble.
2. **Connect footage**: Connect a Loader or MediaIn node that contains a planar surface to the orange background input and view the Planar Tracker node in a viewer.
3. **Select a reference frame**: Move to a frame where the planar surface to be tracked is not occluded and click the Set button to set this as a reference frame.
4. **Choose the pattern**: In the viewer, make sure the onscreen controls are visible, and draw a polygon around the planar surface you want to track. This is called the “pattern.” In most cases, this will probably be a rectangle, but an arbitrary closed polygon can be used. The pixels enclosed by this region will serve as the pattern that will be searched for on other frames. Note that it is important that the pattern is drawn on the reference frame. Do not confuse the pattern with the region to corner pin (which always has four corners and is separately specified in Corner Pin mode).
5. **Adjust render range**: In the Keyframes Editor, adjust the render range to match the range of frames where the planar surface is visible.
6 **Adjust track options:** Frequently changed options include Tracker, Motion Type, and Track Channel.

7 **Mask out occluders:** If moving objects partially cover up the planar surface, you may wish to connect an occlusion mask to the Planar Tracker. When using the Hybrid tracker, providing a mask to deal with occluding objects is strongly recommended, while with the Point tracker it is recommended to try tracking without a mask.

8 **Track:** Click the Go button to return to the reference frame. Press the Track To End button and wait for the track to complete. Click the Go button to return to the reference frame again. Press the Track To Start button and wait for the track to complete. Note that the tracks in the viewer are not selectable or deletable as they are in a Camera Tracker.

9 **Check track quality:** Visually inspect the track to see how accurate it is. Does it stick to the surface? Switching to Steady mode can help here.

10 **Use the track:** At this point, in most cases you will create a Planar Transform node from the Inspector and use it to apply the tracked perspective distortion onto masked images. If the image you are applying the tracking data to is full frame unmasked clip, you can use the Steady, Corner Pin, and Stabilize operation modes in in the Planar Tracker.

---

**Inspector**

The Planar Tracker Controls tab

---

**Controls Tab**

The Controls tab contains controls for determining how the Planar Tracker will be used, setting the reference frame and initiating the track.

**Operation Mode**

The Operation Mode menu selects the purpose of the Planar Tracker node. The Planar Tracker has four modes of operation:

— **Track:** Used to isolate a planar surface and track its movement over time. Then, you can create a Planar Transform node that uses this data to match move another clip in various ways.

— **Steady:** After analyzing a planar surface, this mode removes all motion and distortions from the planar surface, usually in preparation for some kind of paint or roto task, prior to “unsteadying” the clip to restore the motion.
— **Corner Pin**: After analyzing a planar surface, this mode computes and applies a matching perspective distortion to a foreground image you connect to the foreground input of the Planar Tracker node, and merges it on top of the tracked footage.

— **Stabilize**: After analyzing a planar surface, this mode allows smoothing of a clip’s translation, rotation, and scale over time. This is good for getting unwanted vibrations out of a clip while retaining the overall camera motion that was intended.

The last three modes (Steady, Corner Pin, and Stabilize) use the tracking data produced in Track mode.

**NOTE**: None of the operations can be combined together. For example, both Corner Pin and Stabilize cannot be done at the same time, nor can a track be done while in corner pinning mode.

**Reference Time**

The Reference Time determines the frame where the pattern is outlined. It is also the time from which tracking begins. The reference frame cannot be changed once it has been set without destroying all pre-existing tracking information, so scrub through the footage to be tracked and choose carefully. The reference frame must be chosen carefully to give the best possible quality track.

You choose a reference frame by moving the playhead to an appropriate frame and then clicking the Set button to choose that frame.

**Pattern Polygon**

You specify which region of the image you want to track by drawing a polygon on the reference frame. Typically, when you first add a Planar Tracker node, you are immediately ready to start drawing a polygon in the viewer, so it’s best to do this right away. When choosing where to draw a polygon, make sure the region selected belongs to a physically planar surface in the shot. In a pinch, a region that is only approximately planar can be used, but the less planar the surface, the poorer the quality of the resulting track.

As a rule of thumb, the more pixels in the pattern, the better the quality of the track. In particular, this means the reference frame pattern should be:

— As large as possible.
— As much in frame as possible.
— As unoccluded as possible by any moving foreground objects.
— At its maximal size (e.g., when tracking an approaching road sign, it is good to pick a later frame where it is 400 x 200 pixels big rather than 80 x 40 pixels).
— Relatively undistorted (e.g., when the camera orbits around a flat stop sign, it is better to pick a frame where the sign is face-on parallel to the camera rather than a frame where it is at a highly oblique angle).

If the pattern contains too few pixels or not enough trackable features, this can cause problems with the resulting track, such as jitter, wobble, and slippage. Sometimes dropping down to a simpler motion type can help in this situation.
After you’ve drawn a pattern, a set of Pattern parameters lets you transform and invert the resulting polygon, if necessary.

**Track Mode**

Track mode is unlike the other three options in the Operation menu in that it is the only option that initiates the planar tracking. The other modes use the tracking data generated by the Track mode.

**Tracker**

There are two available trackers to pick from:

- **Point**: Tracks points from frame to frame. Internally, this tracker does not actually track points per-se but rather small patterns like Fusion’s Tracker node. The point tracker possesses the ability to automatically create its internal occlusion mask to detect and reject outlier tracks that do not belong to the dominant motion. Tracks are colored green or red in the viewer, depending on whether the point tracker thinks they belong to the dominant motion or they have been rejected. The user can optionally supply an external occlusion mask to further guide the Point tracker.

- **Hybrid Point/Area**: Uses an Area tracker to track all the pixels in the pattern. Unlike the Point tracker, the Area tracker does not possess the ability to automatically reject parts of the pattern that do not belong to the dominant motion, so you must manually provide it with an occlusion mask. Note that for performance reasons, the Hybrid tracker internally first runs the Point tracker, which is why the point tracks can still be seen in the viewer.

There is no best tracker. They each have their advantages and disadvantages:

- **Artist Effort (occlusion masks)**: The Point tracker will automatically create its internal occlusion mask. However, with the Hybrid tracker, you need to spend more time manually creating occlusion masks.

- **Accuracy**: The Hybrid tracker is more accurate and less prone to wobble, jitter, and drift since it tracks all the pixels in the pattern rather than a few salient feature points.

- **Speed**: The Hybrid tracker is slower than the Point tracker.

In general, it is recommended to first quickly track the shot with the Point tracker and examine the results. If the results are not good enough, then try the Hybrid tracker.

**Motion Type**

Determines how the Planar Tracker internally models the distortion of the planar surface being tracked. The five distortion models are:

- Translation.
- Translation, Rotation (rigid motions).
- Translation, Rotation, Scale (takes squares to squares, scale is uniform in x and y).
- Affine includes translation, rotation, scale, skew (maps squares to parallelograms).
- Perspective (maps squares to generic quadrilaterals).

Each successive model is more general and includes all previous models as a special case.

When in doubt, choose Perspective for the initial track attempt. If the footage being tracked has perspective distortions in it, and the Planar Tracker is forced to work with a simpler motion type, this can end up causing the track to slide and wobble.
Sometimes with troublesome shots, it can help to drop down to a simpler motion model—for example, when many track points are clustered on one side of the tracked region or when tracking a small region where there are not many trackable pixels.

Output
Controls what is output from the Planar Tracker node while in the Track operation mode.

- **Background**: Outputs the input image unchanged.
- **Background - Preprocessed**: The Planar Tracker does various types of preprocessing on the input image (e.g., converting it to luma) before tracking. It can be useful to see this when deciding which track channel to choose.
- **Mask**: Outputs the pattern as a black and white mask.
- **Mask Over Background**: Outputs the pattern mask merged over the background.

Track Channel
Determines which image channel in the background image is tracked. It is good to pick a channel with high contrast, lots of trackable features, and low noise. Allowed values are red, green, blue, and luminance.

Tracking Controls
These controls are used to control the Tracker. Note that while tracking, only track to a new frame if the current frame is already tracked or it is the reference frame.

- **Track to start**: Tracks from the current frame backward in time to the start (as determined by the current render range).
- **Step tracker to previous frame**: Tracks from the current frame to the previous frame.
- **Stop tracking**: Stops any ongoing tracking operations.
- **Step tracker to next frame**: Tracks from the current frame to the next frame.
- **Track to end**: Tracks from the current frame forward in time to the end (as determined by the current render range).
- **Trim to start**: Removes all tracking data before the current frame.
- **Delete**: Deletes all tracking data at all times. Use this to destroy all current results and start tracking from scratch.
- **Trim to end**: Removes all tracking data after the current frame. This can be useful, for example, to trim the end of a track that has become inaccurate when the pattern starts to move off frame.

Show Splines
This button to the right of the “Trim to end” button opens the Spline Editor and shows the splines associated with the Planar Tracker node. This can be useful for manually deleting points from the Track and Stable Track splines.

Right-Click Here for Track Spline
While tracking, a spline containing 4 x 4 matrices at each keypoint is created. This is known as the “Track spline” or just “Track” for short. These matrices completely describe the distortions of the tracked pattern.
**Create Planar Transform**

After tracking footage, this button can be pressed to create a Planar Transform node on the Node Editor. The current tracking data is embedded in the Planar Transform node so that it can replicate the planar distortions tracked by the Planar Tracker node. Unless you are compositing a full frame foreground that matches the same dimensions as the raster, it is best to create a Planar Transform and use it to apply motion to the foreground.

**Steady Mode**

In Steady mode, the Planar Tracker transforms the background plate to keep the pattern as motionless as possible. Any leftover motion is because the Planar Tracker failed to follow the pattern accurately or because the pattern did not belong to a physically planar surface.

Steady mode is not very useful for actual stabilization, but is useful for checking the quality of a track. If the track is good, during playback the pattern should not move at all while the rest of the background plate distorts around it. It can be helpful to zoom in on parts of the pattern and place the mouse cursor over a feature and see how far that feature drifts away from the mouse cursor over time.

**Steady Time**

This is the time where the pattern’s position is snapshotted and frozen in place. It is most common to set this to the reference frame.

**Invert Steady Transform**

This causes the Planar Tracker node to reverse the effects of the steady transform. This means two Planar Tracker nodes connected back to back with the second set to invert should give back the original image. If you place an effects node in between the two, then the effect will be locked in place. This should only be used to accomplish effects that cannot be done through corner pinning, since it involves two resamplings, causing softening of the background image.

**Clipping Mode**

Determines what happens to the parts of the background image that get moved off frame by the steady transform:

- **Domain:** The off frame parts are kept.
- **Frame:** The off frames parts are thrown away.

Domain mode is useful when Steady mode is being used to “lock” an effect to the pattern. As an example, consider painting on the license plate of a moving car. One way to do this is to use a Planar Tracker node to steady the license plate, then a Paint node to paint on the license plate, and then a second Planar Tracker to undo the steady transform. If the Clipping mode is set to Domain, the off frame parts generated by the first Planar Tracker are preserved so that the second Planar Tracker can, in turn, map them back into the frame.

**Corner Pin Mode**

In Corner Pin mode, one or more textures can be attached to a previously tracked planar surface and undergo the same perspective distortions as the surface.
The corner pin workflow with Planar Tracker is:

1. **Track**: select a planar surface in the shot that you wish to attach a texture to or replace the texture on. Track the shot (see the tracking workflow in the Track section).

2. **Switch the Operation Mode to Corner Pin**: When Corner Pin mode is entered from Track mode, the pattern polygon is hidden and a corner pin control is shown in the viewer.

3. **Connect in the texture**: In the Node Editor, connect the output of the MediaIn node containing the texture to the Corner Pin 1 input on the Planar Tracker node.

4. **Adjust corner pin**: Drag the corners of the corner pin in the viewer until the texture is positioned correctly. Sometimes the Show Grid option is useful when positioning the texture. Additionally, if it helps to position it more accurately, scrub to other times and make adjustments to the corner pin.

5. **Review**: Play back the footage and make sure the texture “sticks” to the planar surface.

### Merge Mode
Controls how the foreground (the corner pinned texture) is merged over the background (the tracked footage). If there are multiple corner pins, this option is shared by all of them. There are four options to pick from:

- **BG only**
- **FG only**
- **FG over BG**
- **BG over FG**

### Number of Corner Pins
Use the + and - buttons to increase or decrease the number of corner pins. Each time an additional corner pin is created, a corresponding input appears on the node in the Node Editor.

### Corner Pin 1 Input Group
Each corner pin has a group of related inputs:

- **Enable**: Controls the visibility of the corner pin in the viewer.
- **Show Grid**: Shows a grid over the corner pin. This can be useful when positioning the corners.
- **Merge Options**: Controls merging of corner pin texture over the background. (See the documentation for the Merge node.)
- **Reference Time Positions**: The positions of the four corners at the reference time. If the track was not perfect, these positions can be animated to make adjustments on top of the track.

### Stabilize Mode
Stabilize mode is used to smooth out shakiness in the camera by applying a transform that partially counteracts the camera shake. This stabilizing transform (contained in the Stable Track spline) is computed by comparing neighboring frames.

**NOTE**: Stabilize mode only smooths out motions, while Steady mode tries to completely “lock off” all motion.
Be aware that the Planar Tracker stabilizes based on the motion of the pattern, so it is essential to choose the pattern carefully. If the motion of the pattern does not represent the motion of the camera, then there may be unexpected results. For example, if tracking the side of a moving truck and the camera is moving alongside it, the Planar Tracker smooths the combined motion of both the truck and the mounted camera. In some cases, this is not the desired effect. It may be better to choose the pattern to be on some fixed object like the road or the side of a building, which would result in smoothing only the motion of the camera.

One unavoidable side effect of the stabilization process is that transparent edges appear along the edges of the image. These edges appear because the stabilizer does not have any information about what lies off frame, so it cannot fill in the missing bits. The Planar Tracker node offers the option to either crop or zoom away these edges. When filming, if the need for post-production stabilization is anticipated, it can sometimes be useful to film at a higher resolution (or lower zoom).

The Planar Tracker Stabilization Workflow

1. **Track**: Select a roughly planar region that represents the motion that you want to stabilize. Track the shot (see the tracking workflow in the Track section).

2. **Switch the Operation Mode to Stabilize**: Until a stabilization is computed, the Planar Tracker will just output the input footage.

3. **Adjust stabilization options**: Frequently changed options are Parameters to Smooth and Smoothing Radius.

4. **Compute stabilization**: Press the Compute Stabilization button and wait for the stabilization computations to finish. Play back the output of the Planar Tracker node to see the effects of the stabilization. Notice that transparent edges have been introduced around the edges of the image by the stabilization transform.

5. **Refine**: Adjust the stabilization options and recompute the stabilization as many times as desired.

6. **Handle transparent edges (optional)**: Set the Frame Mode to either Zoom or Crop as desired and then click the Auto Zoom or Auto Crop button. Play back the footage to observe the effects. If there is too much zoom or the image has been cropped too small, try reducing the amount of smoothing.

**Parameters to Smooth**

Specify which of the following parameters to smooth:

- X Translation
- Y Translation
- Rotation
- Scale

**Smoothing Window**

When stabilizing a particular frame, this determines how the contributions of neighboring frames are weighted. Available choices are Box and Gaussian.

**Smoothing Radius (Frames)**

Determines the number of frames whose transforms are averaged together to compute the stabilization. A larger Smoothing Radius results in more smoothing but introduces more transparent edges.
**Compute Stabilization**
Clicking this button runs the stabilizer, overwriting the results of any previous stabilization. As soon as the stabilization is finished, the output of the Planar Tracker node will be immediately updated with the stabilization applied.

**NOTE:** The stabilizer uses the Track spline (created by the tracker) to produce the Stable Track spline. Both of these splines’ keyframes contain 4 x 4 matrices, and the keyframes are editable in the Spline Editor.

**Clipping Mode**
Determines what happens to the parts of the background image that get moved off frame by the stabilization:

- **Domain:** The off frame parts are kept.
- **Frame:** The off frames parts are thrown away.

**Frame Mode**
This controls how transparent edges are handled. The available options include:

- **Full:** Do nothing. Leaves the transparent edges as is.
- **Crop:** Crops away the transparent edges. When this option is selected, the size of Planar Tracker’s output image is smaller than the input image. No image resamplings occur. In Crop mode, use the Auto Crop button or manually adjust the crop window by changing the X Offset, Y Offset, and Scale sliders.
- **Auto Crop Button:** When this button is clicked, the Planar Tracker will examine all the frames and pick the largest possible crop window that removes all the transparent edges. The computed crop window will always be centered in frame and pixel aligned. When clicked, Auto Crop updates the X/Y Offset and Scale sliders.
- **Zoom:** Scales the image bigger until the transparent edges are off frame. Choosing this option causes an image resampling to occur. The downside of this approach is that it reduces the quality (slightly softens) of the output image. In Zoom mode, use the Auto Zoom button or manually adjust the zoom window by changing the X Offset, Y Offset, and Scale sliders.
- **Auto Zoom:** When this button is clicked, the Planar Tracker will examine all the frames and pick the smallest possible zoom factor that removes all the transparent edges. The computed zoom window will always be centered in frame. When clicked, Auto Zoom updates the X/Y Offset and Scale sliders.

**Right-Click Here for Stable Track Spline**
Right-clicking over this label provides access to a spline whose keyframes contain 4 x 4 matrices which in turn represent the stabilization transforms. This is mostly here for completeness and for advanced users.
Options Tab

These controls affect the look of onscreen controls in the viewer.

The Planar Tracker Options tab

Darken Image

Darkens the image while in Track mode in order to better see the controls and tracks in the viewer. The Shift+D keyboard shortcut toggles this.

Show Track Markers

Toggles the display of the dots marking the location of trackers at the current time.

Show Trails

Toggles the display of the trails following the location of trackers.

Trail Length

Allows changing the length of tracker trails. If the pattern is moving very slowly, increasing the length can sometimes make the trails easier to follow in the viewer. If the pattern is moving very fast, the tracks can look like spaghetti in the viewer. Decreasing the length can help.

Inlier/Outlier Colors

When tracking, the tracker analyzes the frame and detects which of the multitudinous tracks belong to the dominant motion and which ones represent anomalous, unexplainable motion. By default, tracks belonging to the dominant motion are colored green (and are called inliers) and those that do not belong are colored red (and are called outliers). Only the inlier tracks are used when computing the final resulting track.

Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other Tracking nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Planar Transform Node [PXF]

The Planar Transform node applies perspective distortions generated by a Planar Tracker node onto any input mask or masked image. The Planar Transform node can be used to reduce the amount of time spent on rotoscoping objects. The workflow here centers around the notion that the Planar Tracker node can be used to track objects that are only roughly planar. After an object is tracked, a Planar Transform node can then be used to warp a rotospline, making it approximately follow the object over time. Fine-level cleanup work on the rotospline then must be done.

Depending on how well the Planar Tracker followed the object, this can result in substantial time savings in the amount of tedious rotoscoping. The key to using this technique is recognizing situations where the Planar Tracker performs well on an object that needs to be rotoscoped.

A rough outline of the workflow involved is:

1. **Track**: Using a Planar Tracker node, select a pattern that represents the object to be rotoscoped. Track the shot (see the tracking workflow in the Track section for the Planar Tracker node).

2. **Create a Planar Transform node**: Press the Create Planar Transform button on the Planar Tracker node to do this. The newly created Planar Transform node can be freely cut and pasted into another composition as desired.

3. **Rotoscope the object**: Move to any frame that was tracked by the Planar Tracker. When unsure if a frame was tracked, look in the Spline Editor for a tracking keyframe on the Planar Transform node. Connect a Polygon node into the Planar Transform node. While viewing the Planar Transform node, rotoscope the object.

4. **Refine**: Scrub the timeline to see how well the polygon follows the object. Adjust the polyline on frames where it is off. It is possible to add new points to further refine the polygon.

### Inputs

The Planar Transform has only two inputs:

- **Image Input**: The orange image input accepts a 2D image on which the transform will be applied.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the output of the Planar Transform to certain areas.

### Basic Node Setup

The example below uses a Planar Transform node between a masked MediaIn2 node and the foreground input to a Merge node. The background MediaIn1 node connects to the Planar Tracker, which was used to generate the Planar Transform. Once the Planar Transform is created, the Planar Tracker is no longer needed in the node tree.
A Planar Transform creating a match move

**Inspector**

The Planar Transform Controls tab

**Controls Tab**

The Planar Transform node has very few controls, and they are all located in the Controls tab. It’s designed to apply the analyzed Planar Tracking data as a match move.

**Reference Time**

This is the reference time that the pattern was taken from in the Planar Tracker node used to produce the Planar Transform.

**Right-Click Here for Track Spline**

The Track spline contains information about the perspective distortions stored in 4 x 4 matrices. When a Planar Transform node is exported from a Planar Tracker node, the Track spline produced by the Planar Tracker is shared by connecting it with the Planar Transform node. A consequence of this sharing of the Track spline is that if the track is changed in the Planar Tracker node, the Planar Transform will be automatically updated. Note that this spline can be examined in the Spline Editor, which is useful for seeing the extent of tracked frames.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Tracking nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Camera Tracker [CTra]

The Camera Tracker node

Camera Tracker Introduction

Camera tracking is match moving, and a vital link between 2D and 3D, allowing compositors to integrate 3D renders into live-action scenes. The Camera Tracker node is used to calculate the path of a live-action camera and generate a virtual camera in 3D space. This virtual camera’s motion is intended to be identical to the motion of the actual camera that shot the scene. Using the calculated position and movement of the virtual camera provides the flexibility to add 3D elements to a live-action scene. Also, the Camera Tracker creates a point cloud in 3D space that can be used to align objects and other 3D models to the live-action scene.

For more information about how to use the Camera Tracker, see Chapter 26, “3D Camera Tracking,” in the Fusion Reference Manual or Chapter 86 in the DaVinci Resolve Reference Manual.
**Inputs**

The Camera Tracker has two inputs:

- **Background:** The orange image input accepts a 2D image you want tracked.
- **Occlusion Mask:** The white occlusion mask input is used to mask out regions that do not need to be tracked. Regions where this mask is white will not be tracked. For example, a person moving in front of and occluding bits of the scene may be confusing to the tracker, and a quickly-created rough mask around the person can be used to tell the tracker to ignore the masked-out bits.

**Basic Node Setup**

The Camera Tracker background input is used to connect the image you want tracked. Polygon masks can be connected into the occlusion mask input to identify areas the tracker should ignore.

![The Camera Tracker with occlusion masks](image)

**Inspector**

The Camera Tracker tab

![The Camera Tracker tab](image)

**Track Tab**

The Track tab contains the controls you need to set up an initial analysis of the scene.

**Auto Track**

Automatically detects trackable features and tracks them through the source footage. Tracks will be automatically terminated when the track error becomes too high, and new tracks are created as needed.
The values of the Detection Threshold and Minimum Feature Separation sliders can be used to control the number and distribution of auto tracks.

**Reset**
Deletes all the data internal to the Camera Tracker node, including the tracking data and the solve data (camera motion path and point cloud). To delete only the solve data, use the Delete button on the Solve tab.

**Preview AutoTrack Locations**
Turning this checkbox on will show where the auto tracks will be distributed within the shot. This is helpful for determining if the Detection Threshold and Minimum Feature Separation need to be adjusted to get an even spread of trackers.

**Detection Threshold**
Determines the sensitivity to detect features. Automatically generated tracks will be assigned to the shot and the Detection Threshold will force them to be either in locations of high contrast or low contrast.

**Minimum Feature Separation**
Determines the spacing between the automatically generated tracking points. Decreasing this slider causes more auto tracks to be generated. Keep in mind that a large number of tracking points will also result in a lengthier solve.

**Track Channel**
Used to nominate a color channel to track: red, green, blue, or luminance. When nominating a channel, choose one that has a high level of contrast and detail.

**Track Range**
Used to determine which frames are tracked:

- **Global**: The global range, which is the full duration of the Timeline.
- **Render**: The render duration set on the Timeline.
- **Valid**: The valid range is the duration of the source media.
- **Custom**: A user determined range. When this is selected, a separate range slider appears to set the start and end of the track range.

**Bidirectional Tracking**
Enabling this will force the tracker to track backward after the initial forward tracking. When tracking backward, new tracks are not started but rather existing tracks are extended backward in time. It is recommended to leave this option on, as long tracks help give better solved cameras and point clouds.

**Gutter Size**
Trackers can become unstable when they get close to the edge of the image and either drift or jitter or completely lose their pattern. The Camera Tracker will automatically terminate any tracks that enter the gutter region. Gutter size is given as a percentage of pattern size. By default, it's 100% of pattern size, so a 0.04 pattern means a 0.04 gutter.
**New Track Defaults**

There are three methods in which the Camera Tracker node can analyze the scene, and each has its own strengths when dealing with certain types of camera movement.

— **Tracker:** Internally, all the Trackers use the Optical Flow Tracker to follow features over time and then further refine the tracks with the trusted Fusion Tracker or Planar Tracker. The Planar Tracker method allows the pattern to warp over time by various types of transforms to find the best fit. These transforms are:

— Translation
— Translation and Rotation
— Translation, Rotation, and Scale
— Affine
— Perspective

It is recommended to use the default TRS setting when using the Planar Tracker. The Affine and Perspective settings need large patterns in order to track accurately.

— **Close Tracks When Track Error Exceeds:** Tracks will be automatically terminated when the tracking error gets too high. When tracking a feature, a snapshot of the pixels around a feature are taken at the reference time of the track. This is called a pattern, and that same pattern of pixels is searched for at future times. The difference between the current time pattern and the reference time pattern is called the track error. Setting this option higher produces longer but increasingly less accurate tracks.

— **Solve Weight:** By default, each track is weighted evenly in the solve process. Increasing a track’s weight means it has a stronger effect on the solved camera path. This is an advanced option that should be rarely changed.

**Auto Track Defaults**

Set a custom prefix name and/or color for the automatically generated tracks. This custom color will be visible when Track Colors in the Options tab is set to User Assigned.

**Camera Tab**

The Camera Tracker Camera tab

The controls of the Camera tab let you specify the physical aspects of the live-action camera, which will be used as a starting point when searching for solve parameters that match the real-world camera. The more accurate the information provided in this section, the more accurate the camera solve.
The Camera tab includes controls relating to the lens and gate aspects of the camera being solved for.

**Focal Length**
Specify the known constant focal length used to shoot the scene or provide a guess if the Refine Focal Length option is activated in the Solve tab.

**Film Gate**
Choose a film gate preset from the drop-down menu or manually enter the film back size in the Aperture Width and Aperture Height inputs. Note that these values are in inches.

**Aperture Width**
In the event that the camera used to shoot the scene is not in the preset drop-down menu, manually enter the aperture width (inches).

**Aperture Height**
In the event that the camera used to shoot the scene is not in the preset drop-down menu, manually enter the aperture height (inches).

**Resolution Gate Fit**
This defines how the image fits the sensor size. Often, film sensors are sized to cover a number of formats, and only a portion of the sensor area is recorded into an image.

For example, a 16:9 image is saved out of a full aperture-sized sensor.

Typically, fit to Width or Height is the best setting. The other fit modes are Inside, Outside, or Stretched.

**Center Point**
This is where the camera lens is aligned to the camera. The default is (0.5, 0.5), which is the middle of the sensor.

**Use Source Pixel Aspect**
This will use the squeeze aspect of the pixels that is loaded in the image. HD is square pixels, but NTSC has a pixel aspect ratio of 0.9:1, and Anamorphic CinemaScope is 2:1 aspect. Disabling this option exposes Pixel X and Y number fields where you can customize the source pixel aspect.

**Auto Camera Planes**
When enabled, the camera's image plane and far plane are automatically moved to enclose the point cloud whenever a solve completes. Sometimes, though, the solver can atypically fling points off really deep into the scene, consequently pushing the image plane very far out. This makes the resulting scene unwieldy to work with in the 3D views. In these cases, disable this option to override this default behavior (or delete the offending tracks).
Solve Tab

The Camera Tracker Solve tab

SolveTab

The Solve tab is where the tracking data is used to reconstruct the camera’s motion path along with the point cloud. It is also where cleanup of bad or false tracks is done, and other operations on the tracks can be performed, such as defining which marks are exported in the Point Cloud 3D. The markers can also have their weight set to affect the solve calculations.

For example, a good camera solve may have already been generated, but there are not enough locators in the point cloud in an area where an object needs to be placed, so adding more tracks and setting their Solve Weight to zero will not affect the solved camera but will give more points in the point cloud.

Solve

Pressing Solve will launch the solver, which uses the tracking information and the camera specifications to generate a virtual camera path and point cloud, approximating the motion of the physical camera in the live-action footage. The console will automatically open, displaying the progress of the solver.

Delete

Delete will remove any solved information, such as the camera and the point cloud, but will keep all the tracking data.
Average Solve Error
Once the camera has been solved, a summary of the solve calculation is displayed at the top of the Inspector. Chief among those details is the Average Solve Error. This number is a good indicator of whether the camera solve was successful. It can be thought of as the difference (measured in pixels) between tracks in the 2D image and the reconstructed 3D locators reprojected back onto the image through the reconstructed camera. Ultimately, in trying to achieve a low solve error, any value less than 1.0 pixels will generally result in a good track. A value between 0.6 and 0.8 pixels is considered excellent.

Clean Tracks by Filter
Clicking this button selects tracks based on the Track Filtering options. If the Auto Delete Tracks By Filter checkbox is activated, the selected tracks will be deleted as well.

Clean Foreground Tracks
Clicking this button makes a selection of the tracks on fast-moving objects that would otherwise cause a high solve error. The selection is determined by the Foreground Threshold slider.

Foreground Threshold
This slider sets the detection threshold for finding the tracks on fast-moving objects. The higher the value, the more forgiving.

Auto Delete Tracks by Filter
With this checkbox enabled, tracks that are selected by the Clean Tracks By Filter button will be deleted. Enable the checkbox, and then press Clean Tracks By Filter. Any track that meets the filtering options is then selected and deleted.

Auto Delete Foreground Tracks
With this checkbox enabled, tracks that are selected by the Clean Foreground Tracks button will be deleted. Enable the checkbox, and then press Clean Foreground Tracks. Any track that meets the foreground threshold criteria is deleted.

Accept Solve Error
This slider sets an acceptable maximum threshold level for the solve error. If the solve error is greater than this value, the Camera Tracker will sweep the focal length setting in an attempt to bring the solve error under the Accept Solve Error value. If the solver cannot find a solution, the Camera Tracker will display a message in the console that the solver failed. If a solution cannot be found, ideally you should try to input the correct focal length or alternatively manually clean some noisy tracks then re-solve.

Auto Select Seed Frames
With this enabled, the Camera Tracker nominates two frames that will be used as a reference for initiating the solve. These two frames are initially solved for and a camera is reconstructed, and then gradually more frames are added in, and the solution is “grown” outward from the seed frames. The choice of seed frames strongly affects the entire solve and can easily cause the solve to fail. Seed frames can be found automatically or defined manually.

Disabling this will allow the user to select their own two frames. Manual choice of seed frames is an option for advanced users. When choosing seed frames, it is important to satisfy two conflicting desires: the seed frames should have lots of tracks in common yet be far apart in perspective (i.e., the baseline distance between the two associated cameras is long).
Refine Focal Length
Enabling this will allow the solver to adjust the focal length of the lens to match the tracking points. You can prevent the focal length being adjusted by setting the Focal Length parameter in the Camera Tab.

Enable Lens Parameter
When enabled, lens distortion parameters are exposed to help in correcting lens distortion when solving.

— Refine Center Point: Normally disabled, camera lenses are normally centered in the middle of the film gate but this may differ on some cameras. For example, a cine camera may be set up for Academy 1.85, which has a sound stripe on the left, and shooting super35, the lens is offset to the right.

— Refine Lens Parameters: This will refine the lens distortion or curvature of the lens. There tends to be larger distortion on wide angle cameras.

NOTE: When solving for the camera’s motion path, a simulated lens is internally created to model lens distortion in the source footage. This simulated lens model is much simpler than real-world lenses but captures the lens distortion characteristics important for getting an accurate camera solve. Two types of distortion are modeled by Camera Tracker:

Radial Distortion: The strength of this type of distortion varies depending on the distance from the center of the lens. Examples of this include pincushion, barrel, and mustache distortion. Larger values correspond to larger lens curvatures. Modeling radial distortion is especially important for wide angle lenses and fisheye lenses (which will have a lot of distortion because they capture 180 degrees of an environment and then optically squeeze it onto a flat rectangular sensor).

Tangential Distortion: This kind of distortion is produced when the camera’s imaging sensor and physical lens are not parallel to each other. It tends to produce skew distortions in the footage similar to distortions that can be produced by dragging the corners of a corner pin within Fusion. This kind of distortion occurs in very cheap consumer cameras and is practically non-existent in film cameras, DSLRs, and pretty much any kind of camera used in film or broadcast. It is recommended that it be left disabled.

Enable Lens Parameters
When disabled, the Camera Tracker does not do any lens curvature simulations. This is the default setting and should remain disabled if there is a very low distortion lens or the lens distortion has already been removed from the source clip. Activating the Enable Lens Parameters checkbox determines which lens parameters will be modeled and solved for. Parameters that are not enabled will be left at their default values. The following options are available:

— Radial Quadratic: Model only Quadratic radial lens curvature, which is either barrel or pincushion distortion. This is the most common type of distortion. Selecting this option causes the low and high order distortion values to be solved for.

— Radial Quartic: Model only Quartic radial lens curvature, which combines barrel and pincushion distortion. This causes the low and high order distortion values to be solved for.

— Radial & Tangential: Model and solve for both radial and tangential distortion. Tangential relates to misaligned elements in a lens.
— **Division Quadratic**: Provides a more accurate simulation of Quadratic radial lens curvature. This causes the low and high order distortion values to be solved for.

— **Division Quartic**: Provides a more accurate simulation of Quartic radial lens curvature. This causes the low and high order distortion values to be solved for.

— **Lower Order Radial Distortion**: This slider is available for all simulations. It determines the quadratic lens curvature.

— **Higher Order Radial Distortion**: This slider is available only for Quartic simulations. Determines the quartic lens curvature.

— **Tangential Distortion X/Y**: These sliders are available only for Tangential simulations. Determines skew distortion.

**Track Filtering**

The Camera Tracker can produce a large number of automatically generated tracks. Rather than spending a lot of time individually examining the quality of each track, it is useful to have some less time-intensive ways to filter out large swaths of potentially bad tracks. The following input sliders are useful for selecting large amounts of tracks based on certain quality metrics, and then a number of different possible operations can be made on them. For example, weaker tracks can selected and deleted, yielding a stronger set of tracks to solve from. Each filter can be individually enabled or disabled.

**Minimum Track Length (Number of Markers)**

Selects tracks that have a duration shorter than the slider’s value. Short tracks usually don’t get a chance to move very far and thus provide less perspective information to the solver than a longer track, yet both short and long tracks are weighted evenly in the solve process, making long tracks more valuable to the solver. Locators corresponding to shorter tracks are also less accurately positioned in 3D space than those corresponding to longer tracks. If the shot has a lot of long tracks, it can be helpful to delete the short tracks. For typical shots, using a value in the range of 5 to 10 is suggested. If there are not a lot of long tracks (e.g., the camera is quickly rotating, causing tracks to start and move off frame quickly), using a value closer to 3 is recommended.

**Maximum Track Error**

Selects tracks that have an average track error greater than the slider’s value. When tracking, tracks are automatically terminated when their track error exceeds some threshold. This auto termination controls the maximum track error, while this slider controls the average track error. For example, tracks following the foliage in a tree tend to be inaccurate and sometimes may be detected by their high average error.

**Maximum Solve Error**

Selects tracks that have a solve error greater than the slider’s value. One of the easiest ways to increase the accuracy of a camera solve is to select the 20% of the tracks with the highest solve error and simply delete them (although this can sometimes make things worse).

**Select Tracks Satisfying Filters**

Selects the tracks within the scene that meet the above Track Filtering values. Note that when this button is pressed, the tracks that satisfy the filter values are displayed in the Selected Tracks area of the Solve tab and are colored in the viewer. This button is useful when Auto Select Tracks While Dragging Sliders is turned off or if the selection, for example, was accidentally lost by mis-clicking in the viewer.
**Auto Select Tracks While Dragging Sliders**

When this is ticked on, dragging the above sliders (Minimum Track Length, Maximum Track Error, Maximum Solve Error) will cause the corresponding tracks to be interactively selected in the viewer.

**Operations on Selected Tracks**

Tracks selected directly in the viewer with the mouse or selected via track filtering can have the following operations applied:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Delete</strong></td>
<td>Will remove the tracks from the set. When there are bad tracks, the simplest and easiest option is to simply delete them.</td>
</tr>
<tr>
<td><strong>Trim Previous</strong></td>
<td>Will cut the tracked frames from the current frame to the start of the track. Sometimes it can be more useful to trim a track than deleting it. For example, high quality long tracks that become inaccurate when the feature they are tracking starts to become occluded or when the tracked feature moves too close to the edge of the image.</td>
</tr>
<tr>
<td><strong>Trim Next</strong></td>
<td>Will cut the tracked frames from the current frame to the end of the track.</td>
</tr>
<tr>
<td><strong>Rename</strong></td>
<td>Will replace the current auto generated name with a new name.</td>
</tr>
<tr>
<td><strong>Set Color</strong></td>
<td>Will allow for user assigned color of the tracking points.</td>
</tr>
<tr>
<td><strong>Export Flag</strong></td>
<td>This controls whether the locators corresponding to the selected tracks will be exported in the point cloud. By default all locators flagged as exportable.</td>
</tr>
</tbody>
</table>
| **Solve Weight** | By default, all the tracks are used and equally weighted when solving for the camera’s motion path. The most common use of this option is to set a track’s weight to zero so it does not influence the camera’s motion path but is still has a reconstructed 3D locator. Setting a tracks’ weight to values other than 1.0 or 0.0 should only be done by advanced users.  
Onscreen display of track names and values are controlled by these functions.” |
| **None**     | Will clear/hide the selected tracks.                                        |
| **Toggle**   | Will swap the selected tracks and unselect sets.                            |
| **All**      | Will select all tracks.                                                     |
| **Show Names** | Will display the track name, by default these are a number.                 |
| **Show Frame Range** | Will display the start and end frame of a track.                           |
| **Show Solve Error** | Will display the amount of solve error each selected track has.           |

**Selected Tracks**

This area displays the properties of a track point or group of points. It has options to:

- **Clear**: Deselects all tracks and clears this area.
- **Invert**: Deselects the current selected tracks and selects the other tracks.
- **Visible**: Selects all the trackers at the current frame.
— **All:** Selects all trackers on all frames.
— **Search:** Selects tracks whose names contain a substring.

**TIP:** Also select tracks directly in the 2D viewer using the mouse or in the 3D viewer by selecting their corresponding locators in the point cloud.

---

**Export Tab**

The Export tab lets you turn the tracked and solved data this node has generated into a form that can be used for compositing.

![The Camera Tracker Export tab](image)

---

**Chapter 117 Tracker Nodes**

---
**Export**

The Export button will create a basic setup that can be used for 3D match moving:

- A Camera 3D with animated translation and rotation that matches the motion of the live-action camera and an attached image plane.
- A Point Cloud 3D containing the reconstructed 3D positions of the tracks.
- A Shape 3D set to generate a ground plane.
- A Merge 3D merging together the camera, point cloud, and ground plane. When the Merge 3D is viewed through the camera in a 3D viewer, the 3D locators should follow the tracked footage.
- A Renderer 3D set to match the input footage.

The export of individual nodes can be enabled/disabled in the Export Options tab.

**Update Previous Export**

When this button is clicked, the previously exported nodes are updated with any new data generated. These previously exported nodes are remembered in the Previous Export section at the bottom of this section. Here’s an example of how this is handy:

1. Solve the camera and export.
2. Construct a complex Node Editor based around the exported nodes for use in set extension.
3. The camera is not as accurate as preferred or perhaps the solver is rerun to add additional tracks to generate a denser point cloud. Rather than re-exporting the Camera 3D and Point Cloud 3D nodes and connecting them back in, just press the Update Previous Export button to “overwrite” the existing nodes in place.

**Automatically Update Previous Export After Solves**

This will cause the already exported nodes (Camera 3D, Point Cloud 3D, Lens Distort, Renderer 3D, and the ground plane) to auto update on each solve.

**3D Scene Transform**

Although the camera is solved, it has no idea where the ground plane or center of the scene is located. By default, the solver will always place the camera in Fusion’s 3D virtual environment so that on the first frame it is located at the origin (0, 0, 0) and is looking down the -Z axis. You have the choice to export this raw scene without giving the Camera Tracker any more information, or you can set the ground plane and origin to simplify your job when you begin working in the 3D scene. The 3D Scene Transform controls provide a mechanism to correctly orient the physical ground plane in the footage with the virtual ground plane in the 3D viewer. Adjusting the 3D Scene Transform does not modify the camera solve but simply repositions the 3D scene to best represent the position of the live-action camera.

**NOTE:** If you export the scene and then make changes in the 3D Scene Transform, it is important to manually click Update Previous Export to see the results in the exported nodes.
Aligned/Unaligned

The Aligned/Unaligned menu locks or unlocks the origin and ground plane settings. When set to Unaligned, you can select the ground plane and origin either manually or by selecting locators in the viewer. When in unaligned mode, a 3D Transform control in the 3D viewer can be manually manipulated to adjust the origin.

Once alignment of the ground plane and origin has been completed, the section is locked by switching the menu to Aligned.

Set from Selection

When set to unaligned, buttons labeled Set from Selection are displayed under the Origin, Orientation, and Scale sections. Clicking these buttons takes the selecting locators in the viewer and aligns the ground plane or origin based on the selection.

For instance, to set the ground plane, do the following:

1. After solving, set the 3D Scene Transform menu to Unaligned.
2. Find a frame where the ground plane is at its largest and clearest point.
3. In the viewer, drag a selection rectangle around all the ground plane locators.
4. Hold Shift and drag again to add to the selection.
5. In the Orientation section, make sure the Selection Is menu correctly matches the orientation of the selected locators.
6. Click the Set from Selection button located under the Orientation parameters.
7. Set the 3D Scene Transform menu back to Aligned.

To get the best result when setting the ground plane, try to select as many points as possible belonging to the ground and having a wide separation.

**TIP:** When selecting points for the ground plane, it is helpful to have the Camera Tracker node viewed in side-by-side 2D and 3D views. It may be easier to select tracks belonging to the ground by selecting tracks from multiple frames in the 2D viewer rather than trying to box select locators in the 3D viewer.

Setting the origin can help you place 3D objects in the scene with more precision. To set the origin, you can follow similar steps, but only one locator is required for the origin to be set. When selecting a locator for the origin, select one that has a very low solve error.

Ground Plane Options

These controls let you adjust the ground plane for the scene, which is a crucial step in making sure the composite looks correct.

<table>
<thead>
<tr>
<th>Color</th>
<th>Will set the color of the ground plane.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size</td>
<td>Controls how big the ground plane can be set.</td>
</tr>
<tr>
<td>Subdivision Level</td>
<td>Shows how many polygons are in the ground plane.</td>
</tr>
<tr>
<td><strong>Wireframe</strong></td>
<td>Sets whether the ground plane is set as wireframe or solid surface when displayed in 3D.</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Line Thickness</strong></td>
<td>Adjusts how wide the lines will draw in the view.</td>
</tr>
<tr>
<td><strong>Offset</strong></td>
<td>By default, the center of the ground plane is placed at the origin (0, 0, 0). This can be used to shift the ground plane up and down along the y-axis.</td>
</tr>
</tbody>
</table>

**Export Options**

Provides a checkbox list of what will be exported as nodes when the Export button is pressed. These options are Camera, Point Cloud, Ground Plane, Renderer, Lens Distortion, and Enable Image Plane in the camera.

The Animation menu allows you to choose between animating the camera and animating the point cloud. Animating the camera leaves the point cloud in a locked position while the camera is keyframed to match the live-action shot. Animating the point cloud does the opposite. The camera is locked in position while the entire point cloud is keyframed to match the live-action shot.

**Previous Export**

When the Update Previous Export button is clicked, the previously exported nodes listed here are updated with any new data generated (this includes the camera path and attributes, the point cloud, and the renderer).

**Options Tab**

The Options tab lets you customize the Camera Tracker’s onscreen controls so you can work most effectively with the scene material you have.

The Camera Tracker Options tab

**Trail Length**

Displays trail lines of the tracks overlaid on the viewer. The amount of frames forward and back from the current frame is set by length.
Location Size
In the 3D viewer, the point cloud locators can be sized by this control.

Track Colors, Locator Colors, and Export Colors each have options for setting their color to one of the following:

- User Assigned
- Solve Error
- Take From Image
- White

<table>
<thead>
<tr>
<th>Track Colors</th>
<th>Onscreen tracks in the 2D view.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locator Colors</td>
<td>Point Cloud locators in the 3D view.</td>
</tr>
<tr>
<td>Export Colors</td>
<td>Colors of the locators that get exported within the Point Cloud node.</td>
</tr>
</tbody>
</table>

Darken Image
Dims the brightness of the image in viewers to better see the overlaid tracks. This affects both the 2D and 3D viewers.

Visibility
Toggles which overlays will be displayed in the 2D and 3D viewers. The options are Tracker Markers, Trails, Tooltips in the 2D Viewer, Tooltips in the 3D viewer, Reprojected Locators, and Tracker Patterns.

Colors
Sets the color of the overlays.

- **Selection Color**: Controls the color of selected tracks/locators.
- **Preview New Tracks Color**: Controls the color of the points displayed in the viewer when the Preview AutoTrack Locations option is enabled.
- **Solve Error Gradient**: By default, tracks and locators are colored by a green-yellow-red gradient to indicate their solve error. This gradient is completely user adjustable.

Reporting
Outputs various parameters and information to the Console.

Understanding Camera Tracking
On large productions, camera tracking or 3D match moving is often handed over to experts who have experience with the process of tracking and solving difficult shots. There is rarely a shot where you can press a couple of buttons and have it work perfectly. It does take an understanding of the whole process and what is essential to get a good solved track.

The Camera Tracker must solve for hundreds of thousands of unknown variables, which is a complex task. For the process to work, it is essential to get good tracking data that exists in the shot for a long time. False or bad tracks will skew the result. This section explains how to clean up false tracks and other techniques to get a good solve.
Workflow
Getting a good solve is a repeated process.

Track > Solve > Refine Filters > Solve > Cleanup tracks > Solve > Cleanup from point cloud > Solve > Repeat.

Initially, there are numerous tracks, and not all are good, so a process of filtering and cleaning up unwanted tracks to get to the best set is required. At the end of each cleanup stage, pressing Solve ideally gives you a progressively lower solve error. This needs to be below 1.0 for it to be good for use with full HD content, and even lower for higher resolutions. Refining the tracks often but not always results in a better solve.

False Tracks
False tracks are caused by a number of conditions, such as moving objects in a shot, or reflections and highlights from a car. There are other types of false tracks like parallax errors where two objects are at different depths, and the intersection gets tracked. These moiré effects can cause the track to creep. Recognizing these False tracks and eliminating them is the most important step in the solve process.

Track Lengths
Getting a good set of long tracks is essential; the longer the tracks are, the better the solve. The Bi-Directional tracking option in the Tracker tab is used to extend the beginning of tracks in time. The longer in time a track exists and the more tracks that overlap in time of a shot, the more consistent and accurate the solve.

Seed Frames
Two seed frames are used in the solve process. The algorithm chooses two frames that are as far apart in time yet share the same tracks. That is why longer tracks make a more significant difference in the selection of seed frames.

The two Seed frames are used as the reference frames, which should be from different angles of the same scene. The solve process will use these as a master starting point to fit the rest of the tracks in the sequence.

There is an option in the Solve tab to Auto Detect Seed Frames, which is the default setting and most often a good idea. However, auto detecting seed frames can make for a longer solve. When refining the Trackers and re-solving, disable the checkbox and use the Seed 1 and Seed 2 sliders to enter the previous solve’s seed frames. These seed frames can be found in the Solve Summary at the top of the Inspector after the initial solve.

Refine Filters
After the first solve, all the Trackers will have extra data generated. These are solve errors and tracking errors.

Use the refine filters to reduce unwanted tracks, like setting minimum tracker length to eight frames. As the value for each filter is adjusted, the Solve dialog will indicate how many tracks are affected by the filter. Then Solve again.
Onscreen Culling

Under the Options tab, set the track to 20. This will display each track on footage with +/-20 frame trail. When scrubbing/playing through the footage, false tracks can be seen and selected onscreen, and deleted by pressing the Delete key. This process takes an experienced eye to spot tracks that go bad. Then Solve again.

You can view the exported scene in a 3D perspective viewer. The point cloud will be visible. Move and pan around the point cloud, select and delete points that seem to have no inline with the image and the scene space. Then Solve again.

Repeat the process until the solve error is below 1.0 before exporting.

Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other Tracking nodes. These common controls are described in detail in the following "The Common Controls" section.

The Common Controls

Nodes that handle tracking operations share several identical controls in the Inspector. This section describes controls that are common among Tracking nodes.

Inspector

The Common Tracking Controls Settings tab
**Settings Tab**

The Settings tab in the Inspector can be found on every tool in the Tracking category. The controls are consistent and work the same way for each tool.

**Blend**

The Blend control is used to blend between the tool's original image input and the tool's final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this will cause the tool to skip processing entirely, copying the input straight to the output.

**Process When Blend Is 0.0**

The tool is processed even when the input value is zero. This can be useful if the node is scripted to trigger a task, but the node's value is set to 0.0.

**Red/Green/Blue/Alpha Channel Selector**

These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur will first be applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this will generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

**Apply Mask Inverted**

Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

**Multiply by Mask**

Selecting this option will cause the RGB values of the masked image to be multiplied by the mask channel's values. This will cause all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

**Use Object/Use Material (Checkboxes)**

Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels will be used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

**Correct Edges**

This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

For more information on the Coverage and Background Color channels, see Chapter 18, “Understanding Image Channels,” in the Fusion Studio Reference Manual or Chapter 78 in the DaVinci Resolve Reference Manual.
Object ID/Material ID (Sliders)

Use these sliders to select which ID will be used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the viewer. The image or sequence must have been rendered from a 3D software package with those channels included.

Motion Blur

- **Motion Blur:** This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.

- **Quality:** Quality determines the number of samples used to create the blur. A quality setting of 2 will cause Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.

- **Shutter Angle:** Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one full frame exposure. Higher values are possible and can be used to create interesting effects.

- **Center Bias:** Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.

- **Sample Spread:** Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

Use GPU

The Use GPU menu has three settings. Setting the menu to Disable turns off GPU hardware-accelerated rendering. Enabled uses the GPU hardware for rendering the node. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.

Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 118

Transform Nodes

This chapter details the Transform nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

The Common Controls 2611
Camera Shake Node Introduction

This node can simulate a variety of camera shake-style motions from organic to mechanical. It is not the same as the Shake Modifier, which generates random number values for parameters.

The Camera Shake node concatenates its result with adjacent transformation nodes for higher-quality processing.

Inputs

The two inputs on the Camera Shake node are used to connect a 2D image and an effect mask, which can be used to limit the camera shake area.

- **Input**: The orange input is used for the primary 2D image that shakes.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the camera shake area to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

The Camera Shake background input is used to connect the image you want to transform. Polygon masks can be connected into the occlusion mask input to identify areas the camera shake should ignore.
Controls Tab

The Controls tab includes parameters for adjusting the offsets, strength, speed, and frequency of the simulated camera shake movement.

**Deviation X and Y**

These controls determine the amount of shake applied to the image along the horizontal (X) and vertical (Y) axes. Values between 0.0 and 1.0 are permitted. A value of 1.0 generates shake positions anywhere within the boundaries of the image.

**Rotation Deviation**

This determines the amount of shake that is applied to the rotational axis. Values between 0.0 and 1.0 are permitted.

**Randomness**

Higher values in this control cause the movement of the shake to be more irregular or random. Smaller values cause the movement to be more predictable.

**Overall Strength**

This adjusts the general amplitude of all the parameters and blends that affect in and out. A value of 1.0 applies the effect as described by the remainder of the controls.

**Speed**

Speed controls the frequency, or rate, of the shake.

**Frequency Method**

This selects the overall shape of the shake. Available frequencies are Sine, Rectified Sine, and Square Wave. A Square Wave generates a much more mechanical-looking motion than a Sine.
**Filter Method**

When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called filters. More complex filters can give better results but are usually slower to calculate.

The best filter for the job often depends on the amount of scaling and on the contents of the image itself.

- **Box**: This is a simple interpolation resize of the image.
- **Linear**: This uses a simplistic filter, which produces relatively clean and fast results.
- **Quadratic**: This filter produces a nominal result. It offers a good compromise between speed and quality.
- **Cubic**: This produces better results with continuous-tone images. If the images have fine detail in them, the results may be blurrier than desired.
- **Catmull-Rom**: This produces good results with continuous-tone images that are resized down. This produces sharp results with finely detailed images.
- **Gaussian**: This is very similar in speed and quality to Bi-Cubic.
- **Mitchell**: This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.
- **Lanczos**: This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.
- **Sinc**: This is an advanced filter that produces very sharp, detailed results; however, it may produce visible “ringing” in some situations.
- **Bessel**: This is similar to the Sinc filter but may be slightly faster.

**Window Method (Sinc and Bessel Only)**

Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

- **Hanning**: This is a simple tapered window.
- **Hamming**: Hamming is a slightly tweaked version of Hanning that does not taper all the way down to zero.
- **Blackman**: A window with a more sharply tapered falloff.
- **Kaiser**: A more complex window with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter, however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

**Example**

Resize filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, and Bessel.
**Edges**
This menu determines how the Edges of the image are treated.

- **Canvas:** This causes the edges that are revealed by the shake to be the canvas color—usually transparent or black.
- **Wrap:** This causes the edges to wrap around (the top is wrapped to the bottom, the left is wrapped to the right, and so on).
- **Duplicate:** This causes the Edges to be duplicated, causing a slight smearing effect at the edges.
- **Mirror:** Image pixels are mirrored to fill to the edge of the frame.

**Invert Transform**
Select this control to invert any position, rotation, or scaling transformation. This option might be useful for exactly removing the motion produced in an upstream Camera Shake.

**Flatten Transform**
The Flatten Transform option prevents this node from concatenating its transformation with adjacent nodes. The node may still concatenate transforms from its input, but it will not concatenate its transformation with the node at its output.

**Common Controls**

**Settings Tab**
The Settings tab in the Inspector is also duplicated in other Transform nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

---

**Crop [CRP]**

The Crop node

**Crop Node Introduction**
The Crop node can be used to cut out a portion of an image or to offset the image into a larger image area. However, unlike using a mask, this node actually changes the resolution of the image.

**TIP:** You can crop an image in the viewer by activating the Allow Box Selection in the upper-left corner of the viewer while the Crop node is selected and viewed. Then, drag a crop rectangle around the area of interest to perform the operation.
NOTE: Because this node changes the physical resolution of the image, animating the parameters is not advised.

**Inputs**

The single input on the Crop node is used to connect a 2D image for cropping.

— **Input**: The orange input is used for the primary 2D image you want to crop.

**Basic Node Setup**

Below, the Crop node is inserted between the MediaIn1 node and the background input of the Merge. Unlike using a mask tool, cropping the MediaIn1 changes the resolution of the clip. The cropped MediaIn1 node connected to the orange background input also sets the resolution of the Merge output.

The Crop node can be used to cut out a portion of an image.

**Inspector**

The Crop Controls tab

**Controls Tab**

The Controls tab provides XY Offset and XY Size methods for cropping the image.

**Offset X and Y**

These controls position the image off the screen by pushing it left/right or up/down. The cropped image disappears off the edges of the output image. The values of these controls are measured in pixels.
**Size X and Y**
Use these controls to set the vertical and horizontal resolution of the image output by the Crop node. The values of these controls are measured in pixels.

**Keep Aspect**
When toggled on, the Crop node maintains the aspect of the input image.

**Keep Centered**
When toggled on, the Crop node automatically adjusts the X and Y Offset controls to keep the image centered. The XY Offset sliders are automatically adjusted, and control over the cropping is done with the Size sliders or the Allow Box Selection button in the viewer.

**Reset Size**
This resets the image dimensions to the size of the input image.

**Reset Offset**
This resets the X and Y Offsets to their defaults.

**Change Pixel Aspect**
Enable this checkbox to reveal a Pixel Aspect control that can be used to change the image's pixel aspect.

**Clipping Mode**
This option sets the mode used to handle the edges of the image when performing domain of definition (DoD) rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

- **Frame:** The default option is Frame, which automatically sets the node's domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.
- **Domain:** Setting this option to Domain will respect the upstream DoD when applying the node's effect. This can have adverse clipping effects in situations where the node employs a large filter.
- **None:** Setting this option to None does not perform any source image clipping at all. This means that any data required to process the node's effect that would normally be outside the upstream DoD is treated as black/transparent.

**Auto Crop Tab**
Auto Crop tab analyzes the selected channel and crops the image based on that channel's boundaries. The adjustments from auto crop are seen in the Crop tab parameters.

![Auto Crop tab](image)

The Auto Crop tab
RGBA Color Channels
Select which channels are examined for an Auto Crop. This is useful for auto cropping images with non-solid backgrounds in a specific color channel, like a blue color gradient. Toggling the channel off causes Auto Crop to ignore it when evaluating the image.

Auto Crop
This evaluates the image and attempts to determine the background color. It then crops each side of the image to the first pixel that is not that color.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Transform nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

DVE [DVE]

DVE Node Introduction
The DVE (Digital Video Effects) node is a 3D-image transformation similar to nodes found in old, tape-based online editing suites. The node encompasses image rotations, perspective changes, and Z moves. The axis can be defined for all transformations.

Inputs
The three inputs on the DVE node are used to connect a 2D image, DVE mask, and an effect mask, which can be used to limit the DVE area.

— **Input**: The orange input is used for the primary 2D image that is transformed by the DVE.
— **DVE Mask**: The white DVE mask input is used to mask the image prior to the DVE transform being applied. This has the effect of modifying both the image and the mask.
— **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input causes the DVE to modify only the image within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup
In the example below, the DVE node is inserted between the MediaIn2 node and the foreground input of the Merge. The MediaIn1 node is manipulated in the DVE node and composited over the top of the MediaIn1 node.
The DVE node modifying the foreground input of a Merge node

Inspector

The DVE Controls tab

Controls Tab

The Controls tab includes all the transform parameters for the DVE.

Pivot X, Y, and Z
Positions the axis of rotation and scaling. The default is 0.5, 0.5 for X and Y, which is in the center of the image, and 0 for Z, which is at the center of Z space.

Rotation Order
Use these buttons to determine in what order rotations are applied to the image.

XYZ Rotation
These controls are used to rotate the image around the pivot along the X-, Y- and Z-axis.

Center X and Y
This positions the center of the DVE image onscreen. The default is 0.5, 0.5, which positions the DVE in the center of the image.

Z Move
This zooms the image in and out along the Z-axis. Visually, when this control is animated, the effect is similar to watching an object approach from a distance.
Perspective
This adds additional perspective to an image rotated along the X- or Y-axis, similar to changing the Field of View and zoom of a camera.

Masking Tab
The DVE node allows pre-masking of its input image. This offers the ability to create transformations from the masked area of the image while leaving the remainder of the image unaffected.

The DVE Masking tab

Unlike regular effect masks, the masking process occurs before the transformation. All the usual mask types can be applied to the DVE mask.

Black Background
Toggle this on to erase the area outside the mask from the transformed image.

Fill Black
Toggle this on to erase the area within the mask (before transformation) from the DVE’s input, effectively cutting the masked area out of the image. Enabling both Black Background and Fill Black will show only the masked, transformed area.

Alpha Mode
This determines how the DVE will handle the alpha channel of the image when merging the transformed image areas over the untransformed image.

— **Ignore Alpha**: This causes the input image’s alpha channel to be ignored, so all masked areas will be opaque.

— **Subtractive/Additive**: These cause the internal merge of the pre-masked DVE image over the input image to be either Subtractive or Additive.

— An Additive setting is necessary when the foreground DVE image is premultiplied, meaning that the pixels in the color channels have been multiplied by the pixels in the alpha channel. The result is that transparent pixels are always black, since any number multiplied by 0 always equals 0. This obscures the background (by multiplying with the inverse of the foreground alpha), and then simply adds the pixels from the foreground.

— A Subtractive setting is necessary if the foreground DVE image is not premultiplied. The compositing method is similar to an Additive merge, but the foreground DVE image is first multiplied by its own alpha, to eliminate any background pixels outside the alpha area.
Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Transform nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Letterbox [LBX]

The Letterbox node

Letterbox Node Introduction
Use the Letterbox node to adapt existing images to the frame size and aspect ratios of any other format. The most common use of this node is to convert film resolution images to HD-sized frames for viewing on an external television monitor. Horizontal or vertical black edges are automatically added where necessary to compensate for aspect ratio differences. This node actually changes the resolution of the image.

NOTE: Because this node changes the physical resolution of the image, animating the controls is not recommended.

Inputs
The single input on the Letterbox node is used to connect a 2D image for letterbox/cropping.

— Input: The orange input is used for the primary 2D image you want to letterbox/crop.

Basic Node Setup
The Letterbox node is used in the example below to change the resolution of the Merge node’s output. Depending on how the resolution is modified, side pillars, or a horizontal letterbox mask, is applied to “fill in” the frame area, which the Merge node output does not cover.

The Letterbox node converting the Merge output resolution and adding letterbox masking where needed.
Inspector

The Letterbox Controls tab

Controls Tab

The Controls tab includes parameters for adjusting the resolution and pixel aspect of the image. It also has the option of letterboxing or pan-and-scan formatting.

Width and Height

The values of these controls determine the size of the output image as measured in pixels.

**TIP:** You can use the formatting contextual menu to quickly select a resolution from a list. Place the pointer over the Width or Height controls, and then right-click to display the contextual menu. The bottom of the menu displays a Select Frame Format submenu with available frame formats. Select any one of the choices from the menu to set the Height, Width, and Aspect controls automatically.

Auto Resolution

Activating this checkbox automatically sets the Width and Height sliders to the Frame Format settings found in the Preferences window for Fusion Studio or to the resolution of the DaVinci Resolve Timeline.

Pixel Aspect X and Y

These controls determine the pixel aspect ratio of the output image.

Center X and Y

This Center control repositions the image window when used in conjunction with Pan-and-Scan mode. It has no effect on the image when the node is set to Letterbox mode.

Mode

This control is used to determine the Letterbox node's mode of operation.

- **Letterbox/Envelope:** This corrects the aspect of the input image and resizes it to match the specified width.
- **Pan-and-Scan:** This corrects the aspect of the input image and resizes it to match the specified height. If the resized input image is wider than the specified width, the Center control can be used to animate the visible portion of the resized input.
Filter Method
When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called filters. More complex filters can give better results but are usually slower to calculate. The best filter for the job often depends on the amount of scaling and on the contents of the image itself.

- **Box**: This is a simple interpolation resize of the image.
- **Linear**: This uses a simplistic filter, which produces relatively clean and fast results.
- **Quadratic**: This filter produces a nominal result. It offers a good compromise between speed and quality.
- **Cubic**: This produces better results with continuous-tone images. If the images have fine detail in them, the results may be blurrier than desired.
- **Catmull-Rom**: This produces good results with continuous-tone images that are resized down. This produces sharp results with finely detailed images.
- **Gaussian**: This is very similar in speed and quality to Bi-Cubic.
- **Mitchell**: This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.
- **Lanczos**: This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.
- **Sinc**: This is an advanced filter that produces very sharp, detailed results; however, it may produce visible “ringing” in some situations.
- **Bessel**: This is similar to the Sinc filter but may be slightly faster.

Window Method (Sinc and Bessel Only)
Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

- **Hanning**: This is a simple tapered window.
- **Hamming**: Hamming is a slightly tweaked version of Hanning that does not taper all the way down to zero.
- **Blackman**: A window with a more sharply tapered falloff.
- **Kaiser**: A more complex window with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter; however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

Example
Different resize filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, and Bessel.
Common Controls

Settings Tab
The Settings tab in the Inspector is also duplicated in other Transform nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Resize [RSZ]

The Resize node

Resize Node Introduction

Use the Resize node to increase or decrease the resolution of an input image. This is useful for converting images from one format to another (for example, from film to video resolution). This node actually changes the resolution of the image.

NOTE: Because this node changes the physical resolution of the image, animating the controls is not advised.

Inputs

The single input on the Resize node is used to connect a 2D image for resizing.

— Input: The orange input is used for the primary 2D image you want to resize.

Basic Node Setup

Below, the Resize node is inserted between the MediaIn1 node and the background input of the Merge. Unlike using a Transform tool, resizing the MediaIn1 changes the resolution of the clip. The resized MediaIn1 node connected to the orange background input also sets the resolution of the Merge output.

The Resize node can be used to scale an image and change its resolution.
Inspector

The Resize Controls tab

Controls Tab
The Controls tab includes parameters for changing the resolution of the image. It uses pixel values in the Width and Height controls.

**Width**
This controls the new resolution for the image along the X-axis.

**Height**
This controls the new resolution for the image along the Y-axis.

**TIP:** You can use the formatting contextual menu to quickly select a resolution from a list. Place the mouse pointer over the Width or Height controls, and then right-click to display the contextual menu. The bottom of the menu displays a Select Frame Format submenu with available frame formats. Select any one of the choices from the menu to set the Height and Width controls automatically.

**Auto Resolution**
Activating this checkbox automatically sets the Width and Height sliders to the Frame Format settings found in the Preferences window for Fusion Studio or the resolution in the DaVinci Resolve Timeline.

**Reset Size**
Resets the image dimensions to the original size of the image.

**Keep Frame Aspect**
When toggled on, the Resize node maintains the aspect of the original image, preserving the original ratio between width and height.

**Only Use Filter in HiQ**
The Resize node will normally use the fast Nearest Neighbor filter for any non-HiQ renders, where speed is more important than full accuracy. Disable this checkbox to force Resize to always use the selected filter for all renders.
Change Pixel Aspect
Enable this checkbox to reveal a Pixel Aspect control that can be used to change the image’s pixel aspect.

Filter Method
When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called filters. More complex filters can give better results but are usually slower to calculate. The best filter for the job often depends on the amount of scaling and on the contents of the image itself.

— **Box:** This is a simple interpolation resize of the image.
— **Linear:** This uses a simplistic filter, which produces relatively clean and fast results.
— **Quadratic:** This filter produces a nominal result. It offers a good compromise between speed and quality.
— **Cubic:** This produces better results with continuous-tone images. If the images have fine detail in them, the results may be blurrier than desired.
— **Catmull-Rom:** This produces good results with continuous-tone images that are resized down. This produces sharp results with finely detailed images.
— **Gaussian:** This is very similar in speed and quality to Bi-Cubic.
— **Mitchell:** This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.
— **Lanczos:** This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.
— **Sinc:** This is an advanced filter that produces very sharp, detailed results; however, it may produce visible “ringing” in some situations.
— **Bessel:** This is similar to the Sinc filter but may be slightly faster.

Window Method (Sinc and Bessel Only)
Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

— **Hanning:** This is a simple tapered window.
— **Hamming:** Hamming is a slightly tweaked version of Hanning that does not taper all the way down to zero.
— **Blackman:** A window with a more sharply tapered falloff.
— **Kaiser:** A more complex window with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter; however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.
Example

Different resize filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, and Bessel.

Common Controls

Settings Tab
The Settings tab in the Inspector is also duplicated in other Transform nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Scale [SCL]

The Scale node

Scale Node Introduction
The Scale node is almost identical to the Resize node, except that Resize uses exact dimensions, whereas the Scale node uses relative dimensions to describe the change to the source image’s resolution. This node actually changes the resolution of the image.

NOTE: Because this node changes the physical resolution of the image, animating the controls is not advised.

Inputs
The single input on the Scale node is used to connect a 2D image for scaling.

— Input: The orange input is used for the primary 2D image you want to scale.

Basic Node Setup
Below, the Scale node is inserted between the MediaIn1 node and the background input of the Merge. Unlike using a Transform tool, scaling the MediaIn1 changes the resolution of the clip. The resized MediaIn1 node connected to the orange background input also sets the resolution of the Merge output.
The Scale node can be used to scale an image and change its resolution.

**Inspector**

The Scale Controls tab

**Controls Tab**

The Controls tab includes parameters for changing the resolution of the image. It uses a multiplier of size to set the new resolution. An Edges menu allows you to determine how the edges of the frame are handled if the scaling decreases.

**Lock X/Y**

When selected, only a Size control is shown, and changes to the image's scale are applied to both axes equally. If the checkbox is cleared, individual Size controls appear for both X and Y Size.

**Size**

The Size control is used to set the scale used to adjust the resolution of the source image. A value of 1.0 would have no affect on the image, while 2.0 would scale the image to twice its current resolution. A value of 0.5 would halve the image's resolution.

**Only Use Filter in HiQ**

The Scale node will normally use the fast Nearest Neighbor filter for any non-HiQ renders, where speed is more important than full accuracy. Disable this checkbox to force Scale to always use the selected filter for all renders.

**Change Pixel Aspect**

Enable this checkbox to reveal a Pixel Aspect control that can be used to change the image's pixel aspect.
Filter Method

When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called filters. More complex filters can give better results but are usually slower to calculate. The best filter for the job often depends on the amount of scaling and on the contents of the image itself.

- **Box**: This is a simple interpolation resize of the image.
- **Linear**: This uses a simplistic filter, which produces relatively clean and fast results.
- **Quadratic**: This filter produces a nominal result. It offers a compromise between speed and quality.
- **Cubic**: This produces better results with continuous-tone images. If the images have fine detail in them, the results may be blurrier than desired.
- **Catmull-Rom**: This produces good results with continuous-tone images that are resized down. This produces sharp results with finely detailed images.
- **Gaussian**: This is very similar in speed and quality to Bi-Cubic.
- **Mitchell**: This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.
- **Lanczos**: This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.
- **Sinc**: This is an advanced filter that produces very sharp, detailed results; however, it may produce visible “ringing” in some situations.
- **Bessel**: This is similar to the Sinc filter but may be slightly faster.

Window Method (Sinc and Bessel Only)

Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

- **Hanning**: This is a simple tapered window.
- **Hamming**: Hamming is a slightly tweaked version of Hanning that does not taper all the way down to zero.
- **Blackman**: A window with a more sharply tapered falloff.
- **Kaiser**: A more complex window with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter; however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

**NOTE**: Because this node changes the physical resolution of the image, animating the controls is not advised.
Transform Node Introduction

The Transform node can be used for simple 2D transformations of the image, such as moving, rotating, and scaling. The image’s aspect can also be modified using the Transform node.

The Transform node concatenates its result with adjacent Transformation nodes. The Transform node does not change the image’s resolution.

Inputs

The two inputs on the Transform node are used to connect a 2D image and an effect mask, which can be used to limit the transformed area.

- **Input**: The orange input is used for the primary 2D image that gets transformed.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the transform area to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

The Transform node in the example below is inserted between the MediaIn2 node and the foreground input of the Merge. Unlike using a Scale or Resize tool, transforming the MediaIn2 does not change the resolution of the clip. For that reason, it is the tool most often used to scale, move, and rotate a clip.
The Transform node can be used to scale an image without changing its resolution.

**Inspector**

The Transform Controls tab presents multiple ways to transform, flip (vertical), flop (horizontal), scale, and rotate an image. It also includes reference size controls that can reinterpret the coordinates used for width and height from relative values of 0-1 into pixel values based on the image’s resolution.

**Controls Tab**

The Controls tab presents multiple ways to transform, flip (vertical), flop (horizontal), scale, and rotate an image. It also includes reference size controls that can reinterpret the coordinates used for width and height from relative values of 0-1 into pixel values based on the image’s resolution.

**Center X and Y**

This sets the position of the image on the screen. The default is 0.5, 0.5, which places the image in the center of the screen. The value shown is always the actual position multiplied by the reference size. See below for a description of the reference size.

**Pivot X and Y**

This positions the axis of rotation and scaling. The default is 0.5, 0.5, which is the center of the image.
**Use Size and Aspect**

This checkbox determines whether the Transform node provides independent Size controls for the X and Y scale or if Size and Aspect controls are used instead.

**Size**

This modifies the scale of the image. Values range from 0 to 5, but any value greater than zero can be entered into the edit box. If the Use Size and Aspect checkbox is selected, this control will scale the image equally along both axes. If the Use Size and Aspect option is off, independent control is provided for X and Y.

**Aspect**

This control changes the aspect ratio of an image. Setting the value above 1.0 stretches the image along the X-axis. Values between 0.0 and 1.0 stretch the image along the Y-axis. This control is available only when the Use Size and Aspect checkbox is enabled.

**Angle**

This control rotates the image around the axis. Increasing the Angle rotates the image in a counterclockwise direction. Decreasing the Angle rotates the image in a clockwise direction.

**Flip Horizontally and Vertically**

Toggle this control on to flip the image along the X- or Y-axis.

**Edges**

This menu determines how the edges of the image are treated when the edge of the raster is exposed.

- **Canvas**: This causes the edges of the image that are revealed to show the current Canvas Color. This defaults to black with no Alpha and can be set using the Set Canvas Color node.
- **Wrap**: This wraps the edges of the image around the borders of the image. This is useful for seamless images to be panned, creating an endless moving background image.
- **Duplicate**: This causes the edges of the image to be duplicated as best as possible, continuing the image beyond its original size.
- **Mirror**: Image pixels are mirrored to fill to the edge of the frame.

**Filter Method**

When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called filters. More complex filters can give better results but are usually slower to calculate. The best filter for the job often depends on the amount of scaling and on the contents of the image itself.

- **Box**: This is a simple interpolation resize of the image.
- **Linear**: This uses a simplistic filter, which produces relatively clean and fast results.
- **Quadratic**: This filter produces a nominal result. It offers a good compromise between speed and quality.
- **Cubic**: This produces better results with continuous-tone images. If the images have fine detail in them, the results may be blurrier than desired.
— **Catmull-Rom**: This produces good results with continuous-tone images that are resized down. This produces sharp results with finely detailed images.
— **Gaussian**: This is very similar in speed and quality to Bi-Cubic.
— **Mitchell**: This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.
— **Lanczos**: This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.
— **Sinc**: This is an advanced filter that produces very sharp, detailed results; however, it may produce visible “ringing” in some situations.
— **Bessel**: This is similar to the Sinc filter but may be slightly faster.

**Window Method (Sinc and Bessel Only)**
Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

— **Hanning**: This is a simple tapered window.
— **Hamming**: Hamming is a slightly tweaked version of Hanning that does not taper all the way down to zero.
— **Blackman**: A window with a more sharply tapered falloff.
— **Kaiser**: A more complex window with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter; however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

**Example**

Different resize filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, and Bessel.

**Invert Transform**
Select this control to invert any position, rotation, or scaling transformation. This option is useful when connecting the Transform to the position of a tracker for the purpose of reintroducing motion back into a stabilized image.

**Flatten Transform**
The Flatten Transform option prevents this node from concatenating its transformation with adjacent nodes. The node may still concatenate transforms from its input, but it will not concatenate its transformation with the node at its output.
**Reference Size**

The controls under the Reference Size menu do not directly affect the image. Instead they allow you to control how Fusion represents the position of the Transform node’s center.

Normally, coordinates are represented as values between 0 and 1, where 1 is a distance equal to the full width or height of the image. This allows for resolution independence, because you can change the size of the image without having to change the value of the center.

One disadvantage to this approach is that it complicates making pixel-accurate adjustments to an image. To demonstrate, imagine an image that is 100 x 100 pixels in size. To move the center of the image to the right by 5 pixels, we would change the X value of the transform center from 0.5, 0.5 to 0.55, 0.5. We know the change must be 0.05 because \( \frac{5}{100} = 0.05 \).

The Reference Size controls allow you to specify the dimensions of the image. This changes the way the control values are displayed, so that the Center shows the actual pixel positions in the X and Y number fields of the Center control. Extending our example, if you set the Width and Height to 100 each, the Center would now be shown as 50, 50, and we would move it 5 pixels toward the right by entering 55, 50.

Internally, the Transform node still stores this value as a number between 0 to 1, and if you were to query the Center controls value via scripting, or publish the Center control for use by other nodes, then you would retrieve the original normalized value. The change is visible only in the value shown for Transform Center in the node control.

**Reference Width and Height Sliders**

Set these to the width and height of the image to change the way that Fusion displays the values of the Transform node’s Center control.

**Auto Resolution**

Enable this checkbox to use the current frame format settings in Fusion Studio or the timeline resolution in DaVinci Resolve to set the Reference Width and Reference Height values.
The Common Controls

Nodes that handle Transform operations share several identical controls in the Inspector. This section describes controls that are common among Transform nodes.

Inspector

Settings Tab

The Settings tab in the Inspector can be found on every tool in the Transform category. The Settings controls are even found on third-party Transform-type plug-in tools. The controls are consistent and work the same way for each tool.

Blend

The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this will cause the tool to skip processing entirely, copying the input straight to the output.

Process When Blend Is 0.0

The tool is processed even when the input value is zero. This can be useful if the node is scripted to trigger a task, but the node’s value is set to 0.0.
Red/Green/Blue/Alpha Channel Selector
These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur will first be applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deseleting these channels causes the tool to skip processing that channel entirely. Tools that do this will generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

Apply Mask Inverted
Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

Multiply by Mask
Selecting this option will cause the RGB values of the masked image to be multiplied by the mask channel's values. This will cause all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

Use Object/Use Material (Checkboxes)
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels will be used, if present. The specific Material ID or Object ID affected is chosen using the next set of controls.

Correct Edges
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Object ID/Material ID (Sliders)
Use these sliders to select which ID will be used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the viewer. The image or sequence must have been rendered from a 3D software package with those channels included.

Motion Blur
— **Motion Blur**: This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool's predicted motion is used to produce the motion blur caused by the virtual camera's shutter. When the control is toggled off, no motion blur is created.
— **Quality**: Quality determines the number of samples used to create the blur. A quality setting of 2 will cause Fusion to create two samples to either side of an object's actual motion. Larger values produce smoother results but increase the render time.
— **Shutter Angle:** Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one full frame exposure. Higher values are possible and can be used to create interesting effects.

— **Center Bias:** Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.

— **Sample Spread:** Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

**Use GPU**

The Use GPU menu has three settings. Setting the menu to Disable turns off GPU hardware-accelerated rendering. Enabled uses the GPU hardware for rendering the node. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.

**Hide Incoming Connections**

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

**Comments**

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

**Scripts**

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
This chapter details the Virtual Reality (VR) nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

VR Nodes

You can create and fix spherical (360°) video, often described as Virtual Reality, or VR, using Fusion’s set of VR nodes. Dome productions, planetariums, and other special-venue theaters have utilized the flexibility of Fusion and its 3D system to produce and deliver special content for years.

The equirectangular (lat-long) format often used for 360° video is similar to how a globe is represented by a flat world map, with the poles at the top and bottom edges of the image and the forward viewpoint at the center.

TIP: You can create stereo VR using two stacked Lat Long images, one for each eye.

Fusion supports several common spherical image formats and can easily convert between them.

— **VCross and HCross**: VCross and HCross are the six square faces of a cube laid out in a cross, vertically or horizontally, with the forward view in the center of the cross in a 3:4 or 4:3 image.
— **VStrip and HStrip**: VStrip and HStrip are the six square faces of a cube laid vertically or horizontally in a line, ordered as Left, Right, Up, Down, Back, Front (+X, -X, +Y, -Y, +Z, -Z) in a 1:6 or 6:1 image.
— **LatLong**: LatLong is a single 2:1 image in an equirectangular mapping.
You can display both spherical video and live 3D scenes from the comp directly to headsets, including those from Oculus Rift and HTC Vive.

Fusion’s "Fix it in post" tools for VR make it easy to perform several important tasks that are common in these types of productions.

Lat Long Patcher [LLP]

The Lat Long Patcher node

NOTE: The VR category and Lat Long node are available only in Fusion Studio and DaVinci Resolve Studio.

Lat Long Patcher Node Introduction

Equirectangular stitched images often need patches, paintwork, or other VFX applied. The Lat Long Patcher extracts and de-warp a section of a lat-long (equirectangular) image to be treated, and can warp and merge fixes back over the original. You can quickly pick a section of the spherical image to patch or paint, and then apply it back to the original image. Note that matching rotations are used in both Extract and Apply modes, allowing a node's operation to be easily reversed by a copy or instance with the same rotation settings.

Input

The Lat Long Patcher node includes two inputs. The orange input accepts a 2D image in an equirectangular format, where the X-axis represents 0–360 degrees longitude, and the Y-axis represents –90 to +90 degrees latitude. The effect mask input is provided, although rarely used on VR nodes.

— **Image Input:** The orange image input accepts a equirectangular (lat-long) 2D RGBA image.
— **Effect Mask:** The effect mask input is provided, although rarely used on VR nodes.

Basic Node Setup

The Loader node connects to the input on a Lat Long Patcher node. The output of a Lat Long Patcher node is set to Extract. It is then connected to whatever image-processing operation is required. A second Lat Long Patcher node set to Apply takes an input from the processed extraction and merges it over the top of the original source.
Two Lat Long Patchers used to repair a section

Inspector

The Lat Long Patcher Controls tab

Controls Tab

The Controls tab is used to extract and later reapply a section from an equirectangular image. Rotation controls allow you to select the exact portion you need to repair.

Mode

— Extract: Pulls a de-warped 90-degree square image from the equirectangular image.
— Apply: Warps and merges a 90-degree square image over the equirectangular image. Because the square image’s alpha is used, this allows, for example, paint strokes or text drawn over a transparent black background to be applied to the original equirectangular image, avoiding any double-filtering from de-warping and re-warping the original.

Rotation Order

These buttons choose the ordering of the rotations around each axis. For example, XYZ rotates first around the X axis (pitch/tilt), then around the Y axis (pan/yaw), and then around the Z axis (roll). Any of the six possible orderings can be chosen.

Rotation

These dials rotate the spherical image around each of the X, Y, and Z axes, offering independent control over pitch/tilt, pan/yaw, and roll, respectively.
Common Controls

Settings Tab

The Settings tab in the Inspector is duplicated in other VR nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Pano Map [PaM]

The Pano Map node

NOTE: The VR category and Pano Map node are available only in Fusion Studio and DaVinci Resolve Studio.

Pano Map Node Introduction

The Pano Map node converts images from one spherical layout to another, such as from a cube map to an equirectangular format. The node can also perform rotations of the spherical images when converting.

Input

The Pano Map node includes two inputs. The orange input accepts a 2D image in an equirectangular, cube map or other spherical formats. The effect mask input is provided, although rarely used on VR nodes.

— **Image Input:** The orange Image input accepts a spherical formatted 2D RGBA image that gets converted to another spherical format.

— **Effect Mask:** The effect mask input is provided, although rarely used on VR nodes.

Basic Node Setup

In the example below, a Loader node containing a Lat Long image connects to the input on a Pano Map node. The Pano Map node is used to convert the image to an H-Cross format. It is then connected to whatever image-processing operation is required.
Inspector

The Pano Map Controls tab

Controls Tab

The Controls tab is used to determine the format of the input image and the desired output format.

From/To

- **Auto:** Auto detects the incoming image layout from the metadata and image frame aspect.
- **VCross and HCross:** VCross and HCross are the six square faces of a cube laid out in a cross, vertically or horizontally, with the forward view in the center of the cross in a 3:4 or 4:3 image.
- **VStrip and HStrip:** VStrip and HStrip are the six square faces of a cube laid vertically or horizontally in a line, ordered as Left, Right, Up, Down, Back, Front (+X, -X, +Y, -Y, +Z, -Z) in a 1:6 or 6:1 image.
- **LatLong:** LatLong is a single 2:1 image in equirectangular mapping.

Rotation Order

These buttons choose the ordering of the rotations around each axis. For example, XYZ rotates first around the X axis (pitch/tilt), then around the Y axis (pan/yaw), and then around the Z axis (roll). Any of the six possible orderings can be chosen.

Rotation

These dials rotate the spherical image around each of the X, Y, and Z axes, offering independent control over pitch/tilt, pan/yaw, and roll, respectively.

Common Controls

Settings Tab

The Settings tab in the Inspector is duplicated in other VR nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Spherical Camera [3SC]

The Spherical Camera node

Spherical Camera Node Introduction

The Spherical Camera is not located in the VR category of the Effects Library but in the 3D category. However, it is commonly used in creating and fixing VR content, so it is referenced here. The Spherical Camera allows the 3D Renderer node to output an image covering all viewing angles, laid out in several different formats. This image may be used, for example, as a skybox texture or reflection map or viewed in a VR headset. The Image Width setting in the 3D Renderer sets the size of each square cube face so that the resulting image may be a multiple of this size horizontally and vertically.

Spherical Stabilizer

The Spherical Stabilizer node

NOTE: The VR category and Spherical Stabilizer node are available only in Fusion Studio and DaVinci Resolve Studio.

Spherical Stabilizer Node Introduction

VR live action often uses handheld cameras, causing shaky footage to be a common problem. The Spherical Stabilizer node automatically identifies and tracks visible features in the footage, and then analyzes their movement to identify pan, tilt, and roll rotations. After tracking, it is then possible to smooth out or stabilize the rotation of the footage.
**Inputs**

The Spherical Stabilizer node has a single orange input.

— **Image:** This orange image input node requires an image in a spherical layout, which can be any of Lat Long (2:1 equirectangular), Horizontal/Vertical Cross, or Horizontal/Vertical Strip.

**Basic Node Setup**

In the example below, a 2:1 Lat Long image is connected to the input of the Spherical Stabilizer node. Once the image is stabilized, the output of the Spherical Stabilizer node is a steadied clip.

Spherical Stabilizer set up to steady a 2:1 Lat Long clip

**Inspector**

The Spherical Stabilizer Controls tab

**Controls Tab**

The Controls tab contains parameters to initiate the tracking and modify the results for stabilization or smoothing.

**Reject Dominant Motion Outliers While Tracking**

With this control activated (the default setting), features that move contrary to the majority of other features are ignored. This helps ignore the movement of subjects in the shot, preferring stable and consistent markers from the surrounding environment.
Track Controls
These buttons initiate tracking and analysis of the shot. Be aware that the reference frame used for stabilization is set to the first frame tracked.

— Track Backward from End Frame starts tracking backward from the end of the current render range.
— Track Backward from Current Time starts tracking backward from the current frame.
— Stop ceases tracking, preserving all results so far.
— Track Forward from Current Time starts tracking forward from the start of the current render range.
— Track Forward from Start Frame starts tracking forward from the current time.

Append to Track
— Replace causes the Track Controls to discard any previous tracking results and replace them with the newly-created track.
— Append adds the new tracking results to any earlier tracks.

Stabilization Strength
This control varies the amount of smoothing or stabilization applied, from 0.0 (no change) to 1.0 (maximum).

Smoothing
The Spherical Stabilizer node can eliminate all rotation from a shot, fixing the forward viewpoint (Still mode, 0.0) or gently smooth out any panning, rolling, or tilting to increase viewer comfort (Smooth mode, 1.0). This slider allows either option or anything in between.

Offset Rotation
Often a shot is not entirely level and needs the horizon to be realigned, or perhaps a desired pan should be reintroduced after fully stabilizing the shot. The Offset Rotation controls allow additional manual control of the Spherical Stabilizer’s rotation of the footage, for pitch/tilt (X), pan/yaw (Y), and roll (Z), respectively. Rotation is always performed in the order X, Y, Z.

Common Controls
Settings Tab
The Settings tab in the Inspector is duplicated in other VR nodes. These common controls are described in detail in the following “The Common Controls” section.
The Common Controls

Nodes that handle VR operations share a number of identical controls in the Inspector. This section describes controls that are common among VR nodes.

**Inspector**

The VR Common controls

**Settings Tab**

The Settings tab in the Inspector can be found on every tool in the VR category. The controls are consistent and work the same way for each tool.

**Apply Mask Inverted**

Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

**Use GPU**

The Use GPU menu has three settings. Setting the menu to Disable turns off hardware-accelerated rendering using the graphics card in your computer. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.
**Hide Incoming Connections**
Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node are displayed in the Inspector. Dragging a connected node from the node tree into the empty field hides that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line reappears.

**Comments**
The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

**Scripts**
Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 120

Warp Nodes

This chapter details the Warp nodes available in Fusion.

The abbreviations next to each node name can be used in the Select Tool dialog when searching for tools and in scripting references.

For purposes of this document, node trees showing MediaIn nodes in DaVinci Resolve are interchangeable with Loader nodes in Fusion Studio, unless otherwise noted.

Coordinate Space [CdS]

Coordinate Space Node Introduction

The Coordinate Space node changes the coordinate space of the image from rectangular to polar or from polar to rectangular.

Inputs

The two inputs on the Coordinate Space node are used to connect a 2D image and an effect mask, which can be used to limit the distorted area.

- **Input**: The orange input is used for the primary 2D image that is distorted.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the distortion to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

The Coordinate Space node is used below to make a circular pattern based on a Fast Noise, Mosaic Blur (DaVinci Resolve Resolve FX only), and a Transform node. The Crop node at the end is used to set the desired resolution.

The Coordinate Space node can help create motion graphics backgrounds
Example

To demonstrate a basic tunnel effect that can be achieved with this node:

1. Add a Text+ node with some text, and then animate it to move along a path from the top of the frame to the bottom.

2. Connect the output of the Text+ node to a Coordinate Space node.

3. Select Polar to Rectangular from the Shape menu.

As the text moves from top to bottom along the original path, it appears to move from an infinite distance in the Coordinate Space node. It may be necessary to flip the text using a Transform node to make it appear the correct way in the Coordinate Space node. Another common use for the Coordinate Space node is to use it in pairs: two of them set to different Shape settings with a Drip or Transform node in between. When used in this way, the effect gets modified while the image remains the same.

Inspector

The Coordinate Space Controls tab

The Coordinate Space Controls tab

Controls Tab

The Controls tab Shape menu switches between Rectangular to Polar and Polar to Rectangular. Consider the following example to demonstrate the two coordinate spaces.

Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Corner Positioner [CPn]

Corner Positioner Node Introduction

The Corner Positioner can be used to position the four corners of an image interactively. This would typically be used to replace a sign or other rectangular portion of a scene. Connect all corners to Paths or Trackers for animation purposes.

Inputs

The two inputs on the Corner Positioner node are used to connect a 2D image and an effect mask, which can be used to limit the warped area.

- **Input**: The orange input is used for the primary 2D image that is warped.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the Corner Positioner to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

Below, the Corner Positioner is used to position the rectangular corners of the MediaIn2 to fit within a specific area of the MediaIn1 node. A Planar Tracker tracks the background, and then a Planar Transform is used to keep the Corner Positioner in place as the background clip moves. Once the planar tracking is completed, and the Planar Transform is created, the Planar Tracker node is no longer needed, and you can delete it.

The Corner Positioner corner pins a clip in place and uses a Planar Transform to match move it to the background.
Inspector

The Corner Positioner Controls tab

Controls Tab

The Controls tab includes transform and offset adjustments for the four corners of the image.

Mapping Type

This determines the method used to project the image caused by the Corner Positioner. In Bi-Linear mode, a straight 2D warping takes place. In Perspective mode, the image is calculated with the offsets in 2D space and then mapped into a 3D perspective.

Corners X and Y

There are four points in the Corner Positioner. Drag these around to position each corner of the image interactively. Attach these control points to any of the usual modifiers.

The image input is deformed and perspective corrected to match the position of the four corners.

Offset X and Y

These controls can be used to offset the position of the corners slightly. This is useful when the corners are attached to Trackers with patterns that may not be positioned exactly where they are needed.

Common Controls

Settings Tab

The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Dent [Dnt]

The Dent node

Dent Node Introduction
The Dent node creates a circular deformation of an image similar to a Fish Eye Lens effect, with the choice of six different Dent filters.

Inputs
The two inputs on the Dent node are used to connect a 2D image and an effect mask, which can be used to limit the warped area.

— Input: The orange input is used for the primary 2D image that is warped.
— Effect Mask: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the Dent to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup
The Dent node is used below to make a circular pattern based on a Fast Noise and a Mosaic Blur (DaVinci Resolve Resolve FX only). The Crop node at the end is used to set the desired resolution.

The Dent node can help create lens distortion effects or a motion graphics background.

Inspector

The Dent Controls tab
Controls Tab
The adjustments in the Controls tab are used to change the Dent style, position, size, and strength.

Type
Select the type of Dent filter to use from this menu. All parameters for the Dent can be keyframed.

Dent 1
This creates a bulge dent.

Kaleidoscope
This creates a dent, mirrors it, and inverts it.

Dent 2
This creates a displacement dent.

Dent 3
This creates a deform dent.

Cosine Dent
This creates a fracture to a center point.

Sine Dent
This creates a smooth rounded dent.

Center X and Y
This positions the Center of the Dent effect on the image. The default values are 0.5, 0.5, which center the effect in the image.

Size
This changes the size of the area affected by the dent. Animate this slider to make the dent grow.

Strength
This changes the overall strength of the dent.

Common Controls

Settings Tab
The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Displace [Dsp]

Displace Node Introduction

The Displace node uses a map image to displace or refract another image. This is useful for creating a vast range of effects from bevels and heat distortion to glass and water effects.

Inputs

There are three inputs on the Displace node: The primary image, the displacement map foreground image, and an effect mask.

— **Input:** The orange image input is a required connection for the primary image you wish to displace.

— **Foreground Image:** The green input is also required as the image used to displace the background. Once connected, you can choose red, green, blue, alpha, or luminance channel to create the displacement.

— **Effect Mask:** The optional blue effect mask input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the displacement to only those pixels within the mask. An effects mask is applied to the tool after it is processed.

Basic Node Setup

Below, the Displace node uses a Fast Noise to generate the Displace map. Increasing the seethe rate can produce heat distortion or flag waving effects.
Inspector

The Displace Controls tab

Controls Tab

The Controls tab is used to change the style, position, size, strength, and lighting (embossing) of the displacement.

Type

The Type menu is used to choose in what mode the Displace node operates. The Radial mode uses the map image that refracts each pixel out from the center, while X/Y mode provides control over the amount of displacement along each axis individually.

**NOTE:** There is one set of Refraction controls while in Radial mode, and two sets in XY mode—one for each of the X and Y channels.

Center (Radial Only)

The Center control defines the point from which pixels are displaced toward or away.

Refraction Channel

This drop-down menu controls which channel from the foreground image is used to displace the image. Select from Red, Green, Blue, Alpha, or Luminance channels. In XY mode, this control appears twice, once for the X displacement and once for the Y displacement.

Refraction Strength (Radial)

Controls the strength of the refraction. Higher values cause stronger or more pronounced refraction.

X and Y Refraction (X/Y)

Two separate sliders appear to control the Refraction strength along the X- and Y-axis separately. Otherwise, this is exactly like Refraction Strength.
Light Power
This controls the intensity, or strength, of the simulated light, causing bright and dim areas to form according to the contour of the refraction image. Higher values cause the bright and dim areas to be more pronounced.

Light Angle
This sets the angle of the simulated light source.

Spread
This widens the Displacement effect and takes the edge off the Refraction map. Higher values cause the ridges or edges to spread out.

Light Channel
Select the channel from the refraction image to use as the simulated light source. Select from Color, Red, Green, Blue, Alpha, or Luminance channels.

NOTE: The Radial mode pushes pixels inward or outward from a center point, based on pixel values from the Displacement map. The XY mode uses two different channels from the map to displace pixels horizontally and vertically, allowing more precise results. Using the XY mode, the Displace node can even accomplish simple morphing effects. The Light controls allow directional highlighting of refracted pixels for simulating a beveled look.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Drip [DRP]

Drip Node Introduction
The Drip node creates a ripple effect over the entire image, which has the potential to animate outward from a central source. There are a variety of different Drip effects from which to choose.
Inputs
The two inputs on the Drip node are used to connect a 2D image and an effect mask, which can be used to limit the warped area.

- **Input**: The orange input is used for the primary 2D image that is warped.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the warping to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup
Below, the Drip node is used to make rippling water-style effects using a MediaIn node.

The Drip node can be connected directly after a MediaIn node or any node providing a 2D output.

Inspector

The Drip Controls tab

Controls Tab
The Controls tab is used to change the style, position, size, strength, and phase for animating the “ripples” of the Drip.

Shape
Use this control to select the shape of the Drip.

Circular
This creates circular ripples. This is the default Drip mode.

Square
This creates even-sided quadrilateral drips.
Random
This creates a randomly dispersed noise that distorts your image and is similar to a particle effect.

Horizontal
This creates horizontal waves that move in one direction.

Vertical
This creates vertical waves that move in one direction.

Exponential
This creates a Drip effect that looks like a diamond shape with inverted, curved sides (an exponential curve flipped and mirrored).

Star
This creates an eight-way symmetrical star-shaped ripple that acts as a kaleidoscope when the phase is animated.

Radial
This creates a star-shaped ripple that emits from a fixed pattern.

Center X and Y
Use this control to position the center of the Drip effect in the image. The default is 0.5, 0.5, which centers the effect in the image.

Aspect
Control the aspect ratio of the various Drip shapes. A value of 1.0 causes the shapes to be symmetrical. Smaller values cause the shape to be taller and narrower, while larger values cause shorter and wider shapes.

Amplitude
The Amplitude of the Drip effect refers to the peak height of each ripple. Use the slider to change the amount of distortion the Drip applies to the image. A value of 0.0 gives all ripples no height and therefore makes the effect transparent. A maximum Amplitude of 10 makes each ripple extremely visible and completely distorts the image. Higher numbers can be entered via the text entry boxes.

Dampening
Controls the Dampening, or falloff, of the amplitude as it moves away from the center of the effect. It can be used to limit the size or area affected by the Drip.

Frequency
This changes the number of ripples emanating from the center of the Drip effect. A value of 0.0 indicates no ripples. Move the slider up to a value of 100 to correspond with the density of desired ripples.

Phase
This controls the offset of the frequencies from the center. Animate the Phase value to make the ripple emanate from the center of the effect.
Common Controls

Settings Tab

The Settings Tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

Grid Warp [Grd]

The Grid Warp node

Grid Warp Node Introduction

The Grid Warp node is a 2D deformation grid with flexible vertices. The image is deformed so that the source grid matches the destination grid.

Inputs

The two inputs on the Grid Warp node are used to connect a 2D image and an effect mask, which can be used to limit the warped area.

— **Input:** The orange input is used for the primary 2D image that is warped.
— **Effect Mask:** The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the warping to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

Below, two Grid Warp nodes are used to warp different areas of a frame. This can be useful for chaining the framing in a shot or adding slight movement to a still. Using the Copy Src to Dest button, only the area modified by Grid Warp 2 is pasted as the foreground in the Merge.

The Grid Warp can be used to shift areas within a shot for reframing or adding animation to a still.
Inspector

The Grid Warp Controls tab

The Controls tab contains parameters that configure the onscreen grid as well the type of distortion applied when a control point on the grid is moved.

Source and Destination

The Source and Destination buttons determine whether the source grid or destination grid is currently active. Only one grid can be displayed or manipulated at a time. The selected button is highlighted to indicate that it is the currently active grid.

All other controls in this tab affect the grid selected by this control.

Selection Type

These three buttons determine the selection types used for manipulating the points. There are three options available.

Selected

When in Selected mode, adjustments to the grid are applied only to the currently selected points. This mode is identical to normal polyline operation.

Region

In Region mode, all points within the area around the mouse pointer move when the mouse button is clicked. New points that enter the region during the move are ignored. Choosing this option exposes Magnet Distance and Magnet Strength controls to determine the size and falloff of the area.

Magnetic

In Magnetic mode, all points within the area around the mouse pointer move when the mouse button is clicked. New points that enter the region during the move are affected as well. Choosing this option exposes Magnet Distance and Magnet Strength controls to determine the size and falloff of the area.
**Magnet Distance**

The default node for selecting and manipulating the grid is a Magnet node. The magnet is represented in the viewer by a circle around the mouse pointer. The Magnet Distance slider controls how large the region of effect for the magnet is, as in the size of the circle. Drag on the grid and any vertex within the range of the slider moves.

To increase the size of the magnet, increase the value of this slider. Alternately, adjust the size of the magnet by holding down the D key while dragging the mouse.

**Magnet Strength**

The Magnet Strength slider increases or decreases the falloff of the magnet cursor’s effect. At a setting of 0.0, the magnetic cursor has no effect, and vertices do not move at all. As the values increase, the magnet causes a greater range of motion in the selected vertices. Use smaller values for a more sensitive adjustment and larger values for broad-sweeping changes to the grid.

**X and Y Grid Size**

The X and Y Grid Size sliders control the number of divisions in the grid. Where the X and Y divisions intersect, a control vertex is created.

Be aware that changing either of these controls after applying changes in the grid resets the entire grid. Set the X and Y grid sizes to the appropriate resolution before making detailed adjustments to the grid.

**Subdivision Level**

The Subdivision Level determines how many subdivisions there are between each set of divisions. Subdivisions do not generate vertices at intersections. The more subdivisions, the smoother the deformation is likely to be, but the slower it is to render.

**Center**

The Center coordinates determine the exact center of the grid. The onscreen Center control is invisible while editing the grid. Select the Edit Rect mode, and the grid center becomes visible and available for editing.

Use the Center control to move the grid through a scene without affecting the animation applied to the individual vertices. For example, while deforming lips, track the motion of the face with a Tracker, and connect the grid center to the Tracker. This matches the grid with slight movements of the head while focusing on the deformation of the lips.

**Angle**

This Angle control rotates the entire grid.

**Size**

The Size control increases or decreases the scale of the grid.

**Edit Buttons**

There are four edit modes available, each of which can be selected by clicking on the appropriate button.

**Edit None**

Set the grid to Edit None mode to disable the display of all onscreen controls.
**Edit Grid**

The Edit Grid mode is the default mode. While this mode is enabled, the grid is drawn in the viewer, and the control vertices of the grid can be manipulated directly.

**Edit Rectangle**

When the grid is in Edit Rectangle mode, the onscreen controls display a rectangle that determines the dimensions of the grid. The sides of the rectangle can be adjusted to increase or decrease the grid's dimension. This mode also reveals the onscreen Center control for the grid.

**Edit Line**

The Edit Line mode is beneficial for creating grids around organic shapes. When this mode is enabled, all onscreen controls disappear, and a spline can be drawn around the shape or object to be deformed. While drawing the spline, a grid is automatically created that best represents that object. Additional controls for Tolerance, Over Size, and Snap Distance appear when this mode is enabled. These controls are documented below.

**Set Mesh to Entire Image**

The Set Mesh to Entire Image button automatically resets the size of the grid to the exact dimensions of the image. Any adjustments to vertices within the grid are reset.

**Copy Buttons**

These two buttons provide a technique for copying the exact shape and dimensions of the source grid to the destination, or the destination grid to the source. This is particularly useful after setting the source grid to ensure that the destination grid's initial state matches the source grid before beginning a deformation.

**Point Tolerance**

This control is visible only when the Edit Line mode is enabled. The Point Tolerance slider determines how much tessellation the grid applies to match the density of points in the spline closely. The lower this value, the fewer vertices there are in the resulting grid, and the more uniform the grid appears. Higher values start applying denser grids with variations to account for regions in the spline that require more detail.

**Oversize Amount**

This control is visible only when the Edit Line mode is enabled. The Oversize Amount slider is used to set how large an area around the spline should be included in the grid. Higher values create a larger border, which can be useful when blending a deformation back into the source image.

**Snap Distance**

This control is visible only when the Edit Line mode is enabled. The Snap Distance slider dictates how strongly the drawn spline attracts surrounding vertices. If a vertex is close enough to a spline's edge, the vertex moves to line up with the spline. The higher the value, the farther the reach of the spline.

**Right-Click Here for Mesh Animation**

The grids are static by default. Right-clicking on the Right-Click Here for Mesh Animation label provides a contextual menu with options for animating the grid or connecting it to another grid in the composition.

The grid uses a Polychange spline. Any adjustment to the control points adds or modifies the keyframe for all points on that spline.
Right-Click Here for Shape Animation
This label appears only in the Edit Line mode. Right-clicking on the Right-Click Here for Shape Animation label reveals a pop-up menu used to animate the shaping polyline or to connect it to other polylines.

The Grid Warp Render tab

Render Tab
The Render tab controls the final rendered quality and appearance of the warping.

Render Method
The Render Method drop-down menu is used to select the rendering technique and quality applied to the mesh. The three settings are arranged in order of quality, with the first, Wireframe, as the fastest and lowest of quality. The default mode is Render, which produces final resolution, full-quality results.

Anti-Aliasing
The Anti-Aliasing control appears only as a checkbox when in Wireframe Render mode.
In other modes, it is a drop-down menu with three levels of quality. Higher degrees of anti-aliasing improve image quality dramatically but vastly increase render times. The Low setting may be an appropriate option while setting up a large dense grid or previewing a node tree, but rarely for a final render.

Filter Type
When the Render Method is set to something other than Wireframe mode, the Filter Type menu is visible and set to Area Sample. This setting prevents the grid from calculating area samples for each vertex in the grid, providing good render quality. Super Sample can provide even better results but requires much greater render times.

Wireframe Width
This slider appears only when the Render Method is set to Wireframe. It determines the width of the lines that make up the wireframe.

Anti-Aliased
This checkbox appears only when the Render Method is set to Wireframe. Use this checkbox to enable/disable anti-aliasing for the lines that make up the wireframe.
**Black Background**
The Black Background checkbox determines whether pixels outside of the grid in the source image are set to black or if they are preserved.

**Object ID and Material ID**
Enable the Object ID or Material ID checkboxes to have the grid output the proper ID channel in the final render.

**Set Image Coordinates at Subdivision Level**
This checkbox defaults to enabled and sets the image coordinates at the subdivision level.

**Force Destination Render**
This checkbox defaults to enabled and forces a destination render.

**Contextual Menu Options**
The Grid Warp node places a submenu for both source and destination grids in the viewer’s contextual menu. Both menus have the exact same name, where only the menu for the active grid is populated with options. The other menu is empty. The contextual menu options are also available from the toolbar that appears in the viewer.

![Grid Warp Contextual Menu options](image)

**Modify Only/Done**
These two options set the mesh to Modify Only and Done modes, respectively. Select Modify Only to edit the mesh or Modify Done to prevent any further changes to a mesh.
Smooth/Linear
Use Smooth and Linear options to apply or remove smoothing from selected vertices.

Auto Smooth Points
When Auto Smooth Points is enabled, the vertices in the grid are automatically smoothed whenever they are moved. This is generally enabled by default.

Z Under/Z Same/Z Over
When two vertices in a grid overlap, one ends up getting clipped by the other. Z Under, Z Same, and Z Over are used to select which vertices are rendered on top and which are rendered behind.

Select All
This option selects all points in the mesh.

Show Key Points, Handles, Grid, and Subdivisions
Use these four options to enable or disable the display of the grid, key points (vertices), Bézier handles, and subdivisions in the viewers.

Reset Selected Points
This resets Selected Points (vertices) to their default positions.

Reset All Points
This resets all points (vertices) in the mesh to their default positions.

Stop Rendering
This option stops rendering, which disables all rendering of the Grid Warp node until the mode is turned off. This is frequently useful when making a series of fine adjustments to a complex grid.

Grid Warp Toolbar
Whenever the Grid Warp node is selected and is in Edit Grid mode, the Grid Warp toolbar is displayed in the views. This toolbar provides a variety of options for manipulating and adjusting the grid. The toolbar buttons in this toolbar are described in the preceding "Contextual Menu Options" section.

The Grid Warp viewer toolbar

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
**Lens Distort Node Introduction**

This node can be used to remove or add lens distortion in an image. The lens distortion in an image depends on the lens, quality, number of elements, and many other factors.

One reason to remove lens distortion is to composite with an undistorted layer. For example, compositing a 3D element over a distorted live-action layer will cause unwanted effects like straight lines not matching up on the foreground and background. The resulting composite will not look believable.

**Inputs**

The two inputs on the Lens Distort node are used to connect a 2D image and an effect mask, which can be used to limit the distorted area.

- **Input**: The orange input is used for the primary 2D image that is distorted.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the distortion to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

**Basic Node Setup**

A simplified example below applies the Lens Distort in Undistort mode to the MediaIn1 live-action layer, composites the 3D elements, and finally applies the Lens Distort at the end with the same settings, but this time in Distort mode to get the original look and distortion back into the image.

Lens Distort applied on the live-action media at the beginning of the node tree, and once again at the end.
The Lens Distort Controls tab

Controls Tab
The Controls tab presents various ways to customize or build the lens distortion model you want. Camera Settings allow you to specify the camera used to capture the content.

Mode
Undistort removes the lens distortion to create a flattened image. Distort brings the original lens distortion back into the image.

Edges
Determines how samples that fall outside the frame are treated.

— **Canvas**: Pixels outside the frame are set to the default canvas color. In most cases, this is black with no alpha.

— **Duplicate**: Pixels outside the frame are duplicated. This results in “smeared” edges but is useful when, for example, applying a blur because in that case black pixels would result in the unwanted blurring between the actual image and the black canvas.
Clipping Mode
— **Domain:** Retains all pixels that might be moved out of the frame for later re-distorting.
— **Frame:** Pixels moved outside the frame are discarded.

Output Distortion Map
Outputs the location of pixels as a warped screen-coordinate map.

Camera Settings
The options known from the Camera 3D are duplicated here. They can either be set manually or connected to an already existing Camera 3D.

Lens Distortion Model
Select the appropriate 3D Equalizer Lens Distortion model here: 3DE Classic Model, 3DE4 Anamorphic, 3DE4 Radial Fisheye, or 3DE4 Radial. Please consult the 3D Equalizer manual for further explanation. The sliders in the 3DE Classic LD Model are most likely best suited for manually applying (un)distortion, without having imported lens data.

Supersampling [HiQ]
Sets the number of samples used to determine each destination pixel. As always, higher supersampling leads to higher render times. 1×1 bilinear is usually of sufficient quality, but with high lens distortion near the edges of the lens, there are noticeable differences to higher settings.

Supersampling Mode [HiQ]
The type of sample done for each supersample. Nearest leads to a crisper but more aliased image. Bi-Linear gives a blurrier result.

Load Distortion Data
Allows the user to load a Lens Distortion profile created, for example, by the 3D Equalizer.

How to Manually Determine Lens Distortion
In an ideal world, one would have exact lens parameters from each lens that was used during the shoot, and one could use those values to undistort the image. However, in the real world, those parameters have not been taken on set or don’t match. Another approach is to use software like 3D Equalizer, which analyzes the footage and delivers a dataset that can be imported into the Lens Distort node right away.

And finally, one could try to manually eyeball the amount of lens distortion using the control sliders. To do that, one could either look for horizontal or vertical lines in the footage that are supposed to be straight and straighten them out using the controls, or shoot a full-frame checkerboard pattern on set as a reference.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Perspective Positioner Node Introduction

The Perspective Positioner is the complementary node to the Corner Positioner node. It “unpins” an image by positioning corner points on a perspective distorted area, thereby removing the perspective from the image. This function can also be used to wobble and warp the image by animating the points over time.

Inputs

The two inputs on the Perspective Positioner node are used to connect a 2D image and an effect mask, which can be used to limit the transformed area.

- **Input**: The orange input is used for the primary 2D image that is transformed.
- **Effect Mask**: The blue input is for a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the transform to only those pixels within the mask. An effects mask is applied to the tool after the tool is processed.

Basic Node Setup

In the example below, the Perspective Positioner is used to unpin a perspective distorted area of the MedianIn2 in order to paint on the flat texture. The MedianIn2 is then corner pinned back into place. The Perspective Positioner and Corner Positioner do not concatenate, so some softness is introduced with these nodes.

The Perspective Positioner unpins an image to paint on a texture map.
The Perspective Positioner Controls tab

**Controls Tab**

The Controls tab contains parameters for selecting vector channels and controlling how much distortion they apply to an image.

**Mapping Type**

The Mapping Type menu is used to select the type of transform used to distort the image. Bi-Linear is available for support of older projects. Leaving this on Perspective is strongly suggested since the Perspective setting maps the real world more accurately.

**Corners X and Y**

There are the four control points of the Perspective Positioner. Interactively drag these in the viewers to position each corner of the image. You can refine their position using the Top, Bottom, Left, and Right controls in the Inspector.

**Common Controls**

**Settings Tab**

The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.

**Vector Distortion [Dst]**

The Vector Distortion node

**Vector Distortion Node Introduction**

The Vector Distortion node distorts the main source image along the X- and Y-axis separately, based on the vector channel data in the source image or vector channels from a second reference image.
**Inputs**

There are three inputs on the Vector Distort node for the primary 2D image, the distort image with vector channels and an effect mask.

- **Input:** The orange image input is a required connection for the primary image you wish to distort. If this image has vector channels, they are used in the distortion.

- **Distort:** The green input is an optional distort image input used to distort the background image based on vector channels. Once connected, it overrides vector channels in the input image.

- **Effect Mask:** The optional blue effect mask input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the displacement to only those pixels within the mask. An effects mask is applied to the tool after it is processed.

**Basic Node Setup**

In the example below, the MediaIn1 node uses an Optical Flow node to generate the vector channels, which are then passed on to the Vector Distort node. MediaIn2 is distorted and composited over the background.

![Basic Node Setup Diagram]

The Vector Distort node relies on the image having vector channels or an Optical Flow node to generate them.

**Inspector**

![Inspector Diagram]

The Vector Distortion Controls tab
Controls Tab
The Controls tab contains parameters for selecting vector channels and controlling how much distortion they apply to an image.

X Channel and Y Channel
These two menus are used to select which channel of the (green) distort image input is used to distort the X and Y channels. If no distort reference image is connected, then channels from the main orange input are used instead.

Flip Channel X and Flip Channel Y
Use these checkboxes to flip the direction of the distortion along the specified axis.

Lock Scale X/Y
Select this checkbox to separate the Scale slider into separate Scale X and Scale Y sliders.

Scale
Use the Scale slider to apply a multiplier to the values of the distortion reference image.

Lock Bias X/Y
Select this checkbox to separate the Bias slider into separate Bias X and Bias Y sliders.

Center Bias
Use the Center Bias slider to shift or nudge the distortion along a given axis.

Edges
This menu determines how the edges of the image are treated.

— Canvas: This causes the edges that are revealed by the shake to be the canvas color—usually transparent or black.
— Duplicate: This causes the edges to be duplicated, causing a slight smearing effect at the edges.

Glow
Use this slider to add a glow to the result of the vector distortion.

Common Controls

Settings Tab
The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail at the end of this chapter in “The Common Controls” section.
Vortex [VTX]

The Vortex node

Vortex Node Introduction

The Vortex effect appears as a swirling whirlpool in specified regions of the image. The Vortex can be made to move and grow by animating the various controls.

Inputs

There are two inputs on the Vortex node for the primary 2D image and the effect mask.

- **Input**: The orange image input is a required connection for the primary image you wish to swirl.
- **Effect Mask**: The optional blue effect mask input expects a mask shape created by polylines, basic primitive shapes, paint strokes, or bitmaps from other tools. Connecting a mask to this input limits the swirling vortex to only those pixels within the mask. An effects mask is applied to the tool after it is processed.

Basic Node Setup

Below, the Vortex is applied to text for creating motion graphics. Since the Vortex will cause the text to swirl outside the text boundary, a Set Domain node is used to expand the text boundary, ensuring that the text is not cropped when the Vortex is applied.

The Vortex is used to create swirling whirlpool effects.
Inspector

The Vector Distortion Controls tab

Controls Tab
The Controls tab contains parameters for adjusting the position, size, and strength of the Vortex effect.

Center X and Y
This control is used to position the center of the Vortex effect on the image. The default is 0.5, 0.5, which positions the effect in the center of the image.

Size
Size changes the area affected by the Vortex. You can drag the circumference of the effect in the viewer or use the Size slider.

Angle
Drag the rotation handle in the viewer or use the thumbwheel control to change the amount of rotation in the Vortex. The higher the angle value, the greater the swirling effect.

Power
Increasing the Power slider makes the Vortex smaller but tighter. It effectively concentrates it inside the given image area.

Common Controls
Settings Tab
The Settings tab in the Inspector is also duplicated in other Warp nodes. These common controls are described in detail in the following "The Common Controls" section.
The Common Controls

Nodes that handle Warp operations share a number of identical controls in the Inspector. This section describes controls that are common among Warp nodes.

Inspector

**Settings Tab**

The Settings tab in the Inspector can be found on every tool in the Warp category. The Settings controls are even found on third-party Warp-type plug-in tools. The controls are consistent and work the same way for each tool.

**Blend**

The Blend control is used to blend between the tool’s original image input and the tool’s final modified output image. When the blend value is 0.0, the outgoing image is identical to the incoming image. Normally, this will cause the tool to skip processing entirely, copying the input straight to the output.
**Process When Blend Is 0.0**
The tool is processed even when the input value is zero. This can be useful if the node is scripted to trigger a task, but the node’s value is set to 0.0.

**Red/Green/Blue/Alpha Channel Selector**
These four buttons are used to limit the effect of the tool to specified color channels. This filter is often applied after the tool has been processed.

For example, if the Red button on a Blur tool is deselected, the blur will first be applied to the image, and then the red channel from the original input will be copied back over the red channel of the result.

There are some exceptions, such as tools for which deselecting these channels causes the tool to skip processing that channel entirely. Tools that do this will generally possess a set of identical RGBA buttons on the Controls tab in the tool. In this case, the buttons in the Settings and the Controls tabs are identical.

**Apply Mask Inverted**
Enabling the Apply Mask Inverted option inverts the complete mask channel for the tool. The mask channel is the combined result of all masks connected to or generated in a node.

**Multiply by Mask**
Selecting this option will cause the RGB values of the masked image to be multiplied by the mask channel’s values. This will cause all pixels of the image not included in the mask (i.e., set to 0) to become black/transparent.

**Use Object/Use Material (Checkboxes)**
Some 3D software can render to file formats that support additional channels. Notably, the EXR file format supports Object ID and Material ID channels, which can be used as a mask for the effect. These checkboxes determine whether the channels will be used, if present. The specific Material ID or Object ID affected is chosen using the Object and Material ID sliders explained below.

**Correct Edges**
This checkbox appears only when the Use Object or Use Material checkboxes are selected. It toggles the method used to deal with overlapping edges of objects in a multi-object image. When enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. If this option is disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

**Object ID/Material ID (Sliders)**
Use these sliders to select which ID will be used to create a mask from the object or material channels of an image. Use the Sample button in the same way as the Color Picker: to grab IDs from the image displayed in the viewer. The image or sequence must have been rendered from a 3D software package with those channels included.
Motion Blur

- **Motion Blur**: This toggles the rendering of Motion Blur on the tool. When this control is toggled on, the tool’s predicted motion is used to produce the motion blur caused by the virtual camera’s shutter. When the control is toggled off, no motion blur is created.

- **Quality**: Quality determines the number of samples used to create the blur. A quality setting of 2 will cause Fusion to create two samples to either side of an object’s actual motion. Larger values produce smoother results but increase the render time.

- **Shutter Angle**: Shutter Angle controls the angle of the virtual shutter used to produce the motion blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one full frame exposure. Higher values are possible and can be used to create interesting effects.

- **Center Bias**: Center Bias modifies the position of the center of the motion blur. This allows for the creation of motion trail effects.

- **Sample Spread**: Adjusting this control modifies the weighting given to each sample. This affects the brightness of the samples.

Use GPU

The Use GPU menu has three settings. Setting the menu to Disable turns off GPU hardware-accelerated rendering. Enabled uses the GPU hardware for rendering the node. Auto uses a capable GPU if one is available and falls back to software rendering when a capable GPU is not available.

Hide Incoming Connections

Enabling this checkbox can hide connection lines from incoming nodes, making a node tree appear cleaner and easier to read. When enabled, empty fields for each input on a node will be displayed in the Inspector. Dragging a connected node from the node tree into the field will hide that incoming connection line as long as the node is not selected in the node tree. When the node is selected in the node tree, the line will reappear.

Comments

The Comments field is used to add notes to a tool. Click in the empty field and type the text. When a note is added to a tool, a small red square appears in the lower-left corner of the node when the full tile is displayed, or a small text bubble icon appears on the right when nodes are collapsed. To see the note in the Node Editor, hold the mouse pointer over the node to display the tooltip.

Scripts

Three Scripting fields are available on every tool in Fusion from the Settings tab. They each contain edit boxes used to add scripts that process when the tool is rendering. For more details on scripting nodes, please consult the Fusion scripting documentation.
Chapter 121

Modifiers

This chapter details the modifiers available in Fusion.

Contents

Modifiers 2657
Anim Curves 2657
Bézier Spline 2660
B-Spline 2662
Calculation 2662
CoordTransform Position 2665
Cubic Spline 2666
Custom Poly 2666
Expression 2669
From Image 2674
Gradient Color 2676
Key Stretcher Modifier 2678
MIDI Extractor 2678
Natural Cubic Spline 2681
Offset (Angle, Distance, Position) 2682
Path 2685
Perturb 2687
Probe 2689
Publish 2691
Resolve Parameter 2691
Shake 2692
Track 2693
Vector Result 2695
XY Path 2697
Modifiers

Modifiers are extensions to a node’s standard set of parameters found in the Inspector; in fact, modifiers are designed to control other parameters. They can be as simple as a motion path or linking two parameters. However, they can also be elaborate expressions, procedural functions, external data, third-party plug-ins, or scripted Fuses. You can add modifiers by right-clicking over a parameter in the Inspector and choosing a modifier from the menu. Alternatively, you can right-click a control in the viewer. Not all modifiers are displayed in the right-click menu for all parameters. Some modifiers work only on specific parameter types.

**NOTE:** Text3D and Text+ have additional text-specific modifiers, which are covered in their nodes’ sections.

Anim Curves

The Animation Curves modifier (Anim Curves) is used to dynamically adjust the timing, values, and acceleration of an animation, even if you decide to change the duration of a comp. Using this modifier makes it infinitely easier to stretch or squish animations, create smooth motion, add bouncing properties, or mirror animations curves without the complexity of manually adjusting splines.
When creating Fusion templates for the Edit and Cut page in DaVinci Resolve, the Anim Curves modifier allows the keyframed animation you’ve created in Fusion to stretch and squish appropriately as the transition, title, or effect’s duration changes on the Edit and Cut page Timelines.

**Curve Shape Controls**

The controls for the Anim Curves modifier appear in the modifier’s tab of the Inspector. The Curve Shape controls determine the acceleration or shape of the animation curve.

— **Source**: This drop-down menu has three options based on how the comp is created from DaVinci Resolve’s Edit page.
  - **Transition**: This setting is automatically selected when the comp is created from an Edit page transition effect. If the duration of the transition is updated in the Edit page, the timing of the animation updates as well.
  - **Duration**: Use this setting when the comp is created from a clip on the Edit page. The animation timing will update if the clip’s duration changes by trimming.
  - **Custom**: Displays an Input dial to manually control the timing.

— **Input**: This dial is only visible when Source is set to Custom. It is used to change the input keyframe value.

— **Curve**: The Curve drop-down menu selects the interpolation method used between keyframes. The three choices are: linear, easing, or custom.
  - **Linear**: The default Linear interpolation method maintains a fixed, consistent acceleration between keyframes.
  - **Easing**: Displays interpolation menus for both the start of the curve (In) and the end of the curve (Out).
  - **Custom**: Opens a mini Spline Editor to customize the interpolation from the start of the animation to the end.

— **Mirror**: Plays the animation forward, and after reaching the end, it returns to the starting value. This causes the initial animation to be twice as fast, since the second half of the comp is used for the reverse animation.

— **Invert**: Flips the animation curve upside-down so that the values start high and end low.
Scaling

The Scale parameters modify the animation values using relative adjustments.

— **Scale**: This number is a multiplier applied to the value of the keyframes. If the Scale value is 2 and a keyframe has a value of 0, it remains 0. If the Scale value is 2 and a keyframe has a value of 10, the result is as if the keyframe is set to 20. This can be thought of as the ending value for the animation. It is best to set this while viewing the last frame in the comp.

— **Offset**: The offset is added to the keyframe values and can be thought of as the starting value for the animation. It is best to set this while viewing the first frame in the comp.

— **Clip Low**: Ensures the output value never dips below 0.0.

— **Clip High**: Ensures the output value never exceeds 1.0.

Timing

The Timing parameters adjust the animation timing using relative values.

— **Time Scale**: Stretches or squishes the animation, causing it to run faster or slower. A value of 1.0 keeps the animation running for the comp’s duration (unless you have customized the animation using other controls in the Modifier).

— **Time Offset**: This value delays the animation as a fraction of its total duration. A value of 0.0 applies no delay. A value of 0.5 delays the animation starting point midway into the comp’s duration.

Using the Anim Curves Modifier to Create a Custom Transition

To understand how to use the Anim Curves modifier for a transition, let’s create a simple scaling dissolve.

1. Add a standard cross dissolve in the Edit page Timeline.
2. Right-click over the transition and choose Convert to Fusion Cross Dissolve.
3. Right-click over the transition again and choose Open in Fusion page.
4. Add a Transform node to MediaIn1 and to MediaIn2.
5. Select the Transform node attached to the MediaIn2.
6. In the Inspector, right-click the Size control, then choose Modify With > Anim Curves from the contextual menu. Adding this modifier to the Size control will cause the slider to animate from 0 to 1 for the Cross Dissolve’s duration.
7. Select the Transform node attached to the MediaIn1.
8. In the Inspector, right-click the Size control, then choose Modify With > Anim Curves from the contextual menu.
9. At the top of the Inspector, click the Modifier tab and click the Invert button. Inverting the animation curves causes MediaIn1 to scale opposite of MediaIn2.
10. In the Modifiers tab, set the Curve drop-down menu to Easing, and experiment with the different ease-in ease-out curve types from the In/Out drop-down menus.

Once you create a Macro from this node tree and save it as a Transition template, you can apply it in the Edit page Timeline. If you change the transition duration in the Edit page, the animation timing will update appropriately.
Using the Anim Curves Modifier with Paths

To understand how to use the Anim Curves modifier with a Path modifier, let’s use the premise that you want to create text that falls from the top of the frame and bounces as it reaches the bottom of the frame.

1. In Fusion, create two keyframes that cause text to start at the top of the frame and drop to the bottom. This automatically creates a Path modifier.

2. In the Inspector’s Modifier tab, right-click over the Displacement parameter and choose Insert > Anim Curves. The animation is normalized to the duration of the comp.

3. Set the Source menu to Duration, since this is not a transition and we are not customizing the duration.

4. From the Curve menu, choose Easing, then for the Out menu, choose Bounce.

5. Play the animation to see the Bounce animation.

6. To make the bounce occur halfway down the frame, change the Scale to .05.

7. To make the animation run twice as fast, enter 2.0 in the Time Scale parameter.

Once you create a macro from this node tree and save it as a Title template, you can apply it in the Edit page Timeline. If you change the title’s duration in the Edit page, the animation timing will update appropriately.

**TIP:** To view the resulting animation curve in the Spline Editor, select the parameter name in the Spline Editor’s header. The spline is updated as you change the controls.

Bézier Spline

The Bézier Spline is one of the animation modifiers in Fusion and is typically applied to numerical values rather than point values. It is automatically applied when you keyframe a parameter or each time you right-click a number field and select Animate.
Usage

You can add the Bézier Spline to the Spline Editor by right-clicking a number field and selecting BezierSpline. Since this is the most common choice for animation splines, it is separated from the Modify With menu for quicker access. Selecting BezierSpline from the menu adds a keyframe at the current location and displays a Bézier Spline in the Spline Editor.

Bézier Spline Editor

Unlike most modifiers, this modifier has no actual Controls tab in the Inspector. However, the Spline Editor displays the Bézier Spline, and it can be controlled there. The Bézier Spline offers individual control over each control point’s smoothness using Bézier handles. The smoothness is applied in multiple ways:

— To make the control points smooth, select them, and press Shift-S. The handles can be used to modify the smoothness further.
— To make the control points linear, select them, and press Shift-L. These operations can also be performed using the contextual menu.
— Select the control point(s), right-click, and select Smooth or Linear. The menu also allows the user to smooth a spline using a convolution analysis called a Savitzky-Golay filter. Select the control point(s), right-click, and select Smooth Points -Y Dialog.

Ease In/Out

Traditional Ease In/Out can also be modified by using the number field virtual sliders in the Spline Editor. Select the control points you want to modify, right-click, and select Ease In/Out... from the contextual menu. Then use the number field virtual sliders to control the Ease In/Out numerically.

Spline Ease In/Out modifier
B-Spline

An alternative to the Bézier Spline, B-spline is another animation modifier in Fusion and is typically applied to numerical values rather than point values. It is applied by right-clicking a parameter and selecting Modify With > B-Spline.

Usage

— This animation spline modifier has no actual Controls tab. However, the Spline Editor displays the B-spline, and it can be controlled there. Notice that, though the actual value of the second keyframe is 0, the value of the resulting spline is 0.33 due to the unique smoothing and weighing algorithms of a B-spline.
— The weight can be modified by clicking the control point to select it, holding the W key, and moving the mouse left and right to lower or increase the tension. This is also done with multiple selected control points simultaneously.

Calculation

Calculations are used to create indirect connections between parameters. A Calculation can perform a mathematical expression based on two operands, where each operand can be connected to another parameter or set manually.

Additionally, using Time offsets and Scale controls in the Time tab, the Calculation control can access values of a parameter at times other than the current time.

The Calculation’s most common use is for connecting two parameters when one value range or scope is inappropriate for the other parameter.

NOTE: The Expression modifier is essentially a more flexible version of the Calculation modifier, with a single exception. It is far easier to manipulate the timing of the operands provided in the Calculation modifier than it is to do so with an Expression.
The Calc tab includes two dials used for the connected parameter and value that gets mathematically combined. The Operator menu selects how the Second Operand value combines with the parameter’s value.

**First and Second Operand**
These sliders are connected to published or animated parameters or manually set to the desired values for the calculation.

**Operator**
Select from the mathematical operations listed in this menu to determine how the two operands are combined. Clicking the drop-down arrow opens the menu with the following options:

- Add
- Subtract (First - Second)
- Multiply
- Divide (First / Second)
- Divide (Second / First)
- Subtract (Second - First)
- Minimum
- Maximum
- Average
- First only

The Time tab is used to modify the time of the Calculation modifier. The controls here retime the speed of the effect or offset it in time.

**First and Second Operand Time Scale**
These sliders multiply the frame number and return the value of the operands at the multiplied frame number. A value of 1 returns the value of the operand at frame x when the composition is on frame x. For example, if the first operand is animated with a value of 1 to 50 from frame 0 to 10, then a scale of 0.5 would cause the calculation to return a value of 25 at frame 10 (effectively slowing the animation by half for the purposes of the calculation).
First Operand and Second Operand Time Offset

These sliders return the value of the operand at the Time Offset specified. A value of 10 would return the value of the operand 10 frames forward in time, and -10 would return the value of the operand 10 frames back in time. See the example below for a practical example.

Example

The following example uses a calculation to apply blur to a Text node in inverse proportion to the size of the text.

1. Open a new composition that starts on frame 0 and ends on frame 100.
2. At frame 0, add a Text+ node to the composition.
3. Enter a small amount of text and set the size to 0.05
4. Click the Keyframe button to the right of the Size slider to add a keyframe.
5. Move to frame 100 and set the Size value to 0.50.
6. Connect a Blur node after the Text+ node.
7. View the Blur node in one of the viewers.
   To have the blur decrease in strength as the text gets bigger, a simple “pick whip”-style parameter linking does not work. The controls cannot be directly connected together because the values of the Text Size control are getting bigger instead of smaller.
8. Right-click the Blur Size and select Modify With > Calculation from the contextual menu.
   This adds a Calculation modifier to the Blur node. At the top of the Inspector, a new set of controls appears in the Modifiers tab while the Blur node is selected.
9. At the top of the Inspector, select the Modifiers tab (F11).
10. Right-click the First Operand slider and select Connect To > Text 1 > Size from the contextual menu.
   Although the Blur Size is now connected to the Text Size parameter, this connection isn’t very useful. The maximum value of the Blur Size control is 0.5, which is hardly noticeable as a blur.
11. Set the Operator drop-down menu to Multiply.
12. Set the Second Operand slider to 100.
   Now the first operand is multiplied by 100, and adjusting the dial gives you a much blurrier blur.
13. Switch to the Time tab of the modifier and set the First Operand Time Scale to -1.0.
   Normally, the first operand gets the value of the control it is connected to from the same frame as the current time. So at frame 10, the first operand is set to the same value as the Text size at frame 10. By setting this value to -1, the value is read from one frame back in time whenever the current time of the composition advances by 1 frame.
   However, this means that the Calculation would be reading the value of the Text size at frame -10 when we are at frame 10 in the composition.
To correct for this, set the First Operand Time Offset slider to 100.

Return to the Tools tab at the top of the Inspector and press Play (Spacebar) to watch how the value of the Blur Size relates to the value of the Text Size.

CoordTransform Position

Because of the hierarchical nature of 3D in Fusion, the original position of an object in a 3D scene often fails to indicate the current position of the object. For example, an image plane might initially have a position at 1, 2, 1, but then be scaled, offset, and rotated by other tools further downstream in the node tree, ending up with an absolute location of 10, 20, 5. This can complicate connecting an object further downstream in the composition directly to the position of an upstream object. The Coordinate Transform modifier can be added to any set of the XYZ coordinate controls to calculate the current position of a given object at any point in the scene hierarchy. To add a Coordinate Transform modifier, right-click the numeric input on any node, and select Modify With > CoordTransform Position from the contextual menu.

Inspector

The Coordinate Transform modifier Controls tab

Controls Tab

The Controls tab has two fields for the target and scene input. The target is for the node continuing the original coordinates, while the scene input is used for the scene with the new coordinates.

Target Object

This control is connected to the 3D tool that produces the original coordinates to be transformed. To connect a tool, drag the node from the Node Editor into the text edit control, or right-click the control and select the tool from the contextual menu. It is also possible to type the tool's name directly into the control.

SubID

The SubID slider can be used to target an individual sub-element of certain types of geometry, such as an individual character produced by a Text 3D tool or a specific copy created by a Duplicate 3D tool.
Scene Input
This control should be connected to the 3D tool, which outputs the scene containing the object at the new location. To connect a tool, drag and drop a tool tile from the Node Editor into the text edit control, or right-click the control and select an object from the Connect To pop-up menu.

Cubic Spline
The Cubic Spline is another animation modifier in Fusion that is normally applied to numerical values rather than point values. It can be applied by right-clicking a numerical control and selecting Modify With > Natural Cubic Spline.

Usage
Being an animation spline, this modifier has no actual Controls tab. However, its effect can be seen and influenced in the Spline Editor.

Custom Poly
The Custom Poly modifier can be added to Polygon masks or paths. Similar in function to the Custom and pCustom tools, existing points can be repositioned in the polyline, or replaced completely with a new set of points. The expressions are evaluated for each point on the output polygon. The modifier can be applied by right-clicking on the “Right-click here for shape animation” text at the bottom of the Polygon controls, and selecting Insert > Custom Poly from the contextual menu.
Selecting the Custom Poly modifier

**Inspector**

The Custom Poly Controls tab
Controls Tab

The Custom Poly Controls tab are available once you select the modifiers tab on the Polygon’s inspector. It has a single point input, and number variables to use in animating the expressions. The default is one point and four numbers, but they can be expanded to a maximum of nine. Additional points and numbers can be added from the Config tab.

Polyline Tab

The polyline tab exposes the controls to connect and modify the polyline.

Connect Source Polyline here

Allows you to connect other polylines to the modifier.

Show View Controls

This checkbox toggles the polyline controls visibility in the viewer.

Number of Points

The number of output points can be set, controlling the amount of custom subdivision of the polyline. A value of zero uses the number of original source points.

Poly Expression X/Y

Fields for entering the mathematical expressions. For example, \( px^*(1-n1)+n1*get2x(disp) \) and \( py^*(1-n1)+n1*get2y(disp) \).

It uses most of the same expression variables as the Expression modifier below (i.e., \( n1..n9, p1x..p9x, p1y..p9y \), math functions, etc.), and it adds:

- \( px,py \) for the current point on the source polygon
- \( disp \) for the point’s displacement on the polyline (0.0 is start, 1.0 is end)
- \( index \) for the current point’s index (zero-based)
- \( num \) for the number of output points
- \( getx(disp), gety(disp) \) to get values from anywhere on the polyline
— getx_at(disp, time), gety_at(disp, time) to get values from polylines at other times
— Similarly, get2x/y(), get3x/y(), get2x/y_at(), get3x/y_at() for the second & third source polys

**Config Tab**
The config tab allows you to select the amount of Points and Numbers shown in the modifier (to a maximum of 9), and to give them custom names for easier organization.

**Expression**
An expression is a variable or a mathematical calculation added to a parameter, rather than a straight numeric value. You can add an expression to any parameter in Fusion, or you can add the Expression modifier, which adds several tabs to the modifier Inspector. Adding this modifier to a parameter adds the ability to manipulate that parameter based on any number of controls, either positional or value-based. This modifier offers exceptional flexibility compared to the more limited Calculation or Offset modifiers, but it is unable to access values from frames other than the current time.

The Expression modifier accepts nine value inputs and nine position inputs that are used as part of a user-defined mathematical expression to output a value.

To add the Expression modifier to a parameter, right-click the parameter in the Inspector and choose Modify With > Expression from the contextual menu. The type of value returned by the Expression depends entirely on the type of control it is modifying.

When used with a value control (like a slider), the Expression in the Number Out tab is evaluated to create the result. When used to modify a positional control (like Center), the Point Out tab controls the result.

The Inspector’s Modifiers tab contains the controls for the Expression modifier, described below.

**Inspector**

![Expressions modifier controls](image-url)
Controls Tab

This tab provides nine number controls and nine point controls. The values of the number controls can be referred to in an expression as n1 through n9. The X-coordinate of each point control can be referred to as p1x through p9x, while the Y-coordinate is p1y through p9y.

These values can be set manually, connected to other parameters, animated, and even connected to other Expressions or Calculations.

Number Out Tab

Mathematical formulas are entered using the Number In and Point In values from the Controls tab. The output modifies the control in which the Expression was applied. See below for the syntax to use in this field.

Point Out Tab

The two text boxes in this tab use mathematical formulas, accessing the Number In and Point In values from the Controls tab. The output value modifies the control in which the Expression was applied. The Expression in the top text box control is used to calculate the X-axis value, and the bottom text box is used to calculate the Y-axis control. See below for the syntax to use in this field.
A good expression is reused over and over again. As a result, it can be useful to provide more descriptive names for each parameter or control and to hide the unused ones. The Config Tab of the Expressions modifier can customize the visibility and name for each of the nine point and number controls.

**Config Tab**

The Random Seed control sets the starting number for the Rand() function. The rand(x, y) function produces a random value between X and Y, producing a new value for every frame. As long as the setting of this Random Seed slider remains the same, the values produced at frame x are always the same. Adjust the Seed slider to a new value to get a different value for that frame.

**Show Number or Point X**

There are eighteen of these checkbox controls, one for each of the nine Number and nine Point inputs. Enable this checkbox to display the control for Number x or Point x in the Controls tab.

**Name for Number or Point X**

There are eighteen of these edit controls, one for each of the nine Number and nine Point inputs. Type a new name for the input into this edit control to assign a new name for the Input’s label in the Controls tab.
## Expression Syntax Formulas

Formulas are entered into the Number Out or Point Out tabs as part of an expression. They can be made up of the following functions:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n1...n9</td>
<td>The value of Number Input 1..9.</td>
</tr>
<tr>
<td>p1x...p9x</td>
<td>The X of Positional Control 1..9.</td>
</tr>
<tr>
<td>p1y...p9y</td>
<td>The Y of Positional Control 1..9.</td>
</tr>
<tr>
<td>time</td>
<td>The current time (frame number).</td>
</tr>
<tr>
<td>pi</td>
<td>The value of pi.</td>
</tr>
<tr>
<td>e</td>
<td>The value of e.</td>
</tr>
<tr>
<td>log(x)</td>
<td>The base-10 log of x.</td>
</tr>
<tr>
<td>ln(x)</td>
<td>The natural (base-e) log of x.</td>
</tr>
<tr>
<td>sin(x)</td>
<td>The sine of x (x is degrees).</td>
</tr>
<tr>
<td>cos(x)</td>
<td>The cosine of x (x is degrees).</td>
</tr>
<tr>
<td>tan(x)</td>
<td>The tangent of x (x is degrees).</td>
</tr>
<tr>
<td>asin(x)</td>
<td>The arcsine of x, in degrees.</td>
</tr>
<tr>
<td>acos(x)</td>
<td>The arccosine of x, in degrees.</td>
</tr>
<tr>
<td>atan(x)</td>
<td>The arctangent of x, in degrees.</td>
</tr>
<tr>
<td>atan2(x, y)</td>
<td>The arctangent of x,y, in degrees.</td>
</tr>
<tr>
<td>abs(x)</td>
<td>The absolute (positive) value of x.</td>
</tr>
<tr>
<td>int(x)</td>
<td>The integer (whole) value of x.</td>
</tr>
<tr>
<td>frac(x)</td>
<td>The fractional value of x.</td>
</tr>
<tr>
<td>sqrt(x)</td>
<td>The Square Root of x.</td>
</tr>
<tr>
<td>rand(x, y)</td>
<td>A random value between x and y.</td>
</tr>
<tr>
<td>rands(x, y, s)</td>
<td>A random value between x and y, based on seed s.</td>
</tr>
<tr>
<td>min(x, y)</td>
<td>The minimum (lowest) of x and y.</td>
</tr>
<tr>
<td>max(x, y)</td>
<td>The maximum (highest) of x and y.</td>
</tr>
<tr>
<td>dist(x1, y1, x2, y2)</td>
<td>The distance between point x1,y2 and x2,y2.</td>
</tr>
<tr>
<td>dist3d(x1,y1,z1,x2,y2,z2)</td>
<td>The distance between 3D points x1,y2,z1 and x2,y2,z2</td>
</tr>
<tr>
<td>noise(x)</td>
<td>A smoothly varying Perlin noise value based on x</td>
</tr>
<tr>
<td>noise2(x, y)</td>
<td>A smoothly varying Perlin noise value based on x and y</td>
</tr>
<tr>
<td>noise3(x, y, z)</td>
<td>A smoothly varying Perlin noise value based on x, y and z</td>
</tr>
<tr>
<td>if(c, x, y)</td>
<td>Returns x if c not 0, otherwise y.</td>
</tr>
</tbody>
</table>
## Expression Syntax Operators

Operators are used to evaluate statements. They are combined with functions to perform logical and mathematical calculations in the Number Out and Point Out tabs.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x + y</code></td>
<td><code>x</code> plus <code>y</code>.</td>
</tr>
<tr>
<td><code>x - y</code></td>
<td><code>x</code> minus <code>y</code>.</td>
</tr>
<tr>
<td><code>x &gt;= y</code></td>
<td>1.0 if <code>x</code> is less than <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x &gt; y</code></td>
<td>1.0 if <code>x</code> is greater than <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>!x</code></td>
<td>1.0 if <code>x</code> = 0, otherwise 0.0.</td>
</tr>
<tr>
<td><code>-x</code></td>
<td><code>(0.0 - x)</code>.</td>
</tr>
<tr>
<td><code>+x</code></td>
<td><code>(0.0 + x)</code> (effectively does nothing).</td>
</tr>
<tr>
<td><code>x ^ y</code></td>
<td><code>x</code> raised to the power of <code>y</code>.</td>
</tr>
<tr>
<td><code>x * y</code></td>
<td><code>x</code> multiplied by <code>y</code>.</td>
</tr>
<tr>
<td><code>x / y</code></td>
<td><code>x</code> divided by <code>y</code>.</td>
</tr>
<tr>
<td><code>x % y</code></td>
<td><code>x</code> modulo <code>y</code>, (remainder of <code>x</code> divided by <code>y</code>).</td>
</tr>
<tr>
<td><code>x &gt;= y</code></td>
<td>1.0 if <code>x</code> is less than or equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x &gt;= y</code></td>
<td>1.0 if <code>x</code> is greater than or equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x == y</code></td>
<td>1.0 if <code>x</code> is exactly equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x != y</code></td>
<td>1.0 if <code>x</code> is not equal to <code>y</code>, otherwise 0.0 (identical to above).</td>
</tr>
<tr>
<td><code>x &amp;&amp; y</code></td>
<td>1.0 if both <code>x</code> and <code>y</code> are not 0.0, otherwise 0.0.</td>
</tr>
<tr>
<td>`x</td>
<td></td>
</tr>
</tbody>
</table>
Example 1
To make a numeric control equal to the Y value of a motion path, add an expression to the desired target control and connect the Path to Point In 1. Enter the formula:

\[ p_{1y} \]

into the Number Out field.

Example 2
To make the result of the Expression’s Number Out be the largest of Number In 1 and Number In 2, multiplied by the cosine of Number In 3, plus the X coordinate of Point In 1, enter the formula:

\[ \text{max}(n1, n2) \times \cos(n3) + p_{1x} \]

into the Number Out field.

Example 3
Add a Background node set to solid black and a Hotspot node. Set the Hotspot size to 0.08 and set the Strength to maximum. Modify the Hotspot center with an expression. Change the current frame to 0.

Set n1 to 0.0 and add a Bézier Spline. At frame 29, set the value of n1 to 1.0. Select both points and loop the spline using the Spline Editor. Now enter the following equations into the Point Out tab of the expression.

X-Axis Expression
n1

Y-Axis Expression
0.5 + \sin(time\times50) 4

Render out a preview and look at the results. (Try this one with motion blur.)

From Image
The From Image modifier only works on gradients, like the gradient on a Background node. It takes samples of an image along a user-definable line and creates a gradient from those samples.

Unlike other modifiers, From Image is not located in the Modify With menu. This modifier can be applied by right-clicking a Gradient bar in the Inspector and selecting From Image.
Controls Tab

The From Image controls tab in the Inspector is used to select the node that contains the image you want to sample. It allows you to define the starting and ending point in the image as well as how many color samples to use in creating the gradient.

Image to Scan

Drop into this box the node from the Node Editor that you want to be color sampled.

Start X/Y, End X/Y

These two point controls define the Start and End points of the line along which the samples are taken from the image defined in the Image to Scan box.

The points can also be moved directly in the viewer.

Number of Sample Steps

This defines how many individual color samples are taken along the line. You can also see the result of this setting when you look at the actual node’s Gradient control. The more sample steps you define here, the more individual color stops appear on the Gradient control. It is also possible to first create a gradient using the From Image modifier and then remove that modifier from the Gradient control again. The created gradient stays intact and can then be fine tuned by hand.

Edges

Edges determines how the edges of the image are treated when the sample line extends over the actual frame of the image to be sampled.

Black

This outputs black for every point on the sample line outside of the image bounds.

Wrap

This wraps the edges of the line around the borders of the image.

Duplicate

This causes the edges of the image to be duplicated as best as possible, continuing the image beyond its original size.
**Color**

This outputs a user-definable color instead of black for every point on the sample line outside of the image bounds.

**Example**

The source image on the left shows the color selection line in red. The image on the right shows the resulting gradient from that selection.

**Gradient Color**

The Gradient Color modifier allows you to create a customized gradient and map it into a specific time range to control a value. Use the Start and End time controls to set the frames for the animation. If the Start and End time values are set to 0, then the modifier returns the value at the starting point of the gradient. You can use the Offset control to animate the gradient manually.

It can be applied by right-clicking a parameter and selecting Modify With > Gradient Color.

**Inspector**

The Gradient modifier Controls tab
Controls Tab
The Controls tab consists of a Gradient bar where you add and adjust points of the gradient. Start Time and End Time thumbwheels at the bottom of the inspector determine the time range the gradient is mapped into.

Gradient
The Gradient control consists of a bar where it is possible to add, modify, and remove points of the gradient. Each point has its color. It is possible to animate the color as well as the position of the point. Furthermore, a From Image modifier can be applied to the gradient to evaluate it from an image.

Gradient Interpolation Method
The gradient is linearly interpolated from point to point in RGB color space by default. This can sometimes result in unwanted colors. Choosing another color space may provide a better result.

Repeat
Defines how the left and right borders of the gradient are treated.

— **Once:** When using the Gradient Offset control to shift the gradient, the border colors keep their values. Shifting the default gradient to the left results in a white border on the left; shifting it to the right results in a black border on the right.

— **Repeat:** When using the Gradient Offset control to shift the gradient, the border colors are wrapped around. Shifting the default gradient to the left results in a sharp jump from white to black; shifting it to the right results in a sharp jump from black to white.

— **Ping Pong:** When using the Gradient Offset control to shift the gradient, the border colors ping-pong back and forth. Shifting the default gradient to the left results in the edge fading from white back to black; shifting it to the right results in the edge fading from black back to white.

Gradient Offset
Allows you to pan through the gradient.

Time Controls
The Start Time and End Time thumbwheels determine the time range the gradient is mapped into. This is set in frames. The same effect can be achieved by setting the Gradient to Once and animating the offset thumbwheel.
Key Stretcher Modifier

The Keyframe Stretcher modifier is primarily used when creating title templates in Fusion for use in DaVinci Resolve’s Edit page or Cut page. The Keyframe Stretcher modifier is added to an animated parameter, so the keyframes in the animated parameter stretch when the template is trimmed in the Timeline. It can be applied by right-clicking a parameter and selecting Modify with > KeyStretcher.

For more information on the Keyframe Stretcher Modifier controls, see the Keyframe Stretcher Node in Chapter 49, “Miscellaneous Nodes” in the Fusion Reference Manual or Chapter 110 in the DaVinci Resolve Reference Manual.

MIDI Extractor

The MIDI Extractor modifier provides the ability to modify the value of a control using the values stored in a MIDI file. This modifier relies on some knowledge of MIDI, which is beyond the scope of this manual.

The value produced by the modifier is extracted from the MIDI event selected in the Mode menu. Each mode can be trimmed so that only specific messages for that event are processed—for example, only some notes are processed, while others are ignored. The value of the event can be further scaled or modified by additional factors, such as Scale, Velocity, Attack, and Decay.

It can be applied by right-clicking a parameter and selecting Modify With > MIDI Extractor.

Inspector

![The MIDI Extractor modifier Controls tab](image)
Controls Tab

The Controls tab is used to load the MIDI file, modify its timing, and determine which MIDI messages and events trigger changes in the Fusion parameter.

MIDI File

This browser control is used to specify the MIDI file that is used as the input for the modifier.

Time Scale

Time Scale is used to specify the relationship between time as the MIDI file defines it and time as Fusion defines it. A value of 1.0 plays the MIDI events at normal speed, 2.0 plays at double speed, and so on.

Time Offset

Time Offset adjusts the sync between the MIDI file’s timing and Fusion’s timing. If there is an unexpected delay, or if the MIDI file should start partway into or before some animation in Fusion, this control can be used to offset the MIDI data as required.

Result Offset, Result Scale

These sliders adjust the range of values produced by the modifier. By default, values between 0 and 1 (or -1 and 1 for PitchBend mode) are generated. This does not always suit the node/parameter, and scale can be used to make this range larger (such as * 0.0 - 2.0). Offset is used to provide some constant value as a base.

Result Curve

The Result Curve can also be used to adjust the output. However, this adjusts the curve of the result. By default, for any input MIDI data, the results fall linearly between 0.1 and 1.0 (for example, a velocity 127 note generates 1.0, whereas 63 generates approximately 0.5).

The Result Curve applies a gamma-like curve so that middle values can produce higher or lower results while still maintaining the full scale.

Mode

This menu provides Beat, Note, Control Change, Poly AfterTouch, Channel AfterTouch, or Pitch Bend, indicating from which MIDI event the values are being read. Beat mode is slightly different in that it produces regular pulses based on the tempo of the MIDI file (including any tempo maps).

The Beat mode does not use any specific messages; it bases its event timing on the tempo map contained in the MIDI file.

Combine Events

This menu selects what happens when multiple events occur at the same time. In Notes mode, this can happen easily. For other events, this can happen if Multiple Channels are selected.

Use this to take the result from the most recent event to occur, the oldest event still happening, the highest or lowest valued event, the average, sum, or the median of all events currently occurring.

Beat (Quarters) (Beat Mode Only)

This defines how often a beat occurs when in Beat mode. This is in quarter notes, so a value of 1.0 gives a beat every quarter.
Note Range (Note and Poly Aftertouch Modes Only)
This defines what range of notes causes a value to be generated. For example, use this to pick out the kick drum from a GM drum track by setting the note range between 35–36.

Pitch Scale (Note Mode Only)
Pitch Scale defines how much the result changes with pitch. A value of 1.0 causes the result to vary from 0.0 to 1.0 over the entire range.

Velocity Scale (Note Mode Only)
This defines how much the result changes with velocity. A value of 1.0 causes the result to vary from 0.0 to 1.0 over the entire range. This is added to the result from Pitch Scale for the final result.

Control Number (Control Change Mode Only)
This specifies the MIDI controller number from which to extract events.

Envelope Controls (Note and Beat Modes Only)
These define an Envelope to follow for values before, during, and after the note or beat. Pre-Attack Time defines how long before the event it starts ramping up to the pre-attack level. Attack is the Time/Level to ramp to once the event has occurred, followed by the Decay ramp and Sustain, until the event stops. This stage is for Notes only. Beats have an instantaneous duration, so it goes straight to Release. Release is the ramp-down time after the event finishes. When trying to do a Beat, set Release to some value, or there likely will not be much of a beat.

These values can be used to follow actual sounds in the MIDI sequence or just to create interesting effects. All time values used in the MIDI Extractor are in seconds.

Channels Tab
The Channels tab is used to select the Channels used in the modifier.

Channels
Channels checkboxes select which of the 16 channels in the MIDI file are actually considered for events. This is a good way to single out a specific instrument from an arrangement.
About MIDI

A single MIDI interface allows 16 channels. Typically, these are assigned to different instruments within a device or different devices. Usually, MIDI data is 7 bits, ranging from 0–127. In Fusion, this is represented as a value between 0–1 to be more consistent with how data is handled in Fusion.

There are numerous different MIDI messages and events, but the ones that are particularly useful with this modifier are detailed below.

MIDI Messages

— **Note On**: This indicates that a note (on a specific channel) is being turned on, has a pitch (0–127, with middle C being 60) and a Velocity (0–127, representing how fast the key or strings or whatever was hit).

— **Note Off**: This indicates that a note (on a specific channel) is being turned off, has a pitch (0–127, with middle C being 60) and a Velocity (0–127, representing how fast the key or strings or whatever was released).

— **Control Change**: This message indicates that some controller has changed. There are 128 controllers (0–127), each of which has data from 0–127. Controllers are used to set parameters such as Volume, Pan, amount of Reverb or Chorus, and generic things like foot controllers or breath controllers.

MIDI Events

— **Channel Aftertouch**: This event defines that pressure is being applied to the keys (or strings or whatever) during a note. This represents general, overall pressure for this channel, so it simply uses a pressure value (0–127).

— **Poly Aftertouch**: This event defines that pressure is being applied to the keys (or strings or whatever) during a note. It is specific to each particular note and therefore contains a note number as well as a pressure value (0–127).

Pitch Bend

The Pitch Bend controller generally specifies the degree of pitch bending or variation applied to the note. Because pitch bend values are transmitted as a 14-bit values, this control has a range between -1 and 1 and a correspondingly finer degree of resolution.

Natural Cubic Spline

The Natural Cubic Spline is one of the animation modifiers in Fusion and normally is applied to numerical values rather than point values. It can be applied by right-clicking a numerical control and selecting Modify With > Natural Cubic Spline.

**NOTE**: Unlike other spline types, Cubic splines have no control handles. They attempt to automatically provide a smooth curve through the control points.
Usage

Being an animation spline, this modifier has no actual Controls tab. However, its effect can be seen and influenced in the Spline Editor.

Offset (Angle, Distance, Position)

There are three Offset modifiers used to create variances between values. Depending on the modifier, these values relate to controls, paths, and points. The three types of Offset modifiers available in Fusion are:

— Offset Angle
— Offset Distance
— Offset Position

Offset Angle

The Offset Angle modifier outputs a value between 0 and 360 that is based on the angle between two positional controls. The Position and Offset parameters may be static, connected to other positional parameters, or connected to paths of their own. All offsets use the same set of controls, which behave differently depending on the offset type used. These controls are described below.

Offset Distance

The Offset Distance modifier outputs a value that is based on the distance between two positional controls. This modifier is capable of outputting a value based on a mathematical expression applied to a position.

Offset Position

The Offset Position modifier generates a position (X and Y coordinates) that is based on the relationship between positional controls. This modifier is the equivalent of a calculation control except that it outputs X and Y coordinates instead of a value.

It can be applied by right-clicking a control and selecting Modify With > Offset.
Inspector

The Offset Position modifier controls

Offset Tab

The Inspector for all three Offset modifiers is identical. The Offset tab includes Position and Offset values as well as a Mode menu for selecting the mathematical operation performed by the offset control.

Position X and Y

The X and Y values are used by the Position to generate the calculation.

Offset X and Y

The X and Y values are used by the Offset to generate the calculation.

Flip Position Horizontal and Vertical

When these controls are selected, the Position is mirrored along the vertical or horizontal axis of the image.

Flip Offset Horizontal and Vertical

When these controls are selected, the Offset position is mirrored along the vertical or horizontal axis of the image.

Mode

The Mode menu includes mathematical operations performed by the Offset control. Available options include:

- Offset
- Difference (Position - Offset)
- Difference (Offset - Position)
- Average
- Use Position Only
- Use Offset Only
- Maximum
- Minimum
- Invert Position
- Invert Offset
- Invert Sugar
- Random Offset
Image Aspect
Adjust the modifier’s output to compensate for the image aspect (not pixel aspect) of the project. A square image of 500 x 500 would use an Image Aspect value of 1, and a rectangular image of 500 x 1000 would use an Aspect Value of 2. The default value is always based on the current frame format selected in the preferences. To calculate image aspect, divide the width by the height. This control can also be used to create the illusion of aspect.

Time Tab
Position Time Scale
This returns the value of the Position at the Time Scale specified (for example, 0.5 is the value at half the current frame time).

Position Time Offset
This returns the value of the Position at the Time Offset specified (for example, 10 is 10 frames back).

Offset Time Scale
This returns the value of the Offset at the Time Scale specified.

Offset Time Offset
This returns the value of the Offset at the Time Offset specified.

Example
This is a simple comp to illustrate one potential use of offsets.

1. Create a new Comp 100 frames long.
2. Create a node tree consisting of a black background and a Text node foreground connected to a Merge.
3. In the Text Layout tab, use the Center X control to animate the text from the left side of the screen to the right.
4. Move to frame 0.
5. In the Text tab in the Inspector, right-click the Size control and select Modify With > Offset Distance from the contextual menu.

This adds two onscreen controls: a crosshair for the position and an X control for the offset. These onscreen controls represent the Position and Offset controls displayed in the Modifiers tab.
The size of the text is now determined by the distance, or offset, between the two onscreen controls.

6 Drag the X onscreen control in the viewer to see how the distance from the crosshair changes the size of the merge and by association the text.

Both the crosshair and the X onscreen controls are animatable and can be connected to other controls.

7 Position the X centered at the bottom of the viewer.

8 In the Inspector, select the Modifiers tab.

9 In the Offset on Text size section, right-click over Position and choose Connect To > Path

Connect the position value of the Offset to the existing path by right-clicking the Position control and selecting Connect To > Path1 Position.

Play the comp to view the animation.

10 Now, the text shrinks near the center of the path (when the distance between the offset and the path is at its minimum) and grows at its ends (where the distance between the offset and the path is at its maximum).

Path

The Path modifier uses two splines to control the animation of points: an onscreen motion path (spacial) and a Time spline visible in the Spline Editor (temporal). To animate an object’s position control using a Path, right-click the Position control either in the Inspector or in the viewer and select Path from the contextual menu. This adds a keyframe at the current position. You can begin creating a path by moving the playhead and dragging the center position control in the viewer. The Spline Editor shows a displacement spline for editing the temporal value, or “acceleration,” of the path.

Controls

The Path modifier Controls tab
**Controls Tab**

The Controls tab for the path allows you to scale, reposition, and rotate the path. It also provides the Displacement parameter, allowing you to control the acceleration of an object attached to the path.

**Center**

The actual center of the path. This can be modified and animated as well to move the entire path around.

**Size**

The size of the path. Again, this allows for later modification of the animation.

**X Y Z Rotation**

The path can be rotated in all three dimensions to allow for sophisticated controls.

**Displacement**

Every motion path has an associated Displacement spline in the Spline Editor. The Displacement spline represents the position of the animated element along its path, represented as a value between 0.0 and 1.0. Displacement splines are used to control the speed or acceleration of an object’s movement along the path.

To slow down, speed up, stop, or even reverse the motion of the control along the path, adjust the values of the points for the path’s displacement in the Spline Editor or in the Inspector.

— A Displacement value of 0.0 in the Spline Editor indicates that the control is at the very beginning of a path.
— A value of 1.0 indicates that the control is positioned at the end of the path.
— Each locked point on the motion path in the viewer has an associated point on the Displacement spline.
— Unlocked points have a control point in the viewer but do not have a corresponding point on the Displacement spline.

**Heading Offset**

Connecting to the Heading adjusts the auto orientation of the object along the path. For instance, if a mask’s angle is connected to the path’s heading, the mask’s angle will adjust to follow the angle of the path.

**Right-Click Here for Shape Animation**

It’s possible to animate the shape of the path as well or to connect it to other path controls like Polyline Masks or Paint Strokes.

---

**TIP: Switching Default Paths**

You can change the default path type used when animating a position or center control to a path (if this is the preferred type of animation). Open the Preferences window and select the Global Settings. In the Default category, select the Point With menu and choose Path. The next time Animate is selected from a Position or Center control’s contextual menu, a path is used.
Perturb

The Perturb modifier generates smoothly varying random values for a given parameter based on Perlin noise. It can be used to add jitter, shake, or wobble to any animatable parameter, even if the parameter is already animated. Its results are similar to those of the Shake modifier, although it uses a different set of controls that may be more intuitive. Unlike other random modifiers, you can apply the Perturb modifier to polylines, shapes, grid meshes, and even color gradients.

For example, to add camera shake to an existing path, right-click the crosshair and choose Insert > Perturb, and then adjust the Strength down to suit. Alternatively, right-clicking the path’s “Right-click here for shape animation” label at the bottom of the Inspector lets you apply perturb to the path’s polyline. This works best if the polyline has many points—for example, if it has been tracked or hand-drawn with the Draw Append pencil tool. A third usage option is to use the insert contextual menu to insert the modifier onto the Displacement control. This causes the motion along the path to jitter back and forth without actually leaving the path.

**NOTE:** Perturb can only add jitter; it cannot smooth out existing animation curves.

Inspector

The Perturb modifier Controls tab

The Perturb modifier Controls tab

Controls Tab

The Controls tab for Perturb is mainly used for controlling the Strength, Wobble, and Speed parameters of the random jitter.

**Value**

The content of this control depends on what type of control the modifier was applied to. If the Perturb modifier was added to a basic Slider control, the Value is a slider. If it was added to a Gradient control, then a Gradient control is displayed here. Use the control to set the default, or center value, for the Perturb modifier to work on.
The Perturb modifier Gradient controls

**Jaggedness**
(Polylines and meshes only) This allows you to increase the amount of variation along the length of the polyline or mesh, rather than over time. Increasing Jaggedness gives a squigglier polyline or more tangled mesh, independent of its movement.

**Phase**
(Polylines and meshes only) Animating this can be used to move the ripple of a polyline or mesh along itself, from end to end. The effect can be most clearly seen when Speed is set to 0.0.

**Random Seed Randomize**
The Random Seed is used to “seed” the amount of jitter applied by the modifier. Two Perturb modifiers with identical settings, but different random seeds, produce two completely different results. Click the Randomize button to assign a random seed value.

**Strength**
Use this control to adjust the strength of the Perturb modifier’s output, or its maximum variation from the primary value specified above.

**Wobble**
Use the Wobble control to determine how smooth the resulting values are. Less wobble implies a smoother transition between values, while more wobble produces less predictable results.

**Speed**
Increasing the Speed slider value speeds up the rate at which the value changes. This can increase the apparent wobbliness in a more predictable fashion than the Wobble control and make the jitter more frantic or languorous in nature.
Probe

The Probe modifier is one of the most versatile modifiers in Fusion. It allows you to control any numeric parameter by the color or luminosity of a specific pixel or rectangular region of an image. Think of driving the Brightness node by probing the pixel values of flickering lights in a shot, or measuring graded LUTs to compare values.

It can be applied by right-clicking a parameter and selecting Modify With > Probe.

Inspector

The Probe modifier Controls tab

Controls Tab

The Controls tab for the Probe modifier allows you to select the node to probe, define the channel used to drive the parameter, and control the size of the probed area.

Image to Probe

Drag a node from the Node Editor to populate this field and identify the image to probe.

Channel

Select the channel you want to probe. The usual options are:

- Red
- Green
- Blue
- Alpha

Luma

Once a Probe modifier is present somewhere in your comp, you can connect other node's values to its outputs as well. The Probe allows you to connect to its values individually:

- Result
- Red
- Green
- Blue
- Alpha

Position X Y

The position in the image from where the probe samples the values.
 Probe Rectangle
By default, the Probe samples only the value of a single pixel at its position. By using the Probe Rectangle mode, you can sample from a larger area of pixels based on the Evaluation method.

Width Height Controls
These determine the size of the area to be probed.

Evaluation
Sets how the pixels inside the rectangle are computed to generate the output value.

Options include:
- **Average**: All pixel values inside the rectangle are averaged.
- **Minimum**: The smallest value of all pixels inside the rectangle is used.
- **Maximum**: The highest value of all pixels inside the rectangle is used.

The Probe modifier Value tab

Value Tab
The Value tab controls the range or scale of the modifier adjustment, thereby adjusting the sensitivity of the Probe.

Scale Input
By default, the Probe generates the Black Value when the probed area results in a value of 0 (i.e., black), and it generates its White Value when the probed area results in a value of 1 (i.e., white). By using this range control, you can modify the sensitivity of the Probe.

Black Value
The value that is generated by the Probe if the probed area delivers the result set in Scale Input Black.

White Value
The value that is generated by the Probe if the probed area delivers the result set in Scale Input White.

Out of Image Value
The value that is generated by the Probe if the probed area is outside the frame boundaries of the probed image. If probing a rectangle, this value does not generate before the entire rectangle is outside the frame boundaries of the image to be probed.
Publish

Only parameters that are animated will be available from the Connect To menu. To connect to non-animated parameters, you must Publish them first. Animated controls are automatically published, whereas static controls must be published manually.

To publish a static control, right-click the control and select Publish from the contextual menu.

The Publish modifier Controls tab

Controls Tab

The Controls tab shows the published control available for linking to other controls.

Published Value

The display of the published control is obviously dependent on which control is published from which node.

Resolve Parameter

The Resolve Parameter Modifier is used when creating a transition template in Fusion for use in DaVinci Resolve’s Edit page or Cut page. When building a transition in Fusion, the Resolve Parameter modifier is added to any control you want to animate. The Resolve Parameter modifier automatically animates the parameter for the duration of the transition, allowing you to trim the transition in the Edit page or Cut page.

For example, to create a cross dissolve, do the following:

1. From the Effects Library, add a Fusion Composition to the Edit page Timeline.
2. In Fusion, add a Dissolve node to the Node Editor.
3. In the Inspector, right-click the Background/Foreground parameter, and then choose Resolve Parameter from the Modifier contextual menu. Adding the modifier to the Background/Foreground parameter automatically updates the slider if the transition is modified back on the Edit/Cut page.
4. In the Node Editor, right-click the Dissolve node and choose Macro > Create Macro.
5. When creating a macro that’s to be used as a Fusion transition it’s important that two inputs and one output are selected in the Macro Editor. In this example, under the Dissolve heading, enable the Output, Background and Foreground check boxes.
6. Give the transition a name, then save the macro from the top File menu.
Save the macro in the following folder so it appears the Edit page or Cut page Effects Library:

- **For MacOS:** `$TEMPLATE_MAC_OS_PATH/Transitions` or `$TEMPLATE_MAC_USER_PATH/Transitions`
- **For Windows:** `$TEMPLATE_WIN_OS_PATH\Transitions` or `$TEMPLATE_WIN_USER_PATH\Transitions`

Quit and reopen DaVinci Resolve to update the list of transitions in the Effects Library.

On the Edit page, open the Effects Library. Navigate to Video Transitions Fusion Transitions, and the custom Fusion transition will be listed.

**Shake**

The Shake modifier is used to randomize a Position or Value control to create semi-random numeric inputs. The resulting shake can be entirely random. The motion can also be smoothed for a more gentle, organic feel.

To add the Shake modifier to a parameter, select Modify With > Shake from the parameter’s contextual menu. The Shake modifier uses the following controls to achieve its effect. It can be applied by right-clicking a parameter and selecting Modify With > Shake.

**Inspector**

The Shake modifier Controls tab

**Controls Tab**

**Random Seed**

The Random Seed control contains the value used to seed the random number generator. Given the same seed, a random number generator always produces the same results. Change the seed if the results from the randomizer are not satisfying.

**Smoothness**

This control is used to smooth the overall randomness of the Shake. The higher the value, the smoother the motion appears. A value of zero generates completely random results, with no smoothing applied.

**Lock X/Y**

This checkbox is used to unlock the X- and Y-axis, revealing independent slider controls for each axis.
**Minimum and Maximum**

This control is used to determine the overall strength of the shake. The low values represent the lowest value that can be generated by the randomizer, and the high values represent the highest values. To create a Shake that moves a center crosshair anywhere within the image, set the Minimum to 0.0 and the Maximum to 1.0. To restrict the motion to a smaller shake in the bottom-right corner of the image, set the Minimum to 0.70 and the Maximum to 0.90.

**Example**

1. Create a new comp, and then add and view a Text node.
2. Type some text in the Text node.
3. In the viewer, right-click over the Center control of the text and choose Modify With > Shake Position.
4. In the Inspector, select the Modifiers tab and set the smoothing to 5.0.
5. Set the Minimum to 0.1 and the Maximum to 0.9.
   
   This adds some chaotic movement to the text. However, we can change this over Go to frame 0 and in the Inspector click the Keyframe button to the right of both the Minimum and the Maximum controls.

6. Go to frame 0 and in the Inspector click the Keyframe button to the right of both the Minimum and the Maximum controls.
7. Go to frame 90 and adjust the Minimum to 0.45 and the Maximum to 0.55.
8. View the results.
   
   Now, the text starts out by flying all over the screen and tightens in toward the center of the screen as the comp plays.

**Track**

Although there is a standard Tracker node, you can also use a Tracker modifier to add a tracker directly to a parameter. To apply the Tracker modifier, in the viewer right-click the Center control of any transform, text, mask, or other positionable element. From the contextual menu, choose Object x Center > Modify With > Tracker.

Then choose one of three options:

- **Tracker Position**: Tracks a point from the source.
- **Steady Position**: Stabilizes based on a single point in the source.
- **Unsteady Position**: Adds original motion back after stabilizing.

This adds a modifier in the Inspector with a set of controls almost identical to those found in the Tracker node itself.
**Inspector**

![Tracker Modifier](image)

The Tracker modifier

For an in-depth explanation of this node, see Chapter 57, “Tracker Nodes” in the Fusion Reference Manual or Chapter 118 in the DaVinci Resolve Reference Manual.

**Tracker Modifier vs. Tracker Node**

The differences between a Tracker modifier and a Tracker node are as follows:

— The Tracker modifier can only track a single pattern.
— The Tracker modifier can only output a single value and cannot be used for complex stabilization or match-moving procedures.
— The default source image for the modifier is the node immediately upstream of the node that contains the modifier (i.e., when adding a Tracker modifier to a Glow node with a Loader as its input, the Tracker Source input defaults to the output of the Loader). Set a different source image for the Tracker modifier by typing in the name of the node. Alternatively, drag the source node from the Node Editor into the Text Box control.
Example
Imagine that you need to track an actor’s eyes so that an unearthly, alien glow can be applied to the eyes.

1. Select the Loader node.
2. Add a Glow node.
3. Add an Ellipse mask to the Glow in the shape of one of the eyes.
4. Right-click the center of that mask and select Modify With > Tracker > Position.
   Since the track is on the mask, the tracker takes the glow as the image for tracking. This could cause problems since the eye might be very obscured by the glow. A cleaner source will be the Loader that feeds the glow.
5. Drag the Loader into the modifier Inspector’s Track Source field.
6. Track the actor’s eye.
7. Perform the same steps on the other eye.

Vector Result

The Vector Result modifier is used to offset positional controls, such as crosshairs, by distance and angle. These can be static or animated values.

It can be applied by right-clicking a control and selecting Modify With > Vector.

Inspector

The Vector Result modifier Controls tab

Controls Tab

Origin
This control is used to represent the position from which the vector’s distance and angle values originate.
**Distance**
This slider control is used to determine the distance of the vector from the origin.

**Angle**
This thumbwheel control is used to determine the angle of the vector relative to the origin.

**Image Aspect**
This slider control is used primarily to compensate for image aspect differences. A square image of 500 x 500 would use an Image Aspect value of 1, while a rectangular image of 500 x 1000 would use an Image Aspect value of 2. The default for this value is taken from the current Frame Format preferences using width/height. It may be necessary to modify this control to match the current image.

### Example

1. Create a 100-frame comp.
2. Create a simple node tree consisting of a black background and a Text node foreground connected to a Merge.
3. Enter some text in the Text node.
4. Select the Merge node.
5. In the viewer, right-click the Center control of the Merge and choose Modify With > Vector Result.
   This adds a crosshair onscreen control for the Vector distance and angle. The onscreen control represents the Distance and Angle controls displayed in the Modifiers tab.
6. In the Modifiers tab of the Inspector, drag the Distance control to distance the text from the Vector origin.
7. Drag the Angle thumbwheel to rotate the text around the Vector origin.
   This is different from changing a pivot point, since the text itself is not rotating.
   These points are animatable and can be connected to other controls.
8. In the Inspector, right-click the Origin control and choose a path to add a motion path modifier to the Origin control.
9. Verify that the current frame is set to frame 0 (zero) and use the Origin controls in the Inspector or drag the Vector Origin crosshair to the bottom-left corner of the screen.
10. On the Vector Angle thumbwheel, click the Keyframe button to animate this control.
11. Set the Angle thumbwheel to a value of 10.
12. Go to frame 100 and click at the top-left corner of the screen to move the Vector Origin crosshair.
13. Set the Vector Angle thumbwheel to a value of 1000.
14. Play the comp to see the results.
   This causes the text to orbit around the path just created.
XY Path

The XY Path type uses two separate splines for the position along the X-axis and for the position along the Y-axis.

To animate a coordinate control using an XY path, right-click the control and select Modify With > XY Path from the contextual menu.

At first glance, XY paths work like Displacement paths. To describe the path, change frames and position the control where it should be on that frame, and then change frames again and move the control to its new position. Fusion automatically interpolates between the points. The difference is that no keyframes are created on the onscreen path.

Look in the Spline Editor to find the X and Y channel splines. Changes to the control’s values are keyframed on these splines. The advantage to the XY path is that it becomes very easy to work with motion along an individual axis.

Inspector

XY Path modifier controls

X Y Z Values
These reflect the position of the animated control using X, Y, and Z values.

Center
The actual center of the path. This can be modified and animated as well to move the entire path around.

Size
The size of the path. Again, this allows for later modification of the animation.

Angle
The angle of the path. Again, this allows for later modification of the animation.

Heading Offset
If another control (for example, a mask’s Angle) is connected to the path’s heading, this control allows for adding or subtracting from the calculated angle.
**Plot Path in View**

Toggles whether or not the actual path is displayed in the views.

**Switching Default Paths**

You can change the Default Path type to XY path (if this is the preferred type of animation). Open the Default category in the Global Preferences and locate the Point With drop-down menu. Change this from the current value to XY Path. The next time Animate is selected from a Coordinate control’s contextual menu, an XY path is used instead of a Displacement path.

Chapter 122

Introduction to Color Grading

For over thirty years, DaVinci has pioneered the development of color correction hardware and software designed to enhance visual images acquired from film and video.

This release of DaVinci Resolve possesses our newest and most evolved professional color correction tools yet. However, for all its technological sophistication, DaVinci Resolve is merely a tool that requires the hands of a skilled artist to realize its full potential.

Subsequent chapters of this user manual cover the DaVinci Resolve grading tools in the Color page in great detail, but before getting into the specifics of color balancing and contrast adjustment, Power Windows, and Custom Curves, it’s important to step back and consider what these tools are for, and why you’re learning to use this application in the first place.

This introduction is for those of you who are new to this process we call color correction, or color grading. If you’re a veteran colorist then you might want to skip ahead, but if you’re just starting out, the following sections are intended to describe the many goals of color correction, and how the DaVinci Resolve toolset has been designed to address them; making it fast and efficient to alter images in innumerable ways as we elevate raw footage to cinematic art.

Balancing Scenes 2706
Adding Style 2707
Quality Control 2710
Never Stop Experimenting 2711
The Goals of Color Correction

If reality is a fire hose of visual information, then digital cinema and broadcast would be represented by a garden hose. Color correction, therefore, could be considered the process of choosing which parts of the fire hose of raw image data to fit into the garden hose of our displays in order to create a pleasing image for the viewer.

Maximizing the Look of Your Media

Clearly, the most fundamental aspect of the color correction process is that of making every clip look its best. While the job of the cinematographer is to light and expose the image with an artistic intent, your job is to realize this intent by making adjustments to the color and contrast of the image, so that the final result is as close to what the director and cinematographer had in mind as is humanly possible. In the process, you have the opportunity to overcome inconsistencies with exposure and white balance that were, for various reasons, unavoidable. Furthermore, you can make subtle adjustments to add warmth or contrast that was not available during the shoot, but that the cinematographer would have liked.

Increasingly, color correction is seen as a critical stage in the post-production process. For example, the newer generation of digital cinema cameras are capable of shooting raw colorspace image data, or RGB image data with a log exposure, in order to preserve the maximum amount of image data for manipulation during the color correction process. However, when you acquire image data this way, it must be transformed into a viewable image via color correction in the same way that film negative must first be developed and printed to positive film.

Of course, there are also situations in which you may find it necessary to attempt to fix source media with far more substantial problems in color and exposure. In these cases, the tools exist to make far more involved adjustments to the image; however, the quality of your results will depend heavily on the data quality and “latitude” of your source media.

For example, Blackmagic URSA, ARRI ALEXA, and RED DRAGON cameras record quite a bit of image data, making extreme corrections far more possible than more heavily compressed camera formats such as the Canon 5D. However, in either case, DaVinci Resolve provides the tools to process images in many different ways to adjust the image for a better look.
Whether clips need changes large or small, the primary DaVinci Resolve toolset adjusts the characteristics of hue, saturation, and contrast in a variety of ways. In the Color Wheels palette, Color balance wheels let you adjust all three color channels at once, altering the color temperature of the scene at specific ranges of tonal detail referred to as lift, gamma, and gain. Alternately, the slider-based Primaries Bars mode lets you make the same kinds of controls via independently adjustable red, green, and blue lift, gamma, and gain controls.

All of these controls let you adjust the color tone of the shadows, midtones, and highlights independently from each other.
Meanwhile, the Master Lift, Gamma, and Gain wheels work together to let you alter image contrast in different ways: deepening shadows, lightening highlights, and brightening or darkening the midtones in between to create whatever image tonality you prefer for a given scene.

Separate saturation controls let you increase or decrease color intensity throughout the scene, while the Lum vs. Sat and Sat vs. Sat curves give you the ability to fine-tune saturation very specifically.

For more information on these controls, which are essential to the color correction process, see Chapter 128, “Primaries Palette.”
Emphasizing What’s Important

Another important aspect of the color correction process is the ability to make adjustments to emphasize or de-emphasize specific elements within the frame. It’s similar in concept to equalization in audio mixing, in that you’re choosing which color values to boost or suppress using a variety of techniques.

This can be done to direct the viewer’s gaze, for example by surrounding a specific part of the image with a window, which lets you restrict specific adjustments made to the inside and outside of the window’s shape.

![Drawing a window to isolate a region of the picture to highlight](image1)

Specific alterations can also be made to prevent audience distraction. For example, a low-saturation monochromatic tint may be a pleasing look overall, but in the soft wash of color, the viewer might lose track of the watch that’s preoccupying the protagonist. Using tools such as the Hue curves and HSL Qualifier, you can quickly and easily tune the color of the woman’s hands and of the watch to guide the viewer’s eye, and bring some needed depth to the scene.

![Source image](image2) ![Curves and HSL qualification used to distinguish hands and highlight watch](image3)

For more information on Power Windows, see Chapter 134, “Secondary Windows and Tracking.” For more information on Hue curves, see Chapter 131, “Curves.”
Audience Expectations

There is another family of tools, the HSL, RGB, and Luma Qualifiers, that provide even more specific control, and they’re useful for adjusting ranges of color to either play into or against the audience expectations for color in a scene. Substantial research into what has been termed “memory color” shows that people have finely tuned expectations for the hues of particular subjects, such as flesh tone, foliage greens, and sky blues. Deviation from these expectations can create a sense of something being not quite right, which can be either detrimental or beneficial, depending on your goals for a particular scene.

HSL Qualification is effectively a chroma keyer that lets you sample the image to create a key that’s used to define where to apply a specific correction. For example, if you’re happy with the rest of the image, but the skin tone of the actor has an unhealthy green tinge to it as a result, you can isolate the color of that actor’s skin and adjust it to a healthier hue.

Source Image

HSL qualification on the skin

Skin now has warmer grade

Another common example is the adjustment of skies. If you’re aiming for a gorgeous summer day, a washed out sky in the source media can be a bit of a bummer. However, using qualification it’s easy to isolate that wedge of blue, then push and pull it into just the right amount of summertime joy.

Originally graded scene

HSL qualification of the sky
Balancing Scenes

It’s rare when the uncorrected shots of a scene match one another perfectly. Even the most carefully exposed angles of coverage can have small variances that need to be evened out. On the other end of the spectrum, run-and-gun programs using available light often result in edited scenes with huge changes in lighting and color as each shot cuts away to the next.

Small or large, unintended variations from one shot to the next can call undue attention to the editing, and jar the audience’s attention in ways that throw them out of the program. Evening out these differences and balancing the clips in each scene to match is another of the fundamental tasks of the colorist. You know you’re finished when the color in the scene flows unnoticeably from one clip to the next.

DaVinci Resolve has a variety of tools that you can use to help you compare images with one another, the most important of which is the Gallery, in which you can save still images of clips that you can then compare to other clips using an adjustable split screen.

By using the Gallery to play stills, either split or whole (flipping back and forth between the clip you’re adjusting and the still), it becomes easier to use the extensive DaVinci Resolve toolset to match the color and exposure of every clip in a scene.
An additional set of features let you manage grades by copying them from clip to clip, or by linking similar clips, either automatically, or manually using groups.

For more information on using the Still Store, see Chapter 123, “Using the Color Page.” For more information on grade management, see Chapter 138, “Grade Management.”

Adding Style

Of course, it’s not all about subtlety and correction. It’s often appropriate, when grading music videos and commercials, for instance, to add some radical style to a piece. Here, too, DaVinci Resolve provides an abundance of features for manipulating unexpected aspects of the image; for example, by abusing the Custom Curves to create the illusion of chemical cross-processing.
DaVinci Resolve’s node-based image processing makes it possible to use more exotic node structures to create effects using composite modes, such as a colored glow generated by adding two differently graded versions of the same image together using a Layer node.

You can also create complex node trees to build specific mattes, to use for isolating specific elements of the image. For example, if you wanted to isolate an actor in color against a background turned monochromatic, you can create multiple keys (pulled via HSL Qualification) and combine them using a Key Mixer node to build that effect.
Finally, DaVinci Resolve doesn’t just have tools governing color and contrast. A Blur palette provides controls over blurring, sharpening, or adding mist to all or part of the image. When combined with the other tools that are available for isolation and color adjustment, these are powerful additions to your creative arsenal.

For more information on all of these features, see Chapters 124 through 140 of this manual.
Quality Control

Lastly, it’s important to keep in mind that, for all the creative possibilities that DaVinci Resolve affords, it’s still important that the final deliverables that you give to your client has appropriate signal levels relative to their requirements. In particular, programs destined for broadcast have specific outer boundaries of luma and chroma that you must not exceed, or you’ll risk having a show rejected for QC (quality control) violations.

However, even if you’re not delivering a show for broadcast, it’s important to be aware of the mathematical limitations of a digital video signal to make sure you’re not clipping or crushing image detail through overzealous adjustments that you may, in fact, want to preserve.

For example, if you take a look at the next two images, you can see the perils of overzealous adjustments when compared to a clip that, while graded creatively, has been adjusted with respect to the mathematical boundaries of image data.

![Image graded to preserve detail in highlights](image1.png) ![Image graded with highlight detail blown out](image2.png)

Here, too, DaVinci Resolve provides tools designed to help you exercise control over the fine-tuning of the image. A Video Scopes window provides the standard Waveform, Parade, Vectorscope, and Histograms that are used to analyze your image data. These scopes let you see the boundaries of what’s possible, and make it easy to spot subtle problems, and compare the characteristics of one image to another.

![Video scopes](scopes.png)
When the time comes that you want to start clipping data in the highlights and shadows, as part of a creative look, the Soft Clip controls let you introduce a subtle or large roll-off, compressing the extremes of the signal so that what clipping you do is softer and more pleasing.

For more information about the video scopes and the Soft Clip controls, see Chapter 123, “Using the Color Page,” and Chapter 131, “Curves.”

**Never Stop Experimenting**

So now that you’ve gotten an extremely brief overview of the grading process as seen through the toolset of DaVinci Resolve, we invite you to use this manual to explore DaVinci Resolve more thoroughly. You may discover that, the more you work with the different features that are available, the more unexpected uses you’ll find for different controls that you thought you knew well.

Have fun.
Chapter 123

Using the Color Page

Given the origin of DaVinci Resolve as a professional grading application, the Color page is at the heart of the DaVinci Resolve experience.

Within the Color page are all of the controls available for manipulating color and contrast, reducing noise, creating limited secondary color corrections, building image effects of different kinds, adjusting clip geometry, and making many other corrective and stylistic adjustments.

In this chapter, you’ll learn how to understand the Color page interface, how to customize it, and how to work within it to play through and navigate your project’s timeline. You’ll also learn how to analyze and compare clips in preparation for grading using stills, playheads, and DaVinci Resolve’s own internal video scopes.

The Color Page Interface

The Color page is divided into seven main areas that work together to let you build a grade. This section provides an overview of what these areas are and how they function.

The default layout of the Color page

The Interface Toolbar

At the very top of the Color page is a toolbar with buttons that let you show and hide different parts of the user interface. These buttons are as follows, from left to right:

The Interface toolbar

- **Gallery**: Opens and closes the Gallery panel.
- **LUTs**: Opens and closes the LUT Browser.
- **Media Pool**: Opens and closes the Media Pool.
- **Timeline**: Opens and closes the Mini-Timeline.
- **Clips**: Opens and closes the Thumbnail timeline. To the right is a drop-down menu that lets you choose a timeline filtering option for the Thumbnail timeline.
- **Nodes**: Opens and closes the Node Editor.
- **Open FX**: Opens and closes the Open FX panel.
- **Lightbox**: Opens and closes the Lightbox.
Showing Which Panel Has Focus

Whenever you click somewhere on the DaVinci Resolve interface using the pointer, or use a keyboard shortcut to “select” a particular panel (such as in the Edit page), you give that panel of the user interface “focus.” A panel with focus will capture specific keyboard shortcuts to do something within that panel, as opposed to doing something elsewhere in the interface. A highlight appears at the top edge to show you which panel has focus so that you can keep track of which part of the current page is taking precedence, and you can switch focus as necessary to do what you need to do. You can turn the Focus Indicator on and off in Preferences > User > UI Settings > Show focus indicators in the user interface.

![The focus indicator shown at the top edge of the Media Pool, shown next to a Viewer that doesn’t have focus](image)

Viewer

The Viewer shows the frame at the current position of the playhead in the Timeline. At the top of the Viewer is a header that displays the Project and Timeline names, as well as a Viewer Timecode display that shows the source timecode of each clip by default. The Timeline name is also a drop-down display that lets you switch to any other timeline in the project. A scrubber bar underneath the image lets you drag the playhead across the entire duration of the clip, while transport controls underneath that let you control playback. A toolbar at the top provides controls governing Image Wipes, Split-Screen controls, and Highlight display. Additional controls let you loop playback, switch Unmix mode on and off, turn audio playback on and off, and choose which onscreen controls are currently displayed. More information about using the Viewer appears later in this chapter.

![The default Viewer with transport controls](image)
You can also put the Viewer into one of three alternate modes to be able to see a larger image as you work. All three of these modes are available from the Workspace > Viewer Mode submenu.

— **Enhanced Viewer**: (Option-F to toggle this on and off) hides everything to the left and right of the Viewer, giving you a large working area for tasks such as window positioning and rotoscoping, while keeping the palettes and their controls visible as you work.

![The Color page in Enhanced Viewer mode](image1)

— **Full Screen Viewer**: (Shift-F to toggle this on and off) is available to provide more working area for tasks such as window positioning and rotoscoping. Full Screen Viewer also lets you display the Open FX panel at full height, and you can turn the Node Editor on and off to access different effects controls while you work.

![The Color page in Full Screen Viewer mode](image2)
— **Cinema Viewer:** (P to toggle this on and off) expands the Viewer to fill your workstation’s entire monitor. This is useful if you want to play the current Timeline without any distractions. When you move the pointer over the image, transport controls and a jog bar appear to let you control playback. For DITs, a contextual menu is available by right-clicking anywhere on the image with which you can turn on and customize a video scope overlay (which can be dragged to different locations on the Viewer).

The Color page in Cinema Viewer mode

### Gallery

The Gallery is used for storing still frames to use as reference, and grades you might like to copy; stills and grades are stored together. A button lets you open up the Album browser, used for organizing your stills. At the bottom of the Gallery, Memories let you store grade information that you can apply using a control panel or keyboard shortcuts. The Gallery on the Color page mirrors the contents of the Gallery page. For more information on the Gallery page, see Chapter 137, “Using the Gallery.”

The Gallery has Memories, stills saved in albums and your PowerGrades
LUT Browser

The LUT Browser provides a centralized area for browsing and previewing all of the LUTs installed on your workstation. All LUTs appear in the sidebar, by category.

By default, all LUTs appear with a test thumbnail that give a preview of that LUT’s effect, but you can also get a live preview of how the current clip looks with that LUT by hover scrubbing with the pointer over a particular LUT’s thumbnail (this is described in more detail below).

To open the LUT Browser:
— Click the LUT Browser button in the UI Toolbar at the top of the Color page.

Methods of working with the LUT Browser:
— To see the LUTs in any category: Click on a LUT category to select it in the sidebar, and its LUTs will appear in the browser area.

— To make a LUT a favorite: Hover the mouse over a LUT and click the star badge that appears at the upper right-hand corner, or right-click any LUT and choose Add to Favorites. That LUT will then appear when you select the Favorites category.

— To search or filter for specific LUTs: Open a bin that has the LUT you’re looking for, then click the magnifying glass icon to open the search field, and type text that will identify the LUTs you’re looking for.

— To see LUTs in Column or Thumbnail view: Click the Column or Thumbnail buttons at the top right of the LUT Browser to choose how to view LUTs in the browser area.

— To sort LUTs in Thumbnail view: Click the Thumbnail Sort drop-down menu and choose which criteria you want to sort LUTs by. The options are Filename, Type, Relative Path, File Path, Usage, Date Modified. There are also options for ascending and descending sort modes.

— To sort LUTs in Column view: Click the column header to sort by that column. Click a header repeatedly to toggle between ascending and descending modes.

— To update the thumbnail of a LUT with an image from a clip: Choose a clip and frame that you want to use as the new thumbnail for a particular LUT, then right-click that LUT and choose Update Thumbnail With Timeline Frame.
— To reset the thumbnail of a LUT to use the standard thumbnail: Right-click a LUT and choose Reset Thumbnail to go back to using the standard test image.

— To refresh a LUT category with new LUTs that may have been installed: Select a LUT category, then right-click anywhere within the browser area and choose Refresh to refresh the contents of that category from disk.

**Methods of adding LUTs to a grade from the LUT Browser:**

— To apply a LUT to the current node: Select a clip in the Thumbnail timeline, then right-click a LUT and choose Apply LUT to Current Node from the contextual menu.

— To apply a LUT to a specific node: Drag a LUT from the LUT Browser and drop it onto the node you want to apply a LUT to. If you drag a LUT onto a node that already has a LUT, the previous LUT will be overwritten by the new one.

**Media Pool**

The Media Pool is available in the Color page, making it easy to drag and drop clips you want to use as external mattes right into the Node Editor, for easy and fast connection to create various Color page effects. When opened, the Media Pool replaces the Gallery, fitting into the same area. In most respects, the Media Pool in the Color page works the same as the Media Pool on nearly every other page of DaVinci Resolve.

When you drag a clip from the Color page Media Pool to the Node Editor, two things happen:

— That clip is turned into an external matte in the current grade, which you can use as a matte for secondary adjustments, or as a compositing layer (in conjunction with the Layer mixer) for mixing textures or images with your grade.

— That clip is also automatically attached to the Media Pool clip that corresponds to the clip you’re grading as a clip matte, to help you keep track of which clips are using other clips as mattes.

For more information about the Media Pool, see Chapter 18, “Adding and Organizing Media with the Media Pool.”

**Node Editor**

The Node Editor is where you assemble one or more individual corrections (nodes) together into a complete multi-correction grade (node tree). This is a powerful way of assembling grades, since different types of nodes let you create different combinations of corrections and very specific adjustments by reordering operations, combining keys, or changing the layer order of different adjustments.
For more information about the Node Editor, see the “Node Editor Basics” section of Chapter 139, “Node Editing Basics.”

Node Editor to construct your grade processing signal flow

Timeline

The Timeline provides several ways of navigating the clips in your project, as well as keeping track of what has been done to which clips. The Timeline is divided into two parts, each of which shows different information and provides differing controls, and each of which can be opened or closed separately via the Clips and Timeline buttons on the Interface toolbar.

The Thumbnail timeline with a Mini-Timeline below

Thumbnail Timeline

At the top is the Thumbnail timeline, in which each clip is represented by a single frame. The Thumbnail timeline (or its alter-ego, the Lightbox) provides the easiest way of selecting which clip you want to work on and of making clip selections for various grade management operations. The currently selected clip that reveals its controls in the various palettes of the Color page is highlighted in orange.

Much valuable information appears above and below each thumbnail, such as each clip’s clip number, source timecode, track number, whether it’s been flagged, whether it’s automatically linked or part of a group, whether it’s been tracked, and so on.
A clip thumbnail in the Thumbnail timeline

What's displayed underneath each thumbnail can be changed by double-clicking the space underneath each thumbnail. There are several options; you can keep double-clicking to cycle among them:

— Clip format or codec (the default)
— Clip Name (clip name or file name, depending on what View > Show File Name is set to) or Multicam Angle (if you're working with multicam clips)
— Version name or number

Mini-Timeline

Underneath, the Mini-Timeline shows a small representation of the video tracks of the Timeline in the Edit page wherein each clip is as long as its actual duration. This provides the best representation of the structure of the current timeline, in which clip length shows duration and multiple tracks are displayed, so you can see which clips are superimposed. A Timeline Ruler lets you scrub the playhead across multiple clips and can be zoomed out enough to show every clip in your entire program.

The Mini-Timeline lets you see timeline structure, and small track header controls let you enable tracks, disable tracks, and set the playhead to ignore specific tracks

Small track labels at the left of each track in the Mini-Timeline let you enable or disable tracks by clicking them (enabled tracks have white labels, disabled tracks have gray labels). Option-clicking one of these controls sets that track to be enabled but ignored by the playhead when you use the Next and Previous Clip commands, in the event you want to ignore clips you don’t need to grade (tracks in this mode show a red label).

Within the Mini-Timeline the currently selected clip is highlighted in orange, and you can click any clip to select it. A scroll bar at the bottom lets you navigate to the left and right, while using the scroll wheel of your mouse zooms in and out. The Mini-Timeline shows at most six tracks of video. If your project has more tracks than that, you can scroll up and down to reveal the hidden tracks. Any markers that were placed on clips or the Timeline in the Edit page appear here, and you can click any marker to reveal and edit its color and notes.

As seen above, a colored outline appears around the clip number of shots that have been graded, and this outline is doubled if there are additional versions applied to that clip.

For more detailed information about the Color page Timeline, see Chapter 125, “Color Page Timeline and Lightbox.”
Palette Area

Most everyday tools and functions for grading are distributed among a series of palettes found in the palette area of the Color page. These palettes can be accessed via a series of palette buttons running along the Palette bar at the top of this area.

All palettes seen in the Palette bar

These buttons also give you feedback about which palettes have adjustments for the current selected node in the Node Editor. Palettes with adjustments show a small orange dot in the corresponding palette button.

An orange dot in a palette button lets you know there are adjustments in that palette

Left Palettes

A series of palettes at the bottom left of the Color page provide access to different sets of grading tools, used principally for manipulating color, contrast, and raw media format settings. Each individual palette is opened by clicking the corresponding icon at the top of the Palette panel.

Left palette selection buttons

- **Camera Raw palette**: For making metadata adjustments to raw media formats
- **Color Match palette**: Automatic grading based using test charts
- **Primaries**: Graphical color balance controls and master wheels, along with a Slider mode for adjusting YRGB Lift/Gamma/Gain
- **HDR palette**: Advanced primary grading controls designed for wide-gamut media and SDR or HDR mastering
- **RGB Mixer**: For mixing color channels into one another
- **Motion Effects palette**: With controls for noise reduction and artificial motion blur
The five available palettes can be used individually or together depending on what you’re trying to accomplish. For more information on most of these palettes, see Chapter 128, “Primaries Palette.” For more information on the Motion Effects palette, see Chapter 150, “The Motion Effects and Blur Palettes.”

**Center Palettes**

At 1920x1080 resolution or higher, a second set of palettes is organized at the bottom center of the Color page. These palettes span a wide range of functionality, and the adjustments you make with them can be combined with those made using the Color palettes.

![Center palette selection buttons](image)

**NOTE:** At lower resolutions, the Left and Center palettes are merged to fit the DaVinci Resolve interface into a smaller area.

- Curves palette
- Color Warper palette
- Qualifier palette
- Window palette
- Tracker palette
- Magic Matte palette
- Blur palette
- Key palette
- Sizing palette
- Stereoscopic 3D palette

**Keyframe Editor, Video Scopes, and Information**

The bottom right of the Color page can be switched between one of three things:

![The three controls for displaying the Keyframe Editor, video scopes, or Information palette](image)
**Keyframe Editor:** Provides an interface for animating Color, Sizing, and Stereo Format adjustments over time. Each node in the Node Editor corresponds to a track in the Keyframe Editor, which lets you animate each node’s adjustments independently. Furthermore, each node’s track can be opened up to reveal parameter groups, so that you can animate subsets of an individual node’s functions independently of other functions within the same node.

For more information about keyframing, see Chapter 144, “Keyframing in the Color Page.”

**Video scopes:** Provides a docked area where you can expose one video scope at a time for reference while you work. You can also “undock” the video scopes into a stand-alone window, in which you can show four different scopes at a time. More information about using the video scopes appears later in this chapter.

**Information:** Provides a way of seeing clip and system information while you work.

### Dual Monitor Layout

The Color page has a dual monitor layout that provides maximum space for the Viewer, Node Editor, and Control palettes on the primary monitor, and a simultaneously displayed Gallery, Lightbox, Keyframe Editor, Metadata Editor, and Video Scope panel on the secondary monitor.

**To enter dual screen mode:**

— Choose Workspace > Dual Screen > On.
To switch which UI elements appear on which monitors:

— Choose Workspace > Primary Display > (Monitor Name), which reverses the contents of both monitors in dual screen mode.

The Info Palette and Clip Information

The Info palette is hidden by default. Clicking the Info palette button at the far right of the toolbar reveals it at the right of the Center palette. The Info palette has two tabs that display different information. There are no user-editable controls in the Info palette.
Clip Info

The first tab displays information about whichever clip is currently selected in the Timeline. This information is not editable, but is provided for reference, and includes:

- **File Name:** The name of the media file on disk. If the current clip is a Multicam clip, this shows the name of the currently selected angle.
- **Reel Name:** The reel name of that clip, if one is being read properly.
- **Start T/C:** The source timecode value of the first frame in the clip.
- **End T/C:** The source timecode value of the last frame in the clip.
- **Duration:** The duration of the clip, in timecode.
- **Frames:** The duration of the clip, in frames.
- **Version:** The name of the remote or local version used by that clip.
- **Frame Rate:** The frame rate used by that clip.
- **Source Res:** The native resolution of the source clip.
- **Codec:** The codec or format used by the source clip.

System Info

The second tab displays information about operational modes currently in use by DaVinci Resolve. It's meant to provide the status of different DaVinci Resolve features that can be enabled, disabled, or cycled among various options. This information includes:

- **Clips:** The total number of clips in the Timeline.
- **Proxy:** The status of Proxy mode (On or Off).
- **Clip Cache:** The status of the Clip Cache mode (Off, All, Dissolves, User, User & D).
- **Ref Transform:** The status of Reference Still reposition.
- **Ref Mode:** The status of the Reference mode (Gallery, Timeline, Offline).
- **Wipe Style:** The currently selected Wipe Style for split screens (Wipe-H, Wipe-V, Wipe-M, Wipe-A).
- **Convergence:** The current Convergence setting (Linked Zoom, Opposite).
- **Stereo Grade:** The currently displayed Eye and Gang mode (Left or Right - Gang or Solo).
- **Stereo Display:** The current Stereo Display mode (Mono or Stereo).

Clip Details

You can right-click the currently selected clip in the Thumbnail Timeline and choose View Clip Details to show a small window with all of that clip’s information available at a glance. You can drag this window anywhere you like, even to another display.
The Clip Details window

This information is not editable, but is provided for easy reference, and includes:

— **File Name**: The name of the media file on disk appears at top.
— **Start Timecode**: The source timecode value of the first frame in the clip.
— **End Timecode**: The source timecode value of the last frame in the clip.
— **Duration**: The duration of the clip, in timecode.
— **Frames**: The duration of the clip, in frames.
— **Reel Name**: The reel name of that clip, if one is being read properly.
— **Version**: The name of the remote or local version used by that clip.
— **Format**: The format used by the source clip, along with the frame size and bit depth.
— **Codec**: The codec used by the source clip.
— **Folder**: Which directory on disk the source media resides in.
— **Description**: The description field of the Metadata Editor.
— **Comments**: The Comments field of the Metadata Editor.
— **EDL Comments**: EDL comments for that event, if any exist.

**Customizing the Color Page**

The various sections of the Color page can be resized, hidden, and rearranged as needed to accommodate different working styles. This section covers all of the methods that are available for Color page customization.

You can easily resize the Viewer, Gallery, and Nodes Editor relative to one another to make the Viewer larger, expand the width of the Node Editor to have more workspace, or to create more or less room for stills in the Gallery.
To resize the Viewer, Gallery, and Node Editor:
— Move the pointer over the vertical divider between any two areas. When the resize icon appears, drag the divider to the left or right to make one area larger while making the other smaller.

You can also fully expand the Gallery, the Memories, the Node Editor, and the Keyframe Editor to replace completely whichever interface area is adjacent.

To expand the Keyframe Editor, Viewer, and Gallery:
— Click the Expand control at the upper right of whichever interface area you want to expand. Once expanded, clicking the Expand control again will collapse that interface area back to its original size, revealing whatever was hidden.

In Display mode, you can completely hide the Viewer, pushing the Gallery all the way to the right side of the DaVinci Resolve window, and expanding the Node Editor to take the rest of the space.

To toggle Display mode, do one of the following:
— Right-click in the empty area of the Node Editor, and choose Toggle Display Mode from the contextual menu. Do this again to toggle Display Mode off and return the interface to the way it was.
— Press SHIFT UP and DISPLAY/CURSOR, above the fourth trackball of the Center panel of the DaVinci control panel.

To show and hide the Mini-Timeline:
— Click the Timeline button at the right of the palette button bar.

To show and hide the Color page Viewer upper toolbar:
— Click the Viewer option menu and choose Show Viewer Options to uncheck it.

To return all pages to their default layout:
— Choose Workspace > Reset UI Layout.

Undo and Redo in DaVinci Resolve

No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you’ve taken or commands you’ve executed, and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you’ve done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo “stacks” to help you manage your work.

— The Media, Cut, Edit, and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
— Each clip in the Fusion page has its own undo stack so that you can undo changes you make to the composition of each clip, independently.
— Each clip in the Color page has its own undo stack so that you can undo changes you make to grades in each clip, independently.

In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you’re in.

**To simply undo or redo changes you’ve made one at a time:**
— Choose Edit > Undo (Command-Z) to undo the previous change.
— Choose Edit > Redo (Shift-Command-Z) to redo to the next change.
— On the DaVinci control panel, press the UNDO and REDO buttons on the T-bar panel.

**TIP:** If you have the DaVinci control panel, there is one other control that lets you control the undo stack more directly when using the trackballs, rings, and pots. Pressing RESTORE POINT manually adds a memory of the current state of the grade to the undo stack. Since discrete undo states are difficult to predict when you’re making ongoing adjustments with the trackball and ring controls, pressing RESTORE POINT lets you set predictable states of the grade that you can fall back on.

You can also undo several steps at a time using the History submenu and window. At the time of this writing, this only works for multiple undo steps in the Media, Cut, Edit, and Fairlight pages.

**To undo and redo using the History submenu:**
1. Open the Edit > History submenu, which shows (up to) the last twenty things you’ve done.
2. Choose an item on the list to undo back to that point. The most recent thing you’ve done appears at the top of this list, and the change you’ve just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what’s possible. However, if you’ve undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.

Once you’ve selected a step to undo to, the menu closes and the project updates to show you its current state.
To undo and redo using the Undo window:

1. Choose Edit > History > Open History Window.

2. When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you’ve done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.

3. When you’re done, close the History window.
Chapter 124

Viewers, Monitoring, and Video Scopes

Viewers let you see what you’re working on, provide a UI for transport controls and image comparison, draw windows and drag on-screen controls, and provide a variety of warnings and information not found anywhere else.

However, at the same time, professional workflows require real time monitoring via supported video I/O devices on a calibrated display. Lastly, video scopes provide a more precise analysis of the state of the video signal you’re viewing, and DaVinci Resolve has built-in scopes you can use for creative decision making and troubleshooting.

This chapter covers the Color page Viewer, external monitoring and display calibration, and video scopes in more detail.

Using the Viewer

The Viewer is your window into the Timeline. The clip and frame at the current position of the playhead appears in the Viewer. The Viewer also provides a workspace for picking colors, adjusting Windows, using split screen stills for reference, and many other display-oriented tasks. If you have a video out interface connected to a broadcast display or projector, then the contents of the Viewer are typically mirrored by the video output.

The Viewer Title Bar

The Viewer title bar has controls and indicators making it easy to control and keep track of what it is you’re looking at.

The Viewer title bar has the following controls:

— **Zoom and Fit menu**: Lets you zoom to a specific percentage, or choose Fit to fit the image to the total available area of the Viewer.

— **Playback frame rate indicator**: A dot shows green if playback performance matches the frame rate of the project, or red if playback performance drops below real time. To the right, the current frame rate is displayed.

— **Timeline name and selection drop-down**: The name of the currently open timeline is displayed. A drop-down to the right lets you open any other timeline in the current project to take its place.

— **Timecode viewer and drop-down**: A second timecode viewer lets you choose an alternate timecode/frame count/KeyKode value to display simultaneously to the timecode viewer next to the transport controls below. A drop-down lets you pick whether to display source (clip) or record (timeline) timecode.

— **Bypass Color and Fusion and drop-down**: Lets you disable grades and/or Fusion effects.

— **Expand Viewer drop-down**: Expands the Viewer to take up the full area of your workstation’s display above the palettes.

— **Option menu**: Has options that affect the Viewer’s functionality. Commands include: Gang Timeline wipe with current clip, Gang Viewer zoom with video output, Show clip flags on video output, Show Viewer options, Show Marker overlays, and the Marker list for navigating among all Timeline markers in the currently open timeline.
Turning Grades and/or Fusion Effects Off

The Bypass Color Grades and Fusion Effects button/drop-down commands in the Viewer’s title bar are also available via View > Bypass Color and Fusion menu commands. Turning off Fusion effects in the Color page is an easy way to improve playback performance on low power systems when you just need to make a quick set of grading adjustments. Toggling grades off and on is also a convenient way to quickly get a before-and-after look at a shot where the “before” goes all the way back to the source.

If you choose Toggle Bypass or click the Viewer control, you’ll turn off whatever is checked in the optional menu, which lets you choose whether or not you want to bypass both Color and Fusion, or just one or the other.

TIP: If you’re giving your client a before and after look at work you’re doing on a grade, a more effective technique is to select the specific nodes (one or more) that you want to toggle on and off, and press Command-D (Enable/Disable Selected Nodes.)

Viewing Isolated Channels

Use the View > Viewer Channels submenu to switch the Color page Viewer among RGB, R, G, or B channels. This can be useful when evaluating a single channel of an image for noise or other artifacts, or for doing color matching by comparing and adjusting the individual red, green, and blue channels of two different clips.

The Viewer Toolbar

The Color page also exposes a toolbar at the top of the image (underneath the title bar) that makes it easy to enable and disable image wipe, split screen, and highlight viewing by clicking one of these three buttons, which then expose additional controls relating to each of these modes of operation (described elsewhere in this chapter). This toolbar can be shown or hidden by clicking the Viewer option menu and unchecking Show Viewer Options.
The Color page Viewer toolbar showing the Wipe, Split Screen, and Highlight controls

In the process, these buttons provide an easy reference for when a comparison mode is enabled. In each of these Viewer modes, the appropriate controls for customizing that view appear to the right of the Viewer toolbar.

The Onscreen Control (OSC) Menu

The Onscreen Control drop-down menu lets you choose which onscreen controls you want to display and adjust in the Viewer. Some palettes automatically enable corresponding onscreen controls when you open them. For example, opening the Window palette displays the Power Window onscreen controls, and opening the Qualifier palette displays the Qualifier onscreen controls.

There are a variety of choices, each corresponding to different adjustments you can make:

- **Off**: All onscreen controls are hidden from view, giving you an unimpeded display of the image in the Viewer.

- **Qualifier**: Turns on the Color Sample cursor, which lets you choose a color using the fourth trackball of the DaVinci control panel. For more about using Color Sample controls, see Chapter 134, “Secondary Qualifiers.”

- **Power Window**: Turns the Power Windows onscreen control on and off. For more about adjusting windows in the Viewer, see “Power Windows” in Chapter 135, “Secondary Windows and Tracking.”

- **Image Wipe**: Toggles mouse control of dragging the split screen directly on the Viewer on and off. For more about working with split screens, see “Comparing Clips in the Viewer” later in this chapter.

- **Dust Removal**: Activates the interactive Dirt and Dust tool. For more information, see Chapter 152, “Dust Removal.”
Open FX: Shows and hides whatever onscreen controls are exposed by an Open FX plug-in in the currently selected node.

Color Chart: Shows and hides the color chart overlay that lets you identify a color chart in the picture that you want to use with the Color Match palette to create an automatic grade.

**TIP:** As you work, you may find you want to temporarily hide or show the onscreen controls so you can get an uncluttered look at the image you're adjusting. You can toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).

### Toggling Viewer Overlays On and Off

Pressing Shift-` (Tilde) turns the current Viewer overlay on and off. The View > Viewer Overlay submenu contains commands for showing, hiding, and switching different overlays in the Color page Viewer. While most of the options in this menu are unassigned by default, they can be assigned to keys using the Keyboard Customization window.

### Onscreen Controls and External Displays

DaVinci Resolve has been designed for use with calibrated external displays connected to video output interfaces, and for most colorists working on broadcast or theatrical programs, this is the recommended way to work for color critical evaluation.

Because of this, many of the onscreen controls associated with tasks such as color sampling, window adjustment, and key manipulation are mirrored to your video output, making it possible to hide the Viewer on your computer’s monitor and work with only an external display.

**To choose whether onscreen controls are mirrored to video out or disabled:**

- Choose an option from the View > Window Outline submenu. There are three options:
  - **Off:** Hides the window outline on both the external display and the Viewer.
  - **On:** The default, shows the window outline on both the external display and the Viewer.
  - **Only UI:** Hides the window outline on your external display, but leaves it in the Viewer.

**To show clip flags on video output:**

Turn on the “Show clip flags on video output” checkbox option in the Color page Viewer’s Option menu. This enables drawing one or more small colored flag overlays in the bottom-left corner of video output. This way, you can always see which clips are flagged on your grading hero display as you work, if that helps you to keep track of whatever you’re using flags to stay on top of. This is off by default.
Limitations When Grading With the Viewer on a Computer Display

Most computer displays do not operate at the color critical tolerances or specifications required for quality control for streaming, broadcast, or theatrical delivery. An additional issue, however, is that depending on your combination of workstation and computer display, the Viewer does not necessarily display each clip’s image data as it is displayed by the calibration that your operating system applies to your computer display, depending on which OS you’re running DaVinci Resolve on. This makes your computer display potentially unsuitable for monitoring projects destined for the sRGB standard of the web in its default state. For example, if you grade a project using the Color page Viewer on your computer display, the resulting clip may not look the same in the QuickTime player, or in other post-production applications.

You can address this in one of two ways:

– If you’re using DaVinci Resolve on macOS, you can turn on “Use Mac Display Color Profile for viewers” in the Hardware Configuration panel of the System Settings. This lets DaVinci Resolve use whichever of the color profiles you choose in the Color tab of the Displays panel in the macOS System Preferences, thereby taking advantage of ColorSync on macOS to let DaVinci Resolve display color the way your computer monitor does. This now works for all color profiles that ship with macOS, as well as color profiles that have been generated by calibration software, such as that available from X-rite, Datacolor, or other applications. On supported computers, there’s also an option to “Use 10-bit precision in viewers,” if available, that you can turn on. With this option enabled, rendered output displayed in QuickTime Player will match what is seen in the DaVinci Resolve Viewer.

– Alternately, you can apply a dedicated Color Viewer LUT for calibration, using the 1D/3D Color Viewer Lookup Table drop-down menu that’s found in the Color Management panel of the Project Settings. This lets you analyze your computer display for calibration in the same way you would calibrate an external display, using a probe and color management software, and apply the resulting calibration LUT in DaVinci Resolve. Keep in mind that monitor calibration can only make a high quality display standards compliant; it cannot make up for a display gamut that’s too small. For more information, see the “Lookup Tables” section of Chapter 4, “System and User Preferences.”

Strictly speaking, if you’re doing professional work, you should restrict your grading using a calibrated, 10- or 12-bit class A external broadcast display of some type, connected via a Blackmagic Design video interface. Assuming everything is running properly, an image that is output to video from DaVinci Resolve should match an image output to video from any other post-production application you’re using, and this should be your basis for comparison when examining the output of two different applications.
Zooming into the Viewer

When using the Viewer to sample tricky colors or draw a detailed PowerCurve, it can be advantageous to zoom into the image.

**To zoom into or out of the Viewer, do one of the following:**

— Move the pointer to within the Viewer, and then roll the scroll wheel to zoom in or out of the image.
— Press Command-Equal to zoom in, or Command-Minus to zoom out.

**To pan around the Viewer:**

— Move the pointer to within the Viewer, then middle-click and drag to pan around the image.

**To reset the size of the Viewer image:**

— Choose View > Viewer Actual Size (Option-Shift-Z).
— Choose View > Zoom > Zoom to Fit (Shift-Z).

**To enable or disable image zoom being sent to video out:**

— Choose “Gang viewer zoom with video output” from the Option menu of the Viewer to zoom the image shown on video out identically to the zoom level of the Viewer, enabling you to evaluate a zoomed-in portion of the image on your suite’s hero display.

Using the Jog Bar and Transport Controls

One of the principal uses of the Viewer is to control playback. The jog bar, directly underneath the image in the Viewer, contains a playhead that you can drag to the left and right to navigate quickly through the currently selected clip as fast as you can move the pointer. The playhead in the jog bar is locked to the playheads found in the Timeline and Keyframe Editor. Moving one playhead moves all three.

How much of the Timeline the jog bar navigates depends on whether the Node Editor is set to Clip or Timeline mode. In Clip mode, the jog bar width equals the duration of the currently selected clip. In Timeline mode, the jog bar width equals the total duration of the entire Timeline.

A row of transport controls below the jog bar provides more specific control over timeline playback.

— **Previous clip**: Moves the playhead to the first frame of the previous clip.
— **Reverse**: Initiates 100% playback in reverse.
— **Stop**: Stops playback.
— **Play**: Initiates 100% playback.
— **Next clip**: Moves the playhead to the first frame of the next clip.
— **Loop**: Lets you restrict playback to the current clip, looping to the first frame if you’re playing forward to the end of a clip, or looping to the last frame if you’re playing in reverse to the beginning of a clip.
Two other buttons let you control audio playback and clip display in the Viewer:

— **Unmix:** Turning on Unmix disables all transitions, compositing superimpositions, and effects that mix two or more clips together. Unmix allows you to judge the appearance of a clip without distraction whenever you need to make an adjustment based on how the clip looks on its own, or whenever you need to make changes based on frames that would otherwise be hidden underneath a transition such as a dissolve or fade from black. When you’re ready to see how your grades work in context with transitions and composites again, turn Unmix off.

— **Mute:** Audio playback can be turned on or off by clicking on the speaker icon, or adjust the level by right-clicking on the speaker icon and dragging the slider.

**Navigating Using the Arrow Keys**

You can use the Arrow Keys of the keyboard to navigate clips and the Timeline in different ways.

— **Up/Down Arrow:** Moves the playhead to the first frame of the previous or next clip.
— **Left/Right Arrow:** Moves the playhead back or forward one frame at a time.
— **Shift-Left/Right Arrow:** Moves the playhead back or forward one second at a time.

**Controlling Playback Using the Spacebar and JKL Keys**

You can also use the spacebar to start and stop playback, or the JKL keyboard shortcut convention for controlling playback, where J plays in reverse, K stops playback, and L plays forward. There are many additional uses of these keyboard shortcuts; for more information see “Using JKL to Control Playback” in Chapter 36, “Preparing Clips for Editing and Viewer Playback.”

**Fast Review on the Color Page**

The Fast Review playback command (Playback > Fast Review) is now available on the Color page. Intended to help you watch through long sequences of clips quickly, clicking this button begins accelerated playback through the Timeline, where the speed of playback is relative to the length of each clip you’re playing through. Long clips play faster, whereas shorter clips play closer to real time.

**Navigating Using Timecode**

You can also use absolute or relative timecode entry to move the playhead in the Color page Viewer. When entering timecode, type each pair of hour, minute, second, and frame values consecutively, with a period representing a pair of zeros for fast entry. The last pair of timecode values (or period) you enter is always assumed to be the frame number, with any untyped values assumed to be zero. It’s not necessary to enter colons or semicolons. For more information, see “Moving the Playhead Using Timecode” in Chapter 36, “Preparing Clips for Editing and Viewer Playback.”
Viewer and Transport Timecode Displays

The Viewer has two timecode displays, each of which defaults to a different timecode setting. A timecode display at the top, the Header timecode display, shows the Source timecode by default. The timecode display at the bottom, the Transport timecode display, shows the Record timecode by default. The bottom timecode display can be changed to show one of four different options, which are similar to those found in the Data Burn-In palette.

To change a timecode display to a different setting:
The top timecode display is a drop-down menu that can be changed to whatever timecode, frame number, or KeyKode you want to display. The bottom timecode display can also be changed by right-clicking on it and choosing the type of value to show from the contextual menu that appears. There are the following options:

— **Timeline Timecode:** The timecode corresponding to the playhead’s position in the overall Timeline.
— **Source Timecode:** The timecode corresponding to the playhead’s position relative to the currently selected clip.
— **Timeline Frame:** The frame count corresponding to the playhead’s position in the overall Timeline.
— **Source Frame:** The frame count corresponding to the playhead’s position relative to the currently selected clip.
— **KeyKode:** The KeyKode number corresponding to the media’s KeyKode track, if there is one.
— **Show Timecode at 30 FPS:** Displays 24 fps timecode, via 3:2 pulldown, as 29.97 fps timecode. Has no effect on video playback.
— **Copy and Paste Timecode:** Two commands make it easy to copy and paste timecode values.

In the same way, the top timecode display can alternately be changed to show KeyKode, if it’s available, within a DPX media file’s header.

Enhanced, Full, and Cinema Viewing

You can expand the Viewer into Enhanced Viewing mode by choosing Workspace > Viewer Mode > Enhanced Viewer mode (Option-F), or by pressing CURRENT/VIEWER on the T-bar panel of the DaVinci control panel.

**Enhanced Viewing Mode**

In Enhanced Viewing mode, the Viewer works exactly as it does at its regular size, but it expands to fill up the entire area of the screen above the palettes and Keyframe Editor. To exit Enhanced Viewing mode, press (Option-F) again.

This can be useful if you need a closer view of the image for purposes of making detailed corrections, examining noise patterns up close, making a tricky color selection, or drawing a complicated PowerCurve.
Full Viewing Mode

In Full Viewing mode (available by choosing Workspace > Viewer Mode > Full Page Viewer, pressing Shift-F, or Option-clicking the Enhanced Viewing mode button), the Viewer takes up even more room by hiding the palette controls, but leaves room for the transport controls, the Onscreen Control dropdown menu, the timecode display, and the page buttons along the bottom of the DaVinci Resolve UI. This mode is useful when you need an even closer look at the image, but you still want access to a minimal set of onscreen controls.
**Cinema Viewing Mode**

Another option, Cinema mode, allows for full-screen viewing. Cinema mode is available by choosing Workspace > Viewer Mode > Cinema Mode Viewer (P). In Cinema mode, the menu bar is hidden, and the image is presented full screen without any of the ordinary onscreen controls. Moving the pointer over the screen reveals a set of hidden onscreen controls that include a play button, jog bar, mute button, and exit button (which lets you turn off Cinema mode). You also have the option of superimposing scopes over the image, which can be valuable in on-set situations.

![Color page in Cinema mode](image)

Cinema mode is useful for doing detailed reviews of media in on-set and digital dailies workflows when working remotely without a secondary video display.

**TIP:** If you'd like to superimpose timecode over the image in Cinema mode for reference, you can use the controls within the Data Burn-In window (Workspace > Data Burn-In) to set up whatever information you'd like to display during playback.

**Safe Area Overlays in the Viewer**

You can show or hide a series of safe area overlays in the Viewer. All safe area overlay options are found in the View > Safe Area menu. Each safe area overlay option can be individually enabled or disabled from this menu.
— **On/Off:** Turns all currently selected safe area marker options on or off at once.
— **Extents:** An outline showing the exact outer edge of the frame. Especially useful when the safe markers are set to an aspect ratio other than that currently used by the Viewer.
— **Action:** An outline showing the outer 90% action safe area of the frame.
— **Title:** An outline showing the outer 80% title safe area of the frame.
— **Center:** A crosshairs showing the center of the frame.
— **Aspect:** Enables use of the View > Select Aspect Ratio submenu to change the aspect ratio of the safe area markers. You can choose among the following aspect ratios: 1.33 (a.k.a. 4:3), 1.66, 1.77 (a.k.a. 16:9), 1.85, and 2.35.

You can also access these options directly using the DaVinci control panel.

### Use Gray Background

Choosing View > Show Gray Backgrounds in Viewer sets the empty area of the Viewer (if there is any) to a lighter gray, making it easier to see which parts of the Viewer are black because of blanking, and which parts are simply empty because of the way the image is zoomed or panned.

### Monitor Calibration

If you use Light Illusion’s LightSpace CMS or SpectraCal’s Calman for display calibration, you can now use DaVinci Resolve as a sync-able pattern generator. This means you can use DaVinci Resolve to output color patches, synchronized by LightSpace, to your display through whichever video interface is connected to your computer. These synchronized color patches will be analyzed by a monitor probe that’s also controlled by LightSpace, which stores the probe data and compares it to the original color values of the output color values in order to characterize that display.

To use this feature, you must first have a licensed copy of LightSpace CMS, which is a Windows application. Synchronization depends on a wired or wireless LAN being available to connect the LightSpace application with DaVinci Resolve.
To synchronize LightSpace CMS to DaVinci Resolve as a pattern generator client:

1. Open LightSpace on the Windows computer that's running it.

2. When LightSpace is open, click the Network Manager button. A window appears displaying the two network IP addresses used by LightSpace. Note these, and click the Enable button.

4. When the LightSpace dialog opens, enter the second of the two network IP addresses LightSpace lists into the Remote Machine field, and make sure the Port number matches. Then click the Connect button.

If everything is working correctly, the LightSpace dialog in DaVinci Resolve should show the word “Connected,” and the Network Manager dialog in LightSpace should show that there is 1 available client/s.

You can now close the Network Manager dialog in LightSpace and follow the procedures outlined in the LightSpace CMS documentation for characterizing your display and building and exporting a display LUT (in the .cube format) that you can use as a display LUT in DaVinci Resolve. Alternately, you can export a display LUT from LightSpace that can be loaded onto an outboard video processing device.

5. When you're finished, click Disconnect in the LightSpace dialog, and then click Cancel to close the window.
Viewing Broadcast Safe Exceptions

Choosing View > Display Broadcast Safe Exceptions sets the Color Page Viewer to show a false-color overlay that indicates in blue the regions of the picture that violate the currently selected broadcast safe level in the Color Management panel of the Project Settings.

Areas of the image that violate broadcast safe are highlighted in blue.

More information about broadcast safe limiting in the Color Management panel of the Project Settings see Chapter 126, “Automatic Grading Commands and Imported Grades.”

Comparing Clips in the Viewer

The ability to compare different clips to one another is an important part of the color correction process. DaVinci Resolve provides three different ways of doing so. You can use the Gallery to display two clips for split screen comparison. You can also use different reference modes to see a timeline clip or reference movie directly as part of a split screen comparison. Finally, you can use the Split Screen controls to display multi-frame arrangements in the Viewer.

Saving and Wiping Stills in the Gallery and Timeline

The Gallery on the Color page provides fast access to stills that you’ve saved from various clips in the Timeline. While the dedicated Gallery page provides a more comprehensive interface for browsing presaved “looks,” as well as for importing stills from other projects, you can save, organize, and browse stills directly within the Gallery of the Color page.

Stills are saved in the DPX file format. Once you’ve saved one or more stills, you can set up split screen wipes in the Viewer, which will be mirrored to your external display.
Stills from the Gallery can be compared to the current shot making it easier to match grades

This section provides an abbreviated summary of still store and split screen functionality to get you started quickly.

**To save a still, do one of the following:**

— Choose View > Stills > Grab Still (Option-Command-G).
— Right-click on the Viewer and choose Grab Still.

**To wipe a still, do one of the following:**

— Select a still in the Gallery, and click the Image Wipe button on the top Viewer toolbar.
— Choose View > Stills > Play Still (Command-W), or right-click in the Viewer and choose Toggle Wipe.
— Double-click a still in the Gallery.

**To adjust a wipe in the Viewer, do one of the following:**

— Drag the pointer within the Viewer to move the wipe.

**To customize a wipe in the Viewer:**

— Click one of the Wipe mode buttons in the Viewer toolbar. There are the following modes:
  — **Horizontal:** Lets you compare both halves of the wipe to either side of a vertical border. Dragging the pointer moves the wipe border left and right.
  — **Vertical:** Lets you compare both halves of the wipe above and below a horizontal border. Dragging the pointer moves the wipe border up and down.
  — **Diagonal:** Lets you compare both halves of the wipe via an adjustable diagonal border. Dragging the pointer repositions the wipe to the left and right. Hold the option key down and drag while moving the pointer around in a circle to rotate the border of the wipe to any angle you like.
  — **Mix:** Lets you blend both images together to compare them. Dragging the pointer controls the fade percentage from one image to the other.
— **Alpha:** Lets you use a qualifier to define transparency in the image of the current clip while comparing it to a Gallery still used as the background. Add a node to the grade and use the qualifier to key a particular color you want to turn transparent (the green of a green screen, for example). Then, connect that node’s KEY output to the Alpha Output that appears in the Node Editor. The part of the foreground image isolated by the key becomes transparent, allowing the Gallery still in the background to show through. This can be useful for previewing how the lighting or grade of a foreground VFX plate looks when the image is composited against a particular background image stored in the Gallery.

— **Box:** Lets you view the current clip as a picture-in-picture effect against the still in the background. Dragging the pointer resizes the crop box around the outside of the reference image.

— **Venetian Blind:** Lets you compare both images being wiped via alternating horizontal strips. Drag the pointer up or down to change the size of the alternating strips. Good for quickly comparing vertical color uniformity, focusing on color and contrast changes that occur from top to bottom.

— **Checkerboard:** Lets you compare both images being wiped via an alternating checkerboard. Drag the mouse left or right to alternate between images by squeezing each check horizontally. Good for comparing color uniformity across the width and height of two images.

— Choose one of the following from either the View > Wipe Style submenu or the Viewer’s contextual Wipe Style submenu.

— **Wipe Style:** Cycles among the Horizontal, Vertical, Diagonal, Mix, Alpha, Difference, Box, Venetian Blind, and Checkerboard modes.

— **Invert Wipe:** Reverses each half of the wipe.

### Hover Scrub in the Gallery

When Live Preview is enabled in the Gallery option menu, the Hover Scrub Preview submenu lets you choose how you want Live Preview to be shown by a thumbnail in the Gallery and in the Viewer when you hover the pointer over a still or LUT in the LUT Browser:

— You can choose to scrub both the thumbnail you’re hovering over and the Viewer, letting you preview the current still’s grade or a LUT over the duration of the current clip in both the thumbnail and Viewer.

— You can choose to scrub just the thumbnail, leaving the Viewer to show just the grade or LUT over the frame at the position of the playhead.

— You can disable scrubbing altogether, in which case both the thumbnail and the Viewer will only show the grade or LUT over the frame at the position of the playhead.

### Copying Grades from Stills in the Gallery

Stills also store the grade from the clip they came from, and can be used to copy grades from one clip to another, or to store grades that you might want to use later.

**To copy a grade from a still to a clip, do one of the following:**

— Select one or more clips in the Timeline, then right-click a still in the Gallery and choose Apply Grade.

— Select one or more clips in the Timeline, then middle-click a still in the Gallery.
When you copy a still in this way, the saved grade completely overwrites the grade in the target clip, unless you’ve used the “Preserve number of nodes” option, found in the contextual menu of the Gallery. For more detailed information on using the Gallery, including options for organizing the Gallery browser, instructions for using Albums, Power Grades, and Memories, as well as other methods of copying grades and performing advanced grade management tasks, see Chapter 138, “Using the Gallery” and Chapter 139, “Grade Management.”

**Different Viewer Reference Modes for Wipes**

While it’s common to use the Gallery to wipe against reference stills, by changing the reference mode you can also create a wipe against a clip in the Timeline, or against an Offline Reference Clip or Timeline, if one has been assigned to the current Timeline.

To change the Viewer reference mode, do one of the following:

— Choose an option from the View > Reference Wipe Mode submenu.
— Right-click the Viewer and choose an option from the Reference Mode submenu of the contextual menu. There are three reference modes:
  — **Gallery**: The default reference mode. Lets you wipe the current clip against a Gallery still.
  — **Timeline**: Lets you wipe the current clip against another clip in the Timeline using the Wipe Timeline Clip command (see below).
  — **Offline**: Lets you wipe the current clip against an offline video that’s been assigned to the current Timeline. For more information on assigning Offline References to a timeline for comparison, see Chapter 56, “Preparing Timelines for Import and Comparison.”

**Wiping Between Clips in the Timeline**

If you want to wipe the current clip against another clip in the Timeline without saving a still to the Gallery first, there’s a special procedure you can follow.

To wipe between two clips using the Timeline reference mode:

1. Click the thumbnail of the first clip you want to compare.
2. (Optional) A “Gang timeline wipe with current clip” option, available from the Viewer option menu, lets you maintain the offset between the current clip and a timeline clip you’re wiping against when you move the current clip selection to other clips. With this option enabled, the offset between the timeline wiped clip and the current clip is maintained when you move the clip selection. You can step the timeline reference clip forward one frame by pressing Command-Option-Right Arrow, and back one frame by pressing Command-Option-Left Arrow. This allows for precise positioning. When this option is disabled, the timeline wiped clip stays where it is regardless of what clip you select.
3. Right-click the thumbnail of the second clip you want to compare against, and choose Wipe Timeline Clip from the contextual menu.

Both clips appear split screened against one another.

**NOTE:** Wipe Timeline Clip only appears in the contextual menu if you right-click on a thumbnail in the Timeline that has not been selected as the current clip.
Change a Timeline Wipe Using the Timelines Album of the Gallery

While you’re using the Wipe Timeline Clip to show a wipe of the current clip against any other clip in the Timeline, you can open the Timelines album of the Gallery and click different clips to change which timeline clip you’re wiping against (outlined in blue) without changing the current clip (outlined in orange).

Using Split Screen Modes

A set of split screen modes provides additional ways of comparing multiple images in the Viewer at the same time. These provide side-by-side and grid comparisons of multiple shots and multiple versions, all of which are output to video for monitoring on your external video display. For example, you can use the Split Screen Versions mode to display every single version that’s applied to the current clip in a grid, for easy evaluation. The currently selected clip in the Timeline is highlighted in gray, so you can keep track of what you’re doing.

To enable a split screen mode, do one of the following:

— Click the Split Screen button on the top Viewer toolbar, and choose a split screen method from the drop-down menu that appears in the Viewer toolbar at the right.
— Choose an option from the View > Split Screen submenu.
— Press Option-Command-W to turn Split Screen on and off, using the last selected option.
— Right-click the Viewer and choose an option from the Split Screen submenu in the contextual menu.

NOTE: When any of the split screen modes are selected, you cannot see any other onscreen controls in the Viewer, such as Power Window shapes, until you first disable split screen.

Four shots shown in a grid using the Split Screen > Selected Clips mode
Viewing and Choosing the Current Selection

In any of the split screen modes, the current selection is indicated by a gray outline. This outline can be disabled for a more direct comparison by choosing View > Split Screen > Show Outline to toggle the outline off and on.

In certain modes, you can also double-click a particular frame of the split screen view to change the current clip, choose the active version, or apply a gallery grade.

Available Split Screen Modes

You can choose from among the following split screen modes:

— **Current Group**: Shows up to 16 clips that share the same group as the current clip. Double-clicking a frame does nothing in this mode.

— **Highlight Modes**: Shows a four-up display that lets you simultaneously see (clockwise) the clip’s RGB image, the gray matte, the high contrast matte, and a difference matte generated by the node’s input compared against its output. Double-clicking a frame does nothing in this mode.

— **Neighbor Clips**: Shows four clips that immediately surround the current clip. The previous two clips appear as the upper left- and right-hand clips, the current clip appears at the lower left-hand corner, and the next clip appears at the lower right. Double-clicking a frame does nothing in this mode. The “Neighboring Clips in Split Screen” parameter in the Color panel of the User Preferences lets you customize how many neighboring clips appear in this mode.
— **Playheads:** Shows simultaneous comparisons in the Color page Viewer of up to four playheads displayed in the Mini-timeline when you choose multiple playheads from the Color > Active Playhead submenu. For every playhead you expose (up to 4), the frame at each playhead will be displayed in a 2-up, 3-up, or 4-up grid. An outline in the Viewer (if enabled) shows which playhead is currently active. This is useful both for comparing multiple clips, as well as for comparing different frames within the same clip. Switching between the active playheads can be done by clicking on the clips in the split screen Viewer.

Placing three playheads in the Mini-timeline.

— **Selected Album:** When you choose this option, a split screen of the grades of every still in that album are shown in the Viewer as they appear applied to the current clip. Double-clicking a frame applies that gallery grade to the current clip. Up to 16 grades will be shown.

— **Selected Clips:** Shows all currently selected clips in the Timeline, up to 16 at one time. Clicking a clip moves the playhead to the first frame of that clip.

— **Selected LUTs:** Lets you simultaneously display previews of different LUTs effect on the current clip as a split screen in the Viewer by using the LUTs browser to Command-click up to 16 LUTs you want to preview.

The Selected LUTs split screen option lets you preview a bunch of LUT looks at once.
— **Selected Still Grades**: When you choose this option, the act of selecting stills in the Gallery of the Color page shows each of the grades associated with those stills as they appear applied to the current clip, in a split screen arrangement. Double-clicking a frame applies that gallery grade to the current clip.

![Previewing four gallery grades using the Split Screen > Gallery Grades mode](image)

— **Selected Still Images**: Lets you view the current clip against a variety of other stills in the Gallery that you select. This is not a grading preview, you’re actually doing a split screen of the selected still images in the Gallery.

— **Version**: Shows up to 16 versions for the current clip, all at once, making it easy to evaluate a series of different versions in relation to one another. If you have more then 16 versions, you deserve some manner of award. Double-clicking a version changes the active version.

— **Versions and Original**: Shows up to the first 15 versions for the current clip, along with the original ungraded clip at the upper left-hand corner. Double-clicking a version changes the active version, but you cannot double-click to select the original.

### Marker Overlays and Navigation

If you part the playhead on top of a marker in the Timeline of the Color page, that marker’s information appears in a Viewer overlay, just as in the Edit page, making it easier to read notes and see what information is available. These overlays can be easily hidden by clicking the Viewer option menu and turning off “Show marker overlays.”

### Timeline Marker List Available in Color Page

**Viewer Option Menu**

The Option menu of the Color page Viewer has a submenu that lists all Timeline Markers in the currently open timeline. This makes it easy to run down client notes.
Using Video Scopes

While not directly tied to use of the Viewers, video scopes nonetheless work hand in hand to help you evaluate the images you’re working on. DaVinci Resolve has a set of five real-time video scopes that you can use to monitor the internal data levels of clips in your project as you work. Each scope provides an unambiguous graphical analysis of different characteristics of the video signal, showing you the relative strength and range of individual color components including luma, chroma, saturation, hue, gamut, white point, and the red, green, and blue channels that, together, comprise the color and contrast of the images in your program.

Video Scope Location

By default, you can view any one of these scopes at a time at the bottom right corner of the Color page, by clicking the Video Scope button in the palette button bar.

The video scope, docked next to the other palettes at the bottom of the Color page
Optionally, you can click the Expand button at the top right of the video scope to open the video scopes into a floating window, within which you can display all four video scopes together, or individually, on any monitor connected to your workstation.

Additionally, the video scopes can appear docked on a second display as part of many of the dual-screen layouts available in DaVinci Resolve. However, if you have three computer displays and you’re using dual screen layouts, you still have the option to open the floating Scopes window and place it on your third display, as large as you need.

The video scopes aren’t just available in the Color page. They’re also available in the Media and Deliver pages for whenever you need to evaluate the video signal more objectively, such as when you’re setting up to capture from tape or scan from film, or when you’re setting up for output.

To open video scopes from the Media, Color, or Deliver pages, do one of the following:

— Choose Workspace > Video Scopes > On/Off (Command-Shift-W) to open video scopes into a floating window.
— Choose Workspace > Dual Screen > On to open video scopes as part of a dual screen layout.

**Video Scope Measurement Using Scales**

Because you’re evaluating the internal state of the image data, by default the numeric scales of the WFM and Parade scopes always reflect 10-bit full range data from 0–1023, regardless of the Video/Data Level setting you’ve selected in the Master Settings panel of the Project Settings. This gives you a window into how the image is being processed by DaVinci Resolve prior to being output via your computer’s video I/O interface.

If you’re working on an HDR (High Dynamic Range) grade, you can choose HDR (ST.2084/HLG) from the Video Scopes option menu (this feature is only available in Studio version). This replaces the
10-bit scale of the Waveform, Parade, and Histogram video scopes with a scale based on nit values (or cd/m²) instead.

(Left) The Parade scope showing the data range scale, (Right) The Parade scope showing the HDR “nit” scale

**Changing Waveform Scales**

A Waveform Scale Style submenu in the Video Scopes option menu (the three dots menu) lets you choose how you want the numeric scale at the left of Waveform and Parade scopes to be represented. There are options for 10-bit display (the default), 12-bit display, Percentage (0 to 100), millivolt (mV), and HDR (ST.2084/HLG). Aside from the added flexibility this gives you, this also means that it’s no longer necessary to go to the Preferences to change the scope to have an HDR scale shown in nits (cd/m²).

Waveform scale options

**Changing Vectorscope Scales**

A Vectorscope Scale Style submenu in the Video Scopes option menu (the three dots menu) lets you choose how you want the hue reference indicators to be displayed.
Vectorscope scale options

There are four available graticule options:

— **Off**: Disables all graticule overlays in the Vectorscope, giving you a clean view of the Vectorscope graph against black.

— **Standard**: The default layout. Cross hairs indicate the center of the scope, while boxes indicate the center target of each primary and secondary hue (red, magenta, blue, cyan, green, yellow). An outer circle provides a general frame of reference for the angle that any part of the graph might fall along.

— **Simplified**: Shows a crosshairs to indicate the center of the scope and smaller crosshairs to indicate each primary and secondary hue. Useful when you want references without extra complications.

— **Hue Vectors**: A graticule designed to provide a more useful colorist reference for creative decisions and image comparison. This isn’t simply decorative. Graticule lines stretch along the reference angle of each primary and secondary hue from the hue targets to the center, providing a more immediately useful frame of reference when comparing different vector scope graphs to one another. These reference lines fade out within the region of average saturation in most images, so they don’t get in the way of discerning faint details. The center crosshairs are aligned with the red-cyan and yellow-blue axes, indicating the naturalistic warm to cool axis that lies between them. Tic marks indicate both the 75% and 100% levels of image saturation for each hue.

You also have the option of choosing whether or not the primary and secondary hue targets are shown for 75% image saturation, 100% image saturation, or both, and whether or not you want to show the text labels for each hue.

**Displaying Scopes With Data or Video Levels**

For projects being worked on at video levels, a setting in the video scope option menu’s Waveform Scale Style submenu lets you toggle between displaying video scopes scaled to either Data Levels (the default) or Video Levels (by turning on Video Level Scopes). This only affects how your scopes are displayed; it has no effect on monitored or rendered output.
Video Scope Performance and Detail

All video scopes were updated for DaVinci Resolve 16 to show more detail with faster performance than in previous versions. While they’re GPU-accelerated, the video scopes require a certain amount of video processing power to operate. Depending on which combination of video scopes and scope options you have selected, you may notice your real time processing capabilities ever so slightly affected. Closing the video scopes frees up all processing for color correction and effects. On high-powered workstations, you probably won’t notice a difference, but on less powerful computers, closing the scopes might make a small difference.

Two global settings in the video scope option menu affect the performance and detail of all video scopes equally.

— On slower workstations, a quality submenu lets you choose High, Medium, or Low quality scope drawing, to trade off legibility for performance. High quality shows you the most information about the video signal, while an Auto option makes a selection based on your workstation’s capabilities.

— All video scopes have a Low Pass Filter setting in the video scope option menu that filters out a signal’s noise to make the scope graphs clearer to read. While this can act as an “x-ray” to better see detail in the scope graph interiors, it can make the highlight and shadow excursions on the graph seem a bit shy of where they actually are, so it’s recommended to enable the “Extents” option of whichever scope you’re using to get an unambiguous look at the maximum excursions in your scopes. Extents draws an outline highlighting all graph excursions to show you the true level of all overshoots and undershoots in the video signal, even when the Low Pass Filter is on.
Display Qualifier Focus in Video Scope Graphs

The Display Qualifier Focus setting in the video scope option menu helps you identify which features in the video image correspond to which parts of the video scopes. With Display Qualifier Focus turned on, choosing the Qualifier mode of the Viewer and moving the eyedropper around the image draws circles around the sampled pixels as they appear in the currently visible video scope graph. If multiple video scopes are visible, each scope will have an indication of the location of the sampled pixels that’s specific to each scope.

(Left) Hovering the eyedropper over a feature in the Viewer, (Right) The regional analysis of those pixels shown in the overlaid red, blue, and green waveforms of the Waveform scope.

Explanation of Each Video Scope

There are five available video scopes, each of which shows a different analysis of the video signal you’re adjusting.

**Waveform Monitor**

Overlays waveform analyses of the Y (luma/luminance), CBCR (the color difference channels of Y’CBCR), or RGB (red, green, and blue) channels over one another so that you can see how they align.

The Y option presents a true Luma scope that can have Colorize enabled to show false color, which lets you see which colors in the Viewer image are where in the video scope graph.

For the RGB scopes, the relative heights of the red, green, and blue graphs indicate is identical to the description seen for the Parade scope below, and with color enabled the red, green, and blue graphs are tinted with the color they represent. This makes it easy to see where all three graphs align, by looking for where parts of the waveform monitor appear in white, which is the result of the red, green, and blue graphs lining up and adding their color together.
Parade

The Parade scope shows separate waveforms side by side that analyze the strength of individual video signal components. The Parade scope can be set to analyze RGB, YRGB, and Y’CBCR.

By showing a comparison of the intensity of the luma, red, green, and blue channels, the Parade scope makes it possible to detect and compare imbalances by comparing the relative heights of the RGB graphs in the highlights (the top of the R, G, and B graphs), shadows (the bottom of the R, G, and B graphs), and midtones (the middle of the R, G, and B graphs) for the purposes of identifying color casts and performing scene-by-scene correction.

When the YRGB channels are taken altogether, the bottom of all graphs indicates the black point of the image, while the tops of all graphs indicate the white point. It then follows that the difference between the height of the bottom and top of all graphs indicates the overall contrast ratio of the image you’re evaluating. Tall parade graphs indicate a wide contrast ratio, while short parade graphs indicate a narrow contrast ratio.
Vectorscope

Measures the overall range of hue and saturation within an image. Measurements are relative to a centered graticule that you can enable that’s overlaid on the scope, which provides a frame of reference via crosshairs. DaVinci Resolve has a traditional vectorscope, the graph of which emulates a trace-drawn graph, with 75 percent color bar targets indicating the angle of each of the primary and secondary colors around the edge of the graph, and an optional skin tone reference graticule (otherwise known as the In-phase reference).

The Vectorscope can have Colorize enabled to show false color which lets you see which colors in the Viewer image are where in the video scope graph.

More saturated colors in the frame stretch those parts of the graph farther toward the edge, while less saturated colors remain closer to the center of the vectorscope, which represents 0 saturation. By judging how many parts of the vectorscope graph stick out at different angles, you can see how many hues there are in the image, with the specific angle of each part of the graph showing you which hues they are. Furthermore, by judging how well centered the middle of the vectorscope graph is relative to the crosshairs, you can get an idea of whether there’s a color imbalance in the image. If the vectorscope graph is off-centered, the direction in which it leans lets you know that there’s a color cast (tint) in the image.

Histogram (RGB/YRGB parade histogram)

Displays a statistical analysis of how many pixels of each color channel lie at each percentage of tonality, plotted along a digital scale from 0 percent (black) to 100 percent (white). Comparing the left, middle, and right parts of the Y, R, G, and B graphs (Y is optional) lets you evaluate the color balance in the shadows, midtones, and highlights of the image.

Taken altogether, the left of all graphs indicates the black point of the image, while the right of all graphs indicate the white point. It then follows that the difference between the width of the left and right of all graphs indicates the overall contrast ratio of the image you’re evaluating. Wide histogram graphs indicate a wide contrast ratio, while narrow histogram graphs indicate a narrow contrast ratio.
CIE Chromaticity Scope

DaVinci Resolve contains CIE 1931 xy and CIE 1976 uv scopes, which let you see the current image analysis as a graph superimposed against a triangle that represents the tristimulus values of the color gamut you’re working within, along with an indication of the current white point. A label shows the currently selected gamut, with the specific coordinates of these Red, Green, and Blue values as well as the White point, while the overall “horseshoe” shape represents the entire range of visible light, all plotted against an xy graph.

The white point ordinarily appears atop a curve along the center of the shape. This curve indicates the black body locus, along which the various color temperatures of an image’s white point correlate, from orange-ish warm to blue-ish cool. This black body locus corresponds to the color temperatures obtained by progressively heating carbon to different temperatures.

You also have the option of showing a second gamut triangle, in cases where you want to compare the current analysis to two different gamuts. This can be useful when you need to create deliverables in multiple gamuts, and you want to see which parts of the video signal are safe in all gamuts and which parts are exceeding the smaller of the two. When you do this, both gamuts are labeled, and the coordinates of the Red, Green, and Blue values of both gamuts are listed to the side.
In a way, the Chromaticity scope is a 3D scope, but it’s drawn as if you’re looking down at the top of a 3D shape that plots every color value in an image in X, Y, Z space, but you can only perceive the 2D outline around the widest parts of this shape drawn on an X, Y plot. The graph does indeed represent every single value found within a 3D plot of the image data, but the triangle only indicates the widest “slice” of the current gamut and of this 3D shape within the mid-tones.

What this means is that while the Chromaticity scope’s graph gives you a rough idea of whether or not the current image is within gamut relative to your delivery spec, it’s not exact and it’s not foolproof, as part of the image data could fall within this wide triangle and yet overshoot the required gamut elsewhere in the highlights at the top or the shadows near the bottom of the 3D shape you’re looking down on. On the other hand, if any part of the graph does extend past the boundaries of the gamut triangle, then that definitely indicates a gamut violation.

You can add an additional gamut triangle in the scope settings in order to compare the color space you’re working in to another color space, for reference.

Most people who’ve had any exposure to color grading concepts are familiar with the traditional CIE 1931 horseshoe graph, which plots the portion of the spectrum visible to the human eye according to studies done in the late 1920s (subsequent studies have confirmed this analysis). The optional CIE 1976 uv graph is based on an updated color space (CIELUV) that was an attempt by the International Commission on Illumination (CIE) to create a more perceptually uniform graph of color. Whereas the CIE 1931 analysis visually exaggerates certain parts of a color graph, the CIE 1976 graph draws all parts of a color graph more or less proportionally to one another. Overall, neither analysis is more “correct” than the other, it’s simply a matter of what you prefer to look at.

Panning and Zooming the Video Scopes

If you want to examine any part of a video scope’s graph in more detail, you can do the following:

— **To zoom into a graph:** Hold the Option key down, and roll the scroll control.
— **To pan around a graph:** Click and drag with the middle pointer button.
Customizing the Video Scopes

Once you’ve opened the video scopes, there are a variety of ways you can customize how the scopes look, and expose additional onscreen graticule information to help you measure what you need.

Methods of customizing the Scopes window:

— **To change the size of the Scopes window:** Drag the lower right-hand corner to resize the Scopes window to the desired size.

— **To change how many scopes are displayed at once:** Click one of the buttons in the upper right-hand corner of the Scopes window to set 1, 2, 4, or 9 up arrangements of the video scopes. You can also choose how many scopes are simultaneously displayed by choosing Workspace > Video Scopes > 1-Up, 2-Up, or 4-Up.

— **To change which scopes appear in which pane:** Click the Name drop-down at the upper left corner of each scope’s pane, and choose a different scope. If you like, you can instantiate more than one of each kind of video scope in multi-scope layouts, for instances where you want to view variations on a particular type of scope with different settings. For example, you might want to expose three Vectorscopes, setting each to a different tonal range so you can simultaneously view Vectorscope analyses of Low (shadows), Mid (midtones), and High (highlights).

Once open, you can resize the Scopes window to make it as large or small as you require, positioning on a second display if you want to make it even larger.

**To customize each video scope’s display options:**

1. Click the Option button to the right of the Scope drop-down menu to expose the current scope’s Custom Controls window.

2. Adjust any of the available controls to customize the look of that particular scope.

3. Click anywhere outside of the Custom Controls window to make it disappear.

**Parade Scope Display Options**

The Parade scope has the following options:
Options in the Parade scope

- RGB, YRGB, and YCbCr modes, allowing you to evaluate more channels than before.
- A colorize checkbox lets you view graphs in monochrome or false-color (indicating red, green, and blue).
- An Extents checkbox draws an outline highlighting all graph excursions, to unambiguously show you all overshoots and undershoots in each waveform.
- The Parade slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
- The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
- The Show Reference Levels checkbox lets you turn on adjustable Low and High reference level markers by setting the low and high sliders to something other than their defaults. This is especially useful for HDR grading where you’re working within a specific peak luminance threshold.

Waveform Scope Display Options

The Waveform scope has the following options:
— Y (luma) and CbCr (chrominance) modes to show you the true luma or chroma signals in isolation, and RGB to show you only an RGB analysis.
— In RGB mode, R, G, and B buttons that can be individually toggled on and off to see any combination of graphs.
— A colorize checkbox lets you view overlaid graphs in monochrome or false-color (indicating red, green, and blue). If you’re only enabling the Y or C scopes, the different areas of these graphs are drawn with color taken from the image being analyzed, which makes it easier to see which part of the scope graph corresponds to which part of the image.
— An Extents checkbox draws an outline highlighting all graph excursions, to unambiguously show you all overshoots and undershoots in each waveform.
— The Waveform slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
— The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
— The Show Reference Levels checkbox lets you turn on adjustable Low and High reference level markers by setting the low and high sliders to something other than their defaults. This is especially useful for HDR grading where you’re working within a specific peak luminance threshold.

**Vectorscope Display Options**

The Vectorscope has the following options:

— Choose ALL to view the entire tonal range of the image as a Vectorscope graph analysis, or to selectively view just the shadows (Low), mid-tones (Mid), or highlights (High) of the image as a vectorscope graph analysis.
— A Colorize checkbox draws the different areas of these graphs with color taken from the image being analyzed, which makes it easier to see which part of the scope graph corresponds to which part of the image. With colorize turned off, graphs only appear white.
— An Extents checkbox draws an outline highlighting all graph excursions to unambiguously show you all overshoots and undershoots.
— A Combine checkbox lets you see simultaneous overlapping extents for the highlights, mid-tones, and shadows overlaid on one another.
— The Vectorscope slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
— The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
— Low Range and High Range sliders let you manually define the boundaries separating shadows from mid-tones and highlights. Low Range defaults to 0.30, and High Range defaults to 0.70.
— Show 2X Zoom zooms the vectorscope graph by 200%, making it easier to see fine detail and use the vectorscope with charts.
— Show Skin Tone Indicator checkbox shows a line at the traditional Inphase angle that is useful as a general guidepost for average skin tone hue.
— Show Graticule checkbox lets you show or hide the circular degrees indicator surrounding the outer edge and the cross hairs that indicate the center of the vectorscope.

### Histogram Display Options

The Histogram has the following options:

— You can view either RGB or YRGB histograms.
— Gain slider scales that scope’s graph taller or shorter. Taller graphs expand to show greater detail in the histogram’s peaks, shorter graphs reduce the apparent detail.
— Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
— The Show Reference Levels checkbox lets you enable adjustable Low and High reference level markers by setting the Low and High sliders to something other than their defaults. These reference markers are especially useful for HDR grading where you’re working within a specific peak luminance threshold.
CIE Chromaticity Display Options

The CIE Chromaticity scope has the following options:

— You can view a chromaticity analysis in either a CIE 1931 xy graph, or a CIE 1976 uv graph.
— CIE Chromaticity slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
— Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
— Additional Gamut drop-down menu lets you expose a second gamut triangle, for instances where you want to compare how an image fits into two different gamut ranges.
— Show 2X Zoom zooms the CIE graph and graticule by 200%, making it easier to see fine detail and use the vectorscope with the charts.
— Show Graticule checkbox lets you show or hide the circular degrees indicator surrounding the outer edge and the cross hairs that indicate the center of the vectorscope.
Chapter 125

Color Page Timeline and Lightbox

The Timeline in the Color page, consisting of the Thumbnail Timeline and the Mini-Timeline, is primarily used for navigating the current arrangement of clips, and for keeping track of clip properties such as whether they’re graded and ungraded, whether they use tracking, which version they’re using, and so on. It can also be used for quickly copying grades from one clip to another, for creating groups, and for comparing clips in the Viewer.

The Lightbox is the twin sibling of the Thumbnail Timeline, and provides an image-based method of comparing clips, managing grades, and performing a wide variety of organizational tasks.

This chapter covers the use of the Timeline and Lightbox.

Navigating Using the Color Page Timeline

The Color page Timeline consists of two parts that work together, the Thumbnail Timeline and the Mini Timeline. These work together to let you examine and navigate the Timeline of your program in different ways.

The Color page Timeline

The scroll bar for the Mini-Timeline is independent of the scroll bar for the Thumbnail Timeline, and both can be set to show different ranges of clips. Using the scroll control of your pointing device lets you zoom into or out of the Mini-Timeline. When zoomed all the way out, the Mini-Timeline displays the entire timeline within the available width of the screen, making it a fast way of navigating the entire program from the beginning to the end. However, you can zoom into a particular section when you need more information about how an intricate arrangement of superimposed clips are organized while you’re grading.

Thumbnail Timeline

Provides a concise visual representation of your project where each clip is a single numbered thumbnail, regardless of its duration. Clicking a thumbnail moves the playhead to the first frame of that clip, while using the Up/Down Arrow keys moves the selection to the previous or next clip. Whichever clip is at the current position of the playhead appears with its thumbnail outlined in orange. The scroll wheel of your pointing device lets you scroll backward and forward through the thumbnail timeline.

Mini-Timeline

Shows a miniature representation of the Timeline in the Edit page, where each clip’s width is proportional to its duration, and superimposed clips are shown on top of one another. The Mini-Timeline can show a maximum of six video tracks; if your edit uses more, a scroll bar lets you change which...
tracks are displayed. Clicking a clip in the Mini-Timeline selects that clip and moves the playhead to its first frame.

The Color page Mini-Timeline

**Scrolling, Zooming, and Navigation**

A Timeline Ruler contains the top handle of the playhead, displays the record timecode of the current edit, and acts as a scrubber bar that typically spans a longer section of the Timeline. The scroll wheel of your mouse lets you zoom in and out of your edit, and if you zoom all the way out you can fit every clip in the Mini-Timeline into the available width of the ruler, letting you scrub through every clip in the Timeline quickly. Clicking anywhere within the ruler instantly jumps the playhead to that frame.

**Enabling/Disabling Tracks**

The far left of the Mini-Timeline shows numbers for each track, and hovering the pointer over the track number of any track in the Mini-Timeline of the Color page reveals a tooltip showing the name of that track. Clicking a track number enables/disables that track along with all clips on that track, similarly to using the Timeline > Enable/Disable Video Tracks submenu commands (Shift-Command-1 through 9). Clips on disabled tracks are not rendered in the Viewer or video output, and are hidden from the Thumbnail Timeline. If a track has been disabled in the Edit page, it will appear dimmed in the Mini-Timeline.

Option-clicking a track number in the Mini-Timeline turns that track number red, letting you hide clips from the Thumbnail Timeline without actually disabling the video in your program. This is useful in situations where you want to prevent clips in a particular track (such as motion graphics or titles rendered from another application) from intercepting the playhead when using the next/previous clip commands.

**Setting In/Out Points for Looping**

You can use the I and O keyboard shortcuts to set custom In and Out points in the Timeline. Once set, turning on Loop in the Viewer transport controls enables this range to be looped, whether it’s a partial range of one clip, or a range spanning multiple clips together.

**Using Multiple Timeline Playheads**

DaVinci Resolve supports creating up to four separate playheads in the Mini-Timeline, that you can use to jump back and forth among different parts of your timeline. Only one playhead can be selected at any given time, and the currently selected playhead corresponds to the current clip, highlighted in orange. Each playhead in the Mini-Timeline is labeled with a letter, A through D.

Multiple playheads in the Mini-Timeline for multi-region navigation
To add a new playhead to the Mini-Timeline:
— Choose a playhead from the Color > Active Playheads submenu. That playhead will be placed at the same position as the original playhead, but it is now the one that is selected, so dragging the new playhead to a new position of the Mini-Timeline will reveal the original playhead you were using.

To select another playhead to view:
— Click on the top handle of any playhead to select it, making that the currently active playhead controlled by the transport controls. By default, no keyboard shortcuts are mapped to the four playheads that are available, but you can create a custom keyboard mapping that you can use to quickly switch among them.
— Using the DaVinci Advanced control panel, you can use the A, B, C, and D buttons on the jog/shuttle panel to switch to the playhead you want to control.

To eliminate all additional playheads from the Mini-Timeline:
— Choose Color > Active Playheads > Reset Playheads.

Show Current Clip With Handles
If you’re working on a project that’s part of a round-trip workflow, and you know you’ll be rendering handles for each clip, it can be useful to temporarily expose these handles for the current clip that you’re grading, so you can easily apply tracking or keyframing effects to the full frame range of each clip.

To show or hide clip handles in the Mini-Timeline of the Color page:
— Choose View > Show Current Clip With Handles.

(Left) The current clip in the Mini-Timeline, (Right) The same clip shown with Show Current Clip With Handles enabled

While this mode is enabled, Unmix is turned on and cannot be disabled, in order to let you view the overlapping handles of each clip clearly. The duration of handles that are exposed is defined by the Default Handles Length parameter of the Editing panel in the User Preferences. Clip Handles can be shown or hidden at any time.

Thumbnail Info
The thumbnails make it easy to find the clips you’re looking for visually, and they always show the media as it’s currently graded. The most obvious piece of information is the frame that’s used for each clip’s thumbnail. If you feel that a particular clip’s thumbnail isn’t representative of its content, you can change it.
To change the current thumbnail:
— Move the pointer over a thumbnail, drag to the left or right to scrub through the clip, and stop when you find a frame you want to use as the new thumbnail.

![Dragging a thumbnail to change the representative image](image)

If media is replaced in the middle of a color correction timeline, or if you copy or ripple a grade to a range of clips, the thumbnails may not immediately update to accurately represent the current state of each clip. In this case, you can manually refresh the thumbnails.

**To refresh all thumbnails in the Timeline:**
— Right-click anywhere in the Thumbnail timeline and choose Update All Thumbnails.

You can also choose to display the codec, clip names, and version used by each clip in the Timeline.

**To switch the Thumbnail timeline between showing clip names, codecs, and versions:**
— Double-click the thumbnail clip name of any clip to cycle through each clip’s codec, clip name, and version.

Additional information appears above and below each thumbnail, providing a way of keeping track of which clips have been graded, which clips are using different versions, which clips have been cached, and so on.

![Each clip thumbnail has a number of valuable indications permitting quick comparison to other shots.](image)

The following list explains each piece of information that can appear above, within, or below the thumbnails in the Timeline.

— **Clip number:** (top left) Each clip’s number appears above its thumbnail. Clips are numbered in ascending order according to the position of their first frame, from left to right, regardless of the video track in which they appear.

— **Grade indicator:** (top left) If a clip has been graded, a thin rainbow indicator surrounds the clip number.
— **Source Timecode**: (top center) The source timecode from the first frame of each clip appears above each thumbnail.

— **Cache indication**: (red timecode) Any clip that’s marked for caching, whether automatically via the Smart cache, or manually, has its timecode turn red to indicate that it will be cached. After it’s been cached, the timecode turns blue.

— **Track number**: (top right) The video track in which a clip is edited appears above the thumbnail.

— **Clip Color dot**: (upper right) If a clip has a clip color assigned to it, a colored dot appears on top of its thumbnail.

— **Flag icon**: (upper left) If a clip has been flagged, a flag icon of the appropriate color appears on top of its thumbnail. If a clip has multiple flags, as many as can be drawn appear along the top.

— **Linked media or group icon**: (bottom right) If clips are set to use remote versions, and if multiple clips share the same source media file, then by default their remote version 1 grade will be automatically linked. If the current clip is linked, a small link icon appears below the thumbnail of every clip in the Timeline that’s also linked to that clip. When you select another clip that’s not linked, the linked clip icons disappear.

— **Tracker icon**: (bottom right) If any node within a particular clip’s grade has been tracked, a small crosshairs tracker icon appears below the thumbnail.

— **3D indicator**: (bottom right) All stereo 3D clips in the Timeline appear with this icon below the thumbnail. The color indicates which eye you’re monitoring; red for the left eye, blue for the right eye.

— **Version name/Source format**: (bottom left) What text is displayed below each thumbnail can be changed by double-clicking the space underneath each thumbnail. There are several options; keep double-clicking to cycle among them:

  — **Clip format or codec**: This is what’s displayed by default.

  — **Clip Name**: Depending on what View > Show File Name is set to, the clip name or file name is displayed. If you’re working with multicam clips, the multicam angle or name is displayed.

  — **Version name or number**: Provides information about whether a clip is using a remote version, or a local version, indicated by an (L). If you’ve given the current version a name, it appears; otherwise the version will be labeled “Version” with its number.

### Thumbnail Contextual Menu Commands

Right-clicking a clip’s thumbnail in the Thumbnail Timeline reveals a contextual menu with many media and grade management commands that are available in the Color page. The available options are divided into the following rough categories:

— Commands for managing grade versions
— Commands for managing groups
— Commands for editing flags, markers, and clip colors
— A command for displaying the Node Graph of a clip’s grade
— Options for controlling the render cache
— Resolve Color Management clip assignments
— LUT Management commands
— A command to fix Black Sun artifacts
— Commands for viewing clip details, editing Clip Attributes, and finding clips in the Media Pool
— A command for updating clip thumbnails that are slow to update on their own

These capabilities are described in more detail in the other chapters of this manual, but it’s important to know that artists working on the Color page have many clip management options available to them, without needing to go to other pages.

Sorting and Filtering Clips in the Thumbnail Timeline

By default, the Thumbnail Timeline displays every clip of the currently selected edit in the Edit page, sorted in A mode (the record order of your edit). However, the sort order and contents of the Timeline can be changed and filtered to make it easier for you to find specific groups of clips for grading.

Changing Timelines

If you’re working on a project that has more than one timeline, you can switch timelines right from within the Color page.

To switch timelines in the Color page:
Choose another timeline from the Timelines drop-down menu at the top of the Viewer.

To switch among timelines using the DaVinci control panel:
— Press the MODES button above the fourth trackball on the Center panel, then press the SWITCH TIMELINE soft key. Press MODES to return to the main page of controls when you’re done.

A and C Mode Sorting

By default, the Timeline is set to Record mode sorting, otherwise known as A mode sorting. In this mode, clips appear in the Timeline according to the order in which they were edited. This lets you see the order of clips as they’ll appear in the final program.
A Mode sorting, i.e., record order

However, you can change the sort order of the clips in the Timeline to Source mode, or C mode sorting. In C mode sorting, all clips are rearranged in ascending order from left to right according to their source timecode, and their record timecode is temporarily ignored.

C Mode sorting, i.e., source clip order

Sorting by C mode makes it easy to identify a range of similar clips. For example, if you’re working on a narrative project, clips from each angle of coverage in the scene will naturally cluster together. In another example, sorting by C mode in a documentary will arrange all of a particular subject’s head shots from a specific interview contiguously, one after another, since they all come from the same range of timecode on the same source tape. In both examples, the close proximity of similar clips to one another that C mode creates makes it easy to copy grades among them, ripple changes, or group them.

When you’re finished, you can switch the Timeline back to A sort mode, and all of the clips will go back to being arranged in the order in which they were edited.

To toggle between A and C mode sorting, do one of the following:

— Choose an option from the View > Timeline Thumbnail Mode submenu.
— Press Command-Page Down to toggle to C mode sorting.
— Press A/C MODE on the T-bar panel of the DaVinci control panel.
— While in C mode, the word “SOURCE” appears at the right in the Timeline Ruler of the Mini-Timeline.

A checkbox in the Conform Options group in the General Options panel of the Project Settings lets you change the behavior of C mode sorting. Opening the Settings window and clicking the General Options panel of the Project Settings reveals the Sort Timeline Using Reel Name and Timecode checkbox.
With this checkbox turned on (the default), all clips in the Timeline are sorted by reel name first, and then by source timecode. This way, clips with similar timecode from the same reel will appear next to one another in C mode.

If you turn this checkbox off, reel name is ignored, and all clips in the Timeline are sorted only by source timecode. This may result in clips from multiple sources being mixed together, but it is useful in specific situations.

For example, when grading dailies from a three camera shoot, you may want to see consecutive clips from all three cameras lined up one after the other on the Timeline, so that Cam1_Shot1, Cam2_Shot1, and Cam3_Shot1 appear first, followed by Cam1_Shot2, Cam2_Shot2, and Cam3_Shot2, and so on. In this situation, you don’t want clips from cameras 2 and 3 to be placed at the end of the Timeline simply because of their reel name.

**Flags, Clip Colors, and Markers**

You have the option of flagging or marking clips in the Color page just like you can in the Edit page, in order to keep track of specific media or frames that you may need to do something to later. For example, you could flag every closeup of a particular actor with a blemish that you want to spend some time fixing with a green flag.

**Methods of flagging, changing colors, and marking clips in the Color page:**

- **To add a flag to a clip:** Move the playhead to a clip in the Mini-Timeline, and choose a color from the Mark > Add Flag submenu, or Right-click any clip’s thumbnail, and choose a flag color from the Flags submenu. Flags are not frame-specific, so flagging one clip will result in flags also being placed on all other clips that share the same source media in the Media Pool.

- **To remove all of a clip’s flags:** Move the playhead to a clip in the Mini-Timeline, and choose Mark > Clear Flags, or right-click a clip’s thumbnail and choose Flags > Clear All.

- **To change the clip color:** Move the playhead to a clip in the Mini-Timeline, and choose a color from the Mark > Set Color submenu, or Right-click any clip’s thumbnail, and choose a color from the Clip Color submenu. Clip Colors are clip-specific.

- **To remove a clip’s color:** Move the playhead to a clip in the Mini-Timeline, and choose Mark > Set Clip Color > Clear Color, or right-click a clip’s thumbnail and choose Clip Color > Clear Color.

- **To mark a frame of a clip:** Right-click a clip’s thumbnail and choose a marker color from the Marker submenu.

- **To remove a single marker:** Right-click a clip’s thumbnail and choose Delete Marker from the Marker’s submenu. Alternately, you can select the marker in the Mini-Timeline, and press the Delete key.

- **To remove all of a clip’s markers:** Right-click that clip and choose Clear All from the Markers submenu.
Timeline Filtering

A drop-down button to the right of the Clips button at the top right of the Color page Interface Toolbar presents preset options for dynamically filtering which clips are shown in the Timeline. This allows you hide all the other clips in the Timeline except for the subset on which you want to focus.

For example, once you’ve added flags or markers to clips, it’s easy to hide every other clip in the Timeline that doesn’t fit the criteria; for example, hiding clips that don’t have a green flag. This does nothing to alter the original edit, and you can return the Timeline to its original state at any time.

To filter the Timeline:

— Click the Timeline Filtering drop-down button to the right of the Clips button at the top left of the DaVinci Resolve UI, and choose an available option. While the timeline is filtered, an orange line appears underneath the Clips button in the UI toolbar at the top of the page.

To return the Timeline to normal:

— Click the Timeline Filtering drop-down button, and choose All Clips.

You can use timeline filtering in conjunction with A or C mode sorting to arrange clips in whatever way is best for the task you’re trying to accomplish. Clip filtering can also be used in the Lightbox, and a currently selected clip filtering method will simultaneously isolate clips in the Timeline and Lightbox as you switch back and forth.

Preset Timeline Filters

DaVinci Resolve comes with several preset criteria by which you can filter the Timeline, which cover many common organizational workflows:

— **All Clips**: No clips are filtered, and every clip in the current edit is shown.
— **Selected Clips**: Filters all currently selected clips.
Graded Clips: Filters all clips that have been graded.

Clips with Fusion Composition: Clips with Fusion page effects applied to them.

Ungraded clips: Filters all clips that have not yet been graded.

Modified clips: Submenu, filters all clips that have been modified within a specified time.

Unrendered clips: Filters all clips that have not yet been rendered.

Flagged Clips: Filters all clips that have any flag, no flag, or a particular flag; a submenu presents each color.

Marked Clips: Filters all clips that have any marker, no markers, or a particular marker; a submenu presents each color.

Keywords: Filters all clips that have a specific keyword assigned. A submenu presents a list with each keyword that’s used in the Media Pool of the current project.

People: Filters all clips that have a specific person assigned from the People Management Window. A submenu automatically presents a list of each person that’s been identified.

Stereoscopic: Filters stereo 3D clips, a submenu presents options for filtering All Stereo Clips, or just Stereo clips that have been Autoaligned, those with Convergence adjustments, those with Floating Windows adjustments, or stereoscopic clips with swapped media for the left and right eyes.

Grouped: Filters all clips belonging to a particular group, a submenu shows all available groups.

Tracked: Filters all clips with motion tracking.

Noise Reduction: Filters all clips using noise reduction.

OpenFX: Filters all clips using OpenFX.

Different Frame Rate: Filters all clips with frame rates that don’t match that of the project.

Edit Sizing: Filters all clips that have had any Edit Sizing parameters adjusted.

Input Sizing: Filters all clips that have had any Input Sizing parameters adjusted.

Common Media Pool Source: Filters all clips sharing the same source in the Media Pool as the current clip.

Matte Nodes: Filters all clips with an exposed Matte node in the Node Editor.

Mattes Available: Filters all clips with a matte assigned to them, whether they’re used or not.

Collaborative Update Available: (Only available in Collaborative Mode) Filters all clips that have been flagged as having been updated during a collaborative workflow.

Creating and Using Smart Filters

If none of the preset filters does what you need, you can create your own custom Smart Filter in order to sift out clips based on any of the intrinsic or user-entered metadata that’s available in the Metadata Editor, Media Pool, and Color page timeline. Smart Filters work much the same way as Smart Bins, and they’re created and edited using the same procedures. For more information on Smart Bins, see Chapter 18, “Adding and Organizing Media with the Media Pool.”

In fact, Smart Filters can be very sophisticated, allowing you to filter the contents of the Thumbnail timeline by multiple criteria, and using multiple groups of multiple criteria for situations where you need to find clips that match all of one set of criteria, but only one of a second set of criteria. In this way, you can create Smart Filters to solve a wide variety of workflow needs as you work in the Color page.
It’s important to point out, however, that as much intrinsic metadata is available to every clip in DaVinci Resolve (clip properties including frame rate, frame size, codec, file name, and so on), the more time you take entering extra metadata in the Metadata Editor to prepare your project for work for editing and grading (for example, entering scene and take information, and keywords for things like character names, day and night, interior and exterior, framing, and so on), the more powerful Smart Filters can be in helping you to sift and sort through the contents of a program you’re grading.

Imagine being able to filter out all the closeups associated with a particular person in a program, or finding all the establishing shots corresponding to a particular location. If you or an assistant can take the time to enter metadata for the source material in a project that identifies these characteristics, you’ll be able to work even more quickly to match shots together and find the clips you need for any given situation.

**To create a Smart Filter:**

1. Click the Timeline Filtering drop-down button to the right of the Clips button at the top right of the DaVinci Resolve UI, and choose Create Smart Filter.
2. In the Create Smart Filter dialog, enter a name for the filter, and use the following controls to create one or more filter criteria (you can have as many filter criteria as you like):

   — **Show in all projects checkbox:** Lets you create a persistent smart filter that appears in all projects in your project library. Smart filters created this way will be found in the User Smart filters section inside every project’s Clips button in the Color page.
   
   — **Match options:** For multi-criteria filtering, choosing All ensures that every single criteria you specify is met for a clip to be filtered. Any means that if only one out of several criteria is met, that clip will be filtered.

   — **Filter criteria enable checkbox:** Lets you enable or disable any criteria without having to delete it.

   — **Metadata category drop-down:** Lets you choose which category of metadata you want to select a criteria from. Each category of metadata that’s available in the Metadata Editor is available from this drop-down menu. Additionally, Color Timeline Properties (containing many properties unique to the Color page timeline) and Media Pool Properties (containing every column in the Media Pool) provide access to additional metadata you can use for filtering.

   — **Metadata type drop-down:** For choosing which exact type of metadata to use, of the options available in the selected metadata category.

   — **Metadata criteria drop-down:** Lets you choose the criteria by which to filter, depending on the metadata you’ve selected. Options include “true/false,” integer ranges, date ranges, string searches, flag and marker colors, and so on.
**Add filter criteria button:** Lets you add additional criteria to create multi-criteria filters. You could use multiple criteria to, for example, find all clips from Scene 2, that also contain the keyword “Diana,” that also have the keyword “CU” in order to find all the Scene 2 close-ups of Diana. Additionally, if you Option-click this button, you can add a nested match option in order to create even more sophisticated filters, where the filter must match all of one set of criteria, and any of another set of criteria.

A complicated Smart Filter with multiple criteria and a second match option setting

As you’re editing the filter criteria, the Thumbnail timeline automatically updates to show you how the Smart Filter you’re creating is working.

3 When you’re done editing the filter criteria, click Create Smart Filter. The resulting Smart Filter appears at the bottom of the Filter drop-down menu, and is turned on by default.

**Methods of modifying existing Smart Filters:**

- **To rename a Smart Filter:** Click the Timeline Filtering drop-down and choose the Smart Filter you want to rename from the Rename Smart Filter submenu, then change the name in the Smart Filter Name dialog, and click OK.

- **To edit a Smart Filter:** Click the Timeline Filtering drop-down and choose the Smart Filter you want to edit from the Edit Smart Filter submenu, then edit the filter criteria, and click OK.

- **To delete a Smart Filter:** Click the Timeline Filtering drop-down and choose the Smart Filter you want to delete from the Delete Smart Filter submenu. It’s immediately deleted.
Using the Lightbox

The Lightbox shows you all clips in the Timeline as a grid of thumbnails, arranged in rows from left to right and top to bottom. This lets you quickly evaluate, compare, and search for clips you want to use when making selections, creating groups, flagging clips, or when scanning for a particular scene or looking for an individual clip.

The Color page Lightbox displays all the clips in the Timeline.

At the right of the Lightbox is a vertically oriented Timeline Ruler letting you know the timecode value at the beginning of each row of clips. At the top right is a Zoom slider that lets you change the size of the thumbnails.

Selecting a clip in the Lightbox is the same as selecting a clip in the Timeline, and right-clicking a clip in the Lightbox shows the same contextual menu items you’d see if you right-clicked a clip in the Timeline. Furthermore, you can also grade the current clip in the Lightbox using a control panel, or by exposing the color controls to grade the current clip using a mouse or other input device.

Methods of using the Lightbox:

— **To show or hide the Lightbox:** Click the Lightbox button in the toolbar.
— **To show color controls in the Lightbox:** Click the Show Color Controls button in the UI control bar above the Lightbox.

The Color Controls button, with the sidebar and Thumbnail Info buttons below.
— **To show thumbnail info in the Lightbox:** Click the Clip Info button, which is the second control at the upper left-hand corner of the Lightbox, to turn each clip’s thumbnail info off and on.

— **To resize clips in the Lightbox:** Drag the Zoom slider to the right to increase thumbnail size, or to the left to decrease thumbnail size.

The Lightbox button, Zoom slider, and Monitor Output buttons

The contents of the Lightbox can be filtered using the same options that are available for filtering the Thumbnail timeline.

**To filter the Lightbox:**

1. Click the Show sidebar button at the upper left-hand corner of the Lightbox. This reveals all of the filtering options that are available in the Lightbox, including custom Smart Filters you’ve created.

2. Click one of the options appearing in the sidebar. The Lightbox should immediately update to show just those clips that match the selected criteria.

3. To go back to seeing every clip in the Timeline, click All Clips.

The Lightbox can also be output to video, in order to see its contents on a broadcast display or projector.
To output the contents of the Lightbox to video:

— Click the Output Lightbox to Video button at the upper right-hand corner of the Lightbox.

For more information about clip selections, groups, and grade management, see Chapter 138, “Grade Management.”
Chapter 126

Automated Grading Commands and Imported Grades

While DaVinci Resolve has a wide variety of manual grading controls that afford you control over just about every component of digital imagery, DaVinci has spent a lot of time investigating ways of increasing colorist efficiency by creating automated grading tools.

Furthermore, with integrated editing bringing professional editors into the world of editing, grading, and finishing in DaVinci Resolve, the same automated tools being developed to help colorists go home earlier can also be used to give non-colorists a hand in taking care of simple grading tasks.

Color Match Palette

If the camera and lighting departments had the foresight to shoot a color test chart for each of the major lighting setups in the project you’re grading, DaVinci Resolve lets you superimpose a sampling grid over a chart in a clip and mathematically analyze the sampled colors to generate an automatic correction. Using controls in the Color Match palette, you can specify the Source Gamma, Target Gamma, and Target Color Space to make sure that the resulting correction is correct for the camera you used, and the project you’ve set up.

The Color Match palette works with several standardized color charts:

- Datacolor SpyderCheckr 24
- DSC Labs ChromaDumonde 24+4
- DSC Labs SMPTE OneShot
- X-Rite ColorChecker Classic
- X-Rite ColorChecker Classic - Legacy
- X-Rite ColorChecker Video
- X-Rite ColorChecker Passport Video

The X-Rite ColorChecker, Datacolor SpyderCheckr, and DSC Labs SMPTE OneShot charts compared, all of which are supported by the Color Match palette.
The result is analyzed to generate an automatic color correction to use to create a neutral grade for the image, to use as a starting point for the rest of your grade.

**Tips for Properly Shooting a Color Chart**

The results you get using Color Match are completely dependent on how the charts were shot in the field. If the charts were properly shot, you’ll get great results. If the charts were improperly shot, the results will be unpredictable.

To get the best results using Color Match, adhere to the following guidelines:

— The chart must be lit evenly such that the lighting on each patch is the same intensity (level) and color. Any shadows or changes in lighting color across the chart will result in Color Match trying to compensate for these changes, and an inaccurate match will result. When viewing a chart being lit prior to a shoot shooting via a waveform monitor, the top of each individual patch as seen on the scope should appear as a rectangle with a “flat top.”

(Left) Poorly lit chart with irregularly topped waveforms,
(Right) Well lit chart with flat-topped waveforms
— No patches on the chart should be clipped in any of the RGB color channels. A clipped channel will force Color Match to use incorrect RGB values, and the resulting match will be inaccurate.

— The white patch on the recorded chart should be captured between 70–95 IRE/percent. Correct exposure is essential to getting a good result, and while Color Match does allow for some adjustment via the White Level option, this will only give accurate results if the original chart is shot so that the white patch sits within the 70–95 IRE/percent range when viewed on a waveform monitor. It is not recommended that a white patch be shot with a signal level above 95 IRE/percent, since this usually means that one of the RGB channels is close to or actually clipping which will cause an inaccurate match.

— The Source Gamma setting must be set to match the encoded OETF (opto-electrical transfer function, or gamma) of the recorded image. To be able to create an accurate adjustment, the Color Match function requires image data that is scene linear (linear to light). Most captured or recorded image data is encoded with a tone curve (gamma curve) to maximize the efficiency of the bit depth being used, and different cameras use different gamma curves to maximize the image data from different sensors. Since the Color Match algorithm converts image data into a scene linear space before creating an adjustment, it needs to undo the gamma curve created by the camera or debayering process. If the wrong Source Gamma setting is selected in the Match Color palette, then the data will not be linearized correctly and the resulting match will be inaccurate.

— Lighting in the scene with an unusual spectral response or a strong color cast can cause an inaccurate match. Scenes lit with lights that have an unusual spectral response (such as cheap fluorescent bulbs, cheap LED lighting, or mercury vapor fixtures that exhibit a very narrow or spiky spectral power distribution) can cause metameric errors in both the camera’s response and the Color Match function, resulting in the creation of an inaccurate adjustment. The most accurate results are obtained when the scene uses lighting with a chromaticity that is close to the black body locus (with a highly correlated color temperature) and a relatively smooth spectral power distribution. In other words, use high-quality lighting that doesn’t have spikes in specific parts of the spectrum.

— Large differences between the color temperature of the lighting shining directly on the chart and ambient lighting elsewhere in the scene can cause perceptual errors. Often the problem is one of perception and not an incorrect color adjustment. For example, outdoor scenes being artificially lit with instruments shining extremely warm light (low color temperatures of 3200K or less) but that have cooler ambient lighting may appear overly blue if matched with a Target Color Temp of 6500K. This happens because the chart under direct lighting is lit at the lower (yellowish) color temperature, but areas of the scene in shadow are much cooler because of the ambient “blue” light from the sky; the result is an automatic color adjustment that’s correct for the chart, but exaggerated in the background.
How to Use Color Match

The following procedure shows how to use the Color Match palette and overlay to create a color correction.

The Color Match palette

To sample a color chart to make an automatic correction:

1 Select the clip with a chart you want to sample. If necessary, you can use the View > Show Current Clip With Handles option to show additional frames at the beginning of the current clip to reveal a color chart in the leader of your media.

2 If necessary, choose an option from the Source Gamma drop-down menu that corresponds to the gamma with which the media was recorded.

3 Then, choose a target gamma and color space that corresponds to the format you want this clip to be matched to.

4 Click the Viewer tool drop-down, choose the Color Chart overlay, and use its corner-pinning controls to line the sampling boxes up with the color patches of the chart.

Aligning the Color Match target with the chart in the video

5 When you’re finished, click the Match button, and the clip will be automatically corrected.
A clip before and after automatic color matching

**TIP:** Keep in mind that not every shot needs to have a chart. If the lighting of the location used in a scene is consistent, you really only need a single chart analysis to generate a correction that you can copy to all other clips in the same scene. Of course, if you are using multiple cameras in a scene, you should have a chart analysis for each separate camera if you want to try and match them more closely together. If you’re shooting a scene that takes all day, you may also want to shoot charts at significant time changes corresponding to the lighting changes that are happening.

**Configuration Controls**

Here’s a more detailed explanation of each of the parameters found in the Color Match palette.

- **Source Gamma:** Defines the source gamma the media was recorded with. You must select the correct gamma or the results will not be as accurate.
- **Target Gamma:** Lets you select a target gamma that you want the corrected clip to use. While this will most likely be the gamma you’re outputting the finished program at, you can choose other target gamma values for specialized workflows.
- **Target Color Space:** The color space you’ll be outputting the finished program with.
— **Color Temp**: An adjustable color temperature control that lets you manually adjust the target color balance of the resulting correction to be warmer (lower values) or cooler (higher values). The default is 6500K.

— **White Level**: A checkbox that’s disabled by default, which lets you manually choose the target white point that the automatic correction should use. Raising or lowering this value will stretch or compress the contrast of the final correction.

— **Match button**: Once you’ve chosen the appropriate settings, and aligned the color match target with the chart that was recorded, click to execute the match.

— **Chart type drop-down menu**: You can choose from among the supported chart types in this drop-down. At the time of this writing, these include the Datacolor SpyderCheckr24, the ChromaDuMonde 24+4, the DSC Labs SMPTE OneShot, the X-Rite ColorChecker Classic, the X-Rite ColorChecker Classic - Legacy, the X-Rite ColorChecker Video, and the X-Rite ColorChecker Passport Video.

— **Reset All button**: Resets all controls and adjustments in this palette.

### Reset Controls

The Color Match option menu has a variety of commands you can use to reset your work in the Color Match palette.

— **Reset Match Configuration**: Resets the Configuration parameters described above.

— **Reset Applied Match**: Resets the matching operation without resetting the Configuration controls.

### Automatic Adjustments in the Primaries Palette

There are four controls found in the Primaries palette that can be used for automatically making different color adjustments, in order to give you a head start whenever you’re trying to neutralize a color cast in the image or choose better black and white points for exposure.

### White Balance Eyedropper

The White Balance eyedropper, found at the bottom-left corner of the Primaries palette next to the Automatic Correction button, provides an automated way of neutralizing a color cast in your image that you can guide by manually selecting a feature in the image that is supposed to be white.

**To auto white balance an image with an undesirable color cast or tint:**

1. Click the White Balance eyedropper button. The pointer turns into the White Balance eyedropper.
In the Viewer, click on any feature that is supposed to be white such as a white wall, white trim around a window, white blinds, a white shirt, and so on. As you drag the eyedropper around, the RGB values appear as a tooltip to give you a better idea of what the color is of the feature you’re about to click on. Make sure the feature you click on is (a) supposed to be white, and not off-white, and (b) that it corresponds to an image detail that’s not clipped, because that can make parts of the image seem white that aren’t really.

As a result, the white balance of the image should appear much more neutral than before. Note that this adjustment is not applied via any of the controls in the Primaries palette; it’s an invisible, self-contained adjustment.

**Pick Black Point and Pick White Point**

The Pick Black Point and Pick White Point eyedropper controls, found at the upper left-hand corner of the Lift and Gain controls of the Wheels and Bars modes of the Primaries palette, let you adjust contrast by lowering the black point or raising the white point of the image, and also correct for unwanted color casts in the shadows or highlights of the image.

**NOTE:** It’s easy, using the Pick Black and White Point controls, to inadvertently boost the highlights or lower the shadows so much that you end up clipping part of the image. To give these controls the best chance of succeeding, it’s advisable to find the absolute brightest or darkest parts of the image to sample, according to the following instructions.

**To automatically adjust the black point of an image:**

1. Click the Pick Black Point control. The pointer turns into the Black Point tool.

2. In the Viewer, click on any feature that is supposed to be black such as the deepest part of a shadow in the background or within a fold of clothing, black fabric, or something painted black. As you drag the Black Point tool around, the RGB values appear as a tooltip to give you a better idea of what the color is of the feature you’re about to click on. Make sure the feature you click on is (a) supposed to be black, and not some very dark hue, and (b) that it corresponds to an image detail that’s not clipped, because that can make parts of the image seem black that aren’t really.

As a result, the darkest parts of the image should appear much darker than before, and any color imbalance in the shadows should be neutralized. Unlike the White Balance eyedropper, this adjustment is applied via the Lift controls in the Wheels and Bars mode, which should appear with some manner of adjustment as a result.
To automatically adjust the white point of an image:

1. Click the White Point control. The pointer turns into the White Point tool.

   ![The Auto Pick White Point control](image)

2. In the Viewer, click on any feature that is supposed to be white such as a white wall, white trim around a window, white blinds, a white shirt, and so on. As you drag the White Point tool around, the RGB values appear as a tooltip to give you a better idea of what the color is of the feature you’re about to click on. Make sure the feature you click on is (a) supposed to be white, and not off-white, and (b) that it corresponds to an image detail that’s not clipped, because that can make parts of the image seem white that aren’t really.

   As a result, the lightest parts of the image should appear much lighter than before, and any color imbalance in the highlights should be neutralized. Unlike the White Balance eyedropper, this adjustment is applied via the Gain controls in the Wheels and Bars mode, which should appear with some manner of adjustment as a result.

Auto Color

The Auto Color command provides a quick way to automatically balance the blacks and whites of a clip based on the current frame at the position of the playhead. As of DaVinci Resolve 16, the A button in the Primaries palette and the Shot Match command available from the Thumbnail Timeline contextual menu both now use advanced algorithms, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. These controls have been developed to provide optimal results when working in the Rec. 709 color space, and at a gamma of 2.4, so they work well in conjunction with using Resolve Color Management (RCM) to normalize media first.

- The A button performs an automatic analysis of the current frame at the playhead to give a more consistently useful neutral starting point for further adjustment.
- The Shot Match command matches one or more clips to the color and contrast of a graded or ungraded target clip. This updated version of Shot Match has been designed to be used after you’ve used the A button on each clip in the operation, the clips you’re matching and the clip you’re matching to.

If you’re in need of a fast neutral starting point for a range of clips, you can also use these commands together, grading a target clip using the A button, and then using Shot Match to match a range of clips in the same scene to the automatically graded example. Please note that these commands are intended to provide you with a reasonably neutral starting point for continued grading; they’re not meant to create creative or artistic grades.

![The Auto Color button](image)
To make an automatic correction, do one of the following:

— Open the Primaries palette to any mode, and click the A button in the lower left-hand corner.
— Choose Color > Auto Color (Option-Shift-C).
— Press the AUTO COLOR button on the T-bar panel.

The advantage of Auto Color is that it gives you an immediate result for any clip without the requirement for sampling the image or having a specific test pattern to analyze, but the disadvantage is that this lack of guidance makes the usefulness of this command somewhat hit-or-miss. When it works, it can work very well to give you a neutral starting point for further grading. When it fails, you’re better off resetting the resulting adjustment and grading the old fashioned way.

**Legacy Auto Color**

The previous methods for doing Auto Color and Shot Match are available from the Color panel of the User Preferences, via two checkboxes named “Use Legacy Auto Color/Shot Match.” With these enabled, DaVinci Resolve looks for the darkest levels in the image to neutralize the RGB color balance in the blacks, and the brightest levels to neutralize the RGB color balance in the highlights. Furthermore, Master Lift and Master Gain are adjusted to maximize image contrast at the outer boundaries of 0 and 100 percent. Using this control with the Primaries Bars mode open makes it easier to see what’s been changed after these automatic adjustments are made.

**Shot Match**

The previously available automated color correction commands, Auto Color and Color Match, are both useful for adjusting a selected clip to give it a clean, neutral starting point when you’re either in a hurry, or if you’re having trouble manually working out a solution. However, this is only the first step in grading a scene.

After you make a general adjustment to improve the color of a clip in a scene, one of the other principal tasks of the colorist is to adjust all of the clips in that scene so that they match the clip you started with, such that they all look like they were shot at the same time and in the same place. This is called scene-to-scene color correction, scene balancing, or shot matching. While there are abundant tools in DaVinci Resolve to ease the process of doing this manually, wouldn’t it be nice if you could just select a series of clips that you want to match, and have the software do the work?

That’s exactly what Shot Match has been designed to do. Whether you’re a colorist in a hurry, trying to blast through a low-budget feature with an absurd schedule, a DIT making best light dailies who just wants to make them match a little more closely before sending media off to editorial, or an editor who isn’t fast at color correction who needs to give a rough cut a quick color balance before showing the project to the client for the first time, the Shot Match feature of DaVinci Resolve has been created to quickly make different clips in a timeline match one another more closely, with a minimum of steps.

As of DaVinci Resolve 16, the Shot Match command available from the Thumbnail Timeline contextual menu uses an advanced algorithm, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. This control has been developed to provide
optimal results when working in the Rec. 709 color space, and at a gamma of 2.4, so they work well in conjunction with using Resolve Color Management (RCM) to normalize media first.

The updated version of Shot Match has been designed to be used after you’ve used the A button on each clip in the operation, on both the clips you’re matching and the clip you’re matching to.

(Top) Original scene, (Bottom) After using shot match to match all selected clips to clip 62

Legacy Auto Color

The previous methods for doing Auto Color and Shot Match are available from the Color panel of the User Preferences, via two checkboxes named “Use Legacy Auto Color/Shot Match.” With these enabled, DaVinci Resolve looks for the darkest levels in the image to neutralize the RGB color balance in the blacks, and the brightest levels to neutralize the RGB color balance in the highlights. Furthermore, Master Lift and Master Gain are adjusted to maximize image contrast at the outer boundaries of 0 and 100 percent. Using this control with the Primaries Bars mode open makes it easier to see what’s been changed after these automatic adjustments are made.

Shot Match Guidelines

Keep in mind that Shot Match isn’t supposed to make your clips look good, it’s supposed to make them look the same as the clip you choose to match to, or at least get as close as possible without creating a color correction that will do harm to the image. The purpose of Shot Match is to make it easier for you to match a scene’s worth of clips together so you have a starting point for building the rest of the look you want for that scene, on top of this initial match.

The clip you choose to match to may have a correction applied to it, but for the best results, you should limit yourself to simple Lift/Gamma/Gain primary adjustments. If you make Custom curve or secondary adjustments to the image, it will be much more difficult for Shot Match to give you a good result.

Shot Match works best with normalized clips. If you’ve got a timeline edited with log-encoded clips, you may want to use DaVinci Color Management to normalize all the clips in the Timeline before you use Shot Match, to get the most accurate results. It’s certainly possible to use Shot Match with log-encoded media, but the flat color signal of log-encoded media may make it harder to get good results, depending on the scene.

Furthermore, Shot Match is not the right tool to use to try and match un-normalized log-encoded clips that use different types of log encoding, such as LogC and RedLogCine, or to try and match normalized
and un-normalized clips. Because log-encoding is similar to a set of red, green, and blue curve operations, Shot Match is not equipped to achieve a successful result in this situation.

Shot Match is not designed to apply corrections to clips that already have node adjustments. The results will be unpredictable, and probably won’t match. While the clip you’re matching to may have simple primary adjustments applied to it, the other selected clips that are being matched should be completely ungraded.

Lastly, Shot Match has been designed to do no harm to the image. This means if you use Shot Match to try and match an underexposed interior shot to an exterior shot exposed at high noon on a sunlit day, the Shot Match algorithm will do its best to “split the difference” in order to make the difference between these two clips less jarring, while at the same time taking care not to stretch the color and contrast adjustments being made to the underexposed clips to the point where the image falls apart.

**How to Use Shot Match**

There’s no way to easily describe what Shot Match does. It’s a complex algorithm designed to try and deal with an impossibly varied number of different situations. As a result, Shot Match doesn’t apply adjustments to any of the user-editable controls in the Color page. Instead, the image adjustment created by Shot Match is applied invisibly, as the very last adjustment to the node that was selected when Shot Match was used, similar to a LUT.

The procedure for using Shot Match is deceptively simple. However, getting a good result requires some careful thought in terms of choosing which clips to match to one another.

**To match one or more selected clips to a specific clip:**

1. Following the guidelines presented in this section, Command-click or Shift-click one or more clips that you want to be matched. The clip you want to match to may or may not be part of the selection. You may select as few as one clip, or as many as you like.

**TIP:** If you want to make it easier to notice the before and after, you can turn on Split Screen, and choose Selected Clips from the mode drop-down in the Viewer Options. This lets you see all the clips you’re about to match in a grid.
Next, right-click the clip you want to match all of the selected clips to, and choose Shot Match to This Clip.

If the resulting automated match looks good and plays well, then congratulations, you've got an excellent starting point for additional grading. However, keep in mind that even if the resulting match isn't perfect, it may have taken care of enough inconsistencies between the clip you’re matching to and the clips that are being matched, that you need only make smaller, easier-to-spot adjustments in order to nail the final match between the shots in a scene. Either way, you can save time.

**Suggestions for Using Shot Match**

It’s certainly possible to select every clip in a scene and use Shot Match, and the results may be wonderful depending on what kind of visuals are in the scene. However, for other scenes, this may not always get you the best results.

Be strategic about which clips you select to match to one another. Don’t use Shot Match on shots that you know already have the same lighting, as you’ll risk having Shot Match make a minor adjustment that may actually make the shots match less well. Think of Shot Match as a tool for matching clips that look different.

It can also help to use Shot Match an angle at a time, and to do a small test before committing yourself to matching a bunch of clips. For example, suppose you have a scene consisting of angle A (an over of character 1), angle B (an over of character 2), and angle C (a master shot), and you want to match the scene entire scene to angle C since it has the best lighting. First, match one shot from angle B to your favorite shot from angle C, and see how you like the result. If it’s good, then go ahead and select every angle B clip and match them to angle C, before moving on to test one shot from angle A. This way, if there’s ever an angle that doesn’t work well using Shot Match, you can try matching it to one of the other angles in the scene that you’ve already matched to see if you get a better result.

**NOTE:** Keep in mind that, since each clip in the Timeline has its own undo stack, you cannot undo a shot match operation applied to multiple clips all at once.

Beware of clips with large areas of color in the background that don’t match any of the other angles in a scene, such as a shot-reverse-shot sequence that cuts between someone standing in a back yard and someone standing against a purple wall. You can try it to see what happens, but this kind of color distribution can often throw Shot Match results off.
Broadcast Safe

If you regularly deliver to restrictive QC standards, then you can enable Broadcast Safe in the Color Management panel of the Project Settings while you grade to limit both the luma and chroma of the video signal to one of three levels of acceptable overshoots and undershoots.

- **Broadcast safe IRE (mV) levels**: A drop-down menu for choosing one of three levels of aggressiveness when limiting the signal. Choose the range that corresponds to your QC requirements. The options are “–20 - 120” (permissive), “–10 - 110” (conservative), and “0 - 100” (very conservative).

- **Make Broadcast Safe**: A checkbox that turns broadcast safe limiting on and off.

**NOTE**: The clipping imposed by Broadcast Safe itself does not have an inherently soft roll-off. For best results, Broadcast Safe should be used in conjunction with the Soft Clip controls in the Color page, or a Soft Clip LUT. For more information see Chapter 4, “System and User Preferences.”

Black Sun Highlight Correction

If your project uses media shot with one of the Blackmagic Cinema, Production, Pocket, or Ursa cameras, and you have clips that exhibit so-called “black sun” artifacts, where bright onscreen highlights appear with a dark magenta spot, a command exists to quickly and easily remove these artifacts.

(Left) Black Sun artifact seen in image; (Right) Artifact removed using Black Sun Highlight Correction
To remove black sun artifacts from Blackmagic camera footage:

- Right-click the affected clip's thumbnail in the Thumbnail timeline of the Color page, and choose Black Sun Highlight Correction from the contextual menu.

![Image of menu options]

The command for removing black sun artifacts

---

**Using CDL Grades** *(Studio Version Only)*

There are two instances where primary grading adjustments may be applied to a clip outside of adjustments that you make within the Node Editor of the Color page. If you import a CDL (Color Decision List), then the CDL adjustment for each clip is made available to you via a contextual menu command in the Thumbnail timeline of the Color page. For more information, see Chapter 145, “Copying and Importing Grades Using ColorTrace.”

---

**Using ARRI Looks** *(Studio Version Only)*

If you’ve ingested ARRIRAW media or QuickTime-wrapped Apple ProRes from an Amira, Alexa SXT or Alexa LF, or MXF-wrapped Apple ProRes from Alexa Mini LF with embedded ARRI Look metadata (CDL + LUT), the embedded look can be copied to the currently selected node in the Color page.

**To copy an ARRI look from the source media to the current node:**

1. Select a node in the Node Editor to which you want to apply the look data.
2. Right-click that clip’s thumbnail and choose Apply ARRI CDL and LUT. A LUT and Color Wheels adjustment will be applied to the selected node.

![Image of Apply ARRI CDL and LUT]

Using the Apply ARRI CDL and LUT command copies a look from the source media to a node in the Node Editor
Chapter 127

Camera Raw Palette

The Camera Raw palette lets you make clip-specific adjustments to the parameters that are used to debayer a raw clip into an image that can be graded in DaVinci Resolve.

Contents

Introduction to the Camera Raw Palette 2799
Copying, Versioning, and Protecting Camera Raw Settings 2800
Making Changes to Clip Camera Raw Settings 2800
Clip Decoder Settings 2801
Resetting Camera Raw Settings 2802
Updating Sidecar Settings for Blackmagic RAW (BRAW) Clips 2803
Introduction to the Camera Raw Palette

When a timeline uses clips that are linked to camera raw source media recorded from cameras from Blackmagic Design, RED, ARRI, Sony, and Vision Research, all clips in raw media formats are initially debayered using the settings found in the Camera Raw panel of the Project Settings.

However, if there are individual clips that you want to apply different raw settings to, for example altering the ISO to pull more detail out of the highlights or shadows, then you can use the controls found in the Camera Raw palette to individually alter the parameters found within.

The Camera Raw palette showing the available parameters for Blackmagic RAW media.

The Camera Raw palette is automatically set to the mode (seen within the Mode drop-down menu) that is appropriate to the clip that’s currently selected. If the current clip is not in a raw format, then the parameters within the Camera Raw palette are disabled.

All settings that currently populate the Camera Raw palette are also accessible from the DaVinci control panel.

To access camera raw settings on the DaVinci control panel:

1. Press the CAMERA RAW soft key on the Center panel.
2. Use the Center panel knobs to make camera raw parameter adjustments.
3. When you’re finished, press the MAIN soft key to return to the main page of controls.

This section covers general use of the Camera Raw palette. For in-depth documentation about specific camera raw parameters, see Chapter 7, “Camera Raw Settings.”
Copying, Versioning, and Protecting Camera Raw Settings

Ordinarily, a clip’s camera raw settings are copied along with its grade, or saved inside stills grabbed from that clip, when you use the various grade management techniques covered in Chapter 138, “Grade Management.”

When you create new versions, you copy the current Camera Raw settings to the new version, but any changes you make are specific to that version, so each version can have individual Camera Raw adjustments. For example, you could compare the results of two different camera raw adjustments on the same clip.

If you’re copying and rippling grades among multiple clips, you can also protect each clip’s camera raw settings from being overwritten using the “Copy Grade: Preserve Camera Raw Settings” option found in the contextual menu of the Gallery. For more information on the Copy Grade settings, see Chapter 138, “Grade Management.”

Making Changes to Clip Camera Raw Settings

If you want to make individual adjustments to a particular clip’s camera raw settings, choose “Clip” from the Decode Using drop-down menu in the Camera Raw palette. This makes all the parameters in the Camera Raw palette editable, and changes you make override the project-wide camera raw settings.

Changes to the parameters in the Camera Raw palette can also be rippled across multiple clips at once.
To ripple camera raw adjustments across multiple clips:

1 First, you must select a range of clips in the Color page timeline.

2 Open the Camera Raw palette, and make whatever adjustments are necessary to the current clip. The name of each parameter you adjust changes to amber, showing you which parameters have been modified, and which have not.

3 To ripple your changes, do one of the following:
   — Click the Use Changes button to ripple only the altered parameters (in amber) to the other clips you’ve selected in the Timeline. This preserves differences between clips in the parameters you haven’t adjusted (in gray).
   — Click the Use Settings button to ripple every parameter of the current clip to the other clips you’ve selected, overwriting all the camera raw settings at once.

The Use Changes and Use Settings buttons in the Camera Raw palette

Clip Decoder Settings

There’s much more information on the various format-specific Master settings, as well as the occasionally format-specific Clip Decoder settings, in Chapter 7, “Camera Raw Settings.” However, with the exception of the RED Clip Decoder settings that appear for R3D clips, most other formats share a set of DaVinci Resolve-specific controls that provide wide-latitude access to the raw image data for purposes of making different kinds of adjustments.

Camera Raw Clip Decoder settings for BRAW media

While specific raw formats have individual controls, the standard controls include:

— **Color Temp**: Designed to alter the “warmth” of the image. Adjustable in degrees Kelvin. Lower values correct for “warmer” lighting, while higher values correct for “cool” lighting. +6500 is unity. The range is +2000 to +50,000.

— **Tint**: Color balance correction for images with a green or magenta color cast, such as fluorescent or sodium vapor bulbs. 0 is unity. The range is –150 to +150.
— **Exposure**: Increases or lowers image lightness in units relative to f-stops. If your intended exposure adjustment lifts image data above the maximum white level, don’t worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –5 to +5.

— **Sharpness**: A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.

— **Highlights**: Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 through +100.

— **Shadows**: Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 through +100.

— **Color Boost**: A non-uniform saturation operation that affects regions of low saturation more than regions of high saturation. This is sometimes referred to as a vibrance operation. 0 is unity, showing the original color values. Raising color boost from 0-100 increases color intensity, but low-saturation parts of the image are raised more aggressively. Lowering Color Boost from 0 to -100 decreases color intensity, but low-saturation parts of the image are lowered more aggressively. 0 is unity, showing unaltered saturation. The range is –100 through +100.

— **Saturation**: A uniform saturation operation that raises (above 50) or lowers (below 50) the color intensity of every color value within the image. 50 is unity, showing unaltered saturation. The range is 0 through +100 (saturation is doubled).

— **Midtone Detail**: When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 through +100.

— **Lift**: Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.

— **Gain**: Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

— **Contrast**: Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

### Resetting Camera Raw Settings

If you’ve made changes to the parameters of the Camera Raw palette and you decide you need to reset them, there are two options, found in the Options menu.

— **Reset**: Resets all parameters in the Camera Raw palette to their default settings.

— **Revert**: Similar to the “Original Memory” command, Revert changes all camera raw parameters back to the state they were at when you first selected the current clip.
Updating Sidecar Settings for Blackmagic RAW (BRAW) Clips

Blackmagic RAW clips support both embedded look metadata within the .braw media clip and external look metadata in .sidecar files. Ordinarily, these files travel in pairs whenever you manage BRAW media, and whenever a .sidecar file is present, its settings override those of the embedded metadata within the actual .braw clip. Since the .sidecar metadata is in human-readable JSON formatted text, it’s easy to edit and accommodates a wide variety of onset to post-production workflows.

The .braw and .sidecar files as seen in the file system

If you like, you can make changes to the raw look metadata of a .braw clip and upgrade the .sidecar metadata from within the Color page of DaVinci Resolve, so the media on disk reflects these changes in any other BRAW compatible application.

To update the .sidecar raw look metadata:

1. Open the Color page, select a .braw clip in the Thumbnail timeline, and open the Camera Raw palette.
2. Set Decode Using to Clip to enable the palette controls.
3. Make whatever adjustments you want to make using the controls of the Camera Raw palette.
4. When you’re done, click the Update Sidecar button.

The Update Sidecar button in the Camera Raw palette for .braw media
Chapter 128

Primaries Palette

This chapter focuses on the core color adjustments that you’ll be making to create “primary” corrections that alter the overall color and contrast of the image using both the Lift/Gamma/Gain adjustments in the Wheels and Bars modes of the Primaries palette, and the Shadow/Midtone/Highlight/Offset controls in the Log mode, both of which have traditionally formed the foundation of most grades.

Introduction to the Primaries Palette

If you’ve had any exposure to color correction tools in any application, the Lift/Gamma/Gain controls found within the Wheels mode of the Primaries palette should look familiar. These controls correspond to the most traditional and basic color correction functionality available in DaVinci Resolve and are designed to let users without control panels have easy access to color balance and YRGB contrast manipulation using a mouse, tablet, or trackpad.

![Primaries - Color Wheels](image)

As the name implies, the Primaries palette has been designed for the kind of overall “primary” color adjustments to the image that typically serve as the foundation of any grade. “Secondary” adjustments then refer to more specific adjustments made to isolated subjects within the image. However, it’s a time-tested practice that you do everything you can to get the overall image right using one or more primary corrections before moving on to more specific detail work built on top of these initial adjustments. For one thing, it’s a more structured, organized way to work. However, it’s also the most efficient way to make sure you’re tackling the image in a holistic way, that maximizes improvements while minimizing stress on the video signal.

The Primaries palette has three distinct modes of operation:

- **Wheels mode** contains the traditional DaVinci YRGB Lift/Gamma/Gain controls that allow tonally specific yet widely overlapping regions of adjustment. Wheels mode also provides access to the RGB Offset/Printer Points color balance and master controls.

- **Bars mode** gives access to the same YRGB Lift/Gamma/Gain and Offset controls as the Primaries Wheels mode, but the Bars interface lets you make vertical slider-driven adjustments to individual YRGB lift, YRGB gamma, and YRGB gain channels, as well as providing a slider and button-driven interface for the RGB Offset/Printer Points controls.

- **Log mode** is the home of the RGB Offset/Printer Points color balance and master controls that adjust the overall signal in a linear, film-oriented way. Log mode provides Shadow/Midtone/Highlight/Offset controls that offer more restrictive yet customizable regions of adjustment intended for making adjustments to log-encoded image data.

Which mode you use depends entirely on how you like to work, and what kinds of adjustments you need to make.
**HDR Grading With the Primaries Palette**

Starting in DaVinci Resolve 17, some of the palettes of the Color page with which color adjustments are made have been made “color space aware.” This means that the functionality of the palette will be mostly the same no matter what Timeline Color Space you’re using, or whether you’re grading to create SDR or HDR output. However, not every color palette has been made color space aware, and so when using various grading controls in the Color page to grade wide-latitudes images for HDR output, if you find the controls aren’t working smoothly, you may find it useful to enable the HDR Mode of the node you’re working on by right-clicking that node in the Node Editor and choosing HDR Mode from the contextual menu (this is only available in Resolve Studio).

This setting forcibly adapts that node’s controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain or the Log controls.

**Which Do I Start With, the Primaries or HDR Palette?**

The HDR palette, introduced in DaVinci Resolve 17, has also been developed to work as a powerful method of creating primary adjustments to serve as the foundation of your grade. While the Global and Zones controls of the HDR palette operate from a different philosophy of signal adjustment, they’re designed to let you tackle the same issues, so it’s a completely valid choice to start out using the HDR palette instead of the Primaries palette. So, which to use?

Ultimately, this is going to come down to your comfort with the HDR palette, and your experience with the Primaries palette. If your muscle memory of working with the Primaries palette continues to make it the fastest way for you to dial in your adjustments, there’s no reason to stop using it now. In fact, the Offset/Printer Points controls in the HDR palette continue to be adjustments that are distinctly different from the functionality found within the HDR palette.

However, you should also give the HDR palette a try, because it has powerful primary grading capabilities that aren’t possible with the Primaries palette modes. Even if the functionality is new to you, if you give it a week you’ll find innumerable advantages to the HDR palette’s way of doing things, even though it requires some new ways of looking at the process.

The bottom line, however, is that you’ll probably continue using both palettes. If you do, keep in mind that in each Corrector node’s order of image processing operations, the HDR palette controls are processed before the Primaries palette controls, largely because the HDR palette’s more “photographic” approach to grading has been intentionally designed to meet the needs of primary color adjustment in our new world of wide-gamut HDR mastering and output, so it’s been fit into the image processing pipeline as the new foundation of all adjustments.

**Shared Controls in the Primaries Palette**

This section explains, in a generic way, how to use the common control interface conventions used by the Wheels, Bars, and Log modes to make adjustments. It also describes the use of parameters that are shared among all three modes.
Switching Between Primaries Tools

The icons in the upper right of the Primaries Palette allow you to switch between the Primaries Tools at the click of a button.

- **Primaries:** Color Wheels
- **Primaries:** Color Bars
- **Primaries:** Log Wheels

Color Balance Controls

Whether you’re using the Wheels or Log controls, Color Balance controls provide a way to adjust all three color channels of a particular range of the image simultaneously with a single move of the pointer, according to the mode that’s currently selected. There are also a variety of keyboard modifiers that let you make specific adjustments via the GUI. These controls also correspond to the trackballs found on any of the DaVinci or third-party control panels, should you have one connected.

**Methods of making adjustments using the Color Balance controls:**

- **Click and drag anywhere within the color ring:** Moves the Color Balance indicator relative to its previous position, and rebalances the three color channels in whatever range of image tonality is governed by that control. You don’t need to drag the Color Balance indicator itself. This simulates the kind of relative control you get when using a trackball to manipulate these parameters. As the Color Balance indicator moves, the RGB parameters underneath change independently to reflect the independent adjustments being made to each channel.

- **Shift-click and drag within the color ring:** Jumps the Color Balance indicator to the absolute position of the pointer, letting you make faster, more extreme adjustments to the color balance governed by that control.

- **Double-click within the color ring:** Resets the color adjustment without resetting the corresponding contrast adjustment for that control.

- **Command-click and drag within the color ring:** Adjusts YRGB contrast identically as if you were dragging that control’s master ring.

- **Click the reset control at the upper-right of a color ring:** Resets both the Color Balance control and its corresponding master ring.

**Master Wheels**

The Master Wheels, located below the Color Balance controls, let you adjust the YRGB channels for a particular range of image tonality together. This has the practical effect of letting you adjust image lightness and contrast.

Lift, Gamma, and Gain or Shadow, Midtone, and Highlight, plus Offset master wheels to adjust contrast
The Master Wheels correspond to the rings surrounding the trackballs on all of the DaVinci control panels, which let you modify image contrast via YRGB adjustment (as opposed to modifying image contrast via Y-only adjustment, discussed later in this chapter).

**To adjust a Master Wheel:**

— Dragging a Master Wheel to the left makes the corresponding tonal region of the image darker, and dragging it to the right makes that tonal region of the image lighter. The effect will vary according to the mode you’re in. As you make an adjustment, the YRGB parameters located underneath all change together to reflect the simultaneous adjustment you’re making to all channels.

**Numeric Parameters**

Each Color Balance Control and Master Wheel pair of controls also have a set of four YRGB number fields underneath that display the YRGB adjustment being made by both controls. These four values encompass every color and master adjustment you can make with these controls, and they also directly correspond to the Bars interface that mirrors the Wheels controls.

These fields can be edited like any other parameter on the Color page. Even though these values display two decimal places of precision because of space restrictions in the interface, they really contain three decimal places of precision since these are floating point operations; you just can’t see the third decimal place.

**To edit YRGB values directly:**

— You can double-click on a field to edit its value numerically.
— You can insert the text cursor next to a value in this field, and use the Up and Down Arrow keys to adjust the value one digit at a time.
— You can cut, copy, and paste values among fields.
— You can click on the field and drag left or right to adjust its value with a virtual slider.

The number fields for each Color Balance Control and Master Wheel are editable.

**Shared Adjustment Controls**

The three modes of the Primaries palette also share two strips of controls for making more specific adjustments to different aspects of the image, such as Contrast, Saturation, Hue, Highlight retrieval, Color boost, and so on.

Like most parameters in DaVinci Resolve, clicking and dragging a parameter’s name or value to the left or right lowers and raises that parameter with a virtual slider, while double-clicking that parameter’s number lets you edit it numerically, and double-clicking that parameter’s name resets the parameter to its default position.
— **Temp:** A specifically constrained Gain color balance adjustment that lets you adjust the image along a warm/orange to cool/blue axis corresponding to the naturalistic spectrum of color temperatures used for lighting. Raising this parameter performs a Gain color balance adjustment toward orange, while lowering this parameter to a negative value performs a Gain color balance adjustment toward a blue/cyan split. 0 is unity. The range is –4000 to +4000.

— **Tint:** A specifically constrained Gain color balance adjustment that lets you adjust the image along a magenta to green axis corresponding to the unnatural spectrum of color temperatures found in artificial lighting sources such as fluorescent and sodium vapor lighting fixtures. Raising this parameter performs a Gain color balance adjustment toward magenta (sometimes referred to as “minus green” to correct for fluorescent lighting), while lowering this parameter to a negative value performs a Gain color balance adjustment toward green (“plus green” to correct for other kinds of lighting). 0 is unity. The range is –100 to +100.

— **Contrast:** The Contrast parameters let you quickly narrow or widen image contrast about a user-definable pivot point. Regardless of which mode you’re in, these parameters are identical. Contrast and pivot can also be adjusted using the DaVinci control panel via the CONTRAST and PIVOT knobs on the Center panel’s default page, regardless of whether you’re in Lift/Gamma/Gain or Log mode.

— This one parameter lets you increase or reduce the distance between the darkest and lightest values of an image, raising or lowering image contrast. The effect is similar to using the Lift and Gain master controls to make simultaneous opposing adjustments. Bright and dark parts of the image are pushed apart or brought together about a center point defined by the Pivot parameter. The “Use S-curve for contrast” setting in the General Options panel of the Project Settings (on by default) sets the contrast control to apply an “S-curve” to the image, such that the shadows and highlights of a signal will not be clipped when you increase the value. If you would prefer for these contrast adjustments to be made linearly, and for the signal to be allowed to clip when you reach the upper and lower boundaries of the video signal, you can turn this checkbox off.

— **Pivot:** Changes the center of tonality about which dark and bright parts of the image are stretched or narrowed during a contrast adjustment. Darker images may require a lower Pivot value to avoid crushing the shadows too much when stretching image contrast, while lighter images may benefit from a higher Pivot value to increase shadow density adequately.

— **Midtone Detail (MD):** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 through +100.

— **Color Boost:** A non-uniform saturation operation that affects regions of low saturation more than regions of high saturation. This is sometimes referred to as a vibrance operation. 0 is unity, showing the original color values. Raising color boost from 0-100 increases color intensity, but low-saturation parts of the image are raised more aggressively. Lowering color boost from 0 to -100 decreases color intensity, but low-saturation parts of the image are lowered more aggressively. 0 is unity, showing unaltered saturation. The range is –100 through +100.
— **Shadows**: Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 through +100.

— **Highlights**: Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 through +100.

— **Saturation**: A uniform saturation operation that raises (above 50) or lowers (below 50) the color intensity of every color value within the image. 50 is unity, showing unaltered saturation. The range is 0 (completely desaturated) through +100 (saturation is doubled).

— **Hue**: Rotates all hues of the image around the full perimeter of the color wheel. The default setting of 50 shows the original distribution of hues. Raising or lowering this value rotates all hues forward or backward along the hue distribution as seen on a color wheel.

— **Lum Mix**: Lets you control the balance between YRGB contrast adjustments you’ve made using the Master Wheels or ganged Custom curves, and Y-only adjustments to contrast made using the Y channel Lift/Gamma/Gain controls of the Primaries palette or the unganged Luma curve. At the default of 100, YRGB and Y-only adjustments to contrast contribute equally. Reducing this value diminishes the effect of Y-only contrast adjustments until, at 0, Y-only contrast adjustments are turned off.

Additionally, you’ll notice that at the default Lum Mix setting of 100, individual adjustments to R, G, or B using the RGB sliders or unganged Custom curves result in automatic adjustments being made to the other two color channels in order to maintain constant Luma levels. At a Lum Mix setting of 0, individual color channel adjustments have no effect on the other color channels.

**Auto Correction**

The Auto Color command provides a quick way to automatically balance the blacks and whites of a clip based on the current frame at the position of the playhead. As of DaVinci Resolve 16, the A button in the Primaries palette and the Shot Match command that is available from the Thumbnail Timeline contextual menu both now use advanced algorithms, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. These controls have been developed to provide optimal results when working in the Rec. 709 color space, and at a gamma of 2.4, so they work well in conjunction with using Resolve Color Management (RCM) to normalize media first.

For more information on using these, see Chapter 126, “Automated Grading Commands and Imported Grades.”

**Reset Controls**

The Reset control, found at the upper right-hand corner of the Primaries palette, lets you reset every single setting in the entire palette. However, there are a variety of parameter-specific reset controls available to make more targeted resets.

— Each pair of Color Balance and Master Wheel controls have a reset control that resets both.

— Each numeric parameter can be individually reset by double-clicking the name of the parameter.

— The numeric parameters underneath each Color Balance and Master Wheel control pair can be reset by double-clicking the color label that appears underneath them.
Color Wheels and Bars

The Color Wheel palette’s Primaries Wheels mode lets you rebalance color and adjust contrast via the traditional DaVinci controls, which govern three overlapping tonal ranges referred to as Lift, Gamma, and Gain. The Lift/Gamma/Gain color balance and Master Wheel controls are tied to the YRGB Lift/Gamma/Gain sliders found in the Primaries palette; adjustments made to one set of controls are mirrored in the other.

Though they may look different, the Wheels and Bars controls both actually adjust the same components, but in different ways.

These tonal ranges are defined by image lightness, on a scale where 0 is absolute black and 1023 is absolute white. The following illustration shows an approximation of how the Lift, Gamma, and Gain tonal zones broadly overlap, and how each zone’s influence falls off towards the opposing extremes of image tonality.

Graphic displays the relationship of the Lift, Gamma, and Gain controls over the image brightness range that they control.
The Lift color balance control region of influence starts at black, and then falls off through the middle grays to diminish to no influence at white. Meanwhile, the Gamma color balance control has its greatest influence over the image in the middle grays, and its influence diminishes towards black and white. Lastly, the Gain control is the inverse of Lift, having its greatest effect on the image at white, with its influence falling off to diminish at black.

Because these tonal ranges overlap so broadly, you can make very soft, subtle, naturalistic adjustments using these controls. Furthermore, you can capitalize on their overlap by moving an adjacent color balance control toward a color that’s complementary to an adjustment you’ve just made to restrict further how much of the image is affected.

The following image shows the interaction of extreme corrections made to a grayscale image using all three Color Balance controls. Lift has been pushed toward green, Gamma has been pushed toward blue, and Gain has been pushed toward red.

Notice how, even though these corrections are extreme, the colors blend smoothly. This is the reason for the broad overlap among all three controls, and why Lift, Gamma, and Gain are so effective in making corrections to the ambient color temperature of a scene to account for inconsistencies in lighting or camera settings.

3-Way Master Wheel Adjustments

The Master Wheels located below the Color Balance controls let you precisely modify image contrast by YRGB adjustments, which individually alter the black point, the white point, and distribution of midtones that fall in-between.

These controls correspond to the rings surrounding the trackballs on the DaVinci control panel.

— **Lift:** Lets you adjust the perceived shadow density of the image by altering the black point of the image. Dragging the Lift master wheel to the left makes the darkest values in the image darker, increasing the distance between the black and white points of the image, and stretching all the midtone values in-between. Dragging the Lift master wheel to the right makes the darkest values in the image lighter, reducing contrast and squeezing all the midtone values between the black and white points.
— **Gamma:** Lets you adjust the overall perceived lightness of the image by altering the distribution of midtones that fall between the Lift and Gain master wheel settings. Dragging the Gamma master wheel to the left darkens the overall image, while dragging it to the right brightens it. Most Gamma contrast adjustments have a minimal effect on the black and white point of the image, but large adjustments may push either boundary of image lightness farther out. This interaction is described in more detail below.

— **Gain:** Lets you adjust the lightness of the highlights by altering the white point of the image. Dragging the Gain master wheel to the left makes the lightest values of the image darker, squeezing the midtones between the white and black points of the image. Dragging Gain to the right makes the lightest values even lighter, eventually clipping at maximum white.

Waveform display shows the clips contrast range

These contrast adjustments are not limited by one another. For example, raising or lowering the Gamma master wheel by a large amount may push the highlights of the image higher or the shadows of the image lower, regardless of the current Lift or Gain contrast setting.

As a result, these controls are somewhat interactive, and you may find yourself going back and forth between controls as you make your final contrast adjustments. This is one of the reasons a control panel is valuable, as it allows you to adjust all three settings simultaneously.

### Offset Color and Master Controls

The fourth set of Color Balance and Master Wheel controls is actually shared with the Log controls and with the Offset sliders in the Primaries palette. These are the Offset controls, which let you make linear adjustments to rebalance the entire tonal range of the RGB channels. There is no Y-only control for Offset, only a Master RGB adjustment.

— **The Offset color balance control:** Works as a simultaneous adjustment to all three Offset sliders located in the Primaries palette; adjustments made to the Offset color balance control also alter the Offset sliders. Used subtly, this makes it easy to neutralize color imbalances in the darkest part of the image, while simultaneously rebalancing every other part of the image. Used more dramatically, this control makes it easy to add a color wash throughout the entire image.

— **The Offset master wheel:** Acts as a global adjustment to image lightness, an operation sometimes referred to as setup, raising or lowering all RGB channels together.
When using a DaVinci Micro or Mini control panel, the Offset color balance and master controls are adjusted via either the third trackball and ring while in Offset mode, or the fourth trackball and ring of the DaVinci Advanced Panel in Offset mode.

Color Bars Mode

The Bars mode contains the original set of DaVinci Resolve color adjustment sliders. These sliders serve two uses. First, they’re highly visible indicators of the individual YRGB channel adjustments that are made using the trackballs, rings, and knobs of a grading control panel. Second, they provide control of individual YRGB Lift/Gamma/Gain parameters using a mouse, tablet, or trackpad.

The main controls of the Bars mode are the individual Luma (or Y), Red, Green, and Blue sliders, four each for Lift, Gamma, and Gain. These sliders provide precise Lift/Gamma/Gain style control over each of the YRGB channels of the image. When used in conjunction with a Parade Scope video analysis of the image, these controls can enable you to fix irregular color imbalances in specific channels quickly.

Additionally, the Luma (Y) Lift/Gamma/Gain sliders allow easy Y-only adjustments to contrast, where an increase in contrast results in perceptually diminished color saturation. These correspond to the three knobs arranged vertically to the left of the Trackball panel of the DaVinci Advanced control panel, or the three left-most knobs of the DaVinci Micro or Mini control panels.

Making Y-only adjustments to contrast is a great way to increase contrast when you’re going for muted saturation or a gritty look. This kind of adjustment is also useful in situations where you’re trying to increase shadow density without increasing image colorfulness.
Log Wheels Mode

The Shadow/Midtone/Highlight color balance and Master Wheel controls operate independently of the Lift/Gamma/Gain color balance and Master Wheel controls found in the Primaries mode. While the Log mode uses the same types of controls as the Primaries mode, the way each control affects the image is very different.

To switch between the Primaries and Log modes of the Wheels:
— Choose an option from the mode drop-down, click the right mode button, or press Option-Z.

There are two ways of using the Log mode controls. The first takes advantage of the way these controls work to make fast, filmic adjustments to log-encoded media prior to it being normalized or “de-logged” by operations that are performed using nodes appearing after it in the image processing pipeline of your node tree. Normalizing or de-logging the image can be done via Color Space Transform operations, LUTs, and manual adjustments if you’re grading using DaVinci YRGB color science. If you’re using color management, they can be done via the Output Color Space setting of Resolve Color Management (RCM), or via the ACES Output Device Transform (ODT).

The other way of using the Log controls is to take advantage of the more restrictive, but adjustable tonal range of the Shadow/Midtone/Highlight controls to stylize normalized clips by tinting or adjusting the contrast of tonally-specific regions of the image.

Whether or Not to Use Legacy Log Grading Ranges and Curve

DaVinci Resolve 12.5 introduced a modification to the Log grading controls that provides smoother, more pleasing results using the same controls. To maintain backward compatibility with older projects, a “Use legacy Log grading ranges and curve” checkbox in the General Options panel of the Project Settings lets you switch your project between the older Log control behavior and the newer one. Older projects that are opened in DaVinci Resolve have this checkbox turned on by default, while new projects have this turned off by default.
Using the Log Mode Controls to Grade Log-Encoded Media

The Log controls are so named because they’re designed to work specifically with media with Log-C or similar gamma and color encoding, derived from the Cineon Log gamma curve, developed by Kodak to digitally store flat-contrast, wide-gamut image data that preserves image detail with a wide latitude for adjustment.

An example of a log-encoded clip (left), and the same clip after being normalized (right)

You can debayer most raw formats to a log-encoded image in order to derive the maximum amount of image data and adjustable latitude from that source (for more information, see Chapter 7, “Camera Raw Settings”). However, the resulting image needs to be normalized to occupy the final range of color and contrast that you intend for the final result. You can do this one of two ways:

— You can make a very careful curves adjustment in a second node to stretch the log-encoded image out to fit the contrast profile you want. By making this adjustment in Node 2, you make room for a customizing adjustment made using the Log controls in Node 1, prior to the normalization adjustment. This is key.

— You can also apply a 1D Output or 3D LUT to the first node of a clip to normalize the image. This is a faster, if less flexible operation, but a smooth tonal range may be easier to obtain. Since a LUT applied within a node is always the last adjustment within that node’s order of operations, you can also use Node 1’s Log controls to customize the look of the footage.

In either case, it’s important that the normalizing adjustment happens after your Log control adjustments, for the Log control adjustments to work as they should. With your node tree set up in this way, you’ll be monitoring an ordinary-looking image, but taking advantage of the Log mode controls’ unique tonal ranges to manipulate the log-encoded image data with great specificity.

**TIP:** Within corrector nodes, LUTs are applied after Log control adjustments, so if you want to keep the number of nodes in your node tree to a minimum, you can apply a normalizing (or de-logging) LUT to the same node with which you’re making Log adjustments, knowing that the LUT will be properly applied after log adjustments. For more information, see Chapter 140, “Image Processing Order of Operations.”

**When using the Log mode controls, here’s a workflow to consider as you learn how they work:**

— First, use the Offset master wheel to set the black point, and use the Contrast and Pivot parameters to stretch or compress contrast as necessary to achieve the tonal range you require.
— Second, use the Offset color balance control to adjust the overall color balance of the image to your liking.

— Third, use the Shadow/Midtone/Highlight color balance and Master Wheel controls to make specific, targeted adjustments to the color and contrast of the image in tonal ranges that match where that data is in the log-encoded image.

Working in this way, you’ll find that adjustments made with the Offset color balance and Master Wheel controls and Contrast controls control the log-encoded image very nicely to create an overall adjustment, while the Shadow, Midtone, and Highlight controls allow you to fix specific issues, such as shadow balance and density, after your main adjustment has been set.

The following illustration shows an approximation of how the default ranges of the Shadow, Midtone, and Highlight controls divide the tonal range of a log-encoded image.

![Illustration showing tonal range of Log controls](image)

This graphic shows the tonal range of each of the Log controls when used with a log-encoded image

As you can see, when used with a log-encoded image the color interactions between each adjustment overlap very softly, while still allowing more specific adjustments than those made by the Lift/Gamma/Gain controls.

Furthermore, the boundaries of the Shadows, Midtones, and Highlights Log controls can be customized using the Low and High Range parameters. This gives you added flexibility to apply more specific contrast and color adjustments.

Once you’ve made an adjustment using Log mode controls along with a normalizing LUT or curve adjustment, you can always apply additional nodes and use the Wheels mode of the Primaries palette to make further alterations to the now normalized image, working as you normally would with any of the other tools in DaVinci Resolve.

**TIP:** Internal to each node’s image processing order of operations, the Lift/Gamma/Gain adjustments of the Wheels mode are applied prior to the Shadow/Midtone/Highlight/Offset adjustments of the Log mode, so if you want to apply Log mode controls before Wheels mode controls, then you need to use Wheels controls in a subsequently added node. For more information, see Chapter 140, “Image Processing Order of Operations.”
Using the Log Mode Controls to Stylize Normalized Media

You can also use the Log mode controls on already normalized images. Although the results you get will be somewhat different, this can be a fast way to create interesting stylizations. Whereas the broadly overlapping tonal ranges of the Lift, Gamma, and Gain color balance controls allow subtle adjustments to be made very easily, the Log palette’s color balance controls affect much more restrictive tonal zones that overlap much less when used on normalized images.

The following illustration shows an approximation of how the Shadows, Midtones, and Highlights, by default, divide the tonal range of the image into non-overlapping thirds. As you saw in the previous section, these divisions were originally intended to map to log-encoded media. However, with normalized media these divisions provide a different, and potentially useful, set of ranges from the Primaries mode controls.

With normalized media, the Shadows really do only affect the darkest shadows, falling off at approximately the bottom third of image tonality. The Midtones affect only the middle third of grays, and the Highlights affect the brightest top third of image values. However, these default ranges of image tonality can be adjusted using the Low Range and High Range controls, which are described in more detail later.

The following image shows the default interaction of extreme corrections made to a grayscale image using the Log mode controls. The Shadows have been pushed toward green, the Midtones have been pushed toward blue, and the Highlights have been pushed toward red.
As you can see, with normalized media the color interaction between each adjustment is very subtle. The darkest shadows end up bright green, the midtone values are vivid blue, and the highlights are almost pure red. This restrictiveness is useful when you want to limit a correction to a specific tonal range within the image without needing to use a Luma qualifier. It’s also quite useful for making bold, stylistic color adjustments when creating a non-naturalistic look.

**TIP:** The Highlights adjustment of the Log controls can also be extremely useful for boosting or otherwise controlling the highlights of HDR grades. However, the multiple highlight zones of the HDR palette afford a much higher degree of control over this kind of adjustment, using similar control panel-friendly controls.

### Adjusting the Default Tone Ranges in Log Mode

When in Log mode, two additional parameters appear in the top shared controls bar that let you modify the range of Shadows and Highlights image tonality that each Color Balance control affects, in turn narrowing and widening the range of Midtones. Keep in mind that while the ranges can be customized, the amount of overlap between each range cannot.

- **Low Range:** Moves the border where the Shadows and Midtones meet. Lowering this parameter widens the range affected by the Midtones, and narrows the range affected by the Shadows. Raising this parameter narrows the Midtones and widens the Shadows.
- **High Range:** Moves the border where the Midtones and Highlights meet. Lowering the High Range parameter narrows the range affected by the Midtones, and widens the range affected by the Highlights. Raising this parameter narrows the Highlights and widens the Midtones.

There are also Saturation and Hue parameters which mimic these settings found within other palettes and modes.

### Adjusting Contrast in Log Mode

When using the Log mode controls, your primary tools for adjusting image contrast will usually be the Offset master wheel and Contrast and Pivot parameters. Using these three controls, you can set a black point and adjust the overall contrast very quickly.

The Shadow, Midtone, and Highlight master wheels let you adjust image lightness within the same restrictive ranges of image tonality that are defined by the Low Range, High Range, and Pivot parameters. These adjustments should appear smooth, if somewhat narrower then the Lift/Gamma/Gain controls, when used with log-encoded media. However, when used with normalized images, severe adjustments made with one master wheel may not always make a smooth transition to the next adjacent range of image lightness.

**NOTE:** Because these controls are so restrictive when used with normalized images, it’s easy to create solarization effects by raising the shadows to be higher than the Midtones, or lowering the Highlights to fall below the Midtones, to give two examples.
Log Offset Color and Master Controls

The Log controls share the same Offset color balance and Master Wheel controls that appear in the Lift/Gamma/Gain mode of the Wheels and Bars controls. The Offset controls are in fact processed as part of the Log controls, but for convenience they’re presented with the Wheels controls because they’re so useful.

— **The Offset color balance control**: Works as a simultaneous adjustment to all three Offset sliders located in the Primaries palette; adjustments made to the Offset color balance control also alter the Offset sliders. Used subtly, this makes it easy to neutralize color imbalances in the darkest part of the image, while simultaneously rebalancing every other part of the image. Used more dramatically, this control makes it easy to add a color wash throughout the entire image.

— **The Offset wheel**: Acts as a global adjustment to image lightness, an operation sometimes referred to as setup, raising or lowering all YRGB channels together.

Offset and Printer Points

In Bars mode, the Offset controls are represented by three vertical sliders, which mirror the settings of the Offset color balance controls in the Color Wheel palette, except that they provide individual control over the Red, Green, and Blue color channels. In fact, this interface also happens to be the epicenter of the Printer Points functionality offered by DaVinci Resolve.

When you drag one of the Offset sliders up or down, you raise or lower that color channel in its entirety. This can be useful for adjusting color channels that are particularly problematic, but it’s also the way you impose the kinds of traditional linear color adjustments that color timers of film have employed for decades. In fact, many colorists consider the simplicity of these controls a virtue, and embrace the slight shadow or highlight contamination that can result from color balancing in this linear way as a creative hallmark of traditional cinema color adjustment.

**NOTE**: Unlike the other Color Balance control adjustments described in this chapter, the Offset controls do not use the Lum Mix parameter to control whether individual adjustments to the R, G, or B channels result in automatic adjustments being made to the other two color channels in order to maintain constant Luma levels. All Offset and printer points adjustments made to a specific color channel affect only that color channel.
Adjusting Printer Points in the Bars Mode

Each Offset slider also has a pair of arrow buttons, one at the top and one at the bottom. These buttons provide “Printer Point” adjustment of these values, which let you adjust each Offset channel in discrete increments. Printer Points can be useful for projects that have tight integration with a film lab, and are designed to emulate color adjustments made using optical printers.

The Offset wheel control underneath the Offset sliders lets you adjust all three sliders at once, performing a master or setup adjustment. The Offset sliders, Printer Point buttons, and Offset wheel can be adjusted using keyboard shortcuts, or using the DaVinci control panel.

**NOTE:** The DaVinci Resolve Advanced and Mini color grading panels each have support for adjusting printer points using rotary controls for the Red, Green, and Blue channels, as well as All channels together.

Adjusting Printer Points Via Keyboard Shortcuts

One of the best ways of using printer points if you don’t have a color control panel that supports them is to enable the numeric keypad to use dedicated keyboard shortcuts just for printer points.

**To use the Printer Lights Hotkeys:**

— Choose Color > Printer Light Hotkeys, or press Option-Command-Grave Accent (’)

When you enable Printer Light Hotkeys, there are two sets of shortcuts you can use to manipulate printer points. First, if you want to directly manipulate RGB in whole increments, there’s one set for that.

<table>
<thead>
<tr>
<th>Red</th>
<th>Green</th>
<th>Blue</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 - Plus Red</td>
<td>8 - Plus Green</td>
<td>9 - Plus Blue</td>
</tr>
<tr>
<td>4 - Minus Red</td>
<td>5 - Minus Green</td>
<td>6 - Minus Blue</td>
</tr>
</tbody>
</table>
However, if you want to work in the classic way by manipulating cyan, magenta, and yellow in whole increments, there’s another set of shortcuts for that, using the remaining keys on the numeric keypad.

<table>
<thead>
<tr>
<th>Cyan</th>
<th>Magenta</th>
<th>Yellow</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - Plus Cyan</td>
<td>2 - Plus Magenta</td>
<td>3 - Plus Yellow</td>
</tr>
<tr>
<td>Minus (–) - Minus Cyan</td>
<td>0 - Minus Magenta</td>
<td>Period (.) - Minus Yellow</td>
</tr>
</tbody>
</table>

There are also a pair of keyboard modifiers that gives you finer control over printer points adjustments made with these special keyboard shortcuts, while retaining the coarser default adjustments that let you make bigger changes more quickly:

— Hold down Command while using these key shortcuts to adjust printer points in quarter-increments.
— You can use half-increments as well, but you will need to assign the keyboard shortcuts for these manually.

**Printer Light Step Project Settings**

The increments used by the Printer Point buttons are defined by the Printer Light Step Calibration parameters, found in the Color panel of the User Preferences. The default settings are designed to emulate traditional film printer adjustments, but these settings can be customized to align DaVinci Resolve’s printer points adjustments with those of a particular film lab’s equipment. However, if you’re not working with a lab, you can change the Step and Density settings to alter how much of an adjustment each printer point makes according to your own preferences. For more information, see Chapter 4, “System and User Preferences.”

*TIP:* If you’re feeling left out because all the cool kids are using printer points and you’re unfamiliar with them, making the Parade scope visible is a great way to learn how these adjustments work while seeing their specific effects on the red, green, and blue channels of the video signal.
This chapter focuses on the global and zone-based adjustments found in the HDR palette, which is DaVinci’s newest primary grading tool. Despite its name, this palette can be used, as you might the Lift/Gamma/Gain mode of the Primaries palette, to create the foundational adjustment for any SDR or HDR grade.

However, its zone-based nature gives it the power and specificity of curve-based adjustments, making the HDR palette suitable for a multitude of creative and corrective tasks. Furthermore, this palette’s color space awareness, as well as the perceptually uniform color space in which it’s adjustments are made, make this palette uniquely suited for controlling the saturation and highlights of HDR mastered images.

Introduction to the HDR Palette

The HDR palette is specifically designed to enable fast and flexible primary grading of wide-latitude media for either SDR or HDR output. It’s “color space aware” in that it works with Resolve Color Management to fit the known mapping of source image data within the HDR palette’s own perceptually uniform operational color space. Using advanced color processing algorithms, this enables more efficient color and contrast adjustments, and perceptually uniform controls that make it easier to adjust all colors equally across the spectrum, while maintaining careful control of image saturation.

A set of global controls, at the right of the palette, let you make foundational adjustments to the overall image, along with a set of Hue, Midtone Detail, Contrast/Pivot, and Black Offset controls at the bottom. Additionally, a set of overlapping zone-specific controls let you make color and contrast adjustments to specific ranges of image tonality. Altogether, the HDR palette lets you make primary grading adjustments that are both photographically naturalistic and as tonally broad or specific as you require, while minimizing unwanted artifacts.

Despite its sophistication, the HDR palette uses color balance and slider controls that should be familiar to any colorist or editor familiar with the more conventional Lift/Gamma/Gain controls. Whether you’re a grading professional or just getting started with color, the HDR palette will enable great results with less hassle once you learn how to harness its power.

**TIP:** Due to the increasing ubiquity of HDR-capable media and HDR streaming distribution workflows, the node HDR mode and HDR palette are both available without restriction in the free downloadable version of DaVinci Resolve.
What Makes the HDR Palette Special?

Before diving into the detailed use of the HDR palette's controls, it's important to understand a bit more about how the HDR palette processes image data, so you can better understand what advantages this tool presents.

Using the HDR Palette Without Color Management

While the HDR palette has been designed to work hand in hand with color management, you can use it in non-color managed workflows so long as you set it up correctly. The HDR palette option menu has Color Space and Gamma submenus that let you specify how you want to work. By default, both submenus are set to "Timeline" to reflect the color space you're choosing to work within in display-referred workflows.

Color Space Aware Controls When Using Color Management

The HDR palette really shines when you enable Resolve Color Management or ACES, because it's a color space aware palette that uses color management to full advantage. Being color space aware means that the color and contrast controls of the HDR palette conform themselves to the range of each clip's image data as mapped from the Input Color Space assigned to the source clip to the Timeline Color Space your program is working within. Practically, this provides two benefits:

— The controls of the HDR palette work and feel virtually identical no matter what type of source clip you're adjusting, and no matter which timeline color space you're choosing to work within.
— HDR palette adjustments made to one type of media will have a similar result when copied to other types of media. This makes makes matching shots and copying looks from one type of media to another easier than with previous tools.

NOTE: Because the HDR palette is color space aware, it's not necessary to enable the HDR setting on nodes for controls to work intuitively while working within a wide gamut Timeline Color Space, or delivering to an HDR format like ST.2084. The HDR palette takes care of this for you, automatically.

Perceptually Uniform Adjustments

Furthermore, the image data of each clip is converted from the Timeline Color Space to an operational color space used by the HDR palette, where the image is adjusted and then converted back to the Timeline Color Space again, ready for the next operation. The operational color space that's used by the HDR palette is perceptually uniform, which means that the range of values corresponding to each visible hue are distributed evenly throughout this color space.

While the HDR palette works well grading standard dynamic range (SDR) material, the underlying color science used by this palette also addresses issues that have inconvenienced colorists grading high dynamic range programs using traditional controls. These benefits include:

— Since the controls of this palette calculate all color transformations within a perceptually uniform color space, you will experience finer control over color adjustments in a more photographically intuitive way. For example, you may find that yellow hues are easier to grade within this palette, since there's a more even distribution of hues around the circumference of the color wheels.
— The HDR palette lets you make contrast adjustments without altering image saturation, meaning that unlike when you use the master wheels of the Lift, Gamma, and Gain panel, the HDR palette lets you raise image contrast without increasing image saturation, and lower image contrast without decreasing image saturation. You’ll find this is particularly useful while boosting highlights in HDR grades, since you can now do so without causing extreme saturation increases in your highlights. In fact, all adjustments you make to contrast with these controls will adjust the image while keeping saturation unerringly constant (that is to say, perceptually speaking; you will in fact notice small saturation changes in the Vectorscope). This, of course, excludes the saturation controls.

— The HDR palette’s deep integration with Resolve Color Management also makes matching shots and copying looks from one type of media to another easier than with previous tools. Whether you’re a professional, or just getting started with color, the HDR palette will enable better results with less hassle.

**Superior Temp and Tint Controls**

Because the HDR palette is color space aware, the Temperature and Tint adjustments in this palette are themselves made using the same kind of XYZ to LMS color space transform used by the Chromatic Adaptation Resolve FX plug-in. The result is that Temp adjustments are photometrically accurate and create visual results similar to how the human vision system perceives changes to a scene due to a change in the color temperature of lighting.

**Customizable Zones**

Another unique aspect of the HDR palette is how it can be customized to suit a wide variety of working styles, specific tasks, and colorist preferences. Switching to the Zones panel reveals an interface for adjusting the Range and Falloff of each currently defined zone, using graphical controls overlaid onto a histogram of the current image, while a curve shows the user how the contrast and color adjustments they’ve made mathematically affect the RGB channels of the image within each zone. While the default zones preset provides an efficient starting point for many kinds of scenes, the varying tonal range of image data in different scenes, whether daytime, nighttime, interior, or exterior, will often require you to customize these zones to get the best results from adjustments using these controls.

The Zones panel lets you customize the tonal ranges that each set of zone controls affect.

Additionally, the sidebar at the left provides controls for adding and removing zones, so users can customize this palette to work exactly the way they want. Any customized preset can be saved for easy recall. This way, users have the freedom to work in whatever way suits them.
The Option menu provides fast access to additional ways of customizing this palette’s operation, including the selection and management of presets, a choice of methods for numerically editing Color Balance adjustments, and a setting that determines whether or not the Global controls are always exposed, or should be banked to like the other zone controls.

## The HDR Palette Interface

The HDR palette is divided into two panels. The first, containing Color Balance controls and custom sliders, is for making color and contrast adjustments. The second, containing the Zones sidebar and Zones graph, is for customizing the range and falloff of each of the zones that corresponds to each set of controls found on the controls panel. It’s these zones that are used for making detailed image adjustments to tonally-specific areas of the picture.

By default, both panels appear within the same palette area, and you can switch between them using buttons at the top right of the palette. This is useful when you have limited screen real estate, or you’re making simple adjustments. Alternately, you can click a button to expose both panels side-by-side, occupying both the left and middle palette areas of the Color page.

This Side-by-side mode makes it easy to see and customize how each zone is mapped to the source image data, while making adjustments at the same time.

An Option menu at the far right of the title bar (shown as three dots) reveals the preset manager for this palette, as well as different GUI options for customizing how you want to use this palette.

## Navigating Multiple Zones in the Controls Panel

A row of buttons just under the HDR palette’s title bar show you, of all available zones, which ones are currently adjustable using the visible controls below. While the default HDR palette preset has six zone-specific Zone controls, plus the Global controls, most users will only have room in the GUI for four sets of controls to be visible at any time. Meanwhile, grading control panel users will be constrained by how many trackballs their particular control panel has.
Since you’ll almost always have more zones available than you have room to adjust them, this interface lets you see which zones you’re currently using, which zones are mapped to a control panel, and which other zones are available for you to switch to. By default, there are three active zones shown at the top, corresponding to the three sets of Zone controls to the left of the Global controls. Zones that are available, but hidden, are shown in gray to the left and/or right of the currently visible zones, which appear in color. This way, you can bank back and forth among three zones at a time, while always having the Global controls available for adjustment.

There’s also a setting in the HDR palette’s Option menu, “Bank Global With Color Wheels,” that lets you use all four GUI control clusters in this palette to show Zones controls, making it faster to jump among tonally-specific adjustments. In this mode, there are four active zones shown at the top, corresponding to the four sets of Zone controls being shown. However, in this mode you must page all the way to the right to expose the Global controls, which are banked along with all the other zones.

Using these controls, you can switch your visible control among all available zones similarly to how audio mixers switch among banks of tracks with a fader panel.

**Methods of switching among different Zone controls:**

- Click any gray zone button to the left of the currently visible zones to move all zones so that the leftmost visible zone appears at that one.
- Click any gray zone button to the right of the currently visible zones to move all zones so that the rightmost visible zone appears at that one.
- Click the Left or Right Arrow buttons to either size of the zones indicators to move all zones one to the left or one to the right.
Making Global Adjustments

Generally speaking, if you’re using the HDR palette to do primary grading, you’ll probably want to begin with the Global controls. By default, these are found at the right of the Controls panel.

These controls let you take the initial step of making an overall adjustment to the image. To adjust color, you have a color balance wheel, temp and tint sliders (to the left and right of the wheel, and also numerically below), and saturation adjustments. To adjust image contrast, a Global Exposure control lets you stretch overall image contrast up to brighten the image, or compress it down to darken it, relative to the current Black Offset level, which pins pixels corresponding to minimum black in place. A pair of Contrast/Pivot controls at the bottom of this palette let you manipulate overall color contrast by stretching highlights and shadows out or in relative to the pivot point, expressed in stops.

While Global color adjustments are somewhat similar to the offset, temp, and tint controls found in the Color Wheels or Log Wheels controls, there are important differences, described in detail below. The Global Exposure control, on the other hand, operates very differently from Master Offset.

Detailed Explanation of Global controls:

— Global Color Balance: A color balance control lets you simultaneously adjust the red, green, and blue channels, somewhat linearly throughout the tonal range of the image, to freely rebalance the color. However, RCMv2 automatically maintains a smooth saturation and exposure rolloff in the maximum highlights and minimum shadows, so this effect becomes less pronounced in the blackest blacks and the whitest whites of the image (this appears more pronounced in test gradients than real world images). While adjustments made with this control won’t lower the value of the darkest pixels in the image below the Black Offset level, individual color channels may dip below this level in order to preserve colorfulness in darker shadows. The resulting color adjustments made with this control are similar to how optical color filters placed over a lens would affect an image.
Global Exposure: Brightens or darkens the entire image. Dragging to the right stretches image contrast by raising the highlights while keeping the shadows pinned relative to the Black Offset value. Dragging to the left lowers image contrast by lowering the highlights while keeping shadows pinned relative to the Black Offset value. For more explanation about the function of Black Offset, see the following section.

Keep in mind that all contrast adjustments in the HDR palette keep saturation constant as contrast increases or decreases. This means that, when making large contrast adjustments to HDR images, image saturation will remain perceptually the same.
— **Global Saturation**: Raises or lowers the intensity of color throughout the image. Since contrast adjustments don’t affect saturation, you must exercise manual control over any desired changes to image saturation.

— **Global Color Balance Value Fields**: Two numeric values represent how the color balance controls center handle position is represented. There are two ways of numerically showing this: as X and Y, or as Angle and Strength. You can choose either method from the HDR palette’s Option menu; whichever method you choose determines how the center handle of all color balance controls is manipulated if you adjust these values directly.

At the bottom of the HDR palette, additional Global Temp and Tint, Hue, Midtone Detail, and Contrast/Pivot controls let you make other kinds of global adjustments to image color, detail, and contrast, in ways that are very similar to the identically named controls in the Color Wheels or Log Wheels controls. Additionally, there’s a Black Offset control that lets you set the minimum allowable black level in the current shot.

![Global controls found at the bottom of the HDR palette](image)

*Detailed explanation of additional Global controls:*

— **Temp**: This global temp adjustment lets you warm or cool the image with a range from -4000 to +4000 based on a kelvin scale. Adjustment follows the spectral locus line in the CIE graph: the intensity of adjustment is naturalistic. To minimize visual artifacts, this control is capable of warming the image more aggressively than cooling it.

— **Tint**: This global tint adjustment lets you add “plus green” or “minus green” adjustments with a range from -100 to +100 on an arbitrary scale.

— **Hue**: Rotates all hues of the image around the full perimeter of the color wheel. The default setting of 50 shows the original distribution of hues. Raising or lowering this value rotates all hues forward or backward along the hue distribution as seen on a color wheel.

— **Midtone Detail**: When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness. The effect is sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened, while areas of high detail are left alone. 0 is unity. The range is –100 through +100.

— **Contrast**: This one parameter lets you increase or reduce the distance between the darkest and lightest values of an image, raising or lowering image contrast. The effect is similar to using the Lift and Gain master controls to make simultaneous opposing adjustments. Bright and dark parts of the image are pushed apart or brought together about a center point defined by the Pivot parameter. Unlike the Contrast control in the Primaries palette, the Contrast control in the HDR palette ignores the “Use S-curve for contrast” setting in the General Options panel of the Project Settings.

Keep in mind that all contrast adjustments in the HDR palette keep saturation constant as contrast increases or decreases. This means that, even when making large contrast adjustments to HDR images, image saturation will remain perceptually the same to your eye, with small changes made to the actual saturation of the image in order to maintain this perception. Be aware that the tone mapping settings in RCMv2 will have an effect on how much saturation is maintained in the top highlights and bottom shadows of the image, versus being automatically rolled off at the outer boundaries of the signal.
**Pivot:** Changes the center of tonality about which dark and bright parts of the image are stretched or narrowed during a contrast adjustment. This lets you change how contrast is distributed among the shadows and highlights. The default value of 0 pushes highlights above 50% gray higher, and shadows below 50% gray lower, in equal proportion to one another. Changing the pivot point changes the percentage of image tonality about which contrast is either expanded or compressed. Darker images may require a lower Pivot value to push more levels up and avoid crushing the shadows too much when stretching image contrast, while lighter images may benefit from a higher Pivot value to push levels down and increase shadow density.

**Black Offset:** Defines the darkest allowable part of the image. No adjustment by any other control in the HDR palette will ever go below this level, except for the occasional color channel if the shadows become extremely saturated. For more detailed information on this extremely important control, see the very next section.
Black Offset Explained

Of all the Global controls, the Black Offset control is one of the most deceptively important. Black Offset lets you define the darkest pixels of the image. Adjustments made to Black Offset do not offset the entire signal, they only affect the very darkest portion of the signal, letting you raise or lower the black point of the image while smoothly blending the resulting adjustment into the unadjusted portion of the image. The result is that you can compress or expand the bottom of your signal.

If you raise Black Offset, you can add “flaring” to the image, similarly to how light flaring within a lens might lighten the darkest part of the image.

(Left) The original image, (Right) Raising Black Offset in order to add flaring to the darkest pixels of the image

Alternately, you can lower Black Offset to lower the very darkest pixels in the image. If the source image is dark enough, this control can lower the darkest pixels below 0, however this image detail is preserved in the color image processing pipeline.

The most important thing to understand about this control is that level to which you set Black Offset becomes the new level at which Global exposure adjustments are made. In the following example, the first image shows the original color of a clip that was exposed to be dark. In the second image, Black Offset is adjusted to raise the darkest parts of the image, compressing them relative to the midtones and introducing a pleasing flaring effect to the shadows.

(Left) The original image; (Right) The image with Black Offset raised

In the following image, Global Exposure is raised, and you can see in the Waveform scope that the exposure change stretches the contrast of the image up, with the darkest pixels “locked” to the Black Offset you set.

(Left) Before, (Right) After raising Global Exposure to stretch image contrast out from the Black Offset level; notice that the bottom of the signal continues “touching” the same level after global exposure is raised.
The Black Offset level you set also becomes the minimum picture level when you lower exposure, either using the Global Exposure changes, or when you use any of the “darkening” zone controls such as Shadow, Dark, and Black. The following image shows the result of lowering Global Exposure; the shadows of the image are compressed more heavily than the highlights as exposure is lowered, with the result that the minimum value of the image remains at the Black Offset level you set. With shadow detail impressively preserved, this compression rolls off smoothly and nonlinearly through the midtones so that the image continues to look as natural as possible.

(Left) Before, (Right) After lowering Global Exposure to compress image contrast down to the Black Offset level; notice the signal never goes lower than the Black Offset level

This is also true when using other darkening zone exposure controls, such as the Shadow control, which selectively pushes the exposure of the darker part of the image down, while leaving the highlights alone. While reducing Shadow exposure, the darkest pixels still compress so that nothing goes beneath the Black Offset level you set.

Bottom line, you can adjust Black Offset at any time, either before or after any other Global or Zone adjustments, to fine tune the image as necessary.

Making Zone-Based Adjustments

After you’ve made whatever initial global adjustments you want, you can optionally make more tonally-specific adjustments to the image via the Zone-based color and contrast controls to the left. These divide the image into multiple overlapping “zones,” which are somewhat similar in principal to Ansel Adams’ zone system, which divides images into tonally-specific regions based on image luminance, from pure black, through progressively lighter shadows, to 18% gray as the middle value centering the midtones of most images, and then up through progressively lighter highlights on the way to the last zone of pure white.

Simplified illustration of Ansel Adams’ zone system
While Adams’ zone system was meant to teach people how to think about using the available range of the photographic medium when exposing images, the zones of the HDR palette let you put this concept into practice by allowing you to make tonally-specific Color Balance, Saturation, and Exposure adjustments that only affect the range of shadows or highlights that fall within that zone.

Using the default preset, the shadows of your image are divided into overlapping Shadow, Dark, and Black zones, while the highlights of your image are divided into separate overlapping zones for Light, Highlight, and Specular ranges. The chart below illustrates the relationship of these zones to one another.

![Approximation of the overlapping zones in the HDR palette that can be individually adjusted](image)

**NOTE:** All of the examples in this section have Timeline to Output Tone Mapping set to None, to keep the ramp gradient linear for purposes of this explanation.

### Zone-Based Color Adjustments

Understanding how adjustments made using these overlapping zones interact with one another is key to knowing what you can do using the HDR palette. Keep in mind that every zone is customizable, but here’s how the default zone definitions work to let you make detailed image adjustments. For clarity, Zone adjustments are shown made to a linear ramp gradient image, to demonstrate exactly what tonal portion of each image is affected by each control.

— The Light and Shadow zones are the most broadly defined zones. Together, they cover the entire tonal range of your image. They softly overlap one another by two stops at the center of the tonal range (50% gray or 18% exposure); this is where adjustments made to Light mix together with adjustments made to Shadow, resulting in both adjustments softly blending together. Making exposure adjustments to these two zones lets you manipulate overall image contrast by selectively compressing/expanding contrast in the shadows and/or highlights relative to one another. Using the color controls lets you make broad color adjustments to the upper (highlights) and/or lower (shadows) range of image tonality.
Color adjustments to a ramp gradient show the Light (tinted green) and Shadow (tinted orange) zones.

The Dark and Black zones overlap two progressively lower luminance ranges of the Shadow zone. Dark is useful for adjusting the color or contrast of the deeper shadows, while Black is useful as a trim that lets you manipulate the very darkest parts of an image. All adjustments you make to Dark are mixed with any adjustments made to Shadow, and all adjustments made to Black are mixed with the adjustments made to Dark and Shadow. In this way, all color adjustments you make to overlapping Shadow zones mix smoothly together to produce the final result, as seen in the following ramp gradient.

Color adjustments to a ramp gradient show the Dark (tinted blue) overlapping the Shadow (tinted orange) zone.

Color adjustments to a ramp gradient show the Highlight (tinted yellow) overlapping the Light (tinted green) zone.

The Highlight and Specular zones overlap two progressively brighter luminance ranges of the Light zone. Highlight lets you adjust the color and/or contrast of the brightest highlights, while Specular is useful as a trim that lets you manipulate the very brightest highlights of an image. All adjustments you make to Highlight are mixed with any adjustments made to Light, and all adjustments made to Specular are mixed with the adjustments made to Highlight and Light. In this way, all color adjustments you make to overlapping Highlight zones mix smoothly together to produce the final result, as seen in the following ramp gradient.
As you can see, each one of these zones allow the specific adjustment of whichever parts of the image fall within the luminance range of that zone (as defined on the Zones panel), while providing control over how smoothly one adjustment fades into the next, to prevent unwanted contouring. As you make adjustments to the Range and Falloff of each zone using the different sets of zone controls, they work together to smoothly manipulate the contrast and color of the image, similarly to if you were using a more precise and constrained version of the Custom Curves. In fact, you can see the actual adjustment you’re making by exposing the Zone graph.

Working this way allows a tremendous specificity of adjustment, without the need to use curves or qualifiers. For example, zone-specific Color Balance controls allow you to grade the highlights and shadows separately using the Shadow and Light zone controls to quickly create a warm/cool split lighting effect. This makes the creation of dynamic grades more efficient and more creative.

In this next example, the Dark zone’s Color Balance control is used to add a splash of green to the darker shadows of the image, while the Black control is used to neutralize this green in the very blackest shadows.
Zone-Based Exposure Adjustments

Each zone has its own Exposure control that allows you to stretch image contrast from that zone’s Min or Max range boundary either down towards the shadows, or up towards the highlights. As seen on the Zone graph (found on the Zone panel), exposure adjustments are made on a scale measured in stops, to provide a more photographic experience when grading wide dynamic range material.

The scale of the Zone graph shows you the shadow and highlight ranges, in stops, relative to 0 representing 18 percent photographic gray.

On this scale, 0 stops corresponds to photographic 18% gray, at the center of each image’s tonal range. Shadows then fall to the left over -8 stops, while highlights fall to the right over +8 stops, where each stop represents either twice the amount of light (stopping up) or half the amount of light (stopping down).

In conjunction with Resolve Color Management, this range is designed to accommodate any SDR or HDR range you’ll be mastering to. All HDR palette controls are designed to accommodate up to 16 stops of exposure. By comparison, most modern digital cinema cameras claim to be able to capture somewhere between 13-19 stops of dynamic range, while a white paper from the ASC states that modern film negatives are capable of capturing 14 stops of dynamic range.

Unlike the Lift/Gamma/Gain or Log master level controls, the Exposure adjustment of each zone starts at a specific boundary of image tonality, and stretches all the way out through the highlights or shadows, through the maximum or minimum signal level allowable. Since Shadow and Light are the two zones that are centered on the midtones of the image, they’re the best zones for seeing how this works. Because of this, these are also probably the first two zones you’ll want to adjust if you’re making more specific exposure changes to the image.

Using the default preset, Shadow exposure adjustments affects everything in the image from stop 1 down through absolute black.

(Left) The original image, (Right) Darkening all shadows by lowering the Shadow exposure adjustment.
Meanwhile, Light exposure adjustments affect everything in the image from -1 stops all the way through maximum white.

This ability to make open-ended adjustments to image contrast in different overlapping ranges of shadow and highlight tonality makes these controls uniquely suitable for HDR grading, while also being completely suitable when grading at SDR levels. Also, keep in mind that all contrast adjustments in the HDR palette keep saturation constant as contrast increases or decreases.

This is particularly useful when making large contrast adjustments to HDR images, for which a 300 nit expansion of highlight contrast using the Lift/Gamma/Gain or Log controls would create a huge saturation increase. Using the HDR palette to expand highlight contrast keeps image saturation perceptually the same, while offering zone-specific saturation controls that let you choose whether to increase or decrease the saturation falling within that zone.

Exposure adjustments to zones that overlap other zones are smoothly combined to allow targeted contrast adjustments, while making it relatively easy to avoid unwanted artifacts, like contouring or solarizing due to overzealous inversion of the curves caused by these operations.

**An Example of Zone-Based Exposure Adjustment**

To see this in action, let’s see what happens when we make some overlapping adjustments to the Light, Highlight, and Specular zones in order to grade some HDR highlights, focusing our attention on the Waveform scope, since it’s difficult to see HDR grades in print. Keep in mind that you won’t usually be making Zone-based Exposure adjustments by themselves. This example image has had a Contrast/Pivot adjustment to push the midtones and shadows down, to give the shadows greater definition. Then, Black Offset is raised to lift the darkest shadows up just a little bit, so they can breathe. This leaves us with an image that’s mostly under 200 nits to begin with. A perfect starting point for us to begin sculpting those highlights.
Using the default preset, making an exposure adjustment to the Light zone smoothly raises everything in
the source image above -1 stops on the Zone graph. Practically, it’s stretching up all levels above 10 nits
on the HDR scope. This smoothly boosts the brighter part of the image, while leaving the shadows down
where we put them.

(Left) The previous adjustment; (Right) After raising Light Exposure

At this point, making an exposure adjustment to the Highlight zone boosts all levels above 1.5 stops on
the Zone graph. Again, practically speaking, all levels above 100 nits are being boosted, brightening the
top highlights. In the image, you can see that we’re creating a greater differentiation between dimmer
and brighter highlights in the image, creating highlight contrast with greater detail where once there
were simply flat pools of light.

(Left) The previous adjustment; (Right) After raising Highlight Exposure

Now, this might be a fine place to stop, but since we’re interested in turning the HDR in this image up to
11, we can put the highlights over the top by making one more Exposure adjustment, to the Specular
zone. The Specular zone starts at 4 stops and is designed to let you boost or attenuate only the very
brightest, hardest highlights, likely corresponding to specular details such as chrome reflections, eye
glints, and directly photographed light sources. You won’t always use this control, but it’s useful to
know about.

In this example, the default Specular Zone Min Range control is outside of the available image data
in the image (seen as the right edge of the histogram in the Zone graph), so making adjustments with
this control won’t do anything. However, dragging the Min Range control to intersect the end of the
histogram will allow these controls to affect the very brightest pixels in the image.
Now, the Specular Exposure control lets us push the very brightest pixels of our image up, further differentiating them from the other highlights, and widening the audience’s sensation of highlight contrast.

Now, having selectively boosted the Highlight and Specular zones, you might decide that you like the differentiation that’s been created among different brightnesses of highlights, but the overall highlights are too bright. This is easily fixed by lowering the Light zone’s Exposure adjustment. As a result of this one adjustment, all of the highlights are scaled down, while the adjustments you’ve made to the Highlight and Specular zones maintain a relative influence on the parts of the image they’re brightening. The Shadow, Dark, and Black controls work similarly, but for the shadows.

Now that you’ve seen how all overlapping Zone adjustments work together to create a seamless adjustment, it’s time to look at the Zone controls in more detail.
**Zone Controls**

Each individual zone also has controls for Color Balance and Saturation, which let you make focused adjustments that fall within specific ranges of image tonality, all without needing to use a qualifier. Using all of these zones together, you can make fast, precise, and smooth adjustments to the image that feel incredibly natural. Despite the name of the palette, this allows careful adjustment of SDR images, as well as creative adjustment of the spectacular range of highlights that HDR enables. There are also Range and Falloff controls to the left and right of each cluster of controls that let you redefine each zone's area of influence, even if the Zone graph is hidden.

![Zone Controls](image)

The Shadow and Light zone controls next to one another; you can see the Min and Max indicators, along with the Range value (in stops) at the upper left of each group of controls.

---

**Range indicator:** An icon and value at the upper-right-hand corner of each zone control cluster shows that zone's range. A numeric value shows the range value, which is the Luminance level of image tonality at which that zone's adjustment begins. This value is expressed in stops, while an icon shows you whether it's a maximum range (affecting shadows) or a minimum range (affecting highlights).

**Clicking the icon** shows a temporary preview in the Viewer of which parts of the image will be affected by the controls of that zone. Affected areas appear in full color, while unaffected areas appear black.

**Zone-specific Color Balance:** A color balance control lets you readjust the relative strength of the red, green, and blue channels within the current zone of image tonality.

**Zone-specific Exposure:** Zone-specific Exposure controls work in conjunction with an adjustable pivot that defines the Luminance level that each exposure adjustment starts from. To accommodate both shadow and highlight adjustments, there are two kinds of pivots, labeled Maximum and Minimum range, and indicated using an icon. Max Range controls, such as the Shadow control, start at a maximum value with exposure adjustments stretching image contrast downward towards the shadows. Min Range controls, such as Light, start at a minimum value with exposure adjustments stretching contrast upwards towards the highlights. Each zone also has a falloff that specifies how much of that zone overlaps neighboring zones (starting at the pivot level) in order to blend overlapping adjustments softly enough to prevent contouring.

**Zone-specific Saturation:** Adjusts the intensity of color within the current zone of image tonality.

**Min/Max Range:** Defines the level of image tonality at which that zone's adjustment starts. This value is expressed in stops. Identical to the Min or Max Range slider in the Zone panel. Useful for tweaking Range while the Zones graph is hidden.
— **Zone Falloff:** Defines how softly this zone fades into all overlapping zones. Identical to the Falloff slider in the Zone panel, the value is visible in the virtual slider below. Useful for tweaking Falloff while the Zones graph is hidden.

— **Zone-specific Color Balance Values:** Two values expose the current color balance operation numerically. The option menu lets you choose between representing these as X and Y, or as Angle and Strength.

### Customizing Zones Using the Zone Panel

Similarly to the controls of the Log palette, how these zones overlap can be adjusted in order to make each zone’s controls work best for the tonal distribution of the images in any given scene. Zone overlap is governed by individual pairs of Range and Falloff controls, so you can make precise adjustments no matter what the distribution of tonality is in the image you’re grading. All zones are organized and customized using the Zone panel, which is divided into the Zones sidebar to the left, and the Zone graph to the right.

![The Zone panel of the HDR palette](image)

**The Zone Sidebar**

The Zone sidebar show a list of all the zones in the current preset. This list is sorted by range values, with minimum range zones (affecting shadows) appearing at top and maximum range zones (affecting highlights) appearing below. Clicking any zone in the list selects that zone, which also selects that zone’s boundary handle in the Zone graph at the right.

**Zone sidebar controls:**

— **Enable Zone toggle:** Toggles let you turn each zone on and off. Disabled zones will not be rendered.

— **Max/Min button:** Defines whether the adjustment of a particular zone affects the image from the current range value and below (Max) or the current range value and higher (Min). This setting is typically used when creating your own custom preset, to define which zones stretch down toward the shadows and which zones stretch up toward the highlights.
— **Show/Hide Zone button**: This button lets you hide sets of zone controls you don’t want to adjust any further, leaving more room in the UI and on your control surface for the zones you do want to adjust. For example, if you decide you don’t need to use the default Black and Specular zones, you can hide them so that only the Dark, Shadow, Light, and Highlight zones are available to switch among. Zone controls with adjustments made to them continue to affect the image even if the controls are hidden.

— **Delete Zone button**: Deletes that zone. This is primarily useful when you’re creating your own zone preset. At the time of this writing, you cannot delete any of the default zones found in the default Zone preset.

Additionally, you have the option of adding zones, and saving zone presets to create your own custom ways of adjusting the image.

**To create a new zone:**

1. Open the Zones panel.
2. Click Create Zone, at the bottom of the Zones sidebar.
3. When the Create Zone dialog appears, choose the Zone type you want that zone to have (Dark/Min Zone or Light/Max Zone), enter a Name, and define the Pivot and Falloff values. Pivot, Falloff, and Zone type are editable later, so don’t worry if you don’t set them up perfectly the first time.

![Create Zone dialog](image)

4. Click Create. That zone appears added to the list, which is sorted in the order in which Pivot is defined, with Dark Zones appearing at the top, and Light Zones appearing at the bottom.

**Zones Graph**

The Zone graph is a key component of the HDR palette’s use. Along the bottom, a scale in stops shows the range over which the HDR palette operates. At the top, handles let you adjust the editable range boundaries that define the tonal range of each zone’s operation, superimposed over a histogram showing the current image as input into the current node. Running through the middle of the Zone graph, a curve shows you all the Global and Tonal color and contrast adjustments being made by the HDR palette in the current grade.
The Zone graph

The relationship of the range boundaries with the source image histogram in this graph is extremely important. The range boundary for a particular zone must intersect with the part of the source histogram you want to adjust for the controls of that zone to have any effect. If any zone boundaries lie outside of the histogram, that zone’s controls will do nothing. In the screenshot above, the zone’s range boundaries all lie inside of the visible histogram, so each zone’s controls will make a predictable adjustment to the image data in that part of the histogram.

In the following screenshot, the Zone graph shows that the Specular zone boundary lies outside of the source histogram for the image, so adjustments made using the Specular controls will have no effect. For this reason, it’s a good idea to check that the zone boundaries intersect the parts of the image you want to adjust prior to manipulating the controls, but if you notice that a particular zone’s controls aren’t having as much of an effect on the image as you’d like, you can always move the zone boundary after the fact to expand the range of the image that’s affected by that zone.

Customizing zone boundaries in this way is one of the most powerful aspects of the HDR palette, but don’t worry that you’ll be constantly dragging zone boundaries back and forth for every shot you grade. Generally speaking, most well-photographed scenes have similar ranges of image tonality in each shot, so zone boundaries that have been customized for one shot from that scene will likely be good for most
clips in that scene. That said, adjusting zone boundaries is another powerful way of tailoring a grade specifically for a clip with a unique range of contrast.

**Zone Controls**

- **(Min/Max) Range**: Defines the level of image tonality at which that zone’s adjustment starts. This value is expressed in stops.
- **Falloff**: Adjusts how softly the adjustment in that zone will blend into the image. A value of 0 results in an immediate transition to the adjustment created in the current zone, with the color adjustment being a sharper effect. Higher values will blend the current zone’s adjustment into the image more softly, resulting in a more gentle and seamless transition into the effect.

**Customizing and Saving Presets**

If you’ve customized the Zone graph in a way that’s potentially useful for other grading situations, you can save a preset of the Zone settings for future use. Saving, recalling, and managing these presets is simple.

**Methods of managing presets:**

- **To save a preset**: Customize the Zone graph to suit your needs, then choose Save As New Preset from the HDR palette Option menu.
- **To load a preset**: Choose Presets > Name of Preset > Load Preset from the HDR palette Option menu. A new preset will be saved.
- **To update a preset**: Load a preset, make any changes you need to from the Zone graph, and then choose Presets > Name of Preset > Update Preset from the HDR palette Option menu.
- **To delete a preset**: Choose Presets > Name of Preset > Delete Preset from the HDR palette Option menu.
- **To select the default preset**: Choose Default Preset > Name of Preset from the HDR palette Option menu. This preset will now be the one loaded initially into the HDR palette on startup.

**Resetting Color and Zone Adjustments**

In the HDR palette’s Option menu, there’s a Reset submenu with three commands, Reset All, Reset Color Adjustments, and Reset Zone Definitions, which are self-explanatory. These are important because, during the course of developing a grade, there will be many times when you’ll want to reset your color adjustments without changing how you’ve customized the Zone graph, or vice versa.

Additionally, each of the visible reset buttons in the GUI can be used with keyboard modifiers to specifically target what to reset. The master reset button in the HDR palette’s title bar resets the entire palette when clicked (similar to the Reset All command). However, using keyboard modifiers while clicking this button changes what’s reset.

- Hold down Command+Shift while clicking the master reset button to reset only the Zone graph’s Range and Falloff controls, without resetting your color adjustments.
- Hold down Command+Option while clicking the master reset button to reset only the color adjustments, while leaving the zones alone.
Both of these modifiers also work with the zone-specific reset controls found in the Wheels panel, letting you reset only the Zone controls or only the Color controls of each specific zone.

### Using the HDR Palette With DaVinci Control Panels

To use the HDR palette with the original DaVinci Advanced control panel, press SHIFT + AUTO COLOR.

To use the HDR palette with the DaVinci Advanced control panel’s 2020 layout, press HDR on the Trackball panel.

Once selected on the Advanced control panel, all of the current control mappings will appear in the center panel soft buttons and rotaries, and the trackballs and control rings will be mapped to the appropriate zones. The < and > soft keys let you navigate among all the zones available in the current preset.

To use the HDR palette with the DaVinci Mini control panel, press the USER button, then press the HDR soft button above the left-hand display. All of the HDR palette control mappings will appear in the soft knobs and keys, and the trackballs and control rings will be mapped to the color balance and exposure controls of the appropriate zones. The PREV ZONE and NEXT ZONE soft keys let you navigate among all the zones available in the current preset.
Chapter 130

Primary Grading Controls

This chapter focuses on the more esoteric adjustments you can make, mixing colors between channels using the RGB Mixer.

Using the RGB Mixer in Monochrome Mode 2851
Introduction to the RGB Mixer Palette

The RGB Mixer palette lets you remix different amounts of image data from one channel to another, and has a wide variety of creative and utilitarian uses. Furthermore, the RGB Mixer can be used either to remix the color channels, or to add different proportions of each color channel into a monochrome image.

![RGB Mixer palette](image)

By default, the RGB Mixer palette is set to mix any amount of the Red, Green, and Blue color channels into any of the other channels. Each color channel has a dedicated control group of Red, Green, and Blue sliders that you use to do the mixing, and the default values of these can be seen in the screenshot above.

Each slider has an overall range of –2.00 to +2.00. This means that you also have the option of subtracting any combination of color channel values from a particular channel. For example, you can lower the Red control group’s Green slider to –.24 to subtract 24 percent of the Green channel from the Red channel.

Preserve Luminance

With the “Preserve Luminance” checkbox turned on, any channel adjustment you make is prevented from altering the luma of the image by automatically raising or lowering the other two channels to compensate. In the following example, you can see that when “Preserve Luminance” is turned on, lowering the Green control group’s Green slider results in the Red and Blue channels being raised by the same amount (as seen in the Parade scope). Conversely, raising a color channel’s slider ends up lowering the other two channels by the same amount to keep overall image luminosity the same.
Resetting the RGB Mixer

Clicking the Reset button at the top right-hand corner of the RGB Mixer resets each slider to its default position, where Red = 1.00 for Red output, Green = 1.00 for Green output, Blue = 1.00 for Blue output, and all other sliders = 0.

Swap Channels Buttons

A set of three buttons at the bottom of the RGB Mixer lets you easily swap two channels with one another. This can be useful as part of a creative look, or corrective in instances where two channels are accidentally reversed.

- **Swap Red and Green**: Swaps these two color channels.
- **Swap Green and Blue**: Swaps these two color channels.
- **Swap Red and Blue**: Swaps these two color channels.
Using the RGB Mixer in Monochrome Mode

When you turn on the Monochrome checkbox, two of the sliders within each Output group are disabled. This leaves the Red > Red slider, the Green > Green slider, and the Blue > Blue slider as the only available controls.

Keeping in mind that each of the color channels that makes up an image is itself a grayscale channel, the RGB sliders in Monochrome mode let you add different proportions of the Red, Green, and Blue color channels together to create custom grayscale versions of a shot.

To understand why this is useful, let's consider the default values of the Red, Green, and Blue sliders. To emulate the human eye's sensitivity to the wavelengths of light, the Rec. 709 video standard defines an isolated Luma (Y') component as consisting of 0.2126 of the Red channel, 0.7152 of the Green channel, and 0.0722 of the Blue channels added together. This can be seen in the default values (rounded to the nearest integer percentage) of 21, 71, and 7.

This is the standard method of deriving a black and white version of a color image, and in fact produces identical results to those obtained by setting the Saturation parameter to 0.

However, there have traditionally been other ways of mixing the colors of life into different grayscale interpretations. For example, photographers often use colored filters in conjunction with black & white film stocks, such as a yellow/green filter to emphasize pleasing skin tone for lightly complexioned people. A much older example is the use of black & white film stocks with different sensitivities (old orthochromatic stocks were not sensitive to red wavelengths, recording only blue and green to create an image).
Using the RGB Mixer with Monochrome mode turned on gives you the ability to mix your own custom blends of all three color channels to emphasize the creative characteristics you require. For instance, increasing the mix of blue and decreasing red and green can give skin tones a darker, metallic sheen. The following screenshots show multiple versions of the same image with different monochrome mixes.

Three monochrome mixes of the same image. The top image is the result of setting saturation to 0.

Like the parameters in Color mode, you can use the RGB Mixer’s Monochrome mode to subtract one color channel from the others, for even more creative effects.
Chapter 131

Curves

The Color page has a powerful curves interface that provides controls for adjusting color and contrast with the Custom Curves, as well as a variety of “Hue” or “HSL” curves that let you make more targeted adjustments to hue, saturation, and luminance in a variety of ways.

Introduction to Curves

The Curves palette, selectable via one of the toolbar buttons above the Center Palette panel of the Color page, has six modes that provide different curve-based methods of manipulating the color and contrast of an image. Each curve lets you adjust a customizable region of the image based either on image tonality (zones of lightness or darkness), hue (specific colors), or saturation (intensity of color). All curves can be adjusted using either the pointer, or knobs on the DaVinci Resolve Mini or Advanced control panel.

The Curves palette is color-space-aware when you’re using Resolve Color Management (RCM) or ACES. What this means is that the overall range of each curve better fits the overall data range of the current clip no matter what Timeline Color Space you’re using, for both SDR and HDR mastering. This makes curves adjustments easier, more specific, and a more consistent experience, no matter what your workflow happens to be.

**TIP:** All curves in DaVinci Resolve can be used to affect the overall image, or limited to affect only a specific portion of the image as a part of a secondary operation using qualifiers, windows, imported mattes, or any combination of the three.

Adjusting Curves Using the Mouse

All Color curves in DaVinci Resolve use the following controls for basic on-screen adjustment using the pointer, controlled either with your mouse, pen, or other input device of choice.

**Methods of adjusting curves using the on-screen interface:**

— **To add a control point:** Click anywhere on a curve. A control point is added at the position of the mouse where you clicked, and the curve is altered, if necessary, to match the new control point’s position.

— **To add a control point without altering the curve:** Hold the Shift key down, and click anywhere on or around a curve. A control point is added to the curve at the position of the pointer where you clicked, but the curve is not altered.

— **To snap a control point to the neutral diagonal of the curve:** (Custom curve only) Hold the Option key down while dragging any control point on the curve. A diagonal line appears indicating the neutral state of the image, and the control point will snap to it. When you release the Option key and then press the Option key again after releasing, the diagonal guide line disappears.

Snapping a curve’s control point back to its neutral position by holding down the Option key
To remove a control point: Right-click any control point to make it disappear.

To reset a single color channel curve to a completely neutral setting: Click the reset button to the right of that color channel’s intensity slider.

To reset all color channel curves: Click the Reset Custom Curve button at the upper right-hand corner of the Curves palette.

By default, a control point influences the portion of each curve that falls between its neighboring two control points.

In the top screenshot, you can see that the control point at the position of the pointer is affecting the larger part of the curve that falls between the lower left-hand control point (which is there by default), and a user-created control point placed up within the highlights of the curve.

In the bottom screenshot, an additional control point to the left of the one being adjusted limits the area of the curve that is adjusted. By careful placement of additional control points, you can make extremely targeted adjustments to images using the Custom curves.

This example highlights the importance of using control points to “lock off” portions of a curve at a neutral or nearly neutral position to prevent changes to specific portions of an image, even while using other control points to make changes.

**NOTE:** The HSL curves also have an optional adjustment mode using Bezier curves that will be covered in those sections.
Sampling Images to Place Control Points on Curves

Another way you can add control points to curves is to move the pointer to the Viewer, and click to sample a color value and place a control point at the position on the currently open curve that corresponds to that value. This works with Custom, Hue, and HSL curves.

Clicking on a feature of the image Creates a control point on the currently open curve

Showing Picker RGB Values

While you’re dragging the pointer over the Viewer and looking for a feature to sample, you can enable a tooltip that shows you the RGB Value of the pixel under the pointer by right-clicking the Viewer and choosing Show Picker RGB Value to toggle this feature on and off. When you turn this feature on, the View > Show RGB Picker Values In submenu has options for displaying either 8- or 10-bit tristimulus values.

The color picker tooltip that appears when you turn on Show RGB Picker Values

Curves Histograms

The Custom curves and HSL curves all show a histogram that represents the input of the currently selected Correction node, which you can use to guide your adjustments. The Histograms submenu of the Curves palette’s Option menu lets you choose to disable these histograms, or to switch the histograms between showing the input or the output of the node. If you switch to Output, the histograms will update to show you the result of your adjustments, at the expense of seeing the image data that the curve is actually working upon.

The Custom curves show a YRGB histogram:

The histogram appearing underneath the Custom Curves shows a YRGB histogram analysis
Each Hue or HSL curve shows a histogram analysis of the two color channels that Curve acts upon: hue against saturation level, luminance against saturation level, or saturation level against saturation level, to give three different examples. In the case of Hue or HSL curves, these histograms make it easy to see which parts of the Curve controls will actually affect image data.

The histogram appearing underneath the Hue vs Sat curve plots all saturation levels at each value of hue.

Custom Curves

DaVinci's Custom curves provide smooth adjustment of each clip's Y, R, G, and B channels. The Custom curve mode of the Curves palette is divided into two areas, the Curve Editor to the left, and the Curve controls to the right. The editor contains the actual Curve controls you use to adjust the image. The controls at the right let you choose which curves you’re adjusting, and adjust their intensity.

The Custom curves seen used to create a gentle “S” curve adjustment with four additional control points added.

The Custom curves are useful for making more tonally specific, channel-by-channel adjustments to an image than can be accomplished using the Color Balance controls. They’re also useful for making strange and wonderful stylistic adjustments through unusual alterations to different combinations of color channels.

Although the ganged Custom curves appear to be a single curve control, the Custom curve editor is actually presented as a series of overlaid curves, and the YRGB curves all appear within a single editor.
The default, neutral position of the Custom curves is a diagonal line that runs from the lower-left black point of the image through the upper-right white point.

The neutral diagonal position of the curve at which no adjustment is made

The horizontal axis represents the range of image tonality in the original image, from black (at the left) to white (at the right), while the vertical axis represents the range of alteration you can make. By adding control points to the surface of the curve and raising or lowering it at different regions, you are actually remapping the original horizontal “input” value of a color channel to an “output” value of your choosing.

Additional controls appear to the right of the curve editor itself. A top row of buttons let you select the curve corresponding to an individual color channel for isolated adjustment, while a vertical stack of four sliders let you adjust the intensity of each color channel’s curve.

The channel-editing buttons and curve intensity sliders appear to the right of the curve editor

**Editing the Top and Bottom Control Points of Curves**

You can also edit curves using the default two control points that the curve control starts out with in the Curve Editor. The Black Point control (at the lower-left) and the White Point control (at the upper-right) let you expand and compress the video signal similarly to using the Lift and Gain Master Wheel controls in the Color Wheels palette.

The Curve control at its original state

The Black and White Point controls dragged to the right and left to expand the signal
You can use the Black and White Point controls in the following ways:

— **Using the Black Point control:** Dragging this control up makes a lift adjustment to raise the black point of the signal. Dragging this control to the right makes a lift adjustment to lower the black point of the signal.

— **Using the White Point control:** Dragging this control down makes a gain adjustment to lower the white point of the signal. Dragging this control to the left makes a gain adjustment to raise the white point of the signal.

**HDR Grading Using Curves**

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR mode of the node you’re working on by right-clicking that node in the Node Editor and choosing HDR mode from the contextual menu (only available in Resolve Studio).

This setting adapts that node’s controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.

**Enabling Editable Splines in the Custom Curves**

When the Curve palette is in Custom mode, you can choose Editable Splines from the option menu to expose Bezier spline handles on any selected control point, which let you make more precise curve adjustments whenever necessary.
NOTE: Beware of making curve adjustments that are too sharp, or with control points that are too close together, as they can introduce unwanted contouring within the image, causing flattening or solarization in parts of the image that you may not want.

Adding Default Anchors to the Custom Curves

You can also choose Default Anchors from the option menu of the Curve palette in Custom mode to place three additional control points on the curve, dividing the curve into five segments that affect the shadows, low midtones, medium midtones, high midtones, and highlights of the image.

![Custom curve with Default Anchors exposed](image)

Ganging and Unganging Custom Curves

By default, the Custom curves are ganged, so that curve adjustments affect a clip’s YRGB channels all together, resulting in an adjustment to image contrast that’s similar to using the Master Wheels in the Color Wheels palette. When making this type of adjustment, increasing contrast also increases image saturation, while reducing contrast also reduces image saturation. Since curves can be manipulated with greater specificity than the three Master Wheels, you can make much finer contrast adjustments using the YRGB curves than when using the Master Wheels only.

Turning ganging off lets you use the full power of Custom curves to alter the image. Unlike the Color Balance controls, each of which adjust all three color channels simultaneously, the Curve controls let you adjust each channel individually when Gang Custom Curves is turned off.

To disable Custom curve ganging:

— Click the Curve Edit button that corresponds to the curve channel you want to edit. Clicking any Curve Edit button highlights that curve to make it easy for editing when curves overlap one another. Once one or more curves is offset from the others, you can freely edit any curve by dragging its control points.

![Custom Curve Edit buttons are to the left, the Gang button is to the right](image)
To re-enable Custom curve ganging:
— Click the Gang button to the left of the Curve Edit buttons.

Editing color channels via individual curve adjustments lets you make smooth color-channel specific corrections, or you can make radically individual adjustments to create a wide number of creative effects.

Turning off curve ganging lets you independently adjust each curve

**TIP:** When curve ganging is disabled, the Luma curve allows you to adjust the Y channel by itself, which is similar to using the Y-only Lift/Gamma/Gain knobs of the DaVinci Resolve Micro, Mini, or Advanced Control Panels. When making this type of adjustment, increasing luma contrast results in a perceptual decrease of image saturation.

**Copying Custom Curves From One Color Channel to Another**

Even if you’ve unganged the Custom curves, you can still mirror one curve’s adjustments to another by copying it using the “Copy to Red/Green/Blue” commands in the Curve palette’s option menu.

**Curve Intensity Sliders**

Four Curve Intensity sliders to the right of the Curve Editor, one for each channel, let you mix between the current curve’s effect on the clip, and the original state of the image before you altered the curve. The default Intensity of 100 results in that curve exerting its full effect on the image, while an intensity of 0 results in that curve having no effect on the image. The Intensity sliders provide an easy way to “split the difference” between a curve adjustment and the previous state of the image.

Lowering the Curve Mix slider reduces the effect of that curve’s adjustment on the image.
**YSFX Sliders**

Each of the Custom curves (Y', R, G, and B) has a vertical YSFX slider at the upper left-hand corner of the Curve Editor that lets you invert any or all color channels by any amount you want, to create different types of stylized effects.

![Image with the Luma channel modified using the vertical YSFX slider](image)

As with all other adjustments in the Color page, YSFX may be combined with Power Windows or HSL qualification to limit channel inversions to specific portions of the image for creative purposes.

**Soft Clip**

The Soft Clip controls consist of four sliders underneath the Curve controls of the Custom curves, and give you an interface for adjusting highlight and shadow soft clipping either overall, with Ganging enabled, or on a per-channel basis. The Soft Clip controls are intended to provide clip-by-clip adjustment, as opposed to the Generate Soft Clip LUT settings, which let you set one soft-clipping setting for the entire program. For more information on the Soft Clip LUT setting, see Chapter 4, “System and User Preferences.”

![High and Low Soft Clip controls within the Curves palette](image)

Soft clipping lets you apply a “knee” to any clipping that occurs at the upper or lower extremes of the image, and can be used to quickly ease off any unpleasantly harsh loss of detail that occurs as a result of blowing out the highlights or crushing the shadows too aggressively.

In the following example, the screenshot at top has had the highlights deliberately blown out by excessively boosting the highlight contrast. As you can see, the edges of the clipped area lack detail. The screenshot at bottom shows the same image with soft clipping increased for all three color channels. The result retrieves detail, compressing the highlights to bring the tops of each color channel back within the allowable range.
Ganging and Unganging Soft Clip Controls

Soft clipping can be simultaneously applied to all three color channels by enabling the Ganging control (on by default), or you can disable Soft Clip ganging to individually adjust each channel. For example, using soft clipping on individual channels can be useful for legalizing RGB out-of-gamut errors for channels that over- or undershoot your QC standards.

To disable Soft Clip ganging and edit soft clipping for individual color channels:
— Click the channel control button corresponding to the color channel you want to edit, and then drag the sliders to create the desired adjustment.

To re-enable Soft Clip ganging:
— Click the Ganging control to the left of the Soft Clip channel controls.

**TIP:** Applying too much soft clipping to individual color channels may add an unwanted color tint to the corresponding highlights or shadows of an image. To avoid this, use the soft clipping parameters with ganging enabled to clip all three color channels equally.

Soft Clip Controls

Whether all channels are ganged or not, soft clipping is controlled via two sliders and two additional parameters for each color channel.

**High**

The High Clipping Point slider lets you adjust the maximum signal level above which the signal is clipped. Any pixels above the clipping level are made equal to the clipping level.
The High Clipping Point defaults to a digital level of 1023 relative to the DaVinci Resolve internal video scopes. Dragging this slider to the left causes the highlights of the image to clip at a lower level, resulting in lower, dimmer maximum levels.

At the default position, no clipping occurs and image data that you push above 1023 on the internal scopes is preserved and passed through the image processing pipeline to subsequent nodes. For example, in the following two screenshots, the highlights in the screenshot at top are blown out raising the gain dramatically in Node 1. In the screenshot at bottom, a subsequent adjustment in Node 2 lowers the gain and retrieves all the previously clipped values.

The High Clipping Point

RGB Parade displays the clipped image

At the default position, no clipping occurs and image data that you push above 1023 on the internal scopes is preserved and passed through the image processing pipeline to subsequent nodes. For example, in the following two screenshots, the highlights in the screenshot at top are blown out raising the gain dramatically in Node 1. In the screenshot at bottom, a subsequent adjustment in Node 2 lowers the gain and retrieves all the previously clipped values.

The image is clipped using the Gain control in Node 2

The image data that was clipped in Node 1 is retrieved in Node 3 by lowering the Gain control. This illustrates the preservation of deliberately clipped data.
However, if at any point in a node tree you drag the High Clip slider to the left, even by a single digit, all image data above the new clipping threshold is discarded from that node forward. In the following example, the High Clip slider in Node 1 is lowered. The result is that all clipped image data is discarded. As a result, when Node 2 lowers the gain, there is no image detail left to retrieve, and all three channels exhibit flattening.

![Image](image.png)

Lowering the High Clip slider in Node 1 forces all image data above the new High Clip threshold to be irretrievably discarded. Clipped data cannot be brought back by subsequent nodes.

**High Soft**

The High Soft slider sets the threshold, below the clipping point, at which highlights begin to compress before hard clipping. At unity, no soft clipping occurs. As you raise this value, more and more of the clipped highlight values are compressed, rather than clipped, resulting in softer, more pleasant “glowing” highlights.

**IMPORTANT**

Image data that was clipped “in camera” is not necessarily retrievable using the Soft Clip controls, although there may be some preserved overhead in the super-white highlights of Y’CbCr-encoded video data.

**Low**

The Low Soft Clipping Point slider lets you adjust the minimum signal level at which the signal clips. This defaults to a digital level of 0 relative to the DaVinci Resolve internal video scopes. Dragging this slider to the right causes the shadows of the image to clip at a higher level, resulting in lighter minimum levels, and a lower-contrast image with lighter (possibly milky) shadows.

**Low Soft**

The Low Soft slider sets the threshold, above the minimum clipping point, at which shadows begin to compress before hard clipping. At unity, no soft clipping occurs. As you drag this slider to the right, more and more of the clipped shadow values are compressed, rather than clipped, resulting in a softer, more pleasant rolloff in the shadows.
The HSL Curves

Three sets of Hue curves, and additional Lum vs. Sat, Sat vs. Sat, and Sat vs Lum curves, let you make different types of curve-based alterations to the image. Whereas the Custom curves let you make adjustments to the color channels of an image based on tonality (for example, boosting the Red channel in the highlights while lowering it in the shadows), the Hue curves let you make adjustments to the hue, saturation, or luma of elements in an image based on their hue.

For example, you could use the Hue vs. Sat curve to selectively lower the saturation of everything that’s blue, while raising the saturation of everything that’s red.

You can use these curves to make adjustments similar to those made using HSL qualification, but with one critical difference. Curve adjustments are mathematically smoother than the matte-limited adjustments of HSL qualifiers, so it can sometimes be easier to make specific alterations that blend smoothly with the rest of the image, without the potential for artifacts at the edges of qualified keys that can sometimes defeat a seamless result.

On the other hand, it is often easier to define more distinct boundaries between separate elements using HSL qualification. Only time and experience will help you determine which tools are best for which situations.
Unlike the Custom curves, which default to a diagonal position where lower left represents the black point and upper right represents the white point, Hue and Sat curves are flat. In the case of the Hue vs. Hue/Sat/Lum curves, the horizontal range of the curve from left to right represents the overall range of possible hues, from red through green through blue and then cycling back to red.

Because the range of hues cycle smoothly from the left to the right edge, changes that affect the curve near the left boundary of these curves loop smoothly around to the right boundary, and vice versa, such that the left and right sides of the curve always move together (as you can see in the above screenshot).

**IMPORTANT**

When using Hue curves, the range of hue that you isolate with control points is always relative to the RGB input connected to that node. That means if you change the hue of a shirt from blue to red using Hue vs. Hue and you then want to raise the same shirt’s saturation with the Hue vs. Sat curve within the same node, you need to add control points to the same range of blue for both curves.

**Image Sampling for Hue and Sat Curves**

There’s an additional way to use Hue curves in DaVinci Resolve. Whenever one of the Hue vs. Hue, Hue vs. Sat, Hue vs. Lum, Lum vs. Sat, or Sat vs. Sat curve tabs are open, clicking or clicking and dragging over any range of pixels within the Viewer area samples the hues and/or image tonality of that region of the picture, and automatically places three control points on the currently open curve that correspond to the range of color and contrast you sampled. This also works if you use the cursor from the DaVinci control panel with the fourth trackball to sample a range of color.

**Additional Controls in the Hue and Sat Curves**

While the Hue vs. Hue, Hue vs. Sat, Hue vs. Lum, Lum vs. Sat, and Sat vs. Sat curves can be adjusted similarly to the Custom curves, they have additional controls running underneath the curve graph.

— **Enable Bezier button**: Turning this button on forces a curve to use Bezier control handles, rather than the default DaVinci Resolve Curve Control points, to manipulate each control point on the curve. With Bezier handles enabled, click any control point to reveal its two Bezier handles. Drag either handle to alter the shape of the curve at that control point.
Six-Vector Color Patches: The Hue curves each have six buttons for automatically adding control points to manipulate the red/yellow/green/cyan/blue/magenta ranges of hue. Clicking any of these buttons adds three control points; two to define the outer range of hue to be adjusted, and a middle control point that you use to make the adjustment.

Input and Output (Hue Rotate/Saturation/Lum) fields: These two number fields correspond to the horizontal and vertical adjustment values for the currently selected control point. Click any control point on a curve to view or alter these values. The label of the second field depends on the curve that’s selected.

The following sections describe each available curve in more detail. Each type of curve is accessed by selecting the appropriate icon in the upper right of the Curve Palette.

Hue vs. Hue
The Hue vs. Hue curve lets you change any hue to any other hue. In the following example, the image on the left is the unadjusted original. The image on the right has had the orange jacket shifted to an olive green via a set of three control points.

One excellent use of the Hue vs. Hue curve is to quickly and subtly alter elements that require only minor adjustments. For example, a sky that appears a bit too cyan can be made into a richer shade of blue with a small adjustment.

Hue vs. Hue is also useful for making more radical changes to elements that might be too noisy to key successfully using the HSL qualifier controls. For example, red autumnal foliage blowing in the wind might result in a chattery matte, but you can use the Hue vs. Hue curve to change reds to greens, without having to worry about aliased matte edges giving your correction away.
Hue vs. Sat

The Hue vs. Sat curve lets you selectively alter the saturation of any hue within the image. This is a terrific tool for creative effect, allowing you to quickly and easily boost the saturation of elements you want to catch the viewer’s eye, while reducing the saturation of elements you’d prefer the audience not dwell upon.

This can be extremely useful for legalizing over-saturated overshoots or undershoots during a QC pass. For example, desaturating reds that are off the charts while leaving everything else alone.

![Lowering the saturation of the woman’s jacket using the Hue vs. Sat curve; Left–original image, Right–altered image](image)

The Hue vs. Sat curve can also be a powerful tool for increasing the color contrast of images that seem lackluster and flat. By boosting the saturation of colorful elements that are distinct from the dominant palette of a scene, you can add variety to an otherwise monochromatic image.

Hue vs. Lum

The Hue vs. Lum curve lets you increase or decrease the lightness of elements of specific colors.

![Darkening the woman’s jacket using the Hue vs. Lum curve; Left–original image, Right–altered image](image)

This is a tricky curve to use with highly compressed footage, as it can quickly reveal artifacts in the image if you aren’t careful. However, if you’re working with very high-quality footage, this can be a great tool to darken specific hues to add richness and depth, or to lighten colorful elements to which you want to draw attention.
**Lum vs. Sat**

The Lum vs. Sat curve is similar to the Custom curves in that alterations to the saturation of an image are based on user-definable ranges of image tonality, rather than hue. In the following example, the Lum vs. Sat curve is being used to decrease selectively the saturation of everything falling into the highlights and shadows of the image, while increasing the saturation of everything within the midtones.

In the following example, a vividly saturated treatment results in shadows that seem artificially colorful. Using the Lum vs. Sat curve, it’s easy to gradually desaturate everything below a certain range, with a nice smooth falloff.

This is an outstanding curve to use for creative effect, for example, slightly boosting saturation within the midtones while reducing saturation in the shadows to increase the depth of the darkest portions of the image. It’s also a great curve to use to solve QC violations. For example, if you have illegal saturation in the highlights of an image, you can use the Lum vs. Sat curve cleanly and smoothly to lower the specific values that are causing problems.

![Selective desaturation in the shadows and highlights using the Lum vs. Sat curve; Right–original image, Left–altered image](image)

**Sat vs. Sat**

The Saturation vs. Saturation curve lets you selectively manipulate image saturation within specific regions defined by the image’s original image saturation. Control points added to the left of this curve affect areas of progressively lower saturation, effectively letting you increase or decrease the saturation of lower-saturated features. Control points added to the right affect areas of progressively higher saturation, letting you increase or decrease the most saturated features of an image.
Like all curves, this operation is extremely useful for stylizing the image. You can create custom vibrance operations, where you selectively increase the saturation of low-saturated regions of the image in different ways to give the picture more “pop.” It’s also an excellent tool for taking care of over-saturated areas of the picture when adhering to conservative QC requirements. You can specifically desaturate only the most over-saturated parts of the picture, without affecting similar hues at lower levels of saturation.

In the following example, you can see that the portion of the image with the highest saturation has been desaturated, while the rest of the image has been left alone.

Desaturating only the highest saturated elements in the picture by lower control points at the right of the Sat vs. Sat curve

**Sat vs. Lum Curve**

The inverse of the Lum vs. Sat curve, Sat vs. Lum lets you quickly adjust the luminance of pixels that falls within a particular range of saturation. This is useful for cases where regions of the image you want to make lighter or darker happen to coincide with an identifiably consistent range of saturation.

To help guide your adjustment, the histogram drawn for this curve lets you see how many pixels there are at each level of saturation found within the image, with the leftmost part of the curve representing minimum saturation, and the rightmost part of the curve representing maximum saturation. Seeing where the levels of saturation lie in the current image help you to quickly make targeted luminance adjustments when you sample the region of the image you want to adjust to add points to this curve.
The Sat vs. Lum curve

In the following example, the right side of this curve is lowered so that the most saturated parts of
the image become darkened. You might want to make an adjustment like this to emulate one of the
properties of film, where highly saturated colors block more light from passing through the emulsion
than less saturated colors. Or, you may do this in an effort to desaturate bright colors in highlights that
might otherwise clip past maximum white. Or, you might do this to quickly darken highly saturated skies.

(Top Left) The original image, (Top Right) The highly saturated blue sky and sea reflections are
darkened to a more intense blue by lowering the right part of the Sat vs. Lum curve (Bottom).
Chapter 132

Color Warper

The Color Warper is a powerful tool for making both highly specific adjustments to particular things in the frame, and widely general adjustments to create unique looks.

The two modes of the Color Warper each make it easy to simultaneously modify two different color attributes, either saturation and hue, or lightness and hue. This gives the Color Warper an advantage over curves, which only let you adjust one color characteristic at a time. In this chapter, you’ll learn how to use both modes of the Color Warper to perform a wide variety of tasks.

Introduction to the Color Warper

The Color Warper palette is a mesh-based warping tool that, instead of warping the spatial location of pixels, warps one set of colors into another. Better yet, unlike the HSL curves, the Color Warper lets you simultaneously adjust two color parameters at the same time, within user-selectable regions of specific hues. These adjustments, made using a grid of draggable control points, automatically have a smooth falloff from the colors you’re warping to other colors that are locked into place. The smoothness of this falloff depends on the distance between the warp points that are being adjusted and other warp points that are locked in place to prevent change.

There are two ways you can use this tool. You can drag the control points in the grid to make highly specific image adjustments. More intuitively, you can click to sample the image, which selects the closest grid point that affects that color, and then drag to make an adjustment with that control point.

You can use this tool to make extremely specific adjustments to colors in an image, similar to what you might do with a Qualifier key or with the HSL curves. However, by warping the points using a grid, you can manipulate two color characteristics at the same time, adjusting both hue and saturation, or chroma and luma. In the following example, specific adjustments are being made to refine the woman’s shirt, to adjust her skin tone, and to manipulate the greens of the foliage in the shot. All three of these naturalistic adjustments are smooth and artifact-free by virtue of the Color Warper’s method of cleanly remapping color.
You can also use this tool to create wide-ranging stylistic looks for the overall image, bending the color in creative ways that other controls don’t. In the following image, the less saturated and neutral colors of the image are all warped towards a bluish-cyan, while the more saturated oranges are warped towards a saturated orange-red, to quickly create a stylistic treatment of the image.
The Color Warper Interface

You can either use the Color Warper as it appears docked into the middle palette area, or you can click the Expand button to open the Color Warper into a floating window that you can make as large as you like, giving you more detailed control of dense grids of control points. For convenience, the examples in this chapter show the Color Warper side-by-side with the Viewer, in a floating window. While the Color Warper is open in its own window, the Color Warper palette button in the toolbar turns into a “re-docking” button, clicking it puts the palette back in the palette area below.

![Clicking the Expand button opens the Color Warper into a floating window, (Right) Clicking the Re-docking button in the palette toolbar puts the palette back.](image)

There are two overall regions of the Color Warper palette. At the left, the grid area has the actual warping grid with points you manipulate to make adjustments, while controls underneath let you choose the resolution of the grid and the color space in which it works. At the right, the control area provides all the tools, range controls, and feathering controls that are available for manipulating the warping grid in a variety of highly specific ways.

Using the Grid Controls to Manipulate Color

This palette has two modes; each lets you manipulate the colors of the image in different ways, and each has a different style of grid used for warping the different color channels that are affected. Learning how to manipulate the color warping points of each of these grids is central to understanding how this palette works.

![The radial grid in Hue-Saturation mode, (Right) The two rectangular grids in Chroma-Luma mode](image)

Dragging to Warp Colors

Despite the different shapes, each of these grids are manipulated in similar ways. Dragging a control point alters whatever color corresponds to that point, while the colors that surround this dragged point are also adjusted proportionally according to their location between the point being dragged and surrounding points that either (a) aren’t affected, or (b) are locked into place. Locked points prevent the colors at those points from being changed. By locking some parts of a grid and dragging other parts, you can create sophisticated hue-specific adjustments.
The orange control point has been selected and dragged to make an adjustment. Control points with black outlines are locked in place and help prevent control points on the opposite side from being moved. All other control points between the selected and locked control points are stretched or squished depending on the selected point’s adjustment.

The image above shows the three states of control points in the grid:

— **Orange:** Selected points appear orange. You can select multiple points by Command-clicking multiple points, by dragging a bounding box over multiple points, or by using the draw selection tool to click and draw over any points you want to select. Once you’ve selected and moved a control point, it becomes locked to keep that adjustment in place.

— **Outlined:** White control points with a black outline are locked. Locked points do not move automatically when nearby points are dragged, so locked points are important for preventing specific colors you don’t want altered from being changed, as well as for saving changes to points that you’ve adjusted. All adjusted points become locked. The outer corners of the Chroma-Luma grid are locked, as is the outer ring and center point of the Hue-Saturation web.

— **Selected:** Points appear orange; in this example four points are selected to move them all together.
— **White:** White control points are neither selected nor locked, and will be stretched or squished when adjacent control points are moved.

While control points work much the same in either the Hue-Saturation or Chroma-Luma modes, there are some important differences. The radial “spokes” of the Hue-Saturation wheel don’t influence neighboring spokes, so any adjustment you make to a control point on one spoke only affects the colors that fall between it and the two neighboring spokes that surround it. This means it’s not necessary to lock control points on neighboring spokes of this wheel-shaped grid to prevent them from changing.

Both the Hue-Saturation and Chroma-Luma warper grids lock the outer boundary of the grid. You can still drag these points to adjust them, but they can’t be unlocked and they won’t move automatically when you adjust other control points. The Hue-Saturation grid has an additional point locked right in the center, which keeps the neutral colors (black through gray and white) neutral.

**TIP:** Dragging the locked center point of the Hue-Saturation grid lets you alter the color of the white point, while proportionally warping all other colors in the image to smoothly accommodate this change. This can be the starting point of a lot of different looks.
Previewing Which Colors Are Warped By Each Control Point

If you press and hold the Option key while you click on a control point in the warp grid, you get a preview in the Viewer of which colors that control point will affect. Affected pixels appear in color against black, which represents all pixels that will remain unaffected by that control point.

Holding the Option key down while clicking a Color Warper control point shows a preview of affected pixels against black.

Sampling to Warp Colors

While it’s important to learn how control points in the grid are manipulated, the most intuitive way of working with this control is to use the pointer to click within the Viewer to sample a color you want to adjust, hold the pointer button down, and then drag to adjust the color.

When moving the pointer in the Viewer, you’ll see a crosshairs moving around the warping grid that shows you the exact color on the vectorscope graph, while a yellow box indicates the control point that’s closest to the color you’re sampling that will be selected if you click. In the following example, positioning the eyedropper over the sky shows that clicking will select a control point close to the center of the grid.

Moving the pointer in the Viewer shows a preview in the warping grid of which control point you’ll select were you to click.

Clicking and dragging selects and then moves the control point corresponding to that color in the Viewer. As you drag the pointer, you’ll see the selected control point move in the same direction as...
the mouse while the colors of the image update in real time to show the adjustment you’re making. Meanwhile, an arrow in the grid shows you the delta of the current adjustment. Moving a selected control point to another hue in the grid warps the original color to the new color.

Clicking and dragging moves the control point corresponding to that color in the grid to adjust the color and locks it into place.

You can also lock control points by sampling the image. Hold the Command and Shift keys down, and then click on the color or colors you want to lock in the warp grid to prevent them from being changed. This makes it easy to work directly in the Viewer to lock colors you don’t want to change, before adjusting other colors that you do want to change.

In the following example, Command-Shift-clicking on the woman’s shoulder locks the yellowish highlights falling on her uniform in place. Then, clicking and dragging a highlight on her face lets us push the highlights towards teal without losing the warmer highlights on her shoulder, all by sampling directly in the Viewer.

(Top) Command-Shift-clicking to lock the closest control point to a color on the warping grid you don’t want to change, (Bottom) Warping a neighboring color while the control point you just locked keeps that part of the image from changing
Resetting Grid Points

If, at any point, you adjust a point that you want to reset, simply right-click on that point to de-lock and reset it.

Grid Resolution Affects The Specificity and Quality of Adjustments

You can change the resolution of the grids in either Hue-Saturation or Chroma-Luma modes, using the controls at the bottom of the Color Warper palette, underneath the grid itself. Separate drop-down menus let you choose the resolution of control points for hue and saturation, or for chroma and luma separately, although by default they’re linked together.

By default, the Hue-Saturation grid has a resolution of 6x6, which is the lowest resolution available. The Chroma-Luma grid defaults to 6x6, but can be set lower, to 4x4. Low resolution warping grids make it easy to create broad color adjustments affecting large ranges of analogous color with smooth results. Additionally, lower quality media that’s 8-bit, with 4:2:0 chroma subsampling, and/or highly compressed benefits from lower resolution warping grids to avoid artifacts and keep color adjustments smooth.

On the other hand, higher resolution grids let you make more specific adjustments to tighter ranges of color. However, this approach is more useful in projects using high quality media (10- or 12-bit, 4:2:2 or 4:4:4 chroma subsampling, and minimally compressed) to avoid unwanted artifacts. If you’re using high-quality media, you’ll find you can use the Color Warper to make incredibly specific adjustments.

You can set the default Hue and Saturation grid resolutions in the Color Warper’s Option menu by choosing Default Hue Resolution or Default Saturation Resolution and selecting your preferred resolution from the drop-down menu.
The Chroma-Luma grid set to a resolution of 6x6

The Chroma-Luma grid set to a resolution of 24x24

**NOTE:** If you make adjustments with the grid at one resolution, it's possible to change the grid to a higher or lower resolution, and your adjustment will be interpolated to fit the new grid resolution, although the resulting adjustment may change a bit.

**You Can Warp Color in Different Color Spaces**

A drop-down menu at the bottom right of the warping grid lets you choose which color space to use for manipulating the colors of the image. Different color spaces project the colors of the image into the two-dimensional warping grid in different ways, and some may make it easier to manipulate a particular image in the way you want by spreading out different ranges of color more widely.

The color space found underneath the grid controls

The available color spaces are:

- HSV
- HSL
- HSY
- HSP
Hue – Saturation Controls

As the name implies, the Hue-Saturation mode lets you alter hue and saturation simultaneously. For most people, this is likely the most intuitive mode in which to work as the range of hues and saturation in the image is represented radially, just like the Vectorscope; in fact a Vectorscope graph of the image appears underneath the “wheel” grid of control points used to manipulate color.

By default, dragging any point of this grid changes the colors immediately surrounding that point that are between the point being manipulated and adjacent “spokes” of the radial grid that either aren’t influenced by that point, or are locked into place. In fact, you can pull these radial control points well past the boundary of adjacent spokes of the grid to warp those colors to entirely different hues.

When manipulating control points to alter color, adjustments are similar to pushing color around a color wheel. Moving a control point radially around the circumference of the grid changes the hue of the colors corresponding to that control point. Moving a control point closer to the center desaturates those colors, while moving a control point closer to the edge of the grid increases the saturation of those colors.

The following sections describe how the different tools available in this mode work to let you manipulate these radial control points in different ways.

Tools

Each of the available tools let you manipulate control points on the warping grid in different ways when you click on them.

— **Selection Tool:** The default tool mode. Selecting this tool lets you select control points either individually (by clicking on a single point or command-clicking multiple points) or collectively by dragging a bounding box over multiple points, and you can right-click on control points to de-select, unlock, and reset them. You can also Shift-click with this tool to lock points into place without moving them. This is the most useful tool to use when manipulating the image by clicking and dragging in the Viewer to sample a color and adjust it at the same time.
— **Draw Selection:** Selecting this tool lets you make a selection of control points by clicking and dragging to draw over all the points you want to select. This is good for making large, but specific, selections of points.

— **Pin/De-Pin:** Selecting this tool lets you pin multiple control points by either clicking on them or by clicking and dragging to draw over all the points you want to pin/de-pin.

— **Pull Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to pull all neighboring control points towards where you clicked. This can be used to reduce color contrast within a specific range of colors.

— **Push Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to push all neighboring control points within a particular proximity away from where you clicked. This can be used to increase color contrast within a specific range of colors.

**Modifiers**

Each of the Modifier buttons let you manipulate selections and selected control points on the warping grid in different ways immediately upon clicking each button.

— **Increase Falloff/Smooth Selection:** If you’ve selected one or more control points, clicking this button expands the selection to include all adjacent control points surrounding the selection.

— **Decrease Falloff/Smooth Selection:** If you’ve selected a group of control points, clicking this button shrinks the selection by deselecting the outermost ring of selected control points, leaving the inner control points selected.

— **Invert Selection:** Clicking this button selects all unselected control points, and de-selects all selected control points. This is useful when you want to make separate color adjustments to both specifically selected halves of the warping grid.

— **Convert Selection to Pin:** Clicking this button pins all currently selected control points.

— **Select/Pin Column:** If you have one or more control points selected, clicking this button expands the selection to include all points on every column that have at least one selected point.

— **Select/Pin Ring:** If you have one or more control points selected, clicking this button expands the selection to include all points on every ring around the center that have at least one selected point.

— **Select/Pin All, Deselect/Pin All:** Clicking this button toggles the selected state of the entire warping grid on or off.

— **Reset Selection/Pins:** If you have one or more control points selected, clicking this button resets their position to the original default position in the warping grid, without de-selecting them.

**Range**

The Range control is a fast method of selecting multiple control points corresponding to a specific range of colors.

— **Range:** A gradient shows the range of hues currently being presented in the warping grid. Dragging the left and right handles of the Range control selection box lets you automatically select all control points corresponding to the hues that appear within the selection box. This is a fast way of selecting all points within a range of colors for uniform manipulation.
**Auto Lock Controls**

The Auto Lock controls enable DaVinci Resolve to automatically lock a border of control points surrounding any control point you select and adjust, which makes highly-specific color adjustments easier to accomplish.

- **Auto Lock**: Enables and disables this behavior.
- **X Points Border**: Lets you set how many points away from the control point you’re adjusting the border of locked control points that restricts your adjustments is. How large an area this ends up being depends on how many points you choose, and on the resolution of the warping grid. At higher grid resolutions, the same points distance isolates a smaller region of color.

**Smoothing Controls**

The smoothing controls let you “ease off” an adjustment you’ve made by progressively moving one or more selected control points towards their original default position in the warping grid.

- **Smooth Chroma**: Each click of this button rotates the angle of selected control points around the circumference of the circular warping grid towards their original position, bringing the hue of the adjusted colors closer and closer to the original hues of the image. Saturation is unaffected.
- **Reset Chroma**: Resets the angle of all selected control points to the original hues of those control points. Saturation adjustments are unaffected.
- **Smooth Saturation**: Each click of this button moves the position of a control point closer to its original position relative the center of the circular warping grid, thus bringing the saturation at that point closer to the original image saturation of the node’s input. Hue is unaffected.
- **Reset Saturation**: Resets the distance from the center of all selected control points to the original image saturation at those control points.
- **Reset Luma**: Resets luma to the original image values.

**Chroma – Luma Controls**

The Chroma-Luma mode lets you alter the hue and lightness of colors in the image simultaneously. This may not feel like a particularly intuitive way of working, as the grid controls are overlaid on colors projected as different sides of an RGB cube. However, this enables some powerful adjustments once you get the hang of how multiple adjustments interact in this mode, as well as the power of locking control points to limit your adjustments to specific areas of the two grids.

Whether you’re sampling the image or manipulating the control points of this grid directly, dragging any point of this grid changes the color of the image corresponding to that point. Vertical adjustments change lightness, where up makes that part of the image lighter, and down makes that part of the image darker. Horizontal adjustments change hue, depending on which range of hues are shown in the two Chroma-Luma warping controls, and which of these you’re adjusting.
By default, only the outer four corners of this control are locked, so any adjustment you make to any control point pushes and pulls all the other colors throughout the image, depending on your adjustment. Working this way, multiple adjustments to multiple colors gradually pins different colors into place, with each adjustment warping the colors falling in between to maintain a smooth transformation from one adjustment to the next. This can be a good way to make an overall stylistic adjustment to the image.

Another approach to using this mode is to make more targeted corrections by manually locking different colors in the image that you don’t want to adjust. You can do this by using the Selection tool and Shift-clicking any value in the Viewer, or by Shift-clicking any control point on the grid control. By locking colors you don’t want to change, you can focus on manipulating a more specific range of colors without altering the entire image.

Alternately, this is where the Auto Lock controls really shine. When you turn these on, you can choose the type of region you want to affect (vertical column, horizontal row, or a square region), then choose how large a region of color you want to manipulate (one or two points away from the point that’s selected). Keep in mind that the current resolution of the warping grid also has an effect on how large the resulting region of color will be. Lower resolution grids will let you manipulate larger regions of color, while higher resolution grids will let you adjust a more narrow range of color.
Once these controls are enabled, simply clicking once on the image or warping grid selects a control point and automatically locks off the region of the grid you want to focus your adjustment on. In the following example, a medium-resolution grid is used in conjunction with the Auto Lock controls set to lock a 2-point rectangular region. So, clicking on the skin of the woman’s face and dragging adjusts a section of available reds within the locked-off region of the grid.

Making a targeted color adjustment to a locked-off region of the Chroma Luma grid

The following sections describe how the different tools available in this mode work to let you manipulate these radial control points in different ways.

**Axis Angle**

When you’re in Chroma-Luma mode, an additional control appears underneath the warping grids, a slider named Axis Angle. Dragging this slider to the left or right changes the range of hues in each of the two warping grids that’s presented, letting you manipulate different ranges of color.

**Tools**

Each of the available tools let you manipulate control points on the warping grid in different ways when you click on them.

The Tools buttons

— **Grid 1/Grid 2 tabs**: Since the Chroma-Luma controls expose two grids representing two different ranges of hue and luma, these two tabs let you choose which grid will be manipulated when you sample the image in the Viewer, as well as which grid the Tools controls affect.

— **Selection Tool**: The default tool mode. Selecting this tool lets you select control points either individually (by clicking on a single point or command-clicking multiple points) or collectively by dragging a bounding box over multiple points. You can also Shift-click with this tool to lock points into place without moving them, and you can right-click on control points to de-select, unlock, and reset them. This is the most useful tool to use when manipulating the image by clicking and dragging in the Viewer to sample a color and adjust it at the same time.

— **Draw Selection**: Selecting this tool lets you make a selection of control points by clicking and dragging to draw over all the points you want to select. This is good for making large, but specific, selections of points.
— **Pin/De-Pin:** Selecting this tool lets you pin multiple control points by either clicking on them or by clicking and dragging to draw over all the points you want to pin/de-pin.

— **Pull Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to pull all neighboring control points towards where you clicked. This can be used to reduce color contrast within a specific range of colors.

— **Push Points:** Selecting this tool lets you make adjustments by clicking anywhere on the warp grid, even between points, to push all neighboring control points within a particular proximity away from where you clicked. This can be used to increase color contrast within a specific range of colors.

### Modifiers

Each of the Modifier buttons let you manipulate selections and selected control points on the warping grid in different ways immediately upon clicking each button.

— **Increase Falloff/Smooth Selection:** If you’ve selected one or more control points, clicking this button expands the selection to include all adjacent control points surrounding the selection.

— **Decrease Falloff/Smooth Selection:** If you’ve selected a group of control points, clicking this button shrinks the selection by deselecting the outermost ring of selected control points, leaving the inner control points selected.

— **Invert Selection:** Clicking this button selects all unselected control points, and de-selects all selected control points. This is useful when you want to make separate color adjustments to both specifically selected halves of the warping grid.

— **Convert Selection to Pin:** Clicking this button pins all currently selected control points.

— **Select/Pin Column:** If you have one or more control points selected, clicking this button expands the selection to include all points on every column that have at least one selected point.

— **Select/Pin Row:** If you have one or more control points selected, clicking this button expands the selection to include all points on every row that have at least one selected point.

— **Select/Pin All, Deselect/Pin All:** Clicking this button toggles the selected state of the entire warping grid on or off.

— **Reset Selection/Pins:** If you have one or more control points selected, clicking this button resets their position to the original default position in the warping grid, without de-selecting them.
Range

The Range control is a fast method of selecting multiple control points corresponding to a specific range of colors.

![Range Control]

— **Range:** A gradient shows the range of hues currently being presented in the warping grid. Dragging the left and right handles of the Range control selection box, or dragging within the range control to set both boundaries, lets you automatically select all control points corresponding to the hues that appear within the selection box. Once you’ve set a range, you can move the range to the left and right by dragging the center of the selection. This is a fast way of selecting all control points within a range of colors for uniform manipulation.

Auto Lock Controls

The Auto Lock controls enables DaVinci Resolve to automatically lock a border of control points surrounding any control point you select and adjust, which makes highly specific color adjustments easier to accomplish. These are particularly useful in the Chroma-Luma warping grid.

![Auto Lock Controls]

— **Auto Lock:** Enables and disables this behavior.

— **X Points Border:** Lets you set how many points away from the control point you’re adjusting the border of locked control points that restricts your adjustments is. How large an area this ends up being depends on how many points you choose, and on the resolution of the warping grid. At higher grid resolutions, the same points distance isolates a smaller region of color.

— **Lock Column:** Lets you choose to restrict your adjustment to affect all control points within a particular column of the rectangular Chroma-Luma graph. The width of this column is defined by the border width controls. This is useful when you want to primarily adjust the lightness of a range of colors, while making a small adjustment to hues.

— **Lock Row:** Lets you choose to restrict your adjustment to affect all control points within a particular row of the rectangular Chroma-Luma graph. The height of this row is defined by the border width controls above. This is useful when you want to primarily adjust the hue of a range of colors, while making a small adjustment to lightness.

— **Lock Region:** Lets you choose to restrict your adjustment to affect all control points within a rectangular region surrounding the selected point. The is useful when you want to adjust a targeted region of color that corresponds to a well-defined feature of the image, such as a specifically colored hat, shirt, foliage, or skin tone. Smaller regions will make more specific adjustments than larger regions.
Smoothing Controls

If you’ve found that you’ve gone a bit too far with an adjustment and need to back off a little bit, the Smooth controls let you do so gradually, or start over if necessary.

— **Smooth Chroma**: Each click of this button moves selected control points left or right, back towards their original position, bringing the hue of the adjusted colors closer and closer to the original hues of the image. Luma is unaffected.

— **Reset Chroma**: Resets the position of all selected control points to the original hues of those control points. Luma adjustments are unaffected.

— **Smooth Luma**: Each click of this button moves selected control points up or down, back towards their original position, bringing the luma of the adjusted colors closer and closer to the original luma of the image. Chroma is unaffected.

— **Reset Luma**: Resets the position of all selected control points to the original luma of those control points. Chroma adjustments are unaffected.
Chapter 133

Secondary Qualifiers

Secondary correction describes isolating a specific part of the image, or a specific subject, using a key. Keys in DaVinci Resolve are grayscale images that define which areas of the picture you want to alter (in white) and which parts of the picture you want to leave alone (in black).

Keys can be generated either using the controls in the Qualifier palette, by using a Power Window, or by importing an external matte (for more information on how to use external mattes, see Chapter 142, “Combining Keys and Using Mattes”). This chapter focuses on how you can use qualifiers to key a range of color values (similarly to doing a green screen key) in order to create a matte with which to do this kind of isolated adjustment.

Secondary Qualifiers

This section covers the use of the Qualifier palette, which lets you pull a 3D, HSL, RGB, or Luma key, with which to isolate the correction you need. The Qualifier controls are fast and flexible when you need to isolate an irregularly shaped subject with a distinct range of color or lightness. Since you’re generating a key by sampling the image, there’s no need for tracking or keyframing, so in the right situation qualifiers can be your fastest solution. In the following example, the client likes the slightly cool treatment overall, but wishes that the skin tones were a little more vibrant. This is exactly the sort of situation where qualifiers can help out. Adding a second node, and using the 3D or HSL Qualifier to isolate the face makes it relatively simple to add color exactly where you want it.

Adding a second node and using HSL Qualification to isolate the skin tones

The image with a simple primary correction (Top)
The final adjusted image (Bottom)

Just about every control in the Color page can be limited using the Qualifier modes available in DaVinci Resolve. This makes the Qualifier palette a jack-of-all-trades tool with 101 uses. A few practical examples include keying a red element that’s too intense for broadcast, in order to darken it or desaturate it; keying a range of green foliage, so you can shift its hue to a more attractive color; keying an actor’s skin tone in a commercial, to apply some selective softening to it; or keying a range of sky, in which to add blue.
The Qualifier palette is color-space-aware when you’re using Resolve Color Management (RCM) or ACES. This enables Qualifiers to create high-quality keys as you would expect, no matter what the color space of the original media is, or what Timeline Color Space you’re using, for both SDR and HDR mastering. This makes Qualifier isolations easier, and a more consistent experience no matter what your workflow happens to be.

**Adding a Secondary Operation to the Node Editor**

Any node can be switched between functioning as a primary correction, where the adjustments you make affect the entire image, and a secondary correction, where you’re adjusting a specific element in the scene. The only difference is that nodes being used for secondary corrections are limited using a qualifier, Power Windows, or an external matte.

If you’re planning to add a secondary operation to the current grade, you’ll need to first add another node in the Node Editor. When pulling a key to qualify part of the image, it’s important to understand that you’ll be sampling the YRGB values being fed to that node from any previous nodes in the tree. That means that the state of the image being fed to a node you’re qualifying affects the key you’re pulling.

For example, if the image coming out of Node 1 is well saturated and has a neutral color balance with a wide range of colors, but the image coming out of Node 2 applies a low saturation, monochromatically orange color wash, you may find it more difficult to pull a detailed key from Node 2 than you would from Node 1.

Choosing your battles—the image coming out of Node 1 will be easier to key than the highly stylized image coming out of Node 2

This is important because you have the flexibility of determining from what image you want to try pulling a qualified key. By connecting the node that’s outputting the best YRGB image for the key you’re trying to create to the node you’re qualifying, you can control what you’re keying.

For more information about choosing which node to use for setting up a qualifier, see Chapter 142, “Combining Keys and Using Mattes.”

**The Qualifier Interfaces**

The DaVinci Resolve Qualifier palette interface is straightforward. To the left, graphical controls above numeric parameters let you manually adjust what ranges of each color component contributes to the key you’re creating. To the right, Selection Range tools below let you define a key by sampling pixels of the image using the pointer, while below a set of Matte Finesse parameters let you alter the shape of the key that’s been pulled.
The default qualification mode is the HSL Qualifier, which uses three color components, hue, saturation, and luma, to define a key. However, you can also use the RGB or LUM (Luma) qualification modes to pull keys using other combinations of color components. The LUM qualifier mode, in particular, lets you make targeted adjustments to specific ranges of image lightness. This is a technique employed by many colorists to alter color temperature within a specific range of image highlights or shadows.

Alternately, you can use the 3D qualifier to quickly and easily pull well-refined keys by drawing lines to sample colors from the image that correspond to volumes of color within a three-dimensional gamut. While the underlying technology is sophisticated, all you have to do is to draw blue lines to sample colors you want to isolate, or red lines to sample colors you want to subtract from the isolation you’re creating, all of which automatically generate a high-quality key. Each line you draw adds a sample to the selection list; you can turn each sample off and on to evaluate its contribution to the resulting key, or delete samples that don’t make a positive contribution.

No matter which qualifier mode you use, the Matte Finesse controls make it easy to refine the resulting key to be even cleaner and more usable. In some instances, you can even take a marginal key that would otherwise be unusable, and squeeze it into something useful using the Clean Black, Clean White, and Blur Radius controls.
Which Qualifier Do I Use?

The Qualifier palette’s four modes offer you the flexibility to use the best keyer for the job when it comes to isolating a range of color or brightness values. In some cases, keys that are difficult to pull using some modes are easier to pull using others. Here’s a brief summary:

**HSL:** In many instances, the HSL keyer is not as immediately accurate as the 3D keyer, and will include a broader portion of the image for any given sample. On the other hand, if the 3D keyer is not giving you satisfactory results for a particular shot, the HSL keyer can sometimes do a better job. Because of its interface, the HSL keyer makes it easier to “fine-tune” the range and softness of each individual color component that’s sampled, in order to improve the result. The HSL keyer also gives you the option of disabling color components that you don’t want to contribute to the final key, so that you can pull a saturation-only key, or a hue-only key, for instances where that may solve the issue at hand.

**RGB:** The RGB keyer shares many of the limitations and advantages of the HSL keyer, but since you’re sampling and adjusting red, green, and blue color components, the specificity with which you can fine-tune the resulting key works much differently.

**LUM:** The LUM keyer works specifically to isolate parts of the image based on image tonality, lightness, or darkness. This is the perfect tool when you’re trying to isolate highlights or shadows in the image, which let you solve a multitude of different creative and technical issues. The LUM keyer is identical to using the HSL keyer with the Hue and Saturation qualifier controls turned off.

**3D:** The 3D keyer is a good one to start with if you’re trying to isolate a range of color such as a blue shirt, a cyan sky, a performer’s skin tone, or the orange leaves of a tree in autumn. Its interface of drawing lines over the part of the image you want to isolate, coupled with its high quality and extreme specificity, make it a fast and accurate tool to use in a variety of circumstances. However, the 3D keyer always samples every color component of the image; it’s not useful when you want to isolate specific color components, such as luma only, or hue and saturation without luma. The 3D keyer’s greatest strength, the speed with which you can sample areas of the picture to include (or exclude) from the final key, is also occasionally a weakness with images where your initial samples aren’t giving you satisfactory results, because there aren’t many ways to fine tune the key as it’s being generated (although you can manipulate the result). On the other hand, for most images you would want to qualify, two or three samples is all you need, in conjunction with using the Matte Finesse controls to adjust the resulting key. If you need to do some compositing in the Color page, the 3D keyer also does an excellent job doing blue and green screen keying to create transparency, and has a built-in Despill control as well.

The following two sections provide an overview of how to use the 3D and HSL keyer modes in DaVinci Resolve.
Basic Qualification Using the 3D Qualifier

The 3D Qualifier mode offers a fast, simple way of pulling a key to isolate a range of color in the image, by drawing lines over the parts of the image you want to key. Each line you draw over the image adds to or subtracts from the cloud of values you’re carving out of a three-dimensional representation of all available colors; you don’t see this representation, but this “under the hood” functionality is what gives the 3D keyer its name.

The 3D keyer is a general-purpose keyer, letting you isolate any color you like. However, the 3D keyer is not good at pulling luma-only keys. If you’re looking to isolate a range of luma values in the image, you should use the LUM mode.

To use the 3D mode to isolate a subject in the Viewer:

1. Open the Qualifier palette, choose the 3D icon in the upper right and click the eyedropper.
2. Click and drag across the part of the image you want to isolate to draw a line. Lines that add to the key are colored blue.

3. To see the key you’re creating as you work, click the Highlight button in the Viewer Options toolbar at the top of the Viewer. As you draw the line, the viewer will update to show your current key in real time.
If necessary, draw additional lines to add more of the image to the key you’re creating. Ordinarily, it’s a good idea to not to draw more then two or three lines to sample the part of the image you’re trying to isolate. A few long strokes are better than several short ones. Ideally, you want the key you’re pulling to have a somewhat soft edge, which makes it easier to use the Matte Finesse controls to fine-tune your result later on. If you draw too many lines to sample the image, the result can be a key with hard, jagged edges that can sometimes be more difficult to adjust later on.

A hard-edged key created with three samples

Alternately, if there are parts of the image that are included in the key that you want to omit, hold the Option key down and draw a line over these areas. You can see that Option-drawn lines are red, and these subtract areas from the key you’re creating. Again, try not to overdo drawing subtractive red lines, as you can end up with an overly hard-edged key that’s difficult to adjust using other controls in the next few steps. Additionally, you can still use power windows in conjunction with the 3D qualifier to exclude specific parts of the image.

Blue lines add to the key and a red line subtracts the grass from the key, as seen with the highlight turned off
6 If you find yourself wondering whether a particular sample in the list at left is doing any good, you can click the color patch at the left of any entry in the list to toggle that sample off and on. If you decide you don’t need a particular sample, click the trash can button at the right to delete it.

![Controls for toggling samples off and on, and deleting them from the list](image)

7 When you’re satisfied that the key is good enough to start fine-tuning, stop drawing lines. It’s all right if there’s a bit of noise, speckling, or if there are small holes in the key you’re creating, because you can take care of these using the Matte Finesse controls.

![A sampled key that’s ready for further refinement](image)

Nearly every key you pull will benefit from some further “post-key” refinement. What this means is that, once you’ve created the best key you can procedurally through sampling the image, you can now adjust the resulting key itself, which is just a gray-scale image, to improve the isolated result. This is what the Matte Finesse controls are for.
8 The three most common methods of key refinement using the Matte Finesse controls are to increase Clean Black to fill in “holes” in the parts of the image you’re omitting (the background), increase Clean White to close holes in the part of the image you’re isolating (the foreground), and then use Blur Radius and In/Out Ratio controls to blur the edge of the key and push it in and out. Using these controls, you can vastly improve nearly any key without the need to endlessly readjust the Qualifier controls.

More information about using the Matte Finesse controls appears later in this chapter.

9 When you’re finished, click the Highlight control to turn the highlight off, and make whatever adjustment you need. In this example, the orange of the helicopter will be adjusted using the Hue control to make it blue instead.

Adjusting the orange color of the helicopter to be blue instead
Basic Qualification Using the HSL Qualifier

The HSL qualifier is one of the most flexible tools in DaVinci Resolve. Using any combination of sampled hue, saturation, and luma, you can isolate different ranges of color and contrast for specific adjustment. HSL is a general-purpose keyer, meaning you can key any color you like; it’s not restricted to blue or green.

The most straightforward way to use any qualifier is to sample the image in the Viewer. A set of four controls let you sample pixels within the image in different ways. When you sample one or more pixels, the Hue, Saturation, and Luma values are analyzed, and set different ranges in each of the Hue, Saturation, and Luma qualifier controls. There are a number of different eyedropper controls available to control how you sample color in the image.

— **Sample Eyedropper:** The first control you use whenever sampling the image. It defines the initial range of the qualification; you must use this tool before any of the others. Clicking once with this tool selects a single pixel value, while clicking and dragging selects a range of image values that add together.

![Color Picker button]

— **Add/Subtract Color Range:** These two controls let you add areas of the image to, or subtract them from, the currently selected inner range of values that define the core of the key. As with the eyedropper, you can click on single pixels, or drag over a range of color.

![Add and Subtract color buttons]

— **Add/Subtract Softness:** These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Just like the other controls, you can click on single pixels, or drag over a range of color.

![Add and Subtract qualifier softness]

**NOTE:** When you select one of the sampling controls, it remains selected until you select another sampling control. If you select another clip in the Timeline, then click in the Viewer to sample a key and nothing happens, make sure that you select the Eyedropper control in the Qualifier palette.
If you’re working with the DaVinci Resolve onscreen interface, the easiest way to qualify a subject is to use the pointer in conjunction with the sampling controls.

![Example image to qualify](image)

**To use the HSL Qualifier mode to isolate a subject in the Viewer:**

1. Open the Qualifier palette, choose HSL from the mode drop-down, and click the eyedropper.
2. Either click a pixel of the part of the image you want to isolate, or click and drag across a range of pixels within that subject.

![Picking to qualify the ocean](image)

3. To see the key you’re creating as you work, click the Highlight button in the Viewer Options toolbar at the top of the Viewer.
   
   By default, the area of the image you’re isolating appears in color, while the area of the image being excluded appears solid gray.

![Viewer image with highlight turned on, isolated region appears in color, omitted region appears gray](image)
Even though the highlight obscures the rest of the image, this doesn’t prevent you from using the sampling tools to select pixels you can’t see.

4 To subtract from the inner range of the key you’re creating, click the minus Color Range control, and click or drag across the portion of the keyed image that you’d like to exclude.

5 To add softness to the outer range of the key you’re creating, click the plus Softness control and then click or drag across the portion of the image you’d like to include as a soft edge.

Once you’ve finished using the range and softness sampling controls to refine the key you’re using to isolate the subject, nearly every key you pull will benefit from some further “post-key” refinement. What this means is that, once you’ve created the best key you can procedurally through sampling the image, you can now adjust the resulting key itself, which is just a grayscale image, to improve the isolated result. This is what the Matte Finesse controls are for.

6 The three most common methods of key refinement using the Matte Finesse controls are to increase Clean Black to fill in “holes” in the parts of the image you’re omitting (the background), increase Clean White to close holes in the part of the image you’re isolating (the foreground), and then use Blur Radius and In/Out Ratio controls to blur the edge of the key and push it in and out. Using these controls, you can vastly improve nearly any key without the need to endlessly readjust the Qualifier controls.

More information about using the Matte Finesse controls appears later in this chapter.

7 When you’re finished, click the Highlight control to turn the highlight off, and make whatever adjustment you need. In this example, the saturation has been raised and the color balance changed to make the adjustment obvious.
HSL Qualifier Presets

There is a set of HSL Qualifier presets, or Six Vector presets, that you can use to isolate automatically a predefined wedge of color (green, blue, red, magenta, yellow, or cyan) or chroma intensity (chroma light, chroma dark, or both). These presets are available either from the Color > Presets menu, or using the DaVinci Resolve Advanced control panel.

Selecting one of these presets automatically sets the HSL Qualifier to the corresponding range or color or lightness. Afterwards you can continue modifying the HSL Qualifier to suit your purpose.

Using Highlight to See What You’re Isolating

The Highlight control at the top of the Viewer (revealed by turning on Viewer Options in the Viewer’s Option menu) lets you overlay a representation of the key you’re creating over the current image in the Viewer. Overlays are also mirrored to your video output, so they’ll show up on an external display as well, in the event that you’re hiding the onscreen Viewer.

There are two types of highlights with which you can evaluate a qualification you’re creating. Each is useful for different tasks.
— **Flat-Gray:** The default highlight that DaVinci Resolve uses shows the selected portion of the image with the original colors, and the unselected portion of the image with a flat gray. It is useful for seeing the subject you’re isolating even while you’re adjusting the Qualifier controls, which lets you also see the color or contrast adjustments you’re applying at the same time.

![Oranges qualified and highlighted](image)

— **High-Contrast:** Pressing Option-Shift-H, you can show what’s called a “high-contrast” highlight, which should be familiar to you if you’ve used other color correction applications and plug-ins; it’s a more typical display wherein the selected portion of the image is white, and the unselected portion of the image is black. The high-contrast highlight is useful in situations where you need to eliminate holes in a key, or evaluate how “chattery” a key is since irregularities are easier to spot when divorced from the original image.

![High-Contrast B&W highlighting](image)
To enable or disable a highlight, do one of the following:
— In the Viewer Options toolbar at the top of the Viewer, click the Highlight control, and choose the type of highlight you want from the buttons that appear at the right.
— Choose an option from the View > Highlight submenu; a regular Highlight is Shift-H.

To enable or disable a high-contrast highlight, do one of the following:
— Choose View > Highlight > Highlight BW (Option-Shift-H).

To make high-contrast black and white the default highlight:
1 Open the Preferences > User > Color window.
2 Check “Matte display high contrast black and white.”
3 Click Save.
   The next time you click the Highlight control in the Qualifier palette, the high-contrast highlight will display.

Using Highlight to Solo Nodes

There’s one other use of the Highlight control, and that’s to solo individual nodes in the Viewer and video out, rather than outputting the sum of the entire node tree. For example, if you’re trying to adjust a stack of nodes attached to a Parallel or Layer Mixer node, it’s difficult to see what you’re doing while adjusting one of the stack of nodes, because only the final result is being output.

However, if you turn on Highlight while you’re selecting a node with no key, then only the currently selected node is output, making it easy to view just one node as you adjust it. Just make sure you turn Highlight off before moving on, or you may confuse yourself.

Showing Picker RGB Values

While you’re dragging the pointer over the Viewer and looking for a feature to sample, you can enable a tooltip that shows you the RGB Value of the pixel under the pointer by right-clicking the Viewer and choosing Show Picker RGB Value to toggle this feature on and off. When you turn this feature on, the View > Show RGB Picker Values In submenu has options for displaying either 8- or 10-bit tristimulus values.

The Color Picker tooltip that appears when you turn on show RGB Picker Values
Qualifier Parameters

Each of the Qualifier modes, except for the 3D qualifier, has parameters that correspond to the relevant color components for that mode, with which you can identify a range and softness, similar to using the sample tools. These parameters can be edited precisely with virtual sliders using the pointer, or using the knobs of a supported grading control panel. However, mouse and tablet users can take advantage of each qualifier’s draggable white overlays, for more direct adjustment.

— Drag the left and right edges of any qualifier control overlay to adjust the Low and High values (or the Width value of the Hue control).
— Drag the center of any qualifier control to change the center or to simultaneously change the Low and High parameters together.
— Option-drag the left and right edges of any qualifier overlay to adjust softness.

These draggable controls work for the HSL, RGB, and LUMA qualifier controls (the 3D qualifier works differently).

HSL Qualification Controls

The HSL Qualifier is by far the most versatile mode of the Qualifier palette. It’s also the qualifier that’s easiest to understand, and the easiest to adjust by hand if you don’t feel the need to sample the image. By selecting range and softness for each of three different color components, hue, saturation, and luma, you can isolate a wide variety of colorful subjects, or ranges of image lightness and saturation.
One of the HSL Qualifier’s key strengths, and one of its most underutilized features, is that you can enable or disable each of the three HSL components using the Hue, Sat, and Lum buttons, using toggle controls found at the left of each qualifier range control’s name. This lets you ignore specific color components, while focusing on others that are more important.

For example, if you’re trying to isolate the saturated parts of an image, regardless of the hue or brightness, you can turn off the Hue and Lum qualifiers so that only Sat is used to sample the image.

The HSL parameters include:

— **Hue Center**: Defines the center of the range of Hue being isolated.
— **Hue Width**: Defines the width of the range of hue being isolated. Widening or narrowing this parameter widens and narrows the range of hue about the current Hue Center.
— **Hue Soft**: Widens or narrows the falloff at both sides of the currently selected range of hue.
— **Hue Symmetry**: Lets you selectively alter the angle of Hue Soft falloff at either the right or left side. Lowering this parameter makes the softness to the right of the hue range grow steeper. Raising this parameter makes the softness to the left of the hue range grow steeper.
— **Sat Low/High**: Two parameters let you define the upper and lower range of saturation being isolated.
— **Sat Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of saturation.
— **Lum Low/High**: Two parameters let you define the upper and lower range of luma being isolated.
— **Lum Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of luma.

**RGB Qualification Controls**

The RGB Qualifier mode lets you isolate range and softness in the Red, Green, and Blue channels of an image. While this is not necessarily an intuitive way of manually creating a qualification from scratch, it can provide a different way of isolating potentially trickier ranges of the RGB color space.

If you start by sampling the image, then you can widen and narrow each color channel’s isolated range of values. In some cases, you may find it’s faster to isolate a specific range of continuous color by adjusting these controls.

The RGB parameters include:
— **Red Low/High**: Two parameters let you define the upper and lower range of the Red channel being isolated.
— **Red Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of red.
— **Blue Low/High**: Two parameters let you define the upper and lower range of the Blue channel being isolated.
— **Blue Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of blue.
— **Green Low/High**: Two parameters let you define the upper and lower range of the Green channel being isolated.
— **Green Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of green.
Luma Qualification Controls

The Luma Qualifier mode simply pulls a key from the Luma channel all by itself. It’s identical to the HSL qualifier with H and S turned off. This single-component keyer is more useful than you might think; it’s a common technique to isolate a range of highlights, midtones, or shadows throughout the image to alter the color temperature selectively.

The Luma Keyer mode automatically disables the Hue and Saturation controls

Also, keep in mind that the luma component is the sharpest keyable component when you’re working with heavily compressed video. Keys that are noisy or chunky with HSL qualification may be sharper if you just use the Luma Qualifier, although you won’t be able to be chromatically specific.

The Luma Qualifier has four parameters:

- **Lum Low/High**: Two parameters let you define the upper and lower range of the luma component being isolated.
- **Lum Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of luma.

3D Qualifier Controls

As discussed earlier in this chapter, the 3D Qualifier works much differently than the other qualifiers in DaVinci Resolve. In this mode, drawing lines over parts of the image you want to isolate adds samples to the Sample list, some of which add to the key (when you drag with the pointer) and some of which subtract from the key (when you Option-drag with the pointer). While this functionality is very simple to use, there are other controls that are available.
The 3D Stroke Pickers:

**Picker**: Chooses the initial color to qualify. Longer strokes will tend to give you a better key.

**Picker -**: Removes a color region from the qualifier; also available by holding down the Option key.

**Picker +**: Chooses an additional color region to add to the initial qualifier.

**Invert**: Inverts the current key; qualified areas are then unqualified and vice versa.

**Show Paths**: A checkbox that lets you turn the visibility of the lines you’re drawing to sample the image on and off. Turning lines off does not affect the key in any way.

**Auto-B/W Highlight**: With this checkbox enabled, the viewer automatically switches to Highlight B/W mode while drawing a line, to better show you the resulting key in real time. When the button is released the viewer will switch back to its original viewing mode.

**Colorspace**: A drop-down menu that lets you choose whether you’re sampling colors in YUV colorspace, or HSL, HSP, or LAB colorspaces. YUV is the default, but if you find you’re not getting satisfactory results, you can reset the Qualifier palette and switch to different ones to see if that works any better.

**Strokes list**: A list shows each line you drew as a sampled entry. A color patch at the left shows you the average color you sampled; clicking the color patch lets you temporarily turn any color sample off to evaluate its contribution to the overall key. A plus or minus icon shows you whether that patch is adding to or subtracting from the key. The average red, green, and blue color values are shown next, and a trash can icon at the right lets you delete any sample from the list.

The 3D Qualifier Modes:

**Soft**: Provides a softer edge to the key that is more forgiving of Chroma and Luma adjustments. The more gentle drop-off is suitable for situations like subtle light changes across a face. Use the Shadow / Midtone / Highlight Matte Finesse Controls in conjunction with this mode to fine tune the result.

**Flat**: The default mode. Each color selected is 100% keyed, and adjustments are made for small color variations. This is the ideal mode for chroma keying a green or blue screen. Additionally, turning up the Pre-Filter setting in the Matte Finesse controls can make for a smoother, flatter key.

**Tight**: Only keys the exact color picked, and does not apply any softening based on color ranges. You chose that exact color, and only that exact color. Single pixel sharpness levels are expected. This can be used for difficult keying jobs, requiring adjusting the filter and softness manually in the Matte Finesse Controls.
**Luma:** Functions similar to the Tight setting but ignores all chroma data. This mode is used for black and white footage.

**Despill:** If you’re using the 3D qualifier to pull a blue or green screen key to create transparency, this slider lets you adjust an automatic color correction that eliminates blue or green spill from the image, while retaining the image’s original color.

The Chroma and Luma adjustment section is dominated by the Color Space box and the Brightness Range. The Color Space box is laid out roughly in the same manner as the Color Wheels, with primary colors laid out around its edge. The exact colors and layout is determined by the Color Space that you choose in the 3D Qualifier. The Brightness Range is represented as a bar underneath the Color Space, with left being black and right being white. Inside the Color Space and Brightness Range lie the individual colors that you chose with the pickers in the Strokes List. The tools around the periphery adjust the colors within the box in various ways, allowing you to visualize changes to the key.

**The 3D Qualifier Chroma & Luma Adjustments:**

- **Chroma Tolerance:** Click and drag left and right to expand or contract the range of colors selected by the key.

- **Chroma Softness:** Click and drag left and right to change the sensitivity to similar colors selected by the key. This determines whether the key is a hard cutoff or a soft selection of similar colors.

- **Adaptive Chroma Softness:** Activating this icon allows the keyer to operate consistently in both highly saturated and desaturated regions of the image at the same time. The majority of the time you will want to leave this on. The exception is if you are having difficulty in manually adjusting chroma softness in Soft or Flat mode, then turning Adaptive Chroma Softness off will give you more range to work with. Adaptive Chroma Softness is automatically disabled in Tight and Luma modes, as it is contrary to the functionality of these modes.

- **X:** Moves your selected color region within the color space, changing its chroma based on its horizontal position.

Y: Moves your selected color region within the color space, changing its chroma based on its vertical position.

Angle: Moves your selected color region within the color space, changing its chroma based on its rotation around the central origin point.

Low: Expands or contracts the dark areas of the key in the brightness range.

High: Expands or contracts the bright areas of the key in the brightness range.

Low Soft: Controls how well defined the low end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

High Soft: Controls how well defined the high end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

Matte Finesse Controls

After you’ve used the sample controls and qualifier parameters to create the most useful key for your purposes, you may find that it has problems that cannot be overcome easily by the available adjustments. Issues such as chattery edges, holes, or noisy bits can sometimes be easily fixed using the Matte Finesse controls. These controls filter the output of the Qualifier controls and are adjustments that are made to the matte itself, so they may work well in some instances, and poorly in others, depending on what you’re trying to do.

Pre-Filter

This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.
**Clean Black**

Clean Black is a specialized operation that eliminates noise (seen as white speckling when viewing a high-contrast highlight) in the black area of a key that omits the regions of the image you don’t want to isolate, and shrinks the key by making the dark parts of a key darker the higher you raise this parameter, pushing dark gray areas of the key toward black. The practical result is that raising Clean Black lets you “fill holes” in the background portion of a key and erode translucent edges.

![Before/after raising Clean Black, viewing the high contrast matte](image1)

**Black Clip**

Raising Black Clip applies a “lift” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed towards black. The range is 0 to 100, with 0 being the default setting.

![Before/after raising Black Clip](image2)

**Clean White**

Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that includes areas of the image you’re isolating, and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you “fill holes” in the foreground portion of a key and grow translucent edges.

![Before/after raising Clean White, viewing the high contrast matte](image3)
**White Clip**
Lowering White Clip applies a "gain" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed towards white. The range is 0 to 100, with 100 being the default setting.

![Before/after lowering White Clip](image)

**Blur Radius**
In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you’re keying, with the result being a visible “halo” around your subject depending on the adjustment you’re making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.

**TIP:** If haloing is a problem, you can try adjusting the In/Out Ratio parameter, or you may want to consider using the Qualifier Softness parameters to feather the edges of the key, instead.

![Using the Blur parameters to soften the edges of a key](image)

**In/Out Ratio**
Controls whether the “Blur Radius” is applied equally to the inside and outside of the edge of the matte (zero), applied only within the matte (negative values), or applied only outside the matte (positive values). Using In/Out Ratio can help eliminate fringing when using the Blur Radius parameter.

![Left] In/Out Ratio lowered so blurring ends at the edge of the matte and feathers inward,
(Right) In/Out Ratio raised so that blurring starts at the edge of the matte and feathers outward
However, you can also use In/Out Ratio even in situations where no Blur Radius is applied at all. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.

(Left) In/Out Ratio controls lowered to expand holes in the matte, (Right) In/Out Ratio controls raised to fill in small black holes in the matte

**Morph Operation**

Lets you choose how you want to modify the alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.

(Left) A matte with small holes in the face, (Right) Mode set to Shrink, Morph Radius set to 3; used to close holes in a matte

**Morph Radius**

Combined with Morph Operation, this slider adjusts how much to shrink, grow, open, or close the edge’s key.

**Denoise**

Denoise provides a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling holes in a matte.

Before/after raising Denoise, viewing the high contrast matte
Shadow
Adjusts key strength based on the darker parts of the original image.

Midtone
Adjusts key strength based on the midtones of the original image.

Highlight
Adjusts key strength based on the brighter parts of the original image.

Post-Filter
Performs a final clean-up of the key, using the original image for reference, useful for bringing back some fine detail in sharp edges or hair.

The Many Ways to Invert a Key

Sometimes, you'll need to isolate a subject or range of values in an image, and then make a change to everything else. One way to do this is to add an Outside node after the node in which you've created the key. This lets you make one set of adjustments to what you've keyed, and another set of adjustments to everything outside the key.

If you just need to make a simple adjustment, you can invert the key from within the Qualifier palette. However, there are three other ways to invert a key.

— **The Qualifier Invert button**: Clicking this control simply inverts the key being generated by all of the controls within the Qualifier palette.

— **Key Palette Qualifier Invert**: The Qualifier Invert control within the Key palette provides another control with which you can invert the key that’s generated by the Qualifier palette.

— **Key Palette Output Invert**: The Output Invert control within the Key palette is notable because it inverts the sum of all keys applied within that node. For example, if you're using a Qualifier in conjunction with a Window, the two invert controls mentioned previously will only invert the Qualifier key; the Window key remains unaffected. However, using the Output Invert control inverts the overall combination of the Qualifier key and the Window, all together.

Combining Qualifiers and Windows

This is covered in more detail in a subsequent section, but if you create a key using one of the Qualifier modes, and you then add a Window, the final key that’s output by that node is limited to the intersection of the Qualifier key and the Window. This makes it easy to use a Window to “garbage matte” out bits of a key that you don’t want, that can’t be eliminated by further adjustment of the Qualifier controls.
Manipulating Keys Using Additional Nodes

If you need to make more adjustments to a qualified key than the Matte Finesse controls will allow, you can use the Node Editor to feed the key output of one node to the RGB input of another, at which point you can use all of the second node’s color adjustment controls to manipulate the grayscale image that constitutes that key, to improve it.

Connecting a key output to an RGB input, and then connecting the RGB output back to the next node’s KEY input again.
You can also use the Key Mixer node to combine multiple keys in several different ways, adding keys together, or subtracting them from one another, in order to create exactly the key you need.

For more information about these techniques, see Chapter 142, “Combining Keys and Using Mattes.”
Chapter 134

Secondary Windows and Tracking

Secondary correction describes isolating a specific part of the image, or a specific subject, using a key. Keys in DaVinci Resolve are grayscale images that define which areas of the picture you want to alter (in white) and which parts of the picture you want to leave alone (in black).

Keys are generated either using the controls in the Qualifier palette, by using a Power Window, or by importing an external matte (for more information on how to use external mattes, see Chapter 142, “Combining Keys and Using Mattes”). This chapter shows you how to use Power Windows to create shapes with which you can isolate parts of the image in different ways in order to do these kinds of targeted corrections.

Power Windows

Power Windows are another way of making secondary correction, being essentially shapes you can use to isolate regions of the image. Different controls let you use oval, rectangular, polygonal, or custom curved shapes. Because you can isolate regions of the image by drawing, Power Windows produce exceptionally clean results, with edges that can be precisely positioned and feathered to achieve a variety of effects.

Before/after Curve Power Window isolates the sky area for a targeted correction.

Power Windows (also referred to as simply “windows”) are excellent when what you need to adjust can be encompassed within a clearly defined geometrical area. For example, the oval of a person’s face, the front of a car, or a wide expanse of sky are all good candidates for windowed adjustments. A drawback of windows can be that they must be animated to follow whatever subject they’re isolating. Fortunately, this is where DaVinci Resolve’s powerful tracker comes in, making it easy to track Power Windows quickly and accurately to follow along with the subject being isolated.
DaVinci Resolve makes it easy to combine multiple Power Windows in different ways, to intersect with one another and create even more sophisticated shapes. For example, multiple windows can be added together, or one window can be used to cut out part of another window, which saves you from the need to make complicated keyframing operations to animate that window’s shape.

This section covers the use of Power Windows, how to create and modify them, as well as how to combine multiple windows, and combine windows and qualifiers to create highly specific isolations.

**Adding Nodes with Windows**

As with qualifiers, you must first add a node to a grade’s node tree before you begin windowing a correction. This is because all of the windows within a particular node work together to limit that node’s grade. As a reminder, any node can be changed from a primary operation that affects the entire image, to a more targeted secondary operation, simply by turning on a window, using a qualifier, or enabling an external matte.
If you don’t create a new node before creating a window, you’ll discover you’ve inappropriately changed a primary correction into a secondary correction. If you create a new serial node, you’ll then need to use the controls found within the Window palette to turn on a window to customize for your purposes. However, there are also a set of commands you can use to add serial nodes with a window already turned on, saving you a few clicks or button presses in the process.

**To add a new node with a window already turned on:**

— Choose Color > Nodes > Add Serial Node + CPW (Option-C) to create a new serial node with a circular window.

— Choose Color > Nodes > Add Serial Node + LPW (Option-Q) to create a new serial node with a linear window.

— Choose Color > Nodes > Add Serial Node + PPW (Option-G) to create a new serial node with a polygonal window.

— Choose Color > Nodes > Add Serial Node + PCW (Option-B) to create a new serial node with a Curve window.

When you add a node with a Power Window, the Window palette automatically opens up, ready for editing.

The Window palette

The Window palette is divided into three sets of controls: the Window list, the Presets, and the Transform and Softness controls.

**The Window Palette Interface**

Once you’ve created a node with which to apply a Power Window correction, you need to open the Window palette if it hasn’t been opened already.

**To open the Window palette:**

— Click the Window palette button.

The majority of the Window palette is occupied by the Window list, within which you can create as many windows as you need for the task at hand. There are five types of windows you can create, each of which has a different geometry. You can use these windows individually, or you can combine them to create even more complex shapes and interactions. The Window palette has four groups of controls that let you use these windows in different ways.
The Window palette with the Window list

- **Window list**: A row of buttons at the top of this list lets you add new windows, which you can then customize as necessary. Each window in the list exposes an On/Off button that shows the shape type, a Layer Name field (blank until you add some text) that you can use to identify what each window is for, an Invert button, and a Mask button that governs how that window interacts with the other windows that are currently enabled (adding to other windows by default, or subtracting from other windows in Mask mode).

- **Transform parameters**: Controls the overall size, aspect ratio, position, and rotation of the currently selected window.

- **Softness parameters**: Controls the edge softness of the currently selected window. Different window shapes have different softness options.

- **Option drop-down menu**: The Option drop-down menu has commands for creating and modifying custom window presets for easy recall later, resetting windows, deleting windows, saving and managing window presets, and copying and pasting track data.

Using buttons along the top of the Window palette, there are five types of windows you can create:

- **Linear**: A four-point shape that can be edited into any kind of rectangle or trapezoid you might need. In addition to the center and corner controls, you can also drag any of the four sides to change the shape.

- **Circular**: An oval that can be shaped, sized, and feathered to solve an amazing number of problems.

- **Polygonal**: A four-point shape that can be expanded with additional control points to create complex sharp-cornered polygonal shapes.

- **Curve**: A Bezier drawing tool that you can use to create any kind of shape, curved, polygonal, or mixed, that you require.

- **Gradient**: A simple two-handled control for dividing the screen into two halves, with options for the center, angle, and feathering of the shape. Good for fast sky adjustments.

**Managing Windows**

To manipulate a window, first you need to create the type of window you want to use, or if you’ve got a group of windows created already, you need to select the window you want to work on.
Methods of creating and selecting windows:

— **To create a new window**: Click the Shape icon button or click the Create Window button (at the top of the Window list) that corresponds to the window you want to create.

— **To select a window using the onscreen controls**: Click anywhere within a window to select it in the Viewer.

— **To select a window from the Window list**: Click the Shape icon button corresponding to the window you want to select.

**To delete a window you no longer want:**

— Select a window, then click the Delete button.

**To reset a window:**

— **To reset one window to its default shape**: Select a window, then choose Reset Selected Window from the Option drop-down.

---

**Showing and Hiding Onscreen Window Controls**

When you open the Window palette, the Viewer goes into Power Window mode. Enabling a window makes that window’s onscreen controls appear within the Viewer, and are mirrored to video out so you can see the window controls on your external display. If you like, you can change how and where the onscreen controls appear.

**To choose whether onscreen controls are mirrored to video out, or disabled, do one of the following:**

— Choose an option from the View > Window Outline submenu.

  There are three options:

  — **Off**: Hides the window outline on both the external display and the Viewer.
  
  — **On**: The default, shows the window outline on both the external display and the Viewer.
  
  — **Only UI**: Hides the window outline on your external display, but leaves it in the Viewer.

— Press Option-H to toggle among all three of the above modes.

  This command is a three-way toggle. The first use of this command hides the window outline on your external display, but leaves it in the Viewer. The second use of this command hides the window outline on both the external display and Viewer. The third use of this command shows the window outline on both the external display and Viewer.

---

**TIP**: If you leave the onscreen controls visible in the Viewer, you may find that as you work you want to temporarily hide or show the onscreen controls in the Viewer so you can get an uncluttered look at the image you’re adjusting. You can quickly toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).
Using the High-Visibility Power Window Outline Option

Ordinarily, Power Window outlines are white (for the center shape) and gray (for the softness shapes). However, sometimes this color scheme can be difficult to see, so the Color panel of the User Preferences has an option in the General Settings section called “High visibility Power Window outlines.” Turning this on sets Power Window outlines to be drawn as green (for the center shape) and yellow (for the softness shapes), to make these windows easier to see in certain circumstances.

(Left) Default window outlines, (Right) High Visibility window outlines enabled in the Color panel of the User Preferences

Window Transform Controls

Windows have transform parameters that are similar to those found in the Sizing palette. These parameters let you alter the window, affecting all of its control points together.

—— **Size:** Scales the entire window up or down. 50.00 is the default size.
—— **Aspect:** Alters the aspect ratio of the window. 50.00 is the default value, larger values make the window wider, and smaller values make the window taller.
—— **Pan:** Repositions the window along the X axis. 50.00 is the default position, larger values move the window to the right, smaller values move the window to the left.
—— **Tilt:** Repositions the window along the Y axis. 50.00 is the default position, larger values move the window up, smaller values move the window down.
—— **Rotate:** The default value is 0. Increasing this parameter rotates the shape clockwise, decreasing this parameter rotates the shape counterclockwise.
—— **Opacity:** Lets you vary the transparency of an individual window’s contribution to a node’s key.
— **Convergence:** When “Apply stereoscopic convergence to windows and effects” is enabled in the General Options of the Project Settings, this additional Transform parameter appears that lets you create properly aligned convergence for a window placed onto a stereoscopic 3D clip. For more information about working with Stereoscopic 3D projects, see Chapter 15, “Stereoscopic Workflows.”

The transform parameters also correspond to onscreen controls found in the Viewer, which can be manipulated directly using the pointer.

![Manipulating the window position on the Viewer](image)

While many of the onscreen controls correspond to parameters within the Window palette, some onscreen controls, such as the control points that govern reshaping linear, polygonal, and Curve windows, are only adjustable via the pointer.

**Onscreen controls for window transforms:**

— **To select any window:** Click on one of an arrangement of many windows to select it, making that window’s controls active.

— **To reposition any window:** Drag anywhere within the window’s onscreen control. Window position corresponds to the Window palette’s Pan and Tilt parameters. For a gradient window, drag the center control point.

— **To resize a circular window while locking its aspect ratio:** Drag one of the four blue corner points out to enlarge, or inwards to shrink. This corresponds to the Window palette’s Size parameter.

— **To squish or stretch a circular window, altering its aspect ratio:** Drag one of the blue top, bottom, left, or right control points. These adjustments correspond to the Window palette’s Aspect parameter.

— **To rotate a window:** Drag the top inner white rotate handle, in the middle of the window. For a gradient, drag the bottom arrow handle.

— **To alter window softness:** Drag any one of the magenta softness handles. Different window shapes have different sets of handles, which correspond to the Softness parameters.

— **To reshape a linear window:** Drag any of the white corner handles to corner pin the window, or drag one of the white top, bottom, or side handles to move an entire side segment of the window around.
To reshape a polygonal window: Turning on a polygonal window reveals a simple white rectangle with four corner control points. Click anywhere on the surface of the rectangle to add additional control points with which to reshape the polygon, and drag any control point to alter its shape. Polygonal windows are limited to a maximum of 128 control points.

To change the size and aspect of a curve: Shift-drag a bounding box around the control points you want to transform, and then adjust the corners of the box to resize the points while maintaining the aspect ratio of the shape, or adjust the top, bottom, left, or right points to squish or stretch the shape.

To remove control points from polygonal or Curve windows: Middle-click the control point you want to remove.

NOTE: Removing a control point from a polygonal window that’s already been animated using the Keyframe Editor results in that point abruptly popping on and off at the keyframes creating the animation.

**Window Softness**

Each type of window has different Softness parameters, depending on how adjustable that window is.

— **Circular**: A single parameter, Soft 1, lets you adjust the uniform softness of the oval’s edge.

— **Linear**: Four parameters, Soft 1–4, let you adjust the softness of each of the four sides of the linear window independently. Magenta softness control points on the top, bottom, left, and right let you adjust the softness of each side of the linear shape independently.

— **Polygon**: Two parameters, Inside Softness and Outside Softness, let you adjust the overall softness of a polygonal window. There are no onscreen softness control points.

— **Curve**: Two parameters, Inside Softness and Outside Softness, let you adjust the overall softness of a curve. Using the onscreen controls, you can adjust the magenta inside and outside softness control points independently, creating any softness shape you need.

— **Gradient**: A single parameter, Soft 1, lets you adjust the uniform softness of the gradient window’s edge.

**Drawing Curves**

The Curve window is the only window that doesn’t display any onscreen controls when it’s first turned on. Instead, you must click within the Viewer to add control points, drawing your own custom shape to isolate whatever region you want.
**TIP:** Turning on the Viewer's full-screen mode can make it easier to draw detailed shapes. You can also zoom into and out of the Viewer while you’re drawing, using either the scroll wheel of a mouse or by pressing Command-Plus or Command-Minus.

To draw a curve:

1. Turn on the Curve window style control.
2. Click anywhere in the Viewer to start adding control points and drawing the shape you need.
3. Click and drag to add and shape Bezier curves, or just click and release to add a hard angle.
4. To finish drawing and close the shape, click the first control point you created to create a corner, or click and drag on the first control point you created to create a Bezier curve.

Once you’ve drawn a curve, there are many ways of manipulating it.

**Simple methods of modifying a curve:**

- **To add points:** Click anywhere on a curve to add control points.
- **To reshape a curve:** Drag any control point to a new location. You can drag control points even while you’re drawing a new curve, selecting previously drawn points to move them, to adjust their spline handles, or to delete previously added points, without the need to finish the window first.
- **To move a curve:** Drag anywhere within or just outside a curve to move it.
- **To symmetrically alter a Bezier curve:** Drag any Bezier handle. The opposite handle automatically moves in the other direction.
- **To asymmetrically alter a Bezier curve:** Option-drag any Bezier handle. The opposite handle stays in place while you drag the current handle. Once you’ve created an asymmetric pair of Bezier handles, they move together as one if you simply drag a handle. You need to Option-drag to change the angle.
- **To change a curve into a corner:** Option-double-click any Bezier curve control point to change it to a sharp-angled corner point.
- **To change a corner into a curve:** Option-click any corner point and drag to pull out a Bezier handle, changing it to a curve.
- **To remove points:** Middle-click the control point you want to remove.

**NOTE:** Removing a control point from a polygonal window that’s already been animated using the Keyframe Editor results in that point abruptly popping on and off at the keyframes creating the animation.

You can also Shift-drag a bounding box to select multiple control points on a curve to move, delete, or transform them all at once.
To select multiple control points on a curve:

1. Hold the Shift key down and drag a bounding box around the control points you want to manipulate or delete. All included control points will become highlighted.

2. Do one of the following:
   - **To move the control points:** Drag anywhere within the bounding box.
   - **To transform the control points:** Drag one of the outer corners to resize all control points symmetrically, drag the top, bottom, or side handles to squish or stretch the control points relative to one another, or move the pointer to one of the corners until the rotate cursor appears, and then drag to rotate the control points.
   - **To delete the control points:** Press the Backspace key.

3. When you’re finished, press the Escape key to deselect the control points.

Converting Linear, Circular, and Polygon Windows into Bezier Curves

If you start out isolating a subject using one of the simple Linear, Circular, or Polygon shape windows and you realize that you need a more complex shape to accomplish the task at hand, you can easily convert them to a more complex Bezier curve by choosing Convert to Bezier from the Window palette Option menu.
Once you’ve converted a simple shape to a Bezier window, you can add control points and manipulate the shape in any way you need to make it better conform to the subject, just as you would with any curve.

**Resetting the Window Palette**

The entire Window palette can be reset using the Option menu’s Reset command.

**Combining Power Windows with the Mask Control**

Adding multiple windows to a single node is an easy way to create composite keys. When combining windows, the Mask control defines whether one window adds to another window, or subtracts from that window.

In the following example, Circular and Curve windows have both been created, and each window’s Mask control is also turned on (by default), resulting in both masks being added together so that the sunset look correction affects both the sky and the woman’s face.

The two images show the combination of the key mattes.

By turning the Mask control of the circular window off, the circular window is subtracted from the curve.

Turning off the Mask control of the circular window

Now, the woman’s face is being protected from the aggressive sky treatment.
Since windows can be individually tracked and keyframed, you can quickly set up complex interactions of windows to solve common problems you’ll encounter. For example, when you’re tracking a window to follow a moving subject that moves behind something in the frame, you can use a second window with Mask turned off to cover the object in front. Now, when the tracked window intersects the subtractive window, the correction will disappear along with the subject.

You can also use the Mask control to create more complex shapes than you can with a single window.

Furthermore, once you reach the limits of what shapes you can create using the four available windows, you can combine multiple nodes containing multiple shapes and qualifiers using the Key Mixer.

**Copying and Pasting Windows**

If there’s a particular window you’ve created that you want to either duplicate within the current node, or apply to another node, you can copy and paste an individual window’s shape from one item in the Window list to another.

**Methods of copying and pasting windows:**

- **To copy a window:** Click any enabled window in the Window list, then click the Window palette option menu and choose Copy Window.
- **To duplicate a window:** After copying a window, create another window of the same type that you copied, and then click the Window palette option menu and choose Paste Window.
- **To paste a window to another node:** Double-click or otherwise select another node, open the Window palette, choose the same type of window that you copied in the Window list, and then click the Window palette option menu and choose Paste Window.
- **To paste a window to the same node:** Click any enabled window in the Window list, then click the Window palette option menu and choose Copy Window, then click Paste Append Window in the Window Option menu.
Saving Window Presets

If you find there’s a particular window shape or combination of windows that you use frequently, you can save one or more windows as a preset for easy recall whenever needed. For example, if you’re working on a documentary within which you find you need to do a lot of face brightening, you can create preset face ovals for close-up, medium, and wide shots, to save you from having to customize a stock circular window for every single new shot. You can also save groups of windows together as a single preset, in order to reuse complicated multi-window shapes.

Window presets are available from a group of Presets controls in the option menu in the upper right-hand corner of the Window palette.

Controls for saving, applying, and deleting window presets

Methods of working with Power Window presets:

— To save a window preset: Once you’ve created one or more windows you want to save, click the Save as New Preset option in the Window palette’s option menu. Type a name into the resulting dialog, and click OK. That preset is now available in the Preset section of the option menu.

— To recall a window preset: Click to open the Window palette’s option menu, and choose a preset from the list. Loaded window presets overwrite whatever other windows were set up in that node.

— To update an already saved preset: Recall a preset, change the resulting window(s), then click to open the Window palette’s option menu. Select Update Preset, then select the preset name. This will overwrite the selected preset with the altered window arrangement.

— To delete a window preset: Click to open the Window palette’s option menu, and choose Delete Preset, then choose a preset from the list. Make sure you chose the correct preset name; there is no warning before the deletion, and you cannot undo the deletion once it’s done.

Once recalled, windows created by presets can be modified and tracked just like any other window.

Using Windows and Qualifiers Together

Another use of windows is to act as a “garbage matte” when used together with a qualifier. By default, when you use a window and qualifier together, a key is only output where both the window and qualifier intersect. This makes it easy to exclude unwanted parts of a key that are too difficult to eliminate by further refinement of the qualifier controls.

For example, the following qualification is intended to isolate the woman’s face, but some of the similarly colored wood and sky in the background is also included.
Instead of driving yourself crazy trying to eliminate the unwanted parts of the key by modifying the current qualification, which is doing a great job of isolating the skin tones, you could instead use a window to isolate her face, excluding everything outside the window, and simplifying your job considerably.

If she moves, then you can simply track the window to follow. Simple tracking is covered in Chapter 136, “Motion Tracking Windows.”

Furthermore, you can use the window’s Invert control to do the reverse, excluding all qualified portions of the key inside the window, and including all qualified portions of the key outside the window.

If you need to build more complex qualifier/window combinations than this, you can add more windows, or you can use multiple qualifiers and windows with the Key Mixer node, which is discussed in Chapter 142, “Combining Keys and Using Mattes.”
Chapter 135

Magic Mask

The Magic Mask palette uses the DaVinci Neural Engine, guided by the user via a stroke-based interface, to automatically create detailed masks with which to isolate humans, either whole or in part, to which you want to make secondary adjustments in DaVinci Resolve.

This chapter describes how to guide these powerful features using the stroke and tracking controls found within this palette.

The Magic Mask palette uses the DaVinci Neural Engine to automagically create a mask to isolate one or more people in the frame, guided by user-applied paint strokes to identify the subject for isolation. Masks can be generated for either an entire person, or for specific features of that person (their face, hair, arms, shoes, etc.). The following images show these two kinds of masks with Highlight enabled in the Viewer. A red onionskin overlay lets you see what Magic Mask is isolating.

Once the Magic Mask palette has generated a mask, Matte Finesse controls let you adjust the mask's size and feathering. This lets you deal with difficult edges that might tip your hand depending on the kind of adjustment you're trying to make.

While the masks generated by Magic Mask can often be good enough to use directly for making high quality isolated adjustments, it won't always give perfect results. Keep in mind that Magic Mask is as much for the fast creation of detailed garbage masks as it is for doing direct isolation.

In these cases, the Matte Finesse controls let you make the resulting mask softer and looser as necessary to clear the edge of a difficult subject you're isolating with the help of another mask generation technique, such as a Qualifier key or window. When you use the Magic Mask palette within the same node in which you're also creating a key in the Secondary palette, or a window in the Window palette, the key or window and Magic Mask are combined to output a boolean intersection. This means the isolation is limited to areas where both kinds of masks overlap one another.

If you're isolating specific features of a person, you can also mix and match what you're isolating to create exactly the type of mask you require. For example, you might isolate the face, along with exposed skin on the torso, arms, and legs, to create a mask for creating an overall skin tone adjustment that doesn't include the subject's hair or clothes.
As described earlier, this whole process is guided by strokes you draw to identify the subject. In a typical workflow, you’ll draw short positive strokes (colored blue) over the person or feature you want to isolate. Then, if necessary, you can also paint short subtractive strokes (colored red) over parts of the image that are not the person or feature you’re isolating, to correct any problems you see in the generated mask.

Blue strokes identify a person or feature to isolate, while red strokes identify things that shouldn’t be included in the mask.

Ideally, both positive and subtractive guidance strokes should be relatively short, and centered on the part of the person you’re trying to add to the mask. Stroke position is usually more important than stroke length, and in fact if you don’t like the result you’re getting in the mask with a particular stroke you’ve drawn, you can drag it to another position without redrawing it; strokes are live and can be selected using the pointer to move or delete them.

Selecting a stroke with the pointer; selected strokes become highlighted.

Very long paint strokes aren’t usually that useful, and can be counterproductive later on when you’re trying to track strokes to follow motion in the clip. This is particularly true if a stroke needs to follow something that’s changing shape as it moves, like an arm. Furthermore, while you can make as many strokes as you like, fewer strokes work better than many strokes, and as a general rule you shouldn’t use more than five strokes to isolate a particular person or feature (nor should you need to).
As you work, each stroke shows up in the Stroke list, which lets you select, enable/disable, delete, and otherwise manage the different strokes you create to guide automatic mask generation.

(Left) Multiple strokes in Features mode isolating exposed skin, (Right) The Stroke list keeps track of all strokes you’ve made.

But what about camera and/or subject motion, you ask? After you’ve painted one or more strokes to guide the analysis, you can motion track these strokes to follow the subject throughout that shot using the stroke tracking controls within this palette. If you’ve made multiple strokes, they’re all tracked at once, and each stroke automatically follows along with whatever image details immediately surround that stroke, so there’s no setup necessary. You simply draw one or more strokes, then click the track forward or backward button. When you track a stroke, the tracking bar for that stroke in the Stroke list shows you which frames have been tracked (tracked frames are blue).

Controls let you track all mask analysis strokes forward and backward through the shot.

Once you’ve added the strokes that are necessary to isolate the subject, and you’ve motion tracked them to follow along with the motion of the shot, a mask is automatically generated live for each frame of the shot. This is important to know because any change you make, adding or removing strokes or moving them manually, will alter the resulting mask on the fly.
What Magic Mask Is Good For, and What It’s Not

Keep in mind that the Magic Mask tool does not specialize in soft translucent mask edges, such as those created by the HSL, Luma, or 3D Keyers (when they’re used carefully). On the other hand, it excels at creating form-fitting masks that isolate human features in situations where a typical keyer does poorly. For example, Magic Mask can isolate exposed skin in shots where that person is standing in front of a background with wood, stone, or soil that inhabits the same ranges of color as that person. It can isolate beige clothes against a beige background. It can even isolate a person within a black and white clip.

Once you’ve drawn one or more strokes to isolate a mask, a variety of controls let you adjust the resulting mask to better fit the subject, if necessary. Depending on the adjustment you’re making to the subject at hand, you may find that the keys generated using Magic Mask are sufficient to convincingly isolate the person you’re grading, particularly if you’re working in Better mode.

However, real world projects pose plenty of unexpected challenges. Keep in mind that, depending on what you’re trying to do, the resulting automated mask isn’t always going to be perfect enough to replace precise rotoscoping for intensive secondary color adjustments. However, it’s been designed to easily create tight-fitting garbage masks to use in conjunction with secondary keys or windows, with which to exclude the background around a difficult-to-isolate subject.

If you’re using Magic Mask to create a garbage mask, keep in mind that the Faster mode has been optimized to create loosier masks more quickly for situations where you’ll be using it in conjunction with a keyer or window to isolate a specific area for special grading.

**TIP:** The Magic Mask palette can even isolate people in photos and paintings. However, figurative representations must have a minimal level of shadow rendering and anatomical detail for a figure or feature to be recognized. For this reason, cartoony or abstract representations won’t isolate very well.

The Magic Mask Interface

The Magic Mask palette is divided into three sets of controls: the Toolbar, the Stroke list, and the Mask Finesse panel. When you first open the Magic Mask palette, it’s empty, and you’re told to draw a stroke in the Viewer to create a mask.
The controls of the Magic Mask palette, in Features mode

**Magic Mask Toolbar**

A toolbar at the top contains most of the interactive controls of the Magic Mask palette.

— **Target Selection:** A tab control at the left lets you choose the type of mask you want created. There are two choices:
  
  — **Person:** For creating a mask to isolate as much of a person is visible, given the framing of the shot.
  
  — **Features:** For creating a mask isolating just someone's face, or hair, or arms, for example. In Features mode, you can also combine multiple specific features into a single mask.

— **Tracking Controls:** The following controls let you track all available strokes to follow camera or subject motion in the frame. From left to right, these include:
  
  — **Jump to Start of Track:** Moves the playhead to the first tracked frame of a range of tracked frames, in preparation for tracking backwards if there are untracked frames at the beginning of the clip.
  
  — **Track One Frame Backwards:** Tracks one frame backwards and stops. Useful if you’re tracking frame by frame to watch the progress of a particularly complicated bit of motion. If something goes wrong, you can back up to the last frame where the stroke was able to properly track the subject, and drag the stroke to a better location using the pointer to make it follow the subject properly. If necessary, you can go a frame at a time, dragging the stroke to a better position every time it fails to follow the feature you’re using it to isolate.
  
  — **Track All Frames Backwards:** Continuously tracks from the current frame all the way to the beginning of the clip.
  
  — **Stop Tracking:** Stops tracking, in cases where there’s a problem with the track and you want to make a change.
  
  — **Track Forwards and Backwards:** Tracks from the current frame all the way to the end of the clip, then returns to the original tracking point and tracks backwards to the beginning of the clip.
  
  — **Track All Frames Forwards:** Continuously tracks from the current frame all the way to the end of the clip.
— Track One Frame Forwards: Tracks one frame forward and stops. Useful if you’re tracking frame by frame to watch the progress of a particularly complicated bit of motion. If necessary, you can go a frame at a time, dragging the stroke to a better position every time it fails to follow the feature you’re using it to isolate.

— Jump to End of Track: Moves the playhead to the last tracked frame of a range of tracked frames in preparation for tracking forwards if there are untracked frames at the end of the clip.

— Stroke tools: Two tools at the right lets you choose whether to draw strokes to identify the feature you want to isolate, or identify things that aren’t the feature in order to eliminate unwanted excursions in the resulting mask.

— Invert Mask: A button lets you invert the resulting mask in cases where you want to use the feature analysis of this palette to isolate everything except the feature or features being analyzed.

— Mask Overlay: Turns on an onion-skinned overlay with which to see what parts of the image are being masked alongside which aren’t, so you can continue to refine the result by adding, moving, or deleting strokes. The isolated part of the mask is tinted translucent red.

### Stroke List

Once you start drawing strokes to identify features for mask generation, they appear in this Stroke list.

— Stroke list header: The header, at the left of the Stroke list, has controls for selecting, enabling/disabling, and naming each stroke (if you need that level of organization). Right-clicking any stroke in its header reveals controls to Reset Tracking Data and change the mask type (feature or not feature).

— In Person mode, this is just a flat list of strokes, each of which help to either define the person you want to isolate, or the background.

— In Features mode, an additional drop-down menu lets you choose which specific feature you want to identify with a guidance stroke. All strokes are sorted hierarchically by the feature they correspond to, so for example each Face stroke appears underneath a Face title bar. The title bar for each feature has a toggle control that lets you turn that feature off and on. When off, you disable that feature’s contribution to the overall mask being generated.

— Stroke timeline area: A Timeline ruler shows the duration of the current clip you’re creating a mask for. Each stroke in this list has a track that displays how many frames of each stroke have been tracked. As you track each stroke, these tracks fill up with colored bars to show which frames have tracking data.

Tracks of strokes that identify a person or features are blue, while tracks for strokes identifying things that aren’t the feature are red. Using this timeline, you can keep track of which strokes need to be tracked, and manipulate the tracking data as necessary to obtain a useful result.

### Mask Adjustment Controls and Matte Finesse

There are two sets of controls for refining the mask that’s output by the Magic Mask palette. The first set of controls, at top, let you adjust how the mask is generated based on the analysis data, which lets you refine the mask result based on characteristics of the image. These include:

— Quality: Two options let you choose a tradeoff between quality and performance. Faster lets you generate a lower quality mask more quickly, that’s suitable for garbage matting. Better generates a higher quality mask with more detail, that’s more processor-intensive.
— **Smart Refine**: This control lets you expand or contract the resulting mask based on the analysis of the image, such that expanding the mask doesn’t expand it deeply into surrounding parts of the image that aren’t connected to that person. This operation does not introduce softness. Instead, it enlarges or shrinks the overall mask generated by this palette. 0.5 is unity, 0 is the maximum amount of expansion, while 1 is the maximum amount of contraction.

A second set of mask manipulation controls are for manipulating the mask after it’s been generated. Most of these are the same Matte Finesse controls that are available in the Qualifier palette, which are useful for trying to fix issues with problem masks, or soften the edges when you need to have a more feathered result. For more information about the Matte Finesse controls, see Chapter 133, “Secondary Qualifiers,” in the DaVinci Resolve User Manual. There is one additional control, however, that’s unique to the Magic Mask palette.

— **Consistency**: After you’ve tracked each stroke to follow the subject over the duration of the clip, this setting lets you choose how much temporal smoothing is necessary to ameliorate jitter in the edges of the resulting mask in areas of low confidence, such as frizzy hair or translucent clothing. Higher settings apply more smoothing to the edges of the mask but are more processor intensive and may affect how closely the mask follows motion in the image. Lower settings will be faster and more accurate but may allow more edge jitter in the resulting mask, which can be distracting in the final adjustment you’re making. This parameter defaults to 0, so your first application of Magic Mask will always begin with the most accurate (and potentially most active) application of this feature’s analysis.

**IMPORTANT**

Consistency requires a stroke to have a duration of at least a few frames in order to function correctly. This requires you to track each stroke to follow the motion of the camera and subject in order to extend the duration of each stroke. Because Consistency is trying to eliminate one or two frame “noise” in the shape of the mask, strokes of short duration may end up having their effect eliminated.

---

**Choosing What to Isolate**

This section elaborates on the different choices that are available for isolation and offers tips for what each choice is good for.

**Person Mode**

When you choose Person, every stroke you draw over someone helps to isolate that person’s entire body, or however much of that person is visible onscreen. This includes all clothes that person is wearing, including their shirt, pants, shorts, dress or skirt, bathing suit, knickers, jumpsuits, hat, shoes, even armor or space suit (yes, we’ve tested both), whatever. Most clothing should be correctly identified as part of the isolation mask you’re creating. However, excessively flowing garments may need an extra stroke or two to identify them in complex visual compositions.
Drawing negative strokes, when in Person mode, will identify everything that’s not the person you’re isolating; this omits both the background and/or other people from the mask being generated. Drawing negative strokes isn’t mandatory; you only need to draw a negative stroke if you see a problem such as part of the background being included in the isolation mask.

**Features Mode**

When you choose Features, a drop-down menu appears at the top of the Stroke list. You must first choose the feature you want to isolate from this menu, and then draw strokes over the selected feature (face, hair, etc.) you want to isolate. Each feature’s collection of strokes can be turned on or off to add that feature to the overall mask being created.

— **Face:** Isolates just the face and ears, including eyes and glasses. This omits hair and the neck (which is considered part of the torso). Facial hair, particularly bigger beards, will usually be omitted from an initial stroke made on exposed skin of the face, so you can work on just the skin if you want. However, an additional stroke on the beard will include it in the face isolation.

— **Hair:** Isolates just the hair, stopping at the bangs and ears, and omitting as much of the face as possible. Curly, frizzy, or wispy hair will produce oversized masks encompassing as much of the hair detail as possible. This tool does not create fine transparency. Fine and irregular hair detail can cause jittery edges, but this can be ameliorated using the Consistency control.

— **Torso (Exposed Skin):** Isolates exposed skin above the waist and below the face, excluding the arms. This is the selection you want to enable if you want to isolate the neck, neckline, and any part of the chest that’s exposed when wearing v-necks, plunge necks, tank tops, crop tops, or bikini tops.

— **Clothing (Top):** Any clothing above the waist. Exposed skin is omitted.

— **Clothing (Bottom):** Any clothing below the waist. Exposed skin is omitted.

— **Arms (Exposed Skin):** The exposed parts of arms or hands. Shirt and dress sleeves are omitted, as are sun sleeves.

— **Shoes:** Most styles of shoes will be isolated.

— **Legs (Exposed Skin):** Isolates exposed skin below the torso, excluding socks and leggings.

— **Hat:** Most styles of hats will be isolated, although thin accessories such as streaming ribbons or feathers might not be included.

Remember, no matter what feature you’ve selected to isolate, you can always draw negative strokes to omit other parts of the person or their clothing that are erroneously being included in the mask.

**IMPORTANT**

When you’re drawing strokes in Features mode, accidentally drawing a stroke over a feature other than the one that’s selected in the drop-down menu at the top of the Stroke list will result in a completely incorrect mask. If you see this happen, delete the stroke you just made, double-check which feature is currently selected, and either redo the stroke or choose the correct feature you want to isolate.
Identifying More Than One Person

In both Person and Feature mode, you can add strokes to identify more than one person, or more than one person’s features. There’s nothing special you need to do, simply draw strokes over each person you want to isolate, or over the same feature of each person you want to include (for example, drawing stroke over three people’s faces in Face mode).

You can draw strokes over multiple people to isolate them together in the same mask.

Using Matte Finesse Controls

There are plenty of situations where a seemingly problematic mask can be improved using the Smart Refine and Matte Finesse controls at the right of the Magic Mask palette. If the mask is only a few pixels off, and the color adjustment you want to make is reasonably subtle, you can probably use Blur Radius and In/Out Ratio to create a soft edge that falls off just at the outer edge of the subject (so as not to create a halo effect) with which to make your adjustment.

(Left) The hard edges of the initial mask aren’t quite close enough to the edges of the woman’s arm to make a subtle adjustment, (Right) Using the Blur Radius and In/Out Ratio controls to create soft edges that don’t extend past the subject to make a useful mask.
**Using Magic Mask as a Garbage Matte**

In situations where the outer edge of a person is not being detected closely enough for Magic Mask to give a useful result for a more extreme color adjustment, you’re probably better off expanding the result into a closely-fitting garbage matte to use for isolating the person or features using other techniques, such as a keyer in the Qualifier palette. Even for this purpose, you’ll find using Magic Mask is typically faster than rotoscoping a relatively close garbage matte over a moving figure using windows.

![Initial mask and expanded garbage matte](image)

(Left) The initial mask isn’t quite close enough to the edges to make an extreme adjustment. (Right) Using the Mode/Shape/Radius/Iterations/Blur Radius controls to expand the matte to be a garbage matte for use with other keys.

**Dealing With Hair**

Wispy or frizzy hair, individual strands of hair being thrown back, and tips of dreadlocks or heavily moussed hair that comes to points will often require special handling with this tool. Keep in mind that the Magic Mask tool does not specialize in soft translucent mask edges like a keyer does. When it comes to hair styles that are loose and free, in many situations you may be able to finesse an acceptable result using the Matte Finesse controls to expand a softened version of the matte to encompass the entire hairstyle.

If this interferes too much with the edges of other features of the subject you’re isolating, you can create a dedicated hair mask in Features mode by drawing Hair strokes. You can then use the Matte Finesse controls at the right of the palette to create softened edges that work well with the outer boundary of the hair style you’re isolating.

![Creating a soft-edged hair mask](image)

Creating a soft-edged hair mask

At this point, you can try doing different color adjustments using two different correction nodes, one for the subject’s hair, and another using Magic Mask to isolate everything but the hair.
Alternately, if you want a single matte with which to isolate the entire subject, you can then use additional instances of the Magic Matte tool (one per node), using one node to isolate just the face and body without the hair, and a third node to isolate the entire subject but with a very soft edge. Then, you can use a Key Mixer node to combine all these masks together with the original hair mask you created, with which to feed a complete key to another node used to make the correction.

While hair with soft edges can be a challenge, Magic Mask excels at many elaborate hair styles with detailed shapes and hair accessories, including jewelry and ribbons. For example, the stylized hairstyles found in European and Chinese period movies and shows give the DaVinci Neural Engine no trouble at all, particularly as these styles are usually tightly bound with no wispy hair.

Asymmetrical hairstyles may require extra strokes to identify hair that’s significantly longer on one side of the face. This may also be true for unorthodox hair styles, such as hair that’s been sculpted into distinct sculptural shapes. Lastly, tight braids that expose skin on the scalp are also challenging for the kind of hard masks that Magic Mask produces, so you’re better off using Magic Mask as a garbage matte and using a keyer to create a detailed soft mask to use in these instances.

**About Hats**

Magic Mask works with an incredibly wide variety of hats from all time periods. On hats, tassels or details like feathers can be a problem (in testing, the feather on Errol Flynn’s cap in Robin Hood couldn’t consistently be included, even though the cap itself was no problem). Additionally, veils that are part of hats may or may not be easily identified, but an additional stroke usually solves the problem.

**Dealing With Accessories**

Things that people are holding, such as handkerchiefs or umbrellas, can pose problems. Sometimes, something that’s obvious like the blade of a sword will be omitted, while the hilt that’s being held in a hand is included with the figure. In these instances, you can choose whether you want to draw another stroke to include the item in the mask, or try to draw a negative stroke to omit it. Your results will vary with the size of the item.

Jewelry and watches pose a special problem, as they’re typically so thin and small that they can be difficult to omit, but you may not want to include them depending on the adjustment you’re trying to make. Your results will vary with the thickness of the items and the framing of your subject, but in general your results will probably be better if you simply add a stroke or two to include these items in the isolation, since omitting fine detail like a necklace can be problematic.
Adding Strokes to Guide Mask Creation

Here are some tips for how to draw strokes to analyze the image. To identify people, try starting with a single short positive stroke (blue), centered on the face or body.

![Drawing the first stroke to identify an entire person](image)

Depending on the result, more strokes may be needed to differentiate an arm or frizzy hair from the background. If you're adding a stroke to an arm or hair, don’t put it right at the edge; the goal is not to trace the subject, but to use strokes within the body of the subject to clarify what features belong to the subject, and which do not.

![Adding a stroke to the arm to include it as well](image)

As you do this, resist the urge to use too many strokes. One stroke might well be all you need, or you might need two or three, but using more than five strokes for any subject or feature may cause more problems than it solves.

![Adding negative strokes to the reflection to remove](image)
To identify faces, try starting with a single short stroke in the middle of the face, along the nose, or from eyes to the lips. Depending on the result, you may need additional strokes to identify the chin, a beard, or to distinguish the forehead from wispy hair.

Drawing strokes to identify a face; notice that additional strokes are needed to include the beard.

It’s a good idea to start with a single stroke, then track the stroke through the duration of the clip (described later in this section). Over the entire clip, you’ll see which parts of the mask may exhibit problems. This will guide where you put additional strokes, in order to more clearly identify the person versus the background, in order to clean up the resulting mask. As you add additional strokes, track those as well and see how things go.

If you notice parts of the background that are erroneously added to the mask, you can add a negative stroke (red) to clarify that those parts of the image should not be isolated. Short strokes, longer strokes, and zig zags are good for backgrounds. Since strokes just help the analysis update the mask, you can try different types of strokes to see what works best, and delete any stroke that doesn’t give good results. As with positive strokes, don’t use more strokes than are absolutely necessary to get the result you want.

(Left) The microphone incorrectly identified as part of the woman being interviewed, (Right) Drawing negative strokes to identify the microphone as background, using a zig-zag pattern to tag the entire microphone.
Similarly, if you’re isolating features such as a face, and you find other features, such as hair, getting in the way, you can draw a negative stroke on the hair to identify it as not part of the face.

If there’s a “hole” in the resulting mask that’s actually part of the background and not the subject, you can try drawing a stroke connecting that hole to the rest of the background.

Drawing strokes to connect the background with itself, to remove part of the mask that’s not part of the person

If there’s an “island” in the mask that’s actually part of the subject and not the background, you can try drawing a stroke across the island that connects one solid part of the mask to itself.

Drawing strokes to fill an island in the subject being isolated

Of course, extracting a mask using strokes is only the first part of creating a useful mask. The Quality, Consistency, and Smart Refine controls let you refine the stroke analysis of the image to create the best tradeoff between performance and quality for the type of mask you need. These controls work hand in hand with the strokes you draw to extract a mask. A set of Mask Finesse controls then let you adjust the resulting mask to manipulate and soften it, to better suit whatever adjustment you’re trying to make. All of these controls are described earlier in this section.

**Managing Strokes in the Stroke List**

When you draw a stroke, it appears in the Stroke list. By default, all strokes last for the duration of the clip to which they’re applied, so if you draw a stroke to identify a figure that’s not moving, there’s no requirement to motion track or keyframe the stroke. Strokes in Person mode appear in one long list, while strokes in Features mode appear hierarchically, with the strokes for each feature separated by the title of each feature. Once a stroke appears in this list, it has the following controls.
— **Enable/disable feature:** In Features mode, once you draw at least one stroke to identify that feature, the title of that feature appears, underneath which is organized all the strokes for that feature. A toggle next to the feature name lets you turn that feature’s contribution to the overall mask on and off.

— **Enable/disable stroke:** Each individual stroke in this list has a blue dot that lets you turn that stroke’s contribution to the overall mask on or off.

— **Stroke Timeline Area with Stroke Tracks:** The stroke track for each stroke lets you keep track of and manipulate the animation of strokes to follow camera and subject motion. Blue or red frames in this track let you see at a glance how much of each stroke has been motion tracked; blue frames for positive strokes, red frames for negative strokes. You can also use these tracks to identify frames where you’d like to mute that stroke’s contribution to the final mask and to keep track of which frames have been muted. You can draw a bounding box within the stroke track around however many frames of however many strokes for which you want to delete motion tracking, delete keyframes, or mute stroke contributions to the mask.

## Stroke Duration

When you first draw a stroke, that stroke has a duration of one frame, located at the timecode position of the playhead when you drew it. If you move the playhead to the left or right, you’ll see the stroke disappear. If you want one or more strokes to continue analyzing the subject for the duration of that shot, you need to use the Motion Tracking controls to track the stroke to follow along with the motion of whatever it’s drawn on top of. As a stroke is tracked, its duration increases to cover the entire range of tracked frames. If at any point a stroke outlasts its usefulness, such as when a person walks off frame, you can stop tracking that stroke when it’s no longer necessary and it will stop contributing to the analysis.

This is useful, because often you’ll want to place strokes to deal with analysis issues that only last for a few frames, to fix a hole in the mask that only appears briefly. Just be aware, you can’t simply draw a stroke and move on to the next shot; you must track at least one stroke to last for the duration of a subject’s time on screen for that subject to be continuously masked.

## Tracking and Keyframing Strokes to Follow Subject Motion

You can think of each stroke you’ve drawn as a persistent eyedropper that samples the image that overlaps it. The mask that results from all strokes’ collective analysis of the image is generated live over each frame of the clip. This means that if the camera or the subject moves, you need to motion track or otherwise adjust the position of each stroke to follow along with the motion, so the subject continues to be correctly identified. You also need to make sure that each stroke is able to analyze what it’s supposed to, and turn off strokes that can’t for whatever reason.
TIP: Magic Mask is a processor-intensive operation, so to accommodate users of less powerful workstations, there is a Use Fast Tracking option available in the Magic Mask palette’s Option menu, which speeds up the process of tracking at the expense of potentially less accurate tracking for fast or erratically moving subjects.

Methods of Moving Strokes to Follow Subject Motion

For these reasons and more, there are multiple methods of manipulating strokes to refine the final analysis.

— **Motion Tracking**: A set of tracking controls at the top of the Magic Mask palette let you motion track one or more strokes to follow the camera and subject motion in a clip. Every frame that’s motion tracked effectively has a motion-tracked keyframe placed on it that moves the stroke to a new position.

— **Manual Keyframing**: Any time you drag a stroke from its original position in the Timeline, you create a static keyframe at that frame that instantly moves the stroke from its previous position to the new position at that frame. Because these are static keyframes, there’s no motion interpolation from one keyframe to the next in order to create animation. Instead, keyframing in the Magic Mask palette is a simple frame-by-frame operation. Every time you move a stroke at a new frame, you change the stroke’s position at that frame, without changing stroke position on any other frame that’s been previously tracked.

If this seems simplistic, keep in mind that the goal is not to create beautiful stroke animation with this tool. You only need to move each stroke to follow along with whichever subject or background feature it’s supposed to be sampling in each frame. The only important thing is that, in every frame, the stroke overlaps a suitable part of the feature you’re isolating to create the appropriate mask. If the stroke itself jumps around abruptly, that doesn’t matter so long as the mask that’s generated is good. This means that even if you’re stuck doing a limited amount of frame-by-frame animation to make a stroke follow along with a troublesome feature (such as a veil flapping in the wind), it’ll go pretty fast, because in each frame you’re just dragging the stroke to overlap the feature wherever it happens to have moved. This repositioning doesn’t have to be smooth, just accurate.

— **Combining Tracking and Manual Keyframing**: Since each frame that’s motion tracked is effectively keyframed, manually dragging a stroke on a frame that’s already been tracked overrides the tracking data at that frame with a static keyframe that records the new position of the stroke at that frame. If there’s no more tracking data, either before or after that keyframe, then the stroke disappears until you do more tracking. If there’s tracking data immediately after a keyframe, then the stroke jumps to the position dictated by that tracking data.

— **Deleting Stroke Tracking at Specific Frames**: To accommodate cases where a subject you’re isolating moves behind something and becomes hidden for a range of frames, you have the ability to delete stroke tracking for one or more frames. This lets you eliminate the stroke for however many frames the subject you’re tracking is obscured and cannot be sampled. This makes it easy to deal with features that come and go over the duration of a clip, since you can delete stroke tracking over however many ranges of frames the feature disappears. If you’ve muted frames by mistake, you can either undo or re-track the stroke over those frames.

To delete tracking frames, draw a bounding box on the stroke tracks over the range you want to delete, and then choose Clear Selected Track Data from the Magic Mask option menu.
Option Menu Commands for Removing Strokes and Tracking

The Option menu of the Magic Mask palette presents a number of commands for clearing either strokes or stroke tracking data.

- **Clear All Strokes:** Deletes every stroke in the Stoke list, along with tracking.
- **Clear All Strokes of Current Frame:** Deletes the tracking data at the current position of the playhead on all strokes in the list.
- **Clear All Strokes from In to Out:** If you use the I and O keys to set In and Out points in the Stroke Timeline, this command deletes all tracking data on all strokes within that range.
- **Clear Selected Stroke from In to Out:** If you select a stroke in the Stroke list, and then use the I and O keys to set In and Out points in the Stroke Timeline, this command deletes the tracking data of selected strokes within that range.
- **Clear Selected Track Data:** If you drag a bounding box around tracking data for one or more strokes, this command deletes all tracking data within the box.

An Example Stroke Tracking Workflow

By combining motion tracking, manual keyframing, and stroke muting, you’ll be able to make short work of isolating most moving subjects. The following procedure illustrates how you might use these techniques together to make the strokes you’ve drawn follow along with the features you’re isolating.

To track one or more strokes to follow a subject:

1. If necessary, move the playhead to the frame where you want to begin isolating the subject you want to mask. For example, if you’re isolating a person walking into the room through a door, you probably want to begin your work on a frame where the person is already in the room, and work your way backward and forward from that frame. If your subject is already fully visible at the first frame of the shot, you can start there.

2. Draw at least one stroke identifying the subject or feature you want to isolate. You cannot track a stroke to follow the features unless there’s at least one stroke.

3. Choose whether you want to track all strokes or only selected strokes. By default, all existing strokes with at least one frame in the Stroke Timeline at the position of the playhead will be tracked. However, you can choose to track only selected strokes in the Stroke list by choosing Track Selected Stroke Only in the Magic Mask palette’s Option menu.

4. Click the Track Forwards to End or Track Backwards to Beginning buttons if you want to motion track the strokes over the remaining duration of the clip.

By default, each stroke is tracked to follow whatever image detail immediately surrounds it; you don’t have to define a tracking region, this is done automatically. As tracking proceeds, the tracking bar for each stroke will fill up showing you which frames have been tracked, and which have yet to be tracked. Meanwhile, each stroke being tracked will transform to follow along with simple position and rotation changes in the subject. However, things that obscure the subject, as well as more extreme movements, may cause problems.

Strokes that are tracking a feature that moves off screen are automatically excluded from tracking at the frame where the feature is completely off screen, even if that feature returns onscreen in a later frame.
5 (Optional) If a problem occurs during the track, such as the subject being occluded behind something else in the frame (for example, a person’s face moves behind a tree as they walk), click the Pause Track button. You can deal with problems in the track in the following ways:

a. **If a stroke has completely moved off of the subject:** For example, you’re tracking a stroke to follow a person and they turn around 180 degrees, so the stroke moves off onto the background. To fix this, pause the track, move the playhead to the first frame where the stroke hasn’t followed the subject properly, then use the pointer to drag the stroke onto another part of the subject that’s clearly visible. On each frame where you drag the stroke to a new position, it will be automatically keyframed. Continue this process until the subject’s motion is consistent enough to be trackable again, and you can then resume tracking.

b. **If a stroke has moved onto something that’s partially obscuring the subject:** Pause the track, drag a bounding box over the frames where the track is having a problem, and choose Delete Selected Tracking from the Magic Mask Option menu to clear the bad tracking data. Then, move the playhead to the first frame of the deleted tracking data, and use the pointer to drag the stroke onto any part of the subject that’s visible to either side of the occlusion. Move the playhead to each successive frame, and drag the stroke onto whichever part of the subject is visible from behind the occlusion, until the subject moves past the occlusion. At that point, you can use the Track Forwards to End or Track Backwards to Beginning buttons to continue tracking as usual.

c. **If the subject becomes completely hidden:** Clips where the subject appears and disappears over the duration of a clip can be resolved by deleting the stroke or strokes on that subject over all frames where the subject is obscured, so that strokes only sample the image when the subject is visible and thus able to be isolated. You can delete one or more strokes by dragging a bounding box over a range of frames, and then choosing Clear Selected Track Data from the Magic Mask Option menu.

d. **If a stroke is having trouble following the subject:** If the subject you’re tracking is moving too fast, too irregularly, or is changing shape too greatly for the tracker to give a good result (for example, someone lifts their arm towards the camera), you can track through the problem area of the clip one frame by frame using the Track Forward 1 Frame or Track Backward 1 Frame buttons, and then use the pointer to manually drag the stroke to follow along with the subject as you go. Once the problem motion stops and the motion of the subject becomes more regular, you can use the Track Forwards to End or Track Backwards to Beginning buttons to continue tracking as usual.

e. **If the subject is moving off the frame:** If you’ve drawn a stroke in the middle of someone’s face, and their face is moving off screen, you can manually reposition the stroke on the last few frames before the subject completely exits so that stroke continues to identify what parts of the face are still visible even though the part of the face it was originally following becomes hidden. Once the face completely exits the frame, you can mute the stroke for the rest of the shot.

6 (Optional) If you only tracked the stroke’s movement over part of a shot, you can click the Jump to Start or Jump to End buttons to move the playhead to the first or last tracked frame, in preparation for tracking from that frame onward.
Chapter 136

Motion Tracking Windows

While Power Windows can be manually keyframed to follow a moving subject you want to isolate, this chapter shows how you can use the powerful cloud and point-based motion tracking controls in DaVinci Resolve to make Power Windows follow along with the motion of subjects and the camera in the fastest, easiest way possible.

Then, numerous techniques are presented for dealing with complicated tracking scenarios and common problems that arise for subjects that are difficult to track.

Motion Tracking Windows

The Tracker palette has three modes, available from the Palette menu.

— In Window mode, the tracking controls let you match the motion of a window to that of a moving feature in the frame.
— In Stabilizer mode, the same underlying technology is used to smooth or stabilize the motion within the entire frame.
— In FX mode a Point Tracker can be used to animate ResolveFX or OFX plug-ins with positioning controls. For more information about the FX and Stabilizer modes, see Chapter 149, “Sizing and Image Stabilization.”

DaVinci Resolve has an incredibly simple, yet powerful, 3D cloud tracker that allows you to track quickly and accurately any Power Window (Circular, Linear, Polygonal, Curve, or Gradient) to follow any moving feature. This avoids the need to use dynamic keyframes to manually animate a window’s position.

In particular, you can use the tracker to match a window’s position, size, rotation, and its pitch and yaw in 3D space to either foreground or background elements that move within the frame.

Simple Tracking Using the Tracker Menu

The simplest way to track a feature using a Power Window is to use the commands found in the Color > Tracker menu. These commands include:

— **Track Forward (Command-T):** Tracks a window to a feature from the current position of the playhead forward, ending at the last frame of a clip.
— **Track Reverse (Option-T):** Tracks a window to a feature from the current position of the playhead backward, ending at the first frame of a clip.
— **Track Stop (Command-Option-T):** Interrupts any track. This is useful for letting you cancel a long track that goes wrong (the Stop button of a control panel stops tracking as well).
— **One Frame Forward (Option-Right Arrow):** Tracks a window to a feature one frame forward from the current position.
— **One Frame Reverse (Option-Left Arrow):** Tracks a window to a feature one frame backward from the current position.
Most window tracks are easy to accomplish using these three commands.

**To track any Power Window to match a moving feature within the frame:**

1. Move the playhead to the frame of the current shot where you want to begin (you don’t have to start tracking at the first frame of a shot).

2. Turn on any window, and adjust it to surround the feature you want to track. Typically, you’ll have done this anyway, for example, framing someone’s moving face with a Circular window to lighten their highlights.

3. To initiate tracking, do one of the following:
   - Choose Color > Tracker > Track Forward (press Command-T).
   - Choose Color > Tracker > Track Reverse (Option-T).

DaVinci Resolve automatically opens the Viewer page, places a series of tracking points within the window you’ve created, and performs the track from the current frame; forward to the last frame or backward to the first frame.

DaVinci Resolve analyzes a cloud of tracking points that follow the vectors of every trackable group of pixels within the window you’ve created, and the results are fast and accurate. After tracking, the window you’ve placed automatically moves, resizes, rotates, and skews to match the motion of the feature you’re tracking.

Object tracking in progress. Tracking points are automatically placed over trackable features of the image.

Once a clip has tracking data applied to one of its windows, a small tracking icon appears within that clip’s icon in the Thumbnail timeline.

A tracking icon in the top left corner of the Thumbnail timeline shows that clip has been tracked.
If the track you’ve performed is unsuitable, you can reposition the window to cover a different area of the subject you’re trying to track, and initiate tracking again. New tracking data overwrites any previous tracking data applied to that window.

Once you’re satisfied with your track, you can continue to resize, reposition, or reshape the window being tracked. Tracking data is separate from the window transform parameters (which can be keyframed), so changes you make to a window offset it from the originally tracked path.

**Tracking Windows When You’ll Be Exporting Media With Handles**

When you track windows to match moving features in a clip, the windows are only transformed on frames with tracking data. In Round Trip workflows where you add handles to the graded clips you render for editorial flexibility in the footage you deliver, you need to make sure that you track all windows from the beginning to the end of these handles to make sure that, if an editor actually trims any of the clips you give them to use the handles, all windows are doing what they should.

An easy way to do this is to choose View > Show Current Clips With Handles to display each clip you select in the Timeline with handles defined by the “Default handles length” setting in the Editing panel of the User Preferences. Make sure that the “Default handles length” is equal to the handles you export using the “Add X Frame handles” option in the Render Settings list of the Deliver page. With each clip’s handles made visible in this way, you can easily track windows along every frame you’ll be rendering.

**Simple Ways of Working With Existing Tracking Data**

If there’s a portion of a shot that you haven’t tracked (for example, you started tracking at a later frame, or you ended tracking before the end of the shot), then the window you’re tracking remains wherever it was at the first or last frame that was tracked. If you want to fill in these gaps, you can always move the playhead to the first or last frame that was tracked, and then use the Track Backward or Track Forward command to track the rest of the frames in that shot.

**Tips for Better Tracking**

In situations where a feature changes shape in such a way as to confuse the tracker, you can try tracking a smaller part of the feature by using a smaller window. Once you’ve achieved a successful track, you can resize the window as necessary, and it will have no effect on the track that’s already been made.

Also, if you’re tracking a feature that moves behind something onscreen and disappears for the rest of the shot, there’s an easy way to avoid having an awkward window sitting in the middle of the scene. You can use dynamic keyframes to animate the Key Output Gain parameter (in the Key tab of the Color page) to fade from the correction’s full strength of 1.0 down to 0, the value at which the correction disappears, along with the window itself.

**Tracking One Frame at a Time**

You can click the “track one frame forward” or “track one frame backward” buttons in the Tracker palette to track a moving feature one frame at a time, making it easier to make adjustments to follow a difficult track when you’ve set tracking to Frame mode (by clicking the Frame button).

In Frame mode, you can keyframe window transformations to more faithfully conform to troublesome motion as you’re moving one frame at a time through the track; manual changes to a window’s position...
will be keyframed to create frame-specific transformations, rather than used to offset the entire tracked motion path as in Clip mode. When you add multiple keyframes in the Tracker graph, animation will be automatically interpolated from keyframe to keyframe.

**Copying and Pasting Tracking**

There will be plenty of times you’ll apply multiple windows to a single moving subject, such as a car, when you can use a single motion track for all the windows. Commands in the Option menu let you copy and paste track data from one window to another within the same node, saving time when you want several windows tracking together as one.

**To copy track data from one window to another:**

1. Open the Window palette, then select a window that has tracking applied to it (indicated by a tracking badge in the corner of the shape icon), and choose Copy Track Data from the Option pop-up.
2. Select another window, and choose Paste Track Data from the Option pop-up. Once you’ve copied track data from one window, you can paste it to as many other windows as you like.

You can also copy tracking from the FX mode of the Tracker palette and paste it to a window, in case you want to use the same tracking data for both an effect and a window.

**To copy track data from an FX track to a window:**

1. Open the Tracker palette, choose the FX mode that contains the tracking data you want to copy, and choose Copy Track Data from the Option pop-up.
2. Open the Window palette, select a window, and choose Paste Track Data from the Option pop-up. Once you’ve copied track data from one window, you can paste it to as many other windows as you like.

**Tracker Palette Controls in More Detail**

You can easily combine object tracking and keyframing to animate windows. For example, you’ll typically use object tracking to make a window follow the position and orientation of a moving feature, but you can add dynamic marks to the window track of the correction in the Color page with which to alter its size and shape to better conform to a feature’s changing form.

**Controls in the Window Tracker Palette**

Occasionally, you’ll run into a shot that doesn’t quite track well enough using the Tracker menu’s simple controls. In these cases, the Viewer page provides the complete set of object tracking controls that can be used to modify tracking operations in different situations.
The Tracker palette

The object tracking controls are divided into seven groups.

**Tracker Palette Modes**

The Tracker palette’s Option drop-down menu lets you choose between Window mode (for matching a window to the motion of a feature in the frame), Stabilizer mode (for subduing unwanted camera motion; for more information on Stabilizer mode, see Chapter 149, “Sizing and Image Stabilization”), and FX mode (for tracking position to be used with Resolve FX or Open FX plug-ins).

**Types of Tracking**

A pop-up menu below the Tracker graph lets you choose whether to use the Cloud Tracker or the Point Tracker.

There are two options:

— **The Cloud Tracker**: Automatically analyzes all parts of the image for trackable points, and uses these to automatically figure out the motion in the shot that you want to use to move a Power Window or stabilize a shot. This tracker type is great for quickly tracking a window to match the movement of almost any feature, with a minimum of work.

— **The Point Tracker**: Lets you create one or more tracker crosshairs that you can manually position in order to track specific features in the shot. The more crosshairs you create and position, the more accurate the track can be. The Point Tracker is incredibly useful in situations where you need to follow the motion of a very specific feature in the frame. It can also be useful in cases where you want to stabilize a shot that has many subjects moving in different directions, and it’s difficult to obtain a good result with the Cloud Tracker.
Object Tracking

The object tracking controls provide the most basic tracking functions, some of which are mirrored within the Color > Tracker menu.

![Tracking Controls](image)

Choose which type of transform you want to track before tracking.

A series of five checkboxes let you turn on and off which transforms you’d like motion tracking to apply automatically to the window. These checkboxes must be selected before you perform a track in order to restrict the transforms that are used.

- **Pan and Tilt**: Enables tracking of horizontal and vertical position, when you want to transform a window to follow the location of a tracked subject.
- **Zoom**: Enables tracking of size, when you want to transform a window to resize to follow a tracked subject.
- **Rotate**: Enables tracking of orientation, when you want to transform a window to rotate with a tracked subject.
- **Perspective 3D**: Enables tracking of pitch and yaw in 3D space, when you want a window to skew to follow the orientation of a tracked subject within the scene. Good when you want the window to “stick” to a surface.

**NOTE**: Once tracking or stabilization has been done, disabling these checkboxes does nothing to alter the result. To make changes, you need to enable or disable the necessary checkboxes first, and then reanalyze the clip.

After you’ve defined the transforms you want to use for the track, the analyze controls let you proceed with the analysis of the subject being tracked.

- **Track One Frame Reverse button**: Motion tracks a single frame in reverse. Useful for slow tracking of difficult subjects that may require frequent correction.
- **Track Reverse button**: Initiates tracking from the current frame backward, ending at the first frame of the clip. Good for tracking backward when your best starting point is somewhere within the middle of the shot.
- **Pause button**: Stops tracking (if you’re fast enough to click this button before tracking is finished).
- **Track Forward button**: Initiates tracking from the current frame forward, ending at the last frame of the clip.
- **Track Forward and Back button**: Initiates tracking from the current frame forward, then when finished, tracks backward from the original selected frame. This allows you a one button process when tracking from the middle of a shot.
- **Track One Frame Forward button**: Motion tracks a single frame forward. Useful for slow tracking of difficult subjects that may require frequent correction.
**Clip/Frame Controls**

Two buttons let you set how manual adjustments to the position of tracked windows affect the overall track.

- **Clip**: The default mode, in which changes you make to the position of a window are globally applied to the entire track. For example, if you track a feature, and then move the window, the window moves along a motion path that’s consistently offset from the original track for the duration of the clip. Use this mode if you’re happy with the track, but you want to modify the window’s overall shape and position relative to the motion path it’s following.

- **Frame**: In this mode, changes you make to the position or shape of a window create a keyframe at the frame at the position of the playhead. Multiple keyframes are interpolated to create animation with which you can manually transform a window to solve a variety of problems. This mode is useful for rotoscoping the shape and position of windows to match a subject that’s tough to automatically track. Frame mode is also useful for making corrections to individual frames that were badly tracked, for animating windows to go all the way out of frame along with a subject, or for making manual, frame-by-frame adjustments to window position to cover untrackable sections.

**The Tracker Graph**

The Tracker graph provides a visual display of the tracking data that’s being analyzed. Each of the transform controls that can be tracked has an individual curve, which lets you evaluate each tracked parameter on its own, and each curve is color-coded to match the corresponding label of the tracking transforms listed above.

A vertical slider to the right of the Tracker graph lets you scale the height of the curve data within to make it easier to see it all within the graph. A horizontal slider at the bottom of the graph allows you to zoom in and out of the tracker curves, allowing you to see finer detail of the tracking paths. Above the Tracker graph, a Timeline ruler contains a playhead that’s locked to the playheads in the Viewer and Keyframe Editor.

You can draw a bounding box in the Tracker graph with which to select a portion of one or more curves to delete sections of low-quality tracking data using the Clear Selected Keyframes command found in the Tracker Options menu. To eliminate the current bounding box from the Tracker graph, click once anywhere within the graph.
Interactive Mode Controls

The Interactive controls, at the bottom-left of the Tracker palette, let you make manual changes to the automatically generated tracking point cloud that DaVinci Resolve creates when you’re tracking with the Cloud Tracker, so you can try different ways of obtaining better tracking results in challenging situations.

Interactive mode controls

— **Interactive Mode checkbox**: Turns the Interactive tracking mode on and off. When you enter Interactive mode, you can manually alter the point cloud that DaVinci Resolve uses to track the feature within the current window. You’ll then make your track while in Interactive mode.

— **Insert**: Lets you add tracking points to whatever trackable features exist within a bounding box that you’ve drawn in the Viewer. Inserted tracking points are automatically placed based on trackable pixels in the image.

— **Set Point**: Lets you use the cursor (using the DaVinci Resolve Advanced control panel), to manually place individual tracking points, one by one, with which to track a feature. If there is no trackable pixel group at the coordinates where you placed the cursor, a tracking point will be placed at the nearest trackable pixel group.

You must place at least two tracking points at different pixel groups to track rotation, and at least three to track zoom.

— **Delete**: Eliminates all tracking points within a bounding box that you’ve drawn in the Viewer.

Point Tracker Controls

If you’re using the Point Tracker, then the Interactive Mode controls disappear, replaced by the two controls of the Point Tracker.

Point Tracker controls

— **Add Tracker**: Click to create a new tracker that’s automatically positioned in the center of the frame. Once created, you can drag it using the pointer to line up with the feature you want to track. You can create as many trackers as you like. Multiple trackers are all tracked at once.

— **Delete Tracker**: Select any tracker (selected trackers are red, deselected trackers are blue), and click this button to remove it.

Additional Commands in the Tracker Options Menu

There are some additional commands located in the Tracker Options pop-up menu.
— **Reset Track Data on Active Window:** Lets you delete the tracking data corresponding to the currently selected window.
— **Clear Selected Track Data:** When you drag a bounding box over parts of one or more curves in the Tracker graph, this command lets you delete that part of the graph. This is useful when you want to eliminate sections of low-quality track data. Portions of curves that are cleared in this way have linear interpolation automatically applied to them, similar to if you used the Keyframes Interpolation controls.
— **Delete Keyframe:** Deletes tracker graph keyframes at the current position of the playhead.
— **Clear All Tracking Points:** Clears the tracking points in the Power Window at the frame you are on.
— **Show Track:** Turn this checkbox on to show the motion path produced by the tracking you’ve done.
— **Copy Track Data:** Lets you copy track data from the currently selected window. Windows can be selected directly in the Viewer while the Tracker palette is open.
— **Paste Track Data:** Pastes copied track data to the currently selected window. Windows can be selected directly in the Viewer while the Tracker palette is open.

### Cloud Tracker Workflows

The next few examples illustrate how to use the Tracker palette’s controls in practical situations. In many circumstances, objects passing in front of a tracked subject, known as “occlusions,” can cause problems. While the tracker in DaVinci Resolve is highly occlusion-resistant, the following sections show a variety of techniques you can use when an occlusion prevents you from getting a useful track.

#### Using Interactive Mode to Manually Choose Tracking Features

Interactive mode lets you manually remove or add tracking points to improve tracking performance in situations where the automatic image analysis in DaVinci Resolve provides unsatisfactory results.

For example, you can delete tracking points within a window that correspond to overlapping features you don’t want to track. Suppose a car that you’re tracking drives by a sign that partially obscures the car. Without intervention, the PowerCurve that’s isolating the car will deform improperly when the car moves along and then away from the sign.

Using Interactive mode, you can delete the tracking points that will overlap the sign you don’t want to track, improving the result.

**To eliminate specific, unwanted tracking points from a track:**

1. Open the Tracker palette.
2. Turn on the Interactive Mode checkbox.

![Selecting Interactive Mode](image_url)
3 In the Viewer, drag a box around the tracking points you want to eliminate within the window.

![Dragging a box around tracking points that need to be deleted](image)

4 Click the Delete button.

![Deleting tracking points](image)

The points within the selection area are deleted.

![Remaining tracking points ready to be used](image)

5 While Interactive mode is still on, click Track Forward or Track Reverse to track the subject using the remaining tracking points.

6 When you’re finished tracking, turn off the Interactive Mode checkbox.

DaVinci Resolve goes back to using automatically placed tracking points.

In another interactive tracking example, you may sometimes run into situations where you want to eliminate all automatically placed tracking points altogether, placing your own in specific regions of the image.
To eliminate automatic tracking points, adding your own instead:

1. Open the Tracker palette.
2. Turn on the Interactive Mode checkbox.

3. In the Viewer, drag a box around all the tracking points in the window, and click the Delete button to eliminate all tracking points from the image.

4. Click the Delete button to eliminate all tracking points from the image.

5. Drag a box around the specific area where you’d like to add new tracking points. In this case, you only want to track the top half of the woman’s face, since the bottom half is cut off by the fence posts.
Now, click the Insert Track Points button.

The Insert button of Interactive mode automatically adds tracking points within the current bounding box.

New tracking points are automatically added to whichever features are appropriate for tracking within the box you’ve drawn.

NOTE: If no appropriate tracking features can be found, no points will be added.

Dealing With Occlusions When Tracking

Sometimes you’ll find that you need to deal with a gap in the useful tracking data. For example, objects in the frame that pass in front of the feature you’re trying to track cause gaps in the tracking information for a clip.

In situations where a subject being tracked becomes totally occluded by another object in the frame, there’s an easy method of interpolating to cover holes in the available tracking data. In the following example, the woman walks behind another fence post, this time one that’s taller than she is. The window tracking her face will become completely lost at this point, but interpolation will help to salvage this shot.
Interpolating between two sets of tracking data to track past an occlusion:

1. Move the playhead to the first trackable frame of the moving feature you're correcting, and create a Power Window that surrounds it.

![Adding the Power Window](image)

2. Use Track Forward to track the feature as far as you can before it becomes obscured behind something else in the frame.

3. When the Power Window stops tracking the feature reliably, stop the track.

![The Power Window is obscured by the post](image)

4. Open the Tracker palette.

5. Click the Frame button to put the Tracker controls into frame-by-frame adjustment mode. This is an important step.

![Selecting Frame mode](image)

6. Move the playhead to the frame where the feature you're tracking reappears from behind the occlusion, then drag the window so that it again overlaps the feature.

![Moving the playhead and position the window](image)
7 Use Track Forward to continue tracking the feature until the end of the clip. Alternately, you could have started from the end of the clip and used Track Reverse to track the feature as far as possible, if that’s easier.

Now that you've identified the gap in reliable tracking data for this clip, it's time to set up the interpolation.

Notice the gap in the tracking data where the window was behind the post.

8 Drag a bounding box over the portion of the curves in the Tracker graph that fall between the good tracking data at the beginning and end of the shot.

9 Click the Tracker palette option pop-up menu, and choose Clear Selected Track Data.

The portions of curves that you selected are deleted, and have linear interpolation automatically applied to them so that there’s no hole in the track data or the motion of the window, which now moves smoothly from the last outgoing frame of reliable tracking data to the first incoming frame of new reliable tracking data.
Point Tracker Workflows

As advanced as the Cloud Tracking that is the default in DaVinci Resolve is, there are times when it may be simpler to track using good old-fashioned crosshairs. The Point Tracker makes it easy to track very specific features of a subject with motion you need to follow. Unlike the Cloud Tracker, which automatically looks for all trackable points within a region of the image that you identify using a window, the Point Tracker lets you create one or more crosshairs that you must manually position to overlap with whatever high-contrast features you want to track. This section covers the three main workflows you need to know to use the Point Tracker.

Tracking a Window Using the Point Tracker

The following procedure describes, in a general way, how to use the Point Tracker to track a moving subject and apply that motion to a Power Window.

1. Move the playhead to the frame of the current shot where you want to begin (you don’t have to start tracking at the first frame of a shot, since you can always track backward).

2. Turn on any window, and adjust it to surround the feature you want to track. Typically, you’ll have done this anyway, for example, framing someone’s moving face with a Circular window to lighten their highlights. You want to make sure that the window you want to apply the tracked motion to is selected before you begin tracking. In this example, we’ll be tracking a Circular window to follow the woman’s face.

3. Open the Tracker palette, and choose Point Tracker from the bottom right pop-up.

4. Before you start tracking, choose what types of motion you want to track and apply to the window you’re working on. You can choose from among Pan, Tilt, Zoom, Rotate or Perspective 3D. Which methods of transformation can be applied depend on how many points you add to track.
5 Click the Add Tracker Point icon. A new tracker crosshairs appears in the Viewer in the center of the frame.

Clicking the Add Tracker Point icon

6 Move the pointer directly over the tracker crosshairs, and when it turns into the move cursor, click and drag to move the crosshairs to line up on top of the feature you want to track. For the best results, this should be a high-contrast detail such as a corner, the end of a line, a small shape like a pebble, or a jagged detail. Unlike other point trackers, there is no inside or outside region to separately adjust, there’s only the one crosshairs that you need to align. In this example, this first crosshairs is placed at the inside of her stage left eyebrow (the corner of her eye would introduce too much jitter as the tracker will pick up her blinks).

Lining up the tracker crosshairs with the feature you need to track

7 If you want to improve the accuracy of your track, you can create more tracker crosshairs and position them on top of other details within the subject you’re tracking. For the best results, make sure that all crosshairs are placed onto details that are in the same plane of motion. In other words, don’t put some crosshairs on a person’s face in the foreground, and other crosshairs on a tree that’s far in the background, since both these features will have very different vectors of motion. In this example, trackers are placed at her inside eyebrows and at the corner of her lips.

Setting up four trackers to follow the corners of her eyebrows and mouth

8 When you’re done placing crosshairs, click the Track Forward or Track Backward buttons to initiate tracking. The clip will be analyzed, and the Tracker graph will update with the tracking data, and the window you had selected automatically moves to match the motion of the feature you’re tracking.
The final track, accomplished with four point trackers, with the track path turned on

Removing Trackers
If you find that a particular tracker is causing problems, you can remove it by selecting it in the Viewer, and clicking the Delete Tracker icon, before retracking the subject.

Clicking the Delete Tracker icon

Using Frame Mode to Offset Track
A common issue when point tracking is how to deal with occlusions and times when the tracked feature moves off screen. In DaVinci Resolve, the solution is to use the Tracker palette’s Frame mode to move the tracker crosshairs onto another feature to track, while offsetting the resulting motion so that it continues to follow the original motion path.

1 In this example, a point tracker crosshairs has been positioned at a corner of a window of a building that’s being separately adjusted using a Power Window. The window is being used because, as the woman turns to leave, she covers up most of the other trackable outer edges of the building, which would ruin the track.

Setting up to track a building moving off screen

2 As the camera pans, the feature being tracked is about to go off frame, which is about to ruin the track. As this happens, click the Stop Track button.
Stopping the track on the last good frame of the track, before the tracker goes off screen

3 Move the playhead back to the last good frame of tracking, and then click the Frame button in the Tracker palette to go into Frame mode.

Turning on Frame mode, to prepare to offset the track

4 In Frame mode, you can now drag the tracker to another feature of the building, this time the outer edge of the roof, that will be better to follow as the building goes out of frame to the left, since the Power Window will go out of frame before the rightmost corner of the building’s roof does.

Dragging the tracker to another feature that’s better to track

5 Now, click the Track Forward button again, and the crosshairs will begin tracking the new feature, but the motion will be offset, so the movement of the Power Window continues to follow the original motion path.

Tracking an offset feature lets the window go all the way off screen
If you turn on the track path (in the Tracker Option menu), and move the playhead to the frame where you moved the tracker, you can see that the motion before you moved the tracker and the motion after continues smoothly along the same path, with no sudden breaks. When you’re finished, click the Clip button to get out of Frame mode.

The tracker path before and after moving the tracker crosshairs in Frame mode is smooth and continuous.

Rotoscoping Window Shapes After Tracking

While the DaVinci Resolve trackers are pretty miraculous when it comes to making a window follow moving subjects, or elements within a moving scene, there will be plenty of times when the final track isn’t quite perfect. For example, if you’re trying to isolate someone’s face with a very specific window, and the person turns their head, then the resulting change of shape is almost certainly going to require you to make animated adjustments to the window in order to continue making such a specific isolation.

Before and after a window tracking a turning head, the window doesn’t quite follow the edge of the woman’s face as her head turns.
Fortunately, the Tracker palette’s Frame mode makes it easy to animate shape changes you make to windows in order to better follow a moving subject, a task often referred to as rotoscoping. By following the motion of a moving subject, and making a series of automatically keyframed adjustments to the window at every point the subject changes speed or direction, you can make a window isolate a moving target with surprising precision.

![Using Frame mode to rotoscope the window to better follow the edges of her face and the contours of the jaw](image)

Furthermore, you can also use Frame mode to repair imprecise tracks where the window is veering off course because of quickly or irregularly moving features. In these cases, you have the option of manually tracking the window in Frame mode to fit the trajectory of the feature, frame by frame.

Lastly, you don’t even have to have performed a track to use the Tracker graph in Frame mode to keyframe animated changes to a window. In fact, using the Tracker graph in Frame mode can sometimes be more convenient than using the Keyframe Editor in Auto Keyframe mode, depending on what you’re doing.

**Rotoscoping Controls**

The Clip/Frame buttons determine whether or not you’re rotoscoping a shape.

— **In Clip mode**: Any changes you make to a window transform it over the entire duration of that clip. In other words, you can track a window to a moving feature, and in Clip mode any changes you make to the size, rotation, position, or shape of the window occur equally from the beginning to the end of that clip.

— **In Frame mode**: Changes you make to a window automatically create a keyframe at the bottom of the ruler in the Tracker graph. Making two or more changes to a window in Frame mode results in automatically interpolated animation from one keyframed window transformation to the next.

You can freely move back and forth between Clip to Frame modes to make changes to a window. Even if you’ve keyframed a window to change shape, you can turn on Clip mode and make an overall change to the window, enlarging it for example, that results in the window being equally enlarged at every keyframe.
Keyframing in Frame Mode

Once you’ve added keyframes to the Tracker palette, there are a number of ways you can edit them.

Methods of working with keyframes in the Tracker graph:

- **To add a keyframe**: Click the Add Keyframe icon at the upper right-hand corner of the Tracker graph. It looks similar to the Keyframe icons found in the Edit page Inspector. This is useful for adding a keyframe to a frame where the window fits the subject well, prior to moving forward a few frames and making an alteration to the window to follow the subject that will generate another keyframe.

- **To move the playhead from one keyframe to another**: Click the Previous Keyframe and Next Keyframe icons at the upper right-hand corner of the Tracker graph. These controls look similar to those found in the Edit page Inspector.

- **To delete a keyframe**: With the playhead on the same frame as the keyframe you want to delete, open the Tracker option menu, and choose Delete Keyframe.

![The Previous Keyframe, New Keyframe, and Next Keyframe buttons in the Tracker graph](image)

A Rotoscoping Workflow

The following procedure demonstrates how to use a window to rotoscope an onscreen feature that you want to isolate. In the process, it shows how to set up a window for rotoscoping using the Tracker palette, and discusses some best practices for rotoscoping efficiently.

**To rotoscope or manually track a window using automatic keyframing:**

1. Create a window to isolate the feature you’re wanting to adjust, and use the tracker to make it follow the motion of the subject. If the window doesn’t follow the contours of the subject as precisely as you require, then you can begin manually keyframing its shape on top of the tracking you’ve done to rotoscope the subject.

2. With the Tracker palette open, click Frame to change the tracking mode.

![Clicking the Frame button to begin keyframing your shape](image)

The best way to use Frame mode for tracking is to either start at the last successfully tracked frame and work your way forward, or start at the first successfully tracked frame and work your way backward. This takes the best advantage of the automatic keyframing and interpolation between keyframes to animate the window you’re transforming smoothly.

3. With the playhead at either the first or last frame where the window fits the subject you’re isolating, you can either click the Add Keyframe button at the upper right-hand corner of the Tracker graph, or wiggle any control point by a pixel or two, to add a keyframe at that frame.
Adding a keyframe at the last frame where the window follows the subject’s motion well means that any future animated changes you make interpolate from this frame forward, rather than from previous frames where there’s no need for alterations.

While you’re in Frame mode, the changes you make to the window automatically generate a keyframe in the Tracker palette, which appears at the bottom of the Tracker graph’s timeline.

It’s frequently essential to add a keyframe at the last frame where a window conforms well to the subject you’re trying to isolate, in order to limit window animation from that frame to the next keyframed transformation, rather than accidentally animating from the beginning of the clip, or from the next or previous keyframe in the Tracker graph.

4 Next, move the playhead to the next frame where the window requires adjustment to better fit the moving subject, and adjust the position of the window, the control points of the window, or both to isolate the subject as necessary.
This results in a second keyframe being placed in the ruler of the Tracker graph.

Two keyframes creating rotoscoped animation in addition to any motion tracking that's applied.

5 With your first two keyframes placed, scrub the playhead back and forth between them to evaluate how well the window's animation is automatically interpolating to fit the motion of the subject you're isolating. If the window doesn't follow the motion of your subject well enough, move the playhead to the frame where the window divergence is the most pronounced and make another adjustment to correct the shape.

A frame between the two keyframes you've rotoscoped that needs further adjustment.

This creates another keyframe.

6 When you're finished making adjustments between your first two keyframes, move the playhead farther along and add keyframes as necessary to make the window follow the motion of your subject.

In general, look for the frames where your subject’s motion starts, stops, speeds up, slows down, or changes direction. As you work, it's good to try and add the fewest number of keyframes you can to ensure smooth motion from one to another. Too many keyframed adjustments made too close together for a smoothly moving subject risks adding jerky motion if you're not careful. On the other hand, if you have an erratically moving subject, you may have to add more keyframes, possibly frame by frame, to achieve the desired result.
**TIP:** If you’re isolating a subject with a complex shape that moves quite a lot, you might consider using multiple simple overlapping shapes to track and rotoscope it, rather than a single complicated one, to make the task easier.

7 When you’re finished rotoscoping the window, be sure to click the Clip button to switch back to Clip mode, so you can trim the window’s shape across every keyframe you’ve just created, if necessary. This will also prevent you from accidentally adding more keyframes if you select other shapes. This technique requires a bit more work than simply using the Tracker, but it’ll let you quickly adjust the animation of a window to more tightly conform to a moving subject when you need an adjustment to be specific to that subject alone. You can also use this technique to reposition specific motion path points in the middle of an otherwise successful track to make them fit better, or to add keyframes to the beginning or end of a track when the subject moves offscreen but the window does not.

**Viewing a Window’s Motion Path**

You can turn on the motion path of the window you’re tracking by choosing Show Track from the Tracker Option menu.
Chapter 137

Using the Gallery

The Gallery provides a way to save, browse, and use saved still frames from different clips in a program. Each project is saved with its own individual set of stills, and each still you save consists of a DPX image of the saved frame, and the grade metadata. You can use saved stills for reference when matching one clip to another, or you can use them to copy grades to other clips, or other timelines.

There are two ways to work with the contents of the Gallery. The Color page has a small Gallery, to the left of the Viewer, that provides quick access to saved stills and grades as you work. The Gallery window, which can be opened via a button at the top right of the Gallery, provides a dedicated interface for organizing your grades, copying grades and memories between projects, and for accessing a dedicated collection of DaVinci Resolve looks.

Using the Gallery

The Gallery in the Color page and the expanded Gallery window environment share many of the same commands for organizing stills. However, the commands for saving stills and customizing split-screen views are restricted to the Color page.

**Saving Stills**

One of the most common operations is to save a clip as a still (with that clip’s embedded grade) for future reference and use.

**To save an individual still in the Color page, do one of the following:**

— Choose View > Stills > Grab Still (Option-Command-G).
— Right-click on the Viewer and choose Grab Still.
— Press GRAB STILL on the Transport panel of any of the the DaVinci Resolve control panels.

It’s also possible to save stills automatically for every clip in the entire Timeline. This can be useful if you’re planning to export a set of grades to hand off to another colorist, or if you need to apply a series of grades manually from one project to another when ColorTrace™ won’t work.

**To save a still for every clip in the current timeline, right-click the Viewer, and choose one of the following:**

— **Grab All Stills > From First Frame**: The first frame of each clip is saved to the Gallery.
— **Grab All Stills > From Middle Frame**: The middle frame of each clip is saved to the Gallery.
— **Grab Missing Stills > From First Frame:** Only the first frame of clips with no stills in the Gallery are saved to the Gallery.
— **Grab Missing Stills > From Middle Frame:** Only the middle frame of clips with no stills in the Gallery are saved to the Gallery.

By default, when you save one or more stills, they’re named “TrackNumber.ShotNumber.VersionNumber” with dots separating each number. If you like, you can choose an option from the General Options panel of the Project Settings to “Automatically label Gallery stills” in different ways. This is covered in more detail later in this chapter.

## Selecting Stills

**To select a range of stills, do one of the following:**

— Click one still, then Shift-click another to select a contiguous range of stills.
— Command-click any stills you like to make a noncontiguous selection.
— Right-click any still, and choose one of the following commands;
  — **Select All:** Selects every clip in the Gallery.
  — **Select Current to Last:** Selects every still from the one you’ve clicked through the last still in the Gallery.
  — **Select First to Current:** Selects every still from the one you’ve clicked through the first still in the Gallery.

## Deleting Stills

If you need to remove one or more stills, this can only be done using the Gallery’s contextual menu.

**To delete one or more stills, do one of the following:**

1. Select one or more stills in the Gallery.
2. Right-click one of the selected stills and choose Delete Selected.

Each still is also saved with a variety of metadata that is used by DaVinci Resolve to manage the contents of the Gallery in different ways. This metadata can also be used for searching and sorting, and is viewable by opening the Still Properties window.

**To display a still’s properties:**

— Right-click a still in the Gallery and choose Properties.

A floating translucent window appears displaying the date the still was created, what clip it was grabbed from, when it was grabbed, and the source and record timecode values of the frame it came from.
Where are Stills Saved?

By default, all grades/stills you save are saved in the DPX format, and are placed in the directory path defined in the “Gallery stills location” field in the Working Folders section of the Master Settings panel of the Project Settings. This path defaults to a hidden “.gallery” directory that’s created at the location of the first Media Storage Volume you specify in the Media Storage panel of the System Preferences window.

Changing the PowerGrade Still Directory

Optionally, you can change the location where PowerGrade stills are saved by Opening the Gallery Option menu and choosing Change PowerGrades Path. You’ll be prompted via a “Select PowerGrades Folder” dialog to choose a directory where all PowerGrades will be saved.

Live Previews of Gallery Stills

The Live Preview option, found in the Gallery option menu, lets you preview how the current clip would look with a particular Gallery Still grade applied to the currently selected clip simply by moving the pointer over the still you want to preview.

Enabling and Disabling the Gallery Live Preview:

1. Open the Gallery option menu and choose Live Preview.

2. Click a node in the Node Editor you want to preview applying the grade from a still to. The live preview will display how the current clip will appear with the grade of the still you select applied to the currently selected node of current grade, which will affect the result.

3. Move the pointer over the still you want to preview.

The Viewer image updates to show how that clip would look with that still’s grade applied to the currently selected node.

Hover Scrub in the Gallery

When Live Preview is enabled in the Gallery option menu, the Hover Scrub Preview submenu lets you choose how you want Live Preview to be shown by a thumbnail in the Gallery and in the Viewer when you hover the pointer over a still or LUT in the LUT Browser:
— You can choose to scrub both the thumbnail you’re hovering over and the Viewer, letting you preview the current still’s grade or a LUT over the duration of the current clip in both the thumbnail and Viewer.
— You can choose to scrub just the thumbnail, leaving the Viewer to show just the grade or LUT over the frame at the position of the playhead.
— You can disable scrubbing altogether, in which case both the thumbnail and the Viewer will only show the grade or LUT over the frame at the position of the playhead.

The Hover Scrub Preview options when Live Preview is enabled

Playing Stills and Setting Up Image Wipes

There are many ways to play a still in the Color page, making it visible as an image wipe in the Viewer and on the external display connected to your video interface.

To play a still, displaying it as an image wipe or full screen, do one of the following:
— Double-click a still in the Gallery.
— Select a still in the Gallery, and click the Image Wipe button on the top Viewer toolbar.
— Click a still in the Gallery, then right-click in the Viewer and choose Show Reference Wipe.
— From the View > Stills menu, choose Next Still (Option-Command-N) or Previous Still (Option-Command-B) to select a still in the Gallery, and then choose Wipe On/Off (Command-W) to play it.
— Press PREV STILL or NEXT STILL on the DaVinci Resolve Advanced Search Dial panel, or the DaVinci Resolve Advanced control panel to select a still, then press PLAY STILL. Press PLAY STILL again to dismiss the still.

Whenever you play a still, the Viewer mode’s drop-down menu changes to Split mode.

Once displayed, the wipe between the current clip and the still being referenced can be moved and reoriented in different ways. If you want a full-screen view so you can flip back and forth between the still and the current clip, simply adjust the split until the still fills the entire Viewer.

To adjust a wipe in the Viewer, do one of the following:
— Drag the pointer within the Color page’s Viewer to move the wipe.
— Push the T-bar lever up and down on the T-bar panel of the DaVinci Resolve Advanced control panel.
To customize the type of image wipe that’s displayed in the Viewer, do one of the following:

— Click any of the controls at the top right of the Viewer toolbar to choose Horizontal, Vertical, Mix, Alpha, Box, and Difference types of wipe.
— Choose Gallery, Timeline, or Offline from the View > Reference Wipe Mode submenu, or the Viewer contextual menu.
— Choose Horizontal, Vertical, Mix, Alpha, Difference, and Box from either the View > Wipe Style submenu, or the Viewer contextual menu.
— Choose View > Invert Wipe (Option-W), or right-click the Source Viewer and choose Invert Wipe from the contextual menu to reverse each half of the wipe.

Timeline Wipes

A timeline wipe is when you use the Wipe Timeline Clip command in the Thumbnail timeline (it’s found in the contextual menu when you right-click a clip other than the current clip) to wipe the current clip against another clip in the Timeline, without needing to save a still first. When you turn a timeline wipe on, the clip in the timeline that’s being wiped is outlined in blue.

Gang Timeline Wipe With Current Clip

A “Gang timeline wipe with current clip” option, available from the Viewer option menu, lets you maintain the offset between the current clip and a timeline clip you’re wiping against when you move the current clip selection to other clips. With this option enabled, the offset between the timeline wiped clip and the current clip is maintained when you move the clip selection. When this option is disabled, the timeline wiped clip stays where it is regardless of what clip you select.

Change a Timeline Wipe Using the Timelines Album of the Gallery

While you’re using the Wipe Timeline Clip to show a wipe of the current clip against any other clip in the Timeline, you can open the Timelines album of the Gallery and click different clips to change which Timeline clip you’re wiping against (outlined in blue) without changing the current clip (outlined in orange). Make sure you have selected the same timeline in both the Timeline album, and the Color page.

Labeling and Searching for Stills and Sources

By default, all stills are identified by a three-number code. The first number is the video track the clip is on, the second number is the clip’s position number in the current Timeline, and the third number is the version number of the grade.
All stills are numbered Track.Shot.Version

If you’ve saved many stills, it can help to label the important ones with whatever text you find helpful. Once labeled, you can search for stills by label using the Search field, at the upper right-hand corner of the Gallery.

**Automatic Labeling**

If you like, you can choose an option from the Color group in the General Options panel of the Project Settings to “Automatically label Gallery stills” in different ways. There are many options:

- **Clip Name**: Saves the Clip Name, which defaults to the File Name unless you’ve customized it.
- **Clip Version Name**: Automatically saves the name of the current version.
- **Source timecode (HH.MM.SS.FF)**: Saves the source timecode of the current frame.
- **Timeline timecode (HH.MM.SS.FF)**: Saves the timecode for the playhead’s position in the Timeline.
- **Timeline Name**: Saves the name of the currently open Timeline.
- **Display LUT Name**: Saves the name of the currently used Display LUT, if one is applied.
- **Custom label using tags**: Choosing this option reveals a field you can use to either type custom text into, or in which you can use metadata variables to save automatically updated information relating to the currently selected clip and timeline. For more information about using metadata variables, see Chapter 16, “Using Variables and Keywords.”

For all options, there’s also a checkbox you can toggle:

- **Append still number on export**: Turning this checkbox on lets you choose how to include the default still number when exporting stills with the “Use labels on export” option enabled, either as a prefix or suffix.

**Manual Labeling**

Sometimes the easiest thing to do is to just give a particular still a custom name that’s representative of what that still represents, such as “SeemedLikeAGoodIdea.” When naming stills manually, it’s best to avoid using the forward slash character in case you find yourself exporting these stills with file names. In fact, it’s a good idea to avoid using the forward slash character for just about any text that you add in DaVinci Resolve.

**To manually label a still:**

1. **Right-click a still in the Gallery and choose Change Label or double-click directly under the Still ID.**
2. **Type a name into the Change Still Label dialog, and click OK.**
   The new label appears underneath the still number.
Searching For Stills

Once labeled, you can search for stills you need in the Gallery.

To search for a still by label:

— Click the Magnifying Glass button to open the Search field, click to place the cursor within, and then type the name or description you are searching for.

As soon as you start typing, DaVinci Resolve automatically begins to filter the results of the currently selected album in the Gallery to match what’s been typed.

Match Reference Wipe Frame

You can right-click any Gallery still and choose Match Reference Wipe Frame to automatically move the playhead to the exact frame that corresponds to that still, and select that clip in the Color page Timeline.

Gallery Options

In the upper right corner of the Gallery palette there are several options that let you adjust the view and organization of your stills.

— **Still Size Slider:** Dragging this slider to the left makes the still thumbnails smaller, dragging it to the right makes them larger.

— **Sort Stills:** Choosing an option from this submenu changes the sort order of all clips in the Gallery. The options are:
  — **Still ID:** Sorts all stills by their assigned ID number (track, clip number, grade version).
  — **Label:** Sorts all stills by their text label.
  — **Record Timecode:** Sorts all stills by their position in the program.
  — **Source Timecode:** Sorts all stills by the timecode of the source clip they came from.
  — **Grab Date:** Sorts all stills by the date they were originally grabbed.
  — **Create Time:** Sorts stills based on when you saved each still.

— **Thumbnail View:** Pressing this icon puts the gallery in Thumbnail view; each still is represented by an image.

— **List View:** Pressing this icon puts the gallery in List view; each still is represented by columns of text attributes.
— **Search**: Opens up a search dialog box, to find stills based on their text label.

— **Gallery View**: Opens up the full Gallery Management window.

When you right-click the gray area of the Gallery, behind the Still icons, you can open a contextual menu that provides a variety of additional options for controlling how many stills are saved, how they’re displayed, and how they’re arranged in the Gallery. There are the following options:

— **Switch Wipe Mode**: Switches the Reference mode between showing a “Gallery” still, a “Timeline” clip, or an “Offline” reference movie.

— **Trace Timeline**: When enabled, selecting a clip in the Timeline also automatically selects the first still that was saved from that clip to the Gallery.

— **One Still Per Scene**: When enabled, restricts the Gallery to save only a single still for each clip in the Timeline. If multiple stills have already been saved before turning this option on, those stills will remain in the Gallery until you save another still from the same clip, at which time all other stills from that clip will disappear.

— **Apply Display LUT**: If you have a Display LUT selected in the Lookup Tables panel of the Color Management panel of the Project Settings, it’s applied to the video output via a connected video interface, and also to the Viewer. Ordinarily, you don’t also want the Display LUT applied to stills you’re saving since it’s meant to be temporary. Accordingly, stills are saved with a LUT-free image. However, in instances where you may also want to save a reference to the currently used Display LUT, turning on “Apply Display LUT” saves the Display LUT along with the still, and applies that LUT when that still is used for split-screen reference. Keep in mind that the internally saved Display LUT is only used when playing that still in the Viewer; the DPX image that’s saved remains unaffected.

— **Apply Grades Using**: This submenu contains three options for how to apply the keyframes that are automatically saved within each saved grade.

  — **No Keyframes**: No keyframes are copied. The state of the grade at the frame used to save the still is what is applied to the target clip or clips.

  — **Keyframes Aligning Source Timecode**: Keyframes are copied aligning the source timecode of the saved grade with the source timecode of the target clip. This is the ideal setting when you’re copying a grade back to the clip it came from originally, or to a duplicate of that clip elsewhere in the Timeline, and you want the keyframes to align with the same frames as before. If there is no source timecode overlap, keyframes will be pasted aligning with the start frame of the edit, the same as the third option (below).

  — **Keyframes Aligning Start Frames**: Keyframes are copied aligning the start frame of the clip that still was saved from with the start frame of the target clip. This is the ideal setting when you’re copying a grade with keyframes from one clip to a completely different clip, with different timecode.
— **Use labels on still export**: Lets you use labels that you’ve added to stills in the file name of exported stills.

— **Show All Stills**: This command shows all available stills in the current album if any have been hidden, for example by searching or by using the Show Current Timeline Only command.

— **Show Current Timeline Only**: Choosing this option restricts the Gallery to only showing the stills that were saved from the currently selected Timeline. All other stills from other Timelines are hidden until you switch to that Timeline.

**NOTE**: There are a variety of other commands available in this contextual menu that are covered elsewhere in this chapter.

---

**Organizing Stills Using Albums**

All stills you save are always placed into the currently open album of the Gallery, which defaults for new projects to “Stills 1.” However, you can create additional albums with which to organize your stills into whatever categories you require. Albums can be shown, created, and removed using the Gallery in either the Color page or Gallery windows.

To show or hide the Albums list:

— Click the Album button, at the top left of the Gallery.

If the Albums list was hidden, clicking the Album button will make the Albums list appear, to the left of the Gallery, containing all albums that are currently available in the project that’s open, as well as the PowerGrade album at the bottom. If the Albums list is already visible, then it becomes hidden, making more room for still thumbnails in the Gallery.

Once you’ve displayed the Albums list, there are a variety of ways you can quickly and easily work with albums.

**Methods of working with albums:**

— **To add a new album**: Right-click the Albums list, and choose Add Still Album from the contextual menu. A new album is created, numbered incrementally.
— **To add a new PowerGrade album:** Right-click the Albums list, and choose Add PowerGrade Album from the contextual menu. A new album is created, numbered incrementally.

— **To rename an album:** Double-click any album in the list, and when it is selected, type a new name and press Return.

— **To navigate albums:** Click any album to make it the current album. Using the DaVinci Resolve Advanced control panel, you can use the PREV PAGE/NEXT PAGE buttons to move up and down the Album list.

— **To move clips from one album to another:** Drag and drop a still from the Gallery to an album.

— **To remove an album:** Right-click any album, choose Remove Current Album, and click Delete at the prompt. All clips inside that album will be deleted along with the album, so use this carefully.

### PowerGrade Albums

PowerGrade albums are meant to be repositories for grades you want to reuse frequently, or for stills that you need to reference from multiple projects, such as when grading a series that shares common looks from episode to episode.

Unlike stills saved to the other albums in the list, which are ordinarily available only to the project in which they were saved, stills saved to a PowerGrade album are shared among all projects that have been stored within a particular project library. Each project library has its own unique PowerGrade album.

Creating a new project library creates a new PowerGrade album, which starts out as a clean slate. However, you can always use the Gallery window to copy PowerGrade stills from other projects and project libraries to the current one, and you can create as many PowerGrade albums as you need to organize your grades. For more information about project management and project libraries, see Chapter 3, “Managing Projects and Project Libraries.”

Functionally, PowerGrade albums are identical to any other album, and you can save, organize, and use stills in PowerGrade albums as you would with other albums. Since PowerGrade albums are special in that they’re maintained by DaVinci Resolve, the last PowerGrade album cannot be deleted.
Browse all Grades from the Current Timeline

The Gallery has a Timelines album, available at the bottom of the Album list, that lets you browse all the grades in the current timeline, or in other timelines of the current project (using a drop-down menu that appears at the top of the Gallery browser area), making it easy to copy grades from earlier or later in your timeline, or from other timelines that share the same media.

This is particularly useful for reality shows or documentaries where the same clips can appear multiple times in different parts of a program. Being able to simply show all existing grades in the Gallery frees you from having to save a still for every grade you think you might eventually reuse.

The Timelines grade browser in the Gallery automatically shows all grades in the current timeline

The Gallery Management Window

While you can do quite a lot of stills management using the Gallery as it appears in the Color page, the Gallery window provides additional functionality for copying stills among different projects and project libraries, for organizing your stills and memories, and for accessing the DaVinci Resolve looks that accompany the application.

To open the Gallery window:

— Click the Gallery View button at the upper right-hand corner of the Gallery or select Workspace > Gallery.
The Gallery opens into a floating window, divided into four areas:

— **Stills navigator**: Lets you navigate the contents of other projects and project libraries that are available. Independent projects, as well as project library > user > project relationships, appear in this hierarchical list. Click the disclosure triangle next to any item on this list to reveal its contents. Click any project in the list to reveal its albums and stills in the Group Stills browser.

— **Group Stills browser**: Displays the contents of the currently selected item in the Stills navigator. One or more selected stills can be copied to the current project by selecting an album in the Project Stills browser, and dragging and dropping the selected stills to the Project Stills browsing area.

— **Project Stills browser**: Contains the same Album list and Project Stills browser that’s visible in the Color page Gallery.

— **Project Memories**: Provides a larger view of the project memories that are visible in the Color page Gallery.

**To resize different areas of the Gallery window:**

— Move the pointer to the border between any areas of the Gallery. When the pointer changes to the resize cursor, drag the border to resize the adjacent interface areas to whatever size you need. Dragging all the way to the edge of the screen hides that interface area completely.

**What’s Available in the Stills Navigator**

The Stills Navigator accesses a variety of content via a hierarchical list. Disclosure triangles to the left of each item in the Stills browser let you access the contents of each item, and many items have several nested levels of content within, each accessed by its own disclosure triangle.
The Gallery Stills project library show all projects connected so you can import those stills

— **DaVinci Resolve looks**: A collection of predefined grades, categorized by type, that provides excellent examples of different looks available in DaVinci Resolve. These grades are installed with DaVinci Resolve and cannot be altered.

— **Project Libraries**: Each project library that’s available appears within this list. Each project library has a nested series of users, projects, and timelines within, as well as one nested PowerGrade item for each user, which provides access to the saved stills within.

— **Orphans**: Stills are saved to a separate directory which is defined in the Master Settings panel of the Project Settings. Whenever you delete a project library, the stills that corresponded to that project library become orphaned. All orphaned stills that lack a connection to any current project library appear within the Orphan item in the Stills Navigator.

**Browse and Import Timeline Grades From Other Projects**

The Gallery window lets you see and import grades in the timelines of other projects, even if they weren’t saved as stills first. When you open the Gallery Window and use the hierarchical disclosure controls of the Stills panel to open up and select a specific Project Library > User > Project > Timeline, you’ll see at least three browsable albums to the right: the Stills galleries that were created, the Memories, and at the bottom an album called Timeline Media. The Timeline Media album lets you browse the currently used grades for every clip in that timeline, making it easy to copy the ones you need to the current project’s Stills album or Memories.

This is particularly useful if you’re working on a series where and you find that you want to re-use different grades, looks, adjustments, or fixes from previous episodes in the current one. Previously, you’d have to remember to save every clip as a still to be able to browse the grades in this way. Now you can simply browse the clips in the Timeline directly.
Importing and Exporting Stills

It’s possible to import still images in different graphics formats into the Gallery, which can be particularly useful when a client provides reference images to which they’d like you to refer. It’s also possible to export stills from the Gallery, which is good for sending a series of reference stills for approval to a remote client. In both cases, you can choose whether to import or export images with an accompanying LUT.

For both import and export, DaVinci Resolve supports the following file formats: DPX, CIN, TIFF, JPEG, PNG, PPM, BMP, and XPM.

**To import one or more still images:**
1. Right-click anywhere on the gray background of the Gallery.
2. Choose one of the following commands:
   - **Import**: Imports image files, along with a matching DRX file, if one is present in the selected directory.
   - **Import With Output LUT**: Imports an image and DRX file, along with a matching LUT file, if one is present in the selected directory.
3. When the Import Stills dialog appears, choose the type of files you want to import from the “Files of type” drop-down menu, then navigate to the files you want to import, select them, and click Import.

**To export one or more still images:**
1. If you want to export Gallery stills with labels that have been added to them, right-click anywhere in the background of the Gallery and choose “Use labels on still export” in the contextual menu so it becomes checked.
2. Select one or more stills in the Gallery.
Right-click one of the selected stills, and choose one of the following commands:

— **Export:** Two files are saved for each still you selected. An image file in the format of your choice, and a DRX (DaVinci Resolve eXchange) file that contains the grading metadata that was saved with that Gallery still.

— **Export With Display LUT:** If you have a Video Monitor Lookup Table specified for the current project in the Color Management panel of the Project Settings, this command will output the image as it is processed by the specified LUT. A DRX file is also output containing the grading metadata that was saved with that Gallery still.

When the Export Stills dialog appears, choose a file format to export to from the “Files of type” drop-down menu, then choose a location, type a name into the Save As field, and click Save.

Each of the selected stills is exported with all accompanying files. Each file uses as its prefix the name you typed into the Export Stills dialog, followed by an underscore, the still ID number of the selected still, and the three-letter file extension.

### Using and Organizing Memories

Stills and memories contain identical information, and can be split screened, copied, appended, exported, and can display their node graph just like any other still. However, stills that are assigned as a memory make them easier to access via keyboard shortcuts, and from dedicated buttons on the DaVinci control panel.

Memories are hidden by default, but you can reveal them by clicking the Memories button, to the right of the Gallery list button at the top-left of the Gallery.

The Memories thumbnail display makes it easy to keep track of which stills have been assigned to which memories in situations where you’re using multiple memories to copy grades throughout a program.

**To copy stills and memories back and forth, do one of the following:**

— Drag a still onto a memory bank.

— Drag a memory into the Gallery.
**TIP:** In this way, memories can be used to copy stills from one album to another.

**To save the current clip’s grade to a memory for future use, do one of the following:**

— Choose Color > Memories > Save Memory A–H (Option-1 through 8).
— Using the DaVinci Resolve Advanced control panel, press CRNT on the Search Dial panel, then press the letter of the memory bank you want to save to. Use the SHIFT UP and SHIFT DOWN buttons to save to another memory sharing the same button.
— If you save a grade to a memory that already contains something, the previous memory is overwritten.

**To apply a memory to the current clip in a timeline, do one of the following:**

— Right-click a memory and choose Apply Grade.
— Choose Color > Memories > Load Memory A–H (Command-1–8).
— Using the DaVinci control panel, press the letter of the memory bank you want to apply. Use the SHIFT UP and SHIFT DOWN buttons to apply a memory that shares the same button.

**To clear a memory:**
— Right-click a memory, then choose Clear.
Chapter 138

Grade Management

The Color page offers numerous ways of saving grades, copying grades, creating and altering groups of clips to share grades, rippling grades and adjustments, and managing multiple versions of grades.

All of these procedures enable you to work faster by leveraging work you’ve already done to apply to other clips that can benefit from the same adjustments, or by applying changes across multiple clips all at once.

Using Versions to Manage Grades

Working quickly requires a mastery of the numerous grade management features built into DaVinci Resolve. These features are designed to help you copy and ripple grades to individual clips, among manually defined groups of clips via the Node Editor’s Clip mode, or among automatically linked clips that share the same source clip in the Media Pool (when using Remote versions). Multiple versions of grades are supported for every clip, as are various options for previewing, overwriting, and appending these versions.

Choosing to Copy Grades Manually or Automatically Using Versions

Each grade you apply to a clip is a version. Each clip can have multiple versions, although only one version can be applied at a time. By default, the first grade applied to every clip in a timeline is a local version named “Version 1.” A clip’s version name and/or number appears underneath the clip thumbnail, to the right. You can also see the version name, along with a list of all the other versions that are currently available to that clip, by right-clicking a clip in the Timeline and looking for the version names that appear underneath the Local Versions submenu.

There are two different types of versions in DaVinci Resolve, each of which provides a different method of grade management and linking among the clips and timelines of a project.

— **Local versions:** The default mode of grade management. Clips using local versions are unlinked, so each clip has its own grade which is not shared with any other clips in any other timelines. Changing the grade of a clip using a local version has no effect on any other clip in that project.

— **Remote versions:** An alternate mode of grade management that you can enable. All clips using remote versions that share the same source clip in the Media Pool are automatically linked, in all timelines, and share the same set of grades.

If you use local versions to grade all your clips, you don’t have to worry about one clip’s grade being accidentally copied to other clips that happen to come from the same file in the Media Pool, which can make it easier to work. On the other hand, you need to manually copy every grade that you want to duplicate, even among clips that clearly come from the same take or angle. You can always create a group to share a grade among clips using local versions, but that’s an extra step.
Switching to use remote versions, instead, puts you into a mode where clips using remote versions that share the same media file are automatically linked together. This gives you a convenient shortcut for grading your program, since a grade that’s applied to one linked clip is automatically copied to every other clip it’s linked to, which can be convenient when grading a series of headshots appearing throughout a program that come from the same interview take. Another use of remote versions is when you’re importing a new edit of an already graded timeline. Using remote versions, you can set your project up so that new incoming timelines are automatically relinked to the previous timeline’s grades.

The only disadvantage to using remote versions is that when you find you need to make individual adjustments to clips that are linked, it’s an extra step to either create another version, or switch that clip to use a local version, in order to keep its adjustment separate. This will be discussed in more detail later in this chapter.

**Mixing Versions**

Each clip is capable of having multiple local and remote versions at the same time; you get to choose which to apply. Which type of versioning is best depends on the type of project you’re working on, the way in which the media was shot, and how you like to work. The following sections explain the differences in workflow.

**Using Local Versions by Default**

Since local versions are the default method of grading when you first create a new project (unless you’ve edited your settings presets), you don’t need to do anything to enable this mode at first. As the name implies, local versions are local to the Timeline in which they appear, so local versions are not rippled to linked clips, and they’re not shared among different timelines. This makes it easy to avoid accidentally having grades copied when you don’t want them to be, but you lose the conveniences that automatic linking can provide.

However, you can always switch the clips in a timeline to use remote versions if you change your mind, either individually, or all together.

**Using Remote Versions to Enable Automatic Linking**

Remote versions let all clips from the same source media file in the Media Pool share their grades automatically, either within a single timeline, or across multiple timelines in the same project. However, to enable the convenience of remote grades, you need to put DaVinci Resolve into this mode of working using the Settings window.

**To enable remote grades to be used:**

— Open the Project Settings, open the General Options panel, and turn off “Use local version for new clips in timeline” in the Color section.

Turning this option off only affects clips that are added to Timelines from that point onward. You can keep track of which clips use remote versions by the (R) that appears when you double-click the area underneath the thumbnail to hide the codec name in the Thumbnail timeline.
How Automatic Linking Works

When clips using remote versions have been added to a timeline, any other clips in any timeline that (a) use remote versions also, and (b) refer to the same file in the Media Pool are linked. Selecting a clip using a remote grade in the Color page that is automatically linked to one or more clips displays a small “linked” badge at the right of that clip’s timecode in the Thumbnail timeline.

TIP: The Timeline Filtering drop-down in the Color Page toolbar has an option named “Common Media Pool Clips” that only shows clips in the Timeline that are linked to the currently selected clip.

Adjustments that you apply to a remote version of one linked clip are automatically rippled to every other clip it’s linked to, which can save you an enormous amount of time when you’re getting started with a new program. For example, if every reverse angle from the same take in a particular angle of coverage is automatically linked using remote versions, then the grade you apply to one reverse angle clip will ripple to every other reverse angle clip throughout the Timeline.
So long as remote versions are enabled, there are other ways that linked clip relationships are formed. If, after conforming an AAF, XML, or EDL, you used the Split Clips button in the Color page to split one conformed clip into many, each of the clips you split would be linked, since they too would share the same source media in the Media Pool.

Finally, automated linking also occurs for clips that appear in multiple timelines that also use remote versions. As a result, the grade you apply to one linked clip is automatically rippled to every other clip it’s linked to.

**NOTE:** Media management or media consolidation operations that split large source media files into many individual media files will defeat automatic linking within the same timeline, since each clip will be conformed to its own individual media file.

**Starting with Remote Versions, Then Switching to Local Versions**

It’s possible to combine the best aspects of remote and local versions into a single workflow, taking advantage of your ability to freely switch from one to the other. Since remote versions make it easy to copy grades among clips that are similar, you can switch to using remote versions first, and then grade your way through the Timeline until you get to the point where you need to start making much more specific changes to individual clips. Then, it’s easy to either switch each linked clip that needs individual adjustment to use a local version, or to use the Copy Remote Grades To Local command (described later) to copy the current remote version of each and every clip to a local version, at which point you can make all the specific tweaks you need to without worrying about changes being accidentally copied.

**Creating a Master Timeline**

DaVinci Resolve version 9 and earlier would automatically create a Master Timeline whenever you added clips to the Media Pool. This changed in versions 10 and later, which by default have no Master Timeline. However, if you want to create a Master Timeline in order to use it as you would have before, this is easy to do.
If you want a Master Timeline to have a single timeline that always contains all clips currently in the Media Pool, there’s a way you can create one. However, you need to do it immediately upon creating a new project, before adding any media to the Media Pool. Once you’ve added one or more clips to the Media Pool, the option you need to do so will be disabled.

**To create a new Master Timeline:**

1. Create a new project, open the General Options panel of the Project Settings, and turn on the “Automatically match master timeline with media pool” checkbox in the Color section. If you also want all clips to use Remote versions as you grade by default as in previous versions of DaVinci Resolve, you can turn off the “Store grade with local version by default” checkbox.

2. Click Save.

4. When the New Timeline Properties window appears, turn the Empty Timeline checkbox off, and click Create New Timeline.

   Now, in addition to the new Timeline, a Master Timeline appears in the Timeline list.

Once created, the Master Timeline contains every clip in the Media Pool of the current project. If you color correct the clips in the Master Timeline, you’ll find there’s only one set of versions available, found underneath the Local submenu of the Color Page timeline’s contextual menu. It’s important to understand that local versions within the Master Timeline are in fact the remote versions found in every other timeline of that project.

In fact, it would be fair to say that the remote versions found in other timelines are actually the Master Timeline’s versions. When you grade a clip in the Master Timeline, those grades ripple out to every other instance of that clip, in every other timeline within that project, via remote versions.

Sharing of remote versions among the Master Timeline and newly conformed timelines is why you can grade a collection of clips that you import into DaVinci Resolve without any editorial structure, grade and output offline media, and then reimport a project file that relinks to the original clips along with their grades. It’s also why you can grade clips in one timeline, and then import additional re-edited timelines via AAF, XML, or EDL, which automatically inherit all remote versions of grades that were created in previous timelines.

**Differentiating Clips with Individual Versions**

If you’ve enabled DaVinci Resolve to add clips with remote versions, there are times when you may want to suspend automatic linking. As convenient as automatic grade rippling among linked remote versions is, there are many instances where you may need to stop it. For example, if the Media Pool contains a source media file with the entire content of an interview, then every clip that has been conformed to that source media will be linked, which is ordinarily good since you’d expect they’d all share the same grade. However, if the DP fiddled with the exposure of the camera in the middle of the interview, such that some clips are lighter and others are darker, you may find yourself needing to make different adjustments to clips from different parts of the interview.

One way of doing this, which can be useful in timelines where you only need to make a few of these kinds of changes, is to create a new remote version for every clip to which you need to make an individual adjustment. Since each version is its own grade, and differently named versions don’t link to one another, this is a simple solution.
To suspend linking by creating a new remote version:

1. Move the playhead to the clip you need to alter individually.
2. Do one of the following:
   — Choose Color > Grade Version > Add (Command-Y).
   — Right-click the thumbnail in the Timeline, and choose Remote Versions > Create New Version.
   — Using the DaVinci control panel, press ADD VERSION on the T-bar panel.
3. Grade the new version that's appeared.

While this method works well, keep in mind that multiple linked clips using the same version number will always be linked with one another. In other words, suppose Clip 1, Clip 3, and Clip 5 are linked using the default Version 1, which has a strong blue grade applied.

Three clips automatically linked, sharing a blue grade

Then, you set Clip 3 to use Version 2 with a different grade, tinted red. Clip 3 is now unlinked from Clips 1 and 5.

Setting the second of the three clips to use another version with a different remote grade sets it apart

However, switching Clip 5 to also use the red-tinted Version 2 means that Clip 3 and Clip 5 are now linked together, but Clip 1 is no longer linked.

Setting the third of these clips to share the same remote version as the second clip now links those two together, omitting the first clip

Every new remote version you create, and every change you make, becomes available to all other clips in all other timelines that comes from the same source Media Pool clip as the shot you’re working on. However, any clip can use any version, and which version is used by a linked clip is not rippled.
For example, Timeline 1 contains a clip named Max CU, which has three remote versions. Timeline 5 also contains Max CU, which is currently set to use Version 2. If you open Timeline 1 and add one more remote version to Max CU, that new version will also be available to Max CU in Timeline 5, but it will still be set to use Version 2.

**Switching Clips Between Local and Remote Versions**

You can also suspend remote version grade linking by switching individual clips to use local versions. This makes it easy to create a situation where some clips are linked, and other clips are not. Keep in mind that each clip has both local and remote versions, so you can switch from one to the other without losing anything.

**To suspend linking by setting individual clips to use a local version:**

— Right-click a clip thumbnail, choose the submenu of the corresponding remote version you want to copy, and choose Copy to Local. The remote version is copied to a local version, which now appears as the current version that’s used.

You can also set every clip in the entire timeline to use local versions. If you switch an entire timeline to local versions, then no clip in that timeline will be linked to any other unless you create a group (covered later in this chapter). This is the default state, but it’s useful even when you’ve switched to using remote versions when you want to grade one timeline differently from the others in a project, for example when doing a trim pass for another video or stereo 3D format, or when grading another cut, such as a trailer, that uses the same media but requires a different look.

**To suspend linking by switching from remote versions to local versions:**

— Right-click any clip thumbnail, and choose one of the following commands;

— **Use Local Grades:** Switches all clips to their local versions. If there are already local versions defined for each clip, those will appear. If there are no local versions yet defined, each clip will be ungraded.

— **Copy Remote Grades to Local:** Copies the currently assigned remote version of each clip to a local version.

Because Undo is used only for individual clip operations, the Use Local Grades and Copy Remote Grades To Local commands cannot be undone. However, switching a timeline from remote to local versions is not a one-way trip. You can select Use Remote Grades to switch every clip in a timeline back to the remote versions at any time.

**To switch a timeline back to using remote versions:**

— Right-click any clip thumbnail, and choose Use Remote Grades.

Furthermore, you can also copy the local grades you made to be remote grades, for instances where you started grading with local grades, and you want to switch to remote grading using your local grades as a starting point. Be aware that when you do this in a timeline with many clips that share the same source media, the grade of the very last shared clip in the Timeline will be the only remote grade that’s used for those auto-linked clips.
To copy each clip’s local grade to a remote grade for every clip in the current timeline:

— Right-click any clip thumbnail, and choose Copy Local Grades to Remote.
  
  If you’re switching back and forth between local and remote versions, keep the following rules in mind:

— If you select Use Remote Grades, change your remote grades, and then Copy Remote Grades To Local on that timeline again, you’ll overwrite all of your previously graded local versions. This is a good workflow if you don’t like what you’ve done with your local versions, and you want to start over by recopying the remote versions.

— If you select Use Remote Grades, change your remote grades, and then select Use Local Grades, you’ll return to your previously graded local versions, as they were before you selected Use Remote Grades. This is a good workflow if you just want to switch back to your remote versions in order to copy the remote versions of specific clips to local versions.

Working with Versions

Each clip can have as many local and remote versions as you like. There are commands for creating, renaming, and deleting the versions that are available to each clip when using the pointer, keyboard shortcuts, or the DaVinci control panel. When using the DaVinci control panel, the buttons affect whichever type of version (remote or local) is currently applied to the current clip.

Additionally, DaVinci Resolve 15 introduced the ability to batch create, rename, load, and delete versions for multiple clips that are selected at the same time.

To create a new local or remote version quickly for one or more selected clips, do one of the following:

— Choose Color > Grade Version > Add (Command-Y).

— Using the DaVinci control panel, press ADD VERSION on the T-bar panel.

A new version is created, identical to the type of version that was previously selected (remote or local), named “Version x” where x is the number of the versions that have been created. All keyframes and motion tracking are copied from the previously selected version to the new one.

To create a new version for one or more selected clips, with the option to set a name and whether to copy keyframes:

1 Right-click one of the selected clip thumbnails, and choose one of the following:

   — Local Versions > Create New Version
   — Remote Versions > Create New Version

2 Type a name for the version in the dialog that appears, and choose either “Copy all marks” or “Copy the first mark only,” depending on whether or not you want to copy all the keyframes into the new version.

NOTE: Motion tracking will be copied regardless of whether “Copy all marks” is selected or not.
Optionally, you can choose one of the preset version names from the drop-down list. These names are defined in the Versions section of the General Options panel of the Project Settings.

Click OK.

To delete a specific version for one or more selected clips:
— Right-click one of the selected clip thumbnails, choose the submenu of the remote version you want to delete (it can’t be the currently selected version), and choose Delete.

To delete all versions for one or more selected clips:
— Right-click one of the selected clip thumbnails, and choose one of the following commands from the contextual menu corresponding to the scope of the versions you want to delete;
  — Local Versions > Delete All Versions
  — Remote Versions > Delete All Versions
  — Delete All Versions

All versions are deleted as specified, except for the currently selected version, which is now the only one remaining.

To load a particular remote or local version for one or more selected clips, do one of the following:
— Right-click one of the selected clip thumbnails, choose the submenu of the corresponding remote version you want to copy, and choose Load.

To rename the version of one or more selected clips:
1 Right-click one of the selected clip thumbnails, choose the submenu of the corresponding remote version you want to rename, and choose Rename.
2 In the Version Name dialog, type a name into the text field. Optionally, you can choose one of the preset version names from the drop-down list. These names are defined in the Versions section of the General Options panel of the Project Settings.

Selecting a Version name from the dropdown list, the names on the list come from assignments made using the Versions section of the General Options panel of the Project Settings

Click OK.
That name now appears underneath the clip thumbnail in the Timeline.

If you’re going to use predefined names for versions, you need to define these in the Versions group of the General Options panel of the Project Settings. Ten drop-down menus let you choose from preset version names, or enter your own. These names will appear in the drop-down menu of the Version Name dialog.

The Versions section of the Project Settings

The Importance of “Version 1”

There are specific operations in DaVinci Resolve where “Version 1,” otherwise known as “the default version,” is the only version that’s used, regardless of how many other versions are available, or which version was previously selected. The default version can be named anything you want, but whatever its name, the default version is the first version in the list, and it’s important. Here are some examples:

— Importing additional timelines that use the same clips: In this case, if you’re importing timelines and “Use local version for new clips in timeline” is disabled in the Color section of the General Options panel of the Project Settings, then only the default version of each clip is relinked.

— Whenever you switch a timeline between local and remote versions: In this case, every clip in the Timeline will be switched to the default version, regardless of what you had selected previously.

Consequently, if you plan to reconform your clips to a newer version of the edit that you’re importing, or pursue other workflows that are off the beaten path, it’s a good idea to make sure, no matter how many versions you end up creating, that the most important grade is always copied back to the default version.

To copy any version quickly to the default version:

1. Choose Color > Memories > Save Memory A (Option-1). You can use any memory you want, but Memory A is convenient for this example.
2. Choose Color > Grade Version > Default (Command-U).
3. Choose Color > Memories > Load Memory A (Command-1) to apply the saved memory to the default.
To copy any version quickly to the default version using the DaVinci control panel:

1. Press CRNT and then press A (or any memory button you like). These controls are available on either the Transport or T-bar panel.
2. Press DEFAULT VERSION on the T-bar panel.
3. Press A (or whichever Memory button you used) to apply the saved memory.

To jump immediately to the default version, do one of the following:

— Choose Color > Grade Version > Default (Command-U).
— Press DEFAULT VERSION on the T-bar panel.

Deleting Unused Versions

In cases where you want to make absolutely sure there’s no alternative to the grade you want a clip to have, there’s an easy way to delete all versions except for the version that’s currently in use, thereby making it the default version.

To eliminate either local or remote versions except for the current version:

1. Choose the local or remote version you want a clip to use.
2. Right-click the thumbnail of the clip you want to eliminate extra versions from, and choose Delete Unused Versions from the contextual menu.
   
   If you selected a local version, all unused local versions will be deleted, but remote versions will be left alone. Similarly, if you selected a remote version, all unused remote versions will be deleted, but local versions will be left alone.

To eliminate all other local and remote versions except for the current version:

1. Choose the version you want a clip to use.
2. Right-click the thumbnail of the clip you want to eliminate extra versions from, and choose Delete All Versions from the contextual menu.
   
   Regardless of whether you selected a local or remote version, all other local and remote versions not in use will be deleted.

Rendering Versions

When the time comes to render your clips in the Deliver page, each clip’s currently selected version will be rendered. If you need to render a different version for a given clip, you can either make sure it’s selected in the Color Page timeline before you open the Deliver page, or use the Versions submenu in the Color mode of the Deliver page Thumbnail timeline. This contextual menu also provides access to the Stereo 3D commands, the Edit PAR (Pixel Aspect Ratio) command, and a command for updating the Render Window Timeline thumbnails to reflect any changes you’ve made in case they haven’t updated automatically.

Additionally, the Commercial Workflow output option, located in the Deliver page, provides a method of rendering multiple versions for each clip when outputting your project in Source Order (as individual media files). There are two additional options in the Version submenus of each clip in the Thumbnail timeline contextual menu that let you control which versions are rendered when you use Commercial Workflow.
— **Render Disabled:** Turning this option on excludes that version from being rendered when Commercial Workflow is enabled.
— **Enable Flat Pass:** Turning this option on forces the selected version to render with the grade turned off, essentially outputting the original media.

For more information on rendering versions using the Commercial Workflow option, see Chapter 186, “Rendering Media.”

## Copying Grades

There are various methods you can use to copy grades from one clip to another. Which is appropriate to your need depends on your style of working with DaVinci Resolve.

### Protecting Adjustments with the Copy Grade Options

Before going into the myriad of ways that grades can be copied from one clip to another, you should know of a series of options, available from the contextual menu of the Gallery (right-click anywhere in the gray area of the Gallery), that let you carefully specify grading, sizing, and stereo data to be preserved when overwriting grades in clips you’re copying to. There are three options:

— **Copy Grade: Preserve number of nodes:** Lets you choose 0–10 nodes to be protected when applying a grade. When set to 1, the first node of the copied grade is ignored, but all other nodes are copied. When set to 5, the first five nodes of a copied grade are ignored, as long as there are at least five nodes in the grade of the clip you’re copying to. This option is useful for colorists who routinely use the first few nodes for shot matching and scene balancing, with additional nodes applying individual or stylistic adjustments.

— **Copy Grade: Preserve Camera Raw Settings:** When enabled, the camera raw Source settings of the current clip are preserved, letting you apply stylistic grades from unrelated clips without overwriting clip-specific source settings.

— **Copy Grade: Preserve Input Sizing:** When enabled, Input Sizing adjustments are not overwritten by those of the copied grade.

— **Copy Grade: Preserve Convergence:** When enabled, Convergence adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.

— **Copy Grade: Preserve Floating Windows:** When enabled, Floating Windows adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.

— **Copy Grade: Preserve Auto Align:** When enabled, Auto Alignment adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.

— **Copy Grade: Preserve Dolby Vision™ Analysis Metadata:** When enabled, Dolby Vision Analysis Metadata is not overwritten by that of the copied grade. Only available if you’re set up to do Dolby Vision grading. For more information, see Chapter 9, “Data Levels, Color Management, and ACES.”

— **Copy Grade: Preserve Dolby Vision™ Trim Metadata:** When enabled, Dolby Vision Trim Metadata in the Dolby Vision palette is not overwritten by that of the copied grade. Only available if you’re set up to do Dolby Vision grading. For more information, see Chapter 9, “Data Levels, Color Management, and ACES.”
Copy and Paste From One Clip to Another

The simplest way to copy color adjustments from one clip and apply them to another clip is to use the same Edit > Copy and Paste commands shared with nearly every other application ever made. However, you can use this straightforward functionality in one of two ways, depending on the focus of the interface.

— If you click on the clip in the Thumbnail Timeline, you copy and paste the entire grade from one clip to another.
— If you click inside the Node Editor, you copy and paste only the selected node to another selected node.

You can override this focus-based selection, and make the default behavior to only copy between nodes rather than entire grades regardless of the interface focus. Do this by checking the “Always perform copy and paste on selected nodes” box in the Color section of the User panel in Preferences.

Methods of copying and pasting grades and node adjustments.

— **To copy and paste an entire grade:** Choose a clip with a grade you want to copy, and press Command-C. Then select the clip you want to copy the grade to in the Thumbnail Timeline, and choose Command-V to paste the entire grade.

— **To copy and paste a single node:** Choose a clip with a node you want to copy, and press Command-C. Then select the clip you want to copy the node to in the Thumbnail Timeline, and then click anywhere inside the Node Editor. Then choose Command-V to paste the node that was selected when you copied to the currently selected node in the node tree.

Copy and Paste Specific Parameters Using Paste Value

The Edit > Paste Value (Shift-Option-V) command lets you paste only the value of a specific parameter into the node of another clip.

**To paste only a specific value:**

1. Select a Corrector node with a parameter you want to copy, and press Command-C to copy it. You’re really copying the entire grade, but that’s okay.
2. Choose any other node in any grade, and open the palette that contains the parameter you want to paste into.
3. Double-click the number field of the specific parameter you want to paste the copied value into.
4. Choose Edit > Paste Value (Shift-Option-V) to paste that value.

**NOTE:** Paste Value only works for parameters within palettes; it does not work for OFX or Resolve FX in the Inspector.
Applying Saved Grades From the Gallery

Every time you save a still into the Gallery or a memory, it contains both the Clip grade, and the Timeline grade, if one is applied. Which grade is applied from a still using the Apply Grade or Append Node Graph commands depends on which mode the Node Editor is in. This is selectable from the drop-down menu in the upper right-hand corner of the Node Editor.

![Node Editor Clip and Track selector](Image)

If you’re in Clip mode, you’ll only copy the saved clip grade. If you’re in Timeline mode, you’ll only copy the saved timeline grade.

**NOTE:** This mechanism also works for saving and applying grades for clips that are in Groups. The currently selected group grade in the Node Editor determines which grade is saved with a still, and the currently selected mode in the Node Editor determines where a saved grade will be applied.

Preparing to Copy or Apply Grades

For all other methods of copying or applying grades described in this chapter, there are some common methods of controlling how adjustments from the clip or still you’re copying from are applied to the clip you’re pasting or applying to.

**Choosing Which Aspect of a Grade to Apply with All/Color/Sizing**

When applying grades using any of the techniques described in this section, you can use the All/Color/Sizing setting that are available via the Mark > Keyframe Timeline Mode submenu, the drop-down menu that’s visible at the upper-right of the Keyframes Editor, or your DaVinci control panel. When copying a grade in conjunction with the settings in this menu, the following rules apply:

- **All**: When All is selected, both the grade and the sizing are copied.
- **Color**: Only the grade is copied, the target clip retains its original Input Sizing settings.
- **Sizing**: Only the Input Sizing is copied, the target clip retains its original grade.

**Choosing How to Copy Keyframes**

When copying or applying grades that have keyframes, you can choose how these keyframes are copied via a setting in the Gallery contextual menu by right-clicking anywhere in the gray background area of the Gallery, and choosing one of these options from the Apply Grades Using submenu. There are three options:

- **No Keyframes**: No keyframes are copied. The state of the grade at the frame used to save the still is what is applied to the target clip or clips.
— **Keyframes Aligning Source Timecode**: Keyframes are copied aligning the source timecode of the saved grade with the source timecode of the target clip. This is the ideal setting when you’re copying a grade back to the clip it came from originally, or to a duplicate of that clip elsewhere in the Timeline, and you want the keyframes to align with the same frames as before. If there is no source timecode overlap, keyframes will be pasted aligning with the start frame of the edit, the same as the third option (below).

— **Keyframes Aligning Start Frame**: Keyframes are copied aligning the start frame of the clip that still was saved from with the start frame of the target clip. This is the ideal setting when you’re copying a grade with keyframes from one clip to a completely different clip, with different timecode.

From that point on, keyframes, should they exist, will be copied or applied using the selected method whenever you copy a grade using any of the previously described methods.

**Copying Grades Using the Pointer**

An incredibly easy way of copying a grade from one clip to another, or from a still or memory in the Gallery to a clip, is by using the third button of your mouse, usually mapped as the “middle-click” of the mouse scroll wheel.

**To copy a grade from a clip or still to one or more clips using the pointer:**

1. Select the clip thumbnail you want to copy the grade to in the Timeline; a single selected clip appears highlighted orange. If you want to copy a grade to several clips, you can either Command-click multiple non-adjacent clips, or Shift-click a continuous range of clips; multiple selected clips appear highlighted red.
2. Middle-click the clip thumbnail, Gallery still, or memory you want to copy the grade from.

The grade of the clip you middle-clicked is copied to the previously selected clip or clips.

**TIP:** If you’re using a trackpad, third-party software may allow you to define a “three-finger-click” that works the same as mouse button 3. If you’re a pen and tablet or trackball user, you may be able to define a stylus or other button to perform the same button-3 action.

If you don’t have access to a middle-click on the pointing device you’re using, there’s another way of doing this using a contextual menu command.

**To copy a grade from a clip or still to one or more clips using the Apply Grade command:**

1. Select the clip thumbnail you want to copy the grade to in the Timeline; a single selected clip appears highlighted orange. If you want to copy a grade to several clips, you can either Command-click multiple non-adjacent clips, or Shift-click a continuous range of clips; multiple selected clips appear highlighted red.
2. Right-click the clip thumbnail, Gallery still, or memory you want to copy the grade from, and choose Apply Grade from the contextual menu.

The grade of the clip you middle-clicked is copied to the previously selected clip or clips.
Copy Forward Commands

Another simple way of copying grades is to use the equals (=) and minus (–) keys on the keyboard to copy grades forward from one or two clips behind the currently selected clip. This is a great way to copy grades in scenes with a shot-reverse-shot structure, where you’re cutting between two angles of coverage, each of which uses the same grade.

To copy grades forward:

— To copy a grade from one clip back: Choose Color > Apply Grade From One Clip Prior, or press Equals (=).
— To copy a grade from two clips back: Choose Color > Apply Grade From Two Clips Prior, or press Minus (–).

Copying Using Memories

Memories are virtually identical to stills, except that they’re labeled with a letter (A–Z) for easy access via keyboard shortcuts or DaVinci control panel buttons. A memory bank above the Gallery browser provides a visual reference of which saved grade is assigned to which letter. This makes it easy to keep track of multiple saved memories in instances where you’re copying them to several different clips throughout a scene or program.

For example, you might save a memory for each angle of coverage in a complicated scene, making it easy to copy grades forward. In another example, you might save a memory for the grade applied to each interview subject’s headshot in a documentary, so you can copy that grade forward as you work through the documentary.

To save the current clip’s grade to a memory for future use, do one of the following:

— Choose Color > Memories > Save Memory A–H (Option-1–8).

If you save a grade to a memory that already contains something, the previous memory is overwritten.

To apply a memory to one or more clips in a timeline, do one of the following:

1. Choose one or more clips in the Thumbnail timeline to copy to. This can be the current clip, or it can be a range of clips that you select by Command-Clicking or Shift-Clicking.

2. Do one of the following to copy a grade to the selected clips:
   — Right-click a memory and choose Apply Grade.
   — Choose Color > Memories > Load Memory A–H (Command-1–8).

To clear a memory:

— Right-click a memory, then choose Clear.

Copying Using Preview Memory

You can also preview the effect of a memory or saved grade on the current clip, with the option to either keep it if it works, or go back to the previous grade if it doesn’t.
To Preview Memory:

1. Move the playhead to a clip for which you want to preview a memory.
2. Choose Color > Preview Memory (Option-Shift-P).
3. Do one of the following:
   - Right-click any saved still in the Gallery and choose Apply Grade.
   - Choose Memories > Load > Memory A–H (Command-1–8).
The selected grade or memory is now being previewed.
4. Now, do one of the following to either accept or reject the memory:
   - If you like the effect, then you can leave it be and move on to another clip.
   - If you don’t like the effect, then choosing Color > Preview Memory (Option-Shift-P) again reverts the clip to the original grade.

Copying from Stills in the Gallery

As mentioned previously, each still you store in the Gallery contains the grading information as well as the image of the frame it was saved from. This saved grade can be applied to any clip in the Timeline.

**IMPORTANT**

Copied grades overwrite any previously existing grades on the clip or clips you copy to.

To apply a grade from a still to one or more selected clips in a timeline:

1. Choose one or more clips in the Thumbnail timeline to copy to. This can be the current clip, or it can be a range of clips that you select by Command-clicking or Shift-clicking.
2. Do one of the following to copy a grade to the selected clips:
   - Drag the still from the Gallery into the Viewer.
   - Right-click a still in the Gallery and choose Apply Grade.
   - Middle-click a still in the Gallery.
   - Double-click a still to wipe it in the Viewer against the current clip in the Timeline, then right-click the Viewer and choose one of the options from the Apply Grade submenu.

Append Node Graph

You can also append a saved grade to any clip in a timeline. This adds the entire node graph of the saved still to the end of the node tree of the current clip. In other words, the current clip’s grade isn’t overwritten, the applied grade is added to the end of it.

By planning ahead, you can save fragmentary grades that create specific effects or adjustments using only a few nodes. You can then use these fragmentary grades as a toolkit that you can add to other grades in order to mix and match different adjustments and effects.

For example, you could create a three-node glow effect, save it, and then apply that effect at the end of a completely different clip’s grade.
Appending grades places them after the original nodes

To append a saved grade or memory as individual nodes, do one of the following:

— Drag a still or memory from the Gallery onto a connection line in the Node Editor; when the plus icon appears, drop it and its nodes will be appended within the node tree starting at that connection.
— Right-click a still or memory in the Gallery, and choose Append Node Graph.

Ordinarily, when you append the node graph from a memory or still to another node graph, you end up adding a whole shedload of new nodes. This may be exactly what you need, but in situations where you want to keep things a bit tidier, you also have the option of appending node graphs as compound nodes.

To append a saved grade or memory as a compound node:

— Command-drag a still or memory from the Gallery onto a connection line in the Node Editor; when the plus icon appears, drop it and its nodes will be appended to the node tree as a single compound node.

**NOTE:** When you append the nodes from a gallery still to a grade, how keyframes are applied depends on the “Apply Grades Using” setting of the Gallery. For more information, see Chapter 137, “Using the Gallery.”

Aligning Keyframes to a Specific Frame While Copying Grades

If you need to copy a grade with keyframes so that the start keyframe of the copied grade aligns with a specific frame of the Timeline, you can do so using the following procedure:

![Diagram showing node connections and keyframes]

1. Select the grade with keyframes that you want to copy.
2. Right-click the grade and choose “Copy Grade” to copy it to the clipboard.
3. Move to the frame where you want the start keyframe of the copied grade to align.
4. Right-click in the Timeline and choose “Paste Grade.”
5. Adjust the timing of the grade by dragging its keyframes as necessary.

This procedure allows you to precisely align the start of a grade with a specific frame in the Timeline, ensuring smooth transitions and visual consistency in your video.
To copy a grade and align its keyframes to a specific frame of the Timeline:

1. Save a grade with keyframes as a Gallery still by right-clicking the Viewer and choosing Grab Still.
2. Choose the clip you want to copy the saved grade to in the Thumbnail timeline.
3. Double-click the Gallery still to wipe it against the current clip in the Viewer.
4. Move the playhead to the frame of this clip you want the first keyframe of the saved grade to be aligned with.
5. Right-click the Viewer and choose Apply Grade > Align Keyframes to Current Frame.

Copying Individual Nodes and Settings

Copying grades from clip to clip copies everything except for keyframes and motion tracking. However, there is one way you can copy the motion tracking from one clip to another, and that’s by copying and pasting individual node settings. This can save time when you’re assembling complicated node trees by recycling specific nodes or node settings from previous grades.

Copying and Pasting All Settings From One Node to Another

The simplest thing you can do is to copy all of a node’s settings, and paste them into another node. This makes it easy to duplicate things like windows, qualifier settings, keyframing, or motion tracking that you want to reuse in another node as the basis for another operation. This is also a quick way to manually ripple a change you make in a node to that same node in another clip’s grade.

To copy a node’s settings from one clip to another, do one of the following:

— Option-drag one node onto another. When you drop it, the settings of the node you dragged overwrite those of the node you dropped onto.

— Select a node with settings you want to copy and choose Edit > Copy (Command-C). Then, select a node you want to paste these settings to either in the current grade or in the grade of another clip, or create a new node, and choose Edit > Paste (Command-V) to paste the settings you copied. These pasted node settings overwrite any other settings that node previously used.

Paste Attributes on the Color Page

You can copy the settings of one node and paste a subset of those settings to another selected node by choosing Edit > Paste Attributes (Option-V). A Paste Attributes window appears that shows you which node you’re copying from, and which node you’re pasting to, and provides controls for choosing whether you want to paste keyframes and how to align them (Start Frames or Source Timecode), as well as a series of checkboxes for choosing which palettes, windows, and OFX/ResolveFX you want to apply. You can only paste all parameters from a specified palette; there’s no current provision for pasting specific parameters from within a given palette, with the exception of pasting specific windows and their accompanying trackers.
Copying from the Node Graph of Other Clips or Gallery Stills

When constructing new grades, you may sometimes find it convenient to copy existing nodes or node settings from the grade of another clip or gallery still. This can be easily accomplished by exposing the node tree of any still that’s saved in the Gallery, or any clip in the Thumbnail timeline, and using the controls found in the floating node graph to copy individual nodes or node adjustments to the current clip’s grade shown in the Node Editor.

Copying Clip Settings Using Display Node Graph

In Clip mode, the floating Node Graph window has four sets of controls you can use to choose how to copy nodes and adjustments:

— **Clip Node Graph**: By default, the Clip node graph is displayed at the left. You can drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node’s settings or onto a connection line to insert it as a new node.

— **Timeline Node Graph**: (Only available if there is a Timeline grade) You can switch to the Timeline grade, if there is one, by either clicking the second button in the Node Graph title bar, or by choosing Timeline from the drop-down menu at the upper right-hand corner of the floating Node Graph window.

— **Apply Color/PTZR/Source/All buttons**: With the Clip panel selected, four buttons let you selectively copy the entire grade, the sizing, the source settings, or all settings at once to the current clip.
Copying Node Settings Using Display Node Graph

In Node mode, the floating Node Graph window displays all of the available Color Attributes found within each node, instead of the Apply Color/PTZR/Source/All buttons:

— **Node Settings:** Use the checkboxes to choose which node adjustments get copied and which do not. After you’ve checked the settings you want to selectively copy, dragging a node from the floating node graph onto nodes in the Node Editor copies or appends the selected attributes into the target node, leaving all other attributes alone. For Windows and OpenFX, you have the option of also copying any motion tracking that’s available.

Ability to Open Compound Nodes in “Display Node Graph”

When you right-click a Gallery still or a thumbnail and choose Display Node Graph for a grade that uses compound nodes, you can right-click any compound node and choose “Show compound node,” or Command-double-click a compound node to open it and see its individual nodes.
How to Copy Nodes Using Display Node Graph

The following procedures describe how to open the floating node graph in different situations.

**To copy individual nodes or settings from any still in the Gallery:**

1. Click the thumbnail in the Timeline of the clip you want to copy nodes to. Its node graph will appear in the Node Editor.

2. Right-click a still in the Gallery you want to copy nodes from, and choose Display Node Graph. A floating Node Graph window appears displaying that still's node tree.

3. (Optional) While the Gallery Node Graph window is open, you can select any other still, and this window will update to show the currently selected still's node graph, ready for you to copy from.

4. In the floating Node Graph window, choose Clip if you want to copy overall clip attributes, or choose Node to copy individual node attributes.

5. Do one of the following to copy nodes or settings to the Node Editor.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node's settings. If you open the Node panel and choose specific attributes, only those attributes will be copied to the node you drag onto.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node. If you open the Node panel and choose specific attributes, only those attributes will be copied to the new node that's created.
   - In Clip mode, click Apply Color to copy the entire grade from the floating node graph to overwrite the current grade in the Node Editor.
   - In Clip mode, click Apply PTZR to copy the sizing from the floating node graph to overwrite that of the current clip.
   - In Clip mode, click Apply Source to copy the source settings from the floating node graph to overwrite those of the current clip.
   - In Clip mode, click Apply All to copy every setting from the floating node graph to the current clip.
— In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite the settings of that node that you selected.

— In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node with only the settings that you selected.

6. While the floating Node Graph window is open, you can also select any clip in the Thumbnail timeline to change the grade that’s displayed in the Node Editor, ready for you to copy to.

7. Click Close when you’re finished.

To copy individual nodes or settings from any clip in the Timeline:

1. Click the thumbnail in the Timeline of the clip you want to copy nodes to. Its node graph will appear in the Node Editor.

2. Right-click the thumbnail of another clip you want to copy nodes from, and choose Display Node Graph.

   NOTE: The Display Node Graph command only appears in the contextual menu of a clip in the Thumbnail timeline that is not currently selected.

3. (Optional) In the floating Node Graph window, choose Clip if you want to copy overall clip attributes, or choose Node to copy individual node attributes.

4. Do one of the following to copy nodes or settings to the Node Editor.
   — In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node’s settings. If you open the Node panel and choose specific attributes, only those attributes will be copied to the node you drag onto.
   
   — In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node. If you open the Node panel and choose specific attributes, only those attributes will be copied to the new node that’s created.

   — In Clip mode, click Apply Color to copy the entire grade from the floating node graph to overwrite the current grade in the Node Editor.

   — In Clip mode, click Apply PTZR to copy the sizing from the floating node graph to overwrite that of the current clip.

   — In Clip mode, click Apply Source to copy the source settings from the floating node graph to overwrite those of the current clip.

   — In Clip mode, click Apply All to copy every setting from the floating node graph to the current clip.

   — In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite the settings of that node that you selected.

   — In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node with only the settings that you selected.
(Optional) While the floating Node Graph window is open, you can also select any clip in the Thumbnail timeline to change the grade that’s displayed in the Node Editor, ready for you to copy to.

Click Close when you’re finished.

**Rippling Adjustments Among Multiple Clips**

If you’ve graded a sequence of clips and find yourself needing to make a quick change to several clips all at once, you can use the Color > Ripple Node Changes to Selected Clips/Current Group commands to quickly copy changes made to one clip to several others. However, these commands require that you follow certain rules in order to get the results you want.

Node rippling uses the number of each node to determine what changes should ripple to which nodes. In other words, changes made to Node 3 will ripple to Node 3 of every other selected clip, or to Node 3 of every other clip in the current group (depending on which command you use).

Rippling changes from one clip to several others requires that all clips share the same number of nodes, at least for the nodes you’re rippling. If you try to ripple a change to one or more clips that don’t have a node with the same number as the one you’re rippling, then no change will be rippled to those clips.

**To ripple a change in one node to several selected clips:**

1. Select the clip you want to use to make the change so that it’s the current clip, outlined in orange.
2. Now, Command-click or Shift-click to select the range of clips you want to ripple your change to, so that they’re all selected red.

You don’t have to select the clips you’re going to ripple your change to prior to making the change, but it may be easier to keep track of what you’re doing if you set everything up in advance. The clip you’re changing should be outlined in orange, and the clips you’re rippling the change to should be highlighted in red.

3. Select a node to modify. Ideally, every selected clip should have a node sharing the same number as the one you’re modifying. If some clips don’t, then those clips won’t inherit the change you’re going to be rippling.
4. Make whatever changes you need to, adjusting any of the palette controls in the Color page you need to, except for Camera Raw, Sizing, and Data Burn, which aren’t node-specific.
When you’re happy with the change you’ve made, choose Color > Ripple Node Changes to Selected Clips.

The change you’ve made should ripple to every other selected clip with a node of the same number, and in a few moments the thumbnails of those clips should update to show the change.

If you’ve created a group, it’s even easier to ripple node adjustments to the other clips in the group.

**To ripple a change in one node to the current group:**

1. Select the clip you want to use to make the change so that it’s the current clip, outlined in orange. It must be part of a group for this to work.
2. Select a node to modify. Ideally, every selected clip should have a node sharing the same number as the one you’re modifying. If some clips don’t, then those clips won’t inherit the change you’re going to be rippling.
3. Make whatever changes you need to, adjusting any of the palette controls in the Color page you need to, except for Camera Raw, Sizing, and Data Burn, which aren’t node-specific.
4. When you’re happy with the change you’ve made, choose Color > Ripple Node Changes to Current Group.

The change you’ve made should ripple to every other clip in the current group that has a node of the same number, and in a few moments the thumbnails of those clips should update to show the change.

---

**Appending a Node to Multiple Clips**

If you’ve made an adjustment to a node in one clip that you’d like to apply to several other clips, you can quickly do that using the Color > Append Node to Selected Clips command. You can do this as a prelude to using one of the Ripple Node Change commands, as it’s a quick way to make sure several previously ungraded clips have the same nodes, but you can also do this as a quick way to apply the same node change to several clips, regardless of whether they have matching node trees.

**To append a node to other selected clips:**

1. Select the clip you want to use to make the change so that it’s the current clip, outlined in orange.
2. Select the node you want to append to other clips.
3. Now, Command-click or Shift-click to select the range of clips you want to ripple your change to, so that they’re all selected red.
   The clip you’re copying from should be outlined in orange, and the clips you’re rippling the change to should be highlighted in red.
4. Choose Color > Append Node to Selected Clips.
   The selected node should be appended to the end of the node tree of each selected clip, and in a few moments the thumbnails of those clips should update to show the change.
Using Shared Nodes

Shared nodes are meant to be a way to extend the benefits of automatically rippled changes among different clips to colorists that prefer a flatter node structure than Group Grading allows. By turning individual Corrector nodes into Shared nodes, and copying these to multiple clips, you enable linked adjustments right from within the clip grade. This means that the clip grade can freely mix both clip-specific nodes and Shared nodes, all within the same node tree. This makes Shared nodes fast to use as there’s no need to create groups or switch to a group node tree (covered in the next section) to reap the benefits of linked adjustments among multiple clips.

What Are Shared Nodes Good For?

Shared nodes are similar to group grades, except that they don’t require grouping and can be added to any normal grade. Changes made to a Shared node are automatically rippled to all other instances of that node in the grades of other clips. Furthermore, you can add as many Shared nodes to a grade as you like, and you can arrange them in any order to control the order of the operations they apply. And, of course, you can intersperse them with ordinary Corrector nodes.

Shared nodes are extremely flexible. For example, you can use Shared nodes to:

- Add a Color Space Transform Resolve FX or a LUT to the beginning of every clip from a particular source
- Add a base correction to every talking head shot of a particular interviewee
- Add a shot matching adjustment to each clip from a particular angle of coverage within a scene
- Add a stylistic adjustment to every clip in a specific scene
- Make your base adjustments when grading with remote versions, so those adjustments remain linked when you copy your remote versions to local versions for fine tuning

In fact, you can mix and match Shared nodes among differently overlapping sets of clips to accomplish any or all of the above at once. For example, you can add one Shared node to make an adjustment to every clip from a particular camera, add a second Shared node to each of those clips that are in a particular scene, and then add a third Shared node to whichever of those clips happen to be a closeup of the lead actress, before adding one or two regular Corrector nodes that aren’t shared to make clip-specific tweaks.
Creating Shared Nodes

Creating a Shared node is easy, assuming you’ve created a node that has an adjustment you’d like to share among multiple clips.

To create a Shared node:

— Right-click any Corrector node and choose Save as Shared node.

Locking Shared Nodes

Once you turn a node into a Shared node, that node is automatically locked, preventing you from accidentally making adjustments to it that would affect all other grades using that same Shared node.

To toggle the locked status of a Shared node, do one of the following:

— Right-click any Shared node and choose Lock Node from the contextual menu.
— Open the Keyframe Editor, and click the Lock icon in the track header of that node’s keyframe track.

Copying Shared Nodes

Because Shared nodes are essentially Corrector nodes within clip grades, they’re easy to work with. Once you’ve created one or more Shared nodes, there are a variety of ways you can copy them to the grades of other clips in your program to take advantage of the linked adjustments they let you make.

Ways of copying Shared nodes among multiple clips:

— Add a Shared node to another clip’s grade using the Node Editor contextual menu: Once you save a node as a Shared node, it becomes available from the bottom of the Add Node submenu of the Node Editor contextual menu, making it easy to add any Shared node to any clip. If you customize the label of the Shared node, that custom label appears in the contextual menu, making it easier to find what you’re looking for.

— Add Shared nodes to a basic grade you’ll be copying to other clips: If you create one or more Shared nodes when you initially build a grade, copying that grade to other clips naturally copies the Shared nodes as well.

— Save a Shared node as a Gallery still and apply it to other clips: If you save a grade with a Shared node in it to the Gallery, then every time you copy that Gallery still to another clip, you copy its Shared node.

— Create a Shared node and append it to a selection of additional clips: If you’ve already graded several clips in a scene, you can add a Shared node to the end of one of the clips grades and make sure it’s selected, then select all of the other clips in the scene and choose Append Node to Selected Clips.
— **Use Shared nodes to preserve linked adjustments when copying remote grades to local grades:** If you use Shared nodes to make your base adjustments when you grade using Remote Versions to automatically copy those grades to other clips that come from the same source media, those adjustments will remain linked when you copy your remote versions to local versions for fine tuning.

You can also choose options in the Gallery that dictate what happens when you copy a grade that has shared nodes within it.

### Converting Shared Nodes Back to Corrector Nodes

Sometimes you need to stop a node from being shared. For example, if you want to copy a grade from another scene to use as the starting point for a new grade, chances are you don’t want any shared nodes to continue being shared as you customize that grade for the new scene. In this instance, you can convert the Shared node back to a regular Corrector node, make any adjustments you need to customize it for the new scene, and then turn that node into a brand new Shared node that’s specific to the new scene.

**To convert a Shared node back to a Corrector node:**

— Right-click any Shared node, and choose Convert to Corrector from the contextual menu.

### Deleting Shared Nodes

If you’ve created a Shared node that’s being used in multiple clips, and you decide you want to eliminate the linked relationship among these nodes so they all work independently, you can “delete” a specific Shared node. This leaves the now unlinked nodes intact within each node tree in which they appear, but clears their effect. Additionally, that Shared node is removed from the Add Node submenu.

**To Delete a Shared node:**

— Right-click any Shared node, and choose a node to delete from the Delete Shared Node submenu.

### Using Adjustment Clips

You can also apply a single grade to multiple clips in the Timeline using Adjustment clips that have been superimposed over numerous other clips in the Timeline. They can be used to apply a single grade to all clips in a scene, or to add further color adjustments or trims to a section of clips via a second grade that’s applied on top of the individual clip grades that are already applied.

Adjustment clips are a great way to add adjustments to multiple clips that you may be making frequent changes to. If you make changes to a grade in an Adjustment clip, that change is automatically applied to all clips underneath it in the Timeline. Additionally, grades applied via adjustment layers can be turned off by disabling the adjustment layers, either one at a time, or by disabling an entire track with adjustment layers in it.
An Adjustment clip (shown selected in the Mini Timeline) used to apply a cooler grade to four other clips in a scene.

Adjustment clips can be edited into the Timeline on the Edit page, and are available from the Effects bin of the toolbox in the Effects Library. When an Adjustment clip is superimposed above one or more clips in the Timeline, all effects that are applied to the Adjustment clip are also applied to all clips underneath it.

Adjustment clips can be used to apply the following types of effects:

- ResolveFX and OpenFX plug-ins
- Inspector parameters, including Composite, Transform, Cropping, and Dynamic Zoom
- Fusion page effects
- Color page grading and sizing

Effects clips are a fast and easily revised way to apply one or more grades and effects to a range of clips.

**TIP:** Multiple adjustment layers can be grouped together so that you can apply Group and Clip grades to adjustment layers, linking multiple adjustment layers together in situations where you want to apply the exact same trim or stylistic adjustment to multiple scenes in non-contiguous areas of the Timeline.
Using Groups

Grouping is one of DaVinci Resolve’s most powerful features for organizing grades amongst multiple clips. Groups are manually created collections of clips with automatic linking relationships that make it easy for you to control the rippling of grades among sets of clips that you define. When clips have been grouped together, selecting one member of the group reveals a group “linked” badge at the top-right of each clip’s thumbnail belonging to the group.

You can create as many groups within a single project as you need. You can add or remove shots from the current group, and the current group is defined by the last shot you’ve selected (if it belongs to a group, that’s the new current group).

As introduced in DaVinci Resolve 11, the grading of grouped clips is easier than it has ever been. Once grouped, you can choose from one of four Node Editor modes to grade the current clip. Which mode you choose determines whether that grade will automatically ripple to every other member of that group, or whether the grade will only affect that one clip. In this way, you can combine multiple node trees, some which will ripple, and one which won’t, to create the final look of each clip in that group.

For example, you might group together every clip from the same angle of coverage in a scene. You might also group together every clip from a particular section of B-roll that will be graded with the same treatment. This way, whenever you make a change or otherwise update one member of the group using one of the rippled Node Editor modes, every clip in the group will be changed together.

This section discusses how to create and manage groups, how best to use them, and what issues you need to be aware of to use groups to best advantage.

Creating and Managing Groups

The following procedures describe how to create, load, modify, and delete groups.

To create a new group:

1. Select one or more clip thumbnails in the Timeline. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a noncontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
2. Right-click one of the selected clip thumbnails, and choose Add Into New Group.
3. Type a name into the field of the Group Name dialog, and click OK.

The new group is created, and the clips you had selected now appear with the “linked” group badge above the thumbnails.
To load a different group, do one of the following:

— Move the playhead to another clip that’s a member of that group.
— Right-click any clip belonging to any group, and choose Group > “Name of group” > Load.

The selected group now becomes the current group. Using the Add Into Current Group command will add a clip to the newly loaded group.

To add one or more clips to an existing group:

1. Load the group you want to add clips to.
2. Select one or more clip thumbnails in the Timeline. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a noncontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
3. Right-click one of the selected clip thumbnails, and choose Group > “Name of group” > Assign to Group.

The selected clips now appear with the “linked” group badge above the thumbnails.

To remove one or more clips from an existing group:

1. Select one or more clip thumbnails in the Timeline that you want to remove from a group. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a discontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
2. Right-click one of the selected clip thumbnails, and choose Remove From Group.

To rename a group:

1. Right-click any clip belonging to any group, and choose Group > “Name of group” > Rename.
2. Type a new name into the field of the Group Name dialog, and click OK.

The group is renamed. The new name appears as a new submenu of the Timeline contextual menu.

To delete a group:

— Right-click a clip belonging the group you want to delete, and choose Group > “Name of group” > Delete.
— This clears the group, while preserving the last applied grade within each clip.

Using Group Modes to Control Which Grades Ripple and Which Don’t

When you create a group and then select any clip that is a member of that group, additional Node Editor modes become available that let you apply multiple levels of grades to the clips in that group.
For clips that aren’t grouped, two dots at the top of the Node Editor let you switch between Clip and Timeline modes via a single click. If you’re working on a clip that’s part of a group, four dots will be displayed to allow fast access to the Pre-Clip and Post-Clip Group modes as well.

Node trees you create using the Group Pre-Clip and Group Post-Clip modes automatically ripple changes to every member of a group. Node trees created with the Clip mode are specific to each clip. Node trees created with the Timeline grade affect the entire Timeline, all at once. Combining node trees made using these different modes makes it easy combine clip-specific changes with group-wide changes that make grading faster.

— **Group Pre-Clip:** Node trees assembled in this mode affect every clip in the group simultaneously. Pre-Clip adjustments are useful for creating an overall grade that you want to use as a starting point for the scene, such as when you need to normalize a group of log-encoded clips in a specific way, or when you want to create a base grade that generally improves every clip in a scene.

— **Clip:** The Clip grade corresponds to the local or remote version associated with that clip. Node trees assembled in the Clip mode only affect the specific clip that’s selected. All Local and Remote versions you create are in Clip mode. Clip adjustments are useful for matching clips to one another in a scene, doing clip-specific secondary adjustments, or making any other sort of adjustment that you only want applied to the current clip, rather than to the group as a whole. Clip adjustments are applied after Pre-Clip adjustments.

— **Group Post-Clip:** Node trees assembled in this mode also affect every clip in the group simultaneously, but these adjustments are applied after the Clip adjustments. Post-Clip adjustments can be useful for applying a creative look to an overall scene, so that later revisions to a scene’s look can be accomplished with a single set of adjustments that automatically affect the entire group.

— **Timeline:** Node trees assembled in this mode affect every single clip in the entire Timeline. Timeline adjustments are useful when you have a single change that you want to apply to every single clip at once.

The image processing of each Node Editor mode is sequential, making it easy to keep track of the order of operations affecting a particular clip.

**An Example of Grading a Group of Clips**

This section shows an example of how you might approach grading a group of clips using the different Node Editor modes that are available. Keep in mind that this is only one of many possible approaches you could take to the use of groups, and was chosen because it exercises everything you can do to a single grade.
To get started, select a series of clips that you want to group, and right-click one of them and choose Create New Group to group them together, entering a name and clicking OK when prompted. One convenient advantage of simply creating groups from a selection is that you’re not limited to selecting a continuous range of clips in the Timeline. Another advantage is that you can use the View > Timeline Thumbnail Mode > Source (C-mode) command, or Timeline filtering, to isolate the range of clips you want to use for creating a group.

There are different ways you might choose to group clips together:

— All clips within a particular scene
— All clips recorded from a specific camera
— All headshots of a particular person
— All clips from a particular angle of coverage
— All exteriors of a particular location

The list could go on and on, but you get the idea. You can group any selection of clips together that have reason to share a common grade. In this example, a series of shots from an exterior scene are selected and made into a group.

Once you’ve created a group, choose Group Pre-Clip from the Node Editor mode drop-down. This is the first grade that’s applied, as the underlying grade that affects the entire group. Using this node tree, adding a LUT to normalize the clips, a Color Wheel adjustment, and some Curve adjustments to tune the color provide a primary grade that now affects every single clip in the group.

With this accomplished, you can see there’s some variation among the clips in the scene that needs to be corrected in order for every clip to match. Choose Clip from the Node Editor mode drop-down. Grades that you make in Clip mode only affect the clip to which they’re applied, so now you
can work clip by clip using the Image Wipe and Split-Screen controls to compare clips and make whatever adjustments are necessary to make each one match the main look for the scene.

Once all the clips are balanced with one another, you can choose Post-Clip Group from the Node Editor mode drop-down. This lets you add one more grade on top of the Pre-Clip and Clip grades that you’ve already applied, that you can use for any number of things. In this example, a single stylistic adjustment is applied that now affects all of the clips at once. If a client wants to see something different, you can easily make the necessary changes to one clip, and all other clips in that group will immediately be altered as well.

At this point, the scene is graded via a well organized set of corrections. If the client later wants a change affecting the underlying primary grade that everything is built on, you can adjust the Pre-Clip grade. If you spot an inconsistency with your shot matching at any point, you can make a fast tweak to the relevant Clip grade. And if the client wants a stylistic change, you can make any necessary adjustments to the Post-Clip grade to change the overall look of the whole scene. In each case, groups give you total control over which adjustments will ripple across the whole group, and which adjustments will be clip-specific.
Using Undo in Groups

Each Node Editor mode has a separate undo stack, meaning that separate multiple-level undo is saved for Group Pre-Clip, Clip, and Group Post-Clip.

Saving Stills and Grades in Groups

When you save a still for a clip that’s part of a group, the result is that the still reflects the look of the combined Pre-Clip, Clip, and Post-Clip node trees, but the grade that’s saved within depends on the Node Editor mode you had selected when saving the still. For example, if the Node Editor is set to Group Pre-Clip, then you’ll only save the Pre-Clip grade; the Clip, Group Post-Clip, and Track grades will be ignored. Copying a saved grade to a clip in a group results in that grade being copied to the node tree of whichever Node Editor mode is currently open.

Collapse Group Grades

If you want to take a clip out of a group, but you want its grade to continue incorporating all adjustments made in the Pre-Group and Post-Group Node Editor modes, you can use the Collapse Group Grades command to copy all nodes in the Pre-Group and Post-Group grades to the Clip grade. When you do this, Pre-Group nodes are added before any pre-existing nodes in the Clip grade, and all Post-Group nodes are added after, in order to maintain the correct order of operations.
To flatten all group grades into a single Clip mode node tree:
— Right-click a clip’s thumbnail in the Thumbnail timeline, and choose Collapse Group Grades from the contextual menu.

Using Collapse Group Grades on a clip always removes that clip from whatever group it was previously a member of. This can also be an easy way of creating a single flat node tree in preparation for saving a grade to the Gallery for applying to other clips that aren’t themselves in groups.

Groups and Versions
Local or Remote versions you create relate only to the Clip grade. Group Pre-Clip and Group Post-Clip grades cannot be versioned.

Exporting Grades and LUTs

If you find it necessary to exchange grades with other workstations, there are two ways you can do so directly: by exporting grades, or LUTs. This section discusses the export of Grades; for more information about exporting LUTs, see Chapter 146, “Using LUTs.”

To export a grade:
1. Save the grade you want to export as a still in the Gallery.
2. Right-click the saved still in the Gallery, and choose Export.
3. Select the image format you want to save the still as. Choices include: DPX, Cineon, TIFF, JPEG, PNG, PPM, BMP, and XPM.
4. Choose a location for the resulting still image and saved grade files, type a name into the Save As field, and click Save.
   Two files are saved. The image file contains the still image of the frame that was stored. A DRX (DaVinci Resolve eXchange) file contains all the grading information.

To Import a grade:
1. Right-click anywhere in the gray area of the Gallery, and choose Import.
2. Click the Options button to select the specific file type you want to import, or select “All Files” for multiple formats.
3. Choose the image file that was exported from your DaVinci Resolve workstation, or someone else’s. The accompanying DRX file must be in the same location. If you lose the original image file, you can still import the DRX file by itself. It will preserve the node structure of the still, but you will not be able to wipe against it.
   The still you imported appears in the Gallery, containing the grading information you wanted to import.
Chapter 139

Node Editing Basics

This chapter covers the basics of using the Node Editor in DaVinci Resolve to manage all of the adjustments you decide to apply to a clip, as well as the fundamental procedures for editing and organizing nodes within a tree that are the basis for creating more sophisticated effects.

Node Editor Basics

By default, every clip has one node in the Node Editor that contains the first corrections you make. However, you also have the option of creating multiple nodes, where each node contains one or more corrections that affect the image.

The specific arrangement of nodes you create lets you exert precise control over the order of operations performed by your grade, which provides many advantages. This section covers different ways of creating, editing, and arranging node trees to harness the full power of DaVinci Resolve.

Thumbnail-Optional Nodes

The Node Editor option menu provides a Show Thumbnails option that lets you disable or enable the thumbnails attached to each Corrector node.

Disabling thumbnails in the Node Editor option menu makes nodes shorter
How Many Nodes Do I Need to Use?

In this chapter and the ones that follow, you’ll learn many different techniques for combining adjustments and nodes in different ways to achieve highly specific effects. Consequently, new DaVinci Resolve users often wonder, how far do I go? There is no right answer, but suffice it to say that some of the world’s leading colorists achieve stunning results in as few as three or four nodes, while others routinely build carefully organized hierarchies of ten to twenty nodes, or more. The number of nodes you use is often dependent on the quality of media you’ve been given to work with, as well-lit footage usually requires less work than material shot run-and-gun with available light, that typically needs many more adjustments to achieve an acceptable result. Furthermore, the number of nodes you may use can also depend on what kind of program you’re working on, with commercial spots affording the colorist enough time in the schedule to build truly massive grades that adjust every little detail, and narrative features and television shows requiring you to work faster and do more within fewer adjustments in order to stay on track. The real answer? Each grade requires as many nodes as are necessary. No more, no less.

The Node Editor Interface

As you work within the Node Editor, you may find the need to zoom into or out of it to get a better look at the node tree, and to pan around the working area to deal with large collections of nodes.

To expand the size of the Node Editor’s working area:
— Drag the border between the Node Editor and the Viewer to the left or right to make it wider or narrower.
— Right-click anywhere within the Node Editor (except on a node) and choose Toggle Display Mode, which hides the Viewer and moves the Node Editor to the right of the Gallery, enlarging it considerably. Right-click and choose Toggle Display Node again to return to the default layout.

To arrange the node tree to fit your current working area:
— Right-click anywhere in the Node Editor (except on a node) and chose Cleanup Node Graph from the contextual menu. This will rearrange your node tree to fit in whatever size working area you have at the time.

To zoom and pan within the Node Editor, do one of the following:
— Use the Node Editor’s zoom slider to shrink or enlarge the nodes in the Node Editor.
— Click the Pan tool (the hand icon) at the upper left-hand corner of the Node Editor, and drag anywhere within the gray area of the Node Editor to pan around.
— Press the H key to toggle between selection and pan modes in the Node Editor.
— Middle-click and drag anywhere within the Node Editor to pan around.
— Right-click and choose Zoom In or Zoom Out.
— Right-click and choose Zoom to Window to fit the node tree to the current size of the node graph.
— Right-click and choose Original Size to return the node graph to the default size.
The Components of a Node Tree

Ambitious grades may require trees of multiple nodes to create the necessary effect. This section covers the mechanics of putting nodes together into the structures that are described in more detail later in this chapter.

Every node you add is a “Corrector” node, which is capable of either primary or secondary correction, depending on whether or not you enable the Qualifier/Window/Matte controls. Even “Serial” and “Parallel” nodes are simply Corrector nodes that are added in series or in parallel to the previous node in the node tree; the names are a consequence of how they’re added.

Each Corrector node has two inputs and two outputs, which lets you separately manage the RGB image-processing channel, and the Key channel that defines areas of isolation for image processing operations, or transparency for compositing. RGB connections are light green, located at the top left and right of each node. Key connections are blue, located at the bottom left and right of each node. Inputs into the node are triangles, and outputs are squares. These inputs and outputs let you control the flow of image and isolation channels coming into and going out of each node in the tree.

Nodes are attached to one another via “connections,” seen as lines that connect one node to another. Image data flows from left to right, starting with the Source input all the way at the left of the Node Editor, through each node in the tree, and ending at the Node Tree output at the right of the Node Editor.
Here’s an explanation of the different components of a basic node tree where all nodes are connected in serial, one after the other, and how they work together:

— **Source Input**: The green source node to the far left is the clip’s image data as processed by the Sizing and Source decode settings, ungraded. The Source input feeds RGB data to the grade, and is connected to the RGB input of the first node in your tree. If necessary, you can connect the Source input to more than one Corrector node, creating multiple simultaneous streams of image processing emerging from the original source state of the image that you can eventually recombine in different ways using the Parallel or Layer Mixer nodes.

— **Nodes**: Each node in the node graph represents a collection of image processing operations that can be enabled or disabled separately from any other node in the graph. By separating operations into multiple nodes, you’re able to precisely control the order of all image processing operations in DaVinci Resolve to create many different corrections and effects. The green RGB inputs and outputs are used to connect these nodes together. Each node’s thumbnail image shows how the clip looks at that particular stage of the grade, giving you a visual indication of what each node is doing, and small badges below each node show you which specific operations are being applied by that node.

— **RGB Inputs and Outputs**: The green inputs and outputs at the upper right and left of each node are used to connect the RGB image that’s output from one node to the RGB input of the next node. For a Corrector node to have an effect, you must connect both its RGB input and its RGB output to neighboring nodes in the tree. Furthermore, every single node in the Node Editor must be connected for a grade to be enabled; having any disconnected node in the node tree disables that grade until it’s fully connected.

— **Key Inputs and Outputs**: The blue inputs and outputs at the bottom right and left of each node are used to route the key channel generated by a node’s Qualifier or Window controls, or imported via a Matte clip that you previously associated with a clip in the Media page. When you connect the key output of one node to the key input of another, you basically copy the first node’s key to the second node. You can also combine the key outputs of multiple nodes in various ways using the Key Mixer node.

— **Node Tree Output**: The RGB output of the last node in a tree must be connected to the green Node Tree output node, which “completes the circuit” of image processing, and passes that correction on to the next stage in the DaVinci Resolve image processing pipeline. If the output is not connected, the node tree is disabled and has no effect on the clip. You can only connect one RGB output at a time to the Node Tree output.

— **Second Source Input (for RED HDRx)**: You can access the alternate highlight exposure of RED HDRx media by exposing this optional second Source input. For more information, see “Multi-Channel RED HDRx Support” in Chapter 143, “Channel Splitting and Image Compositing.”

— **Second Source Input (from Fusion page)**: You can also create additional sources to route in masks or mattes created in the Fusion page for use as keys in the Color page.

— **Alpha Output**: It’s possible to create regions of transparency for compositing directly in DaVinci Resolve by connecting a key output to an optional Alpha output. For more information, see Chapter 142, “Combining Keys and Using Mattes.”
Node Badges and Labels

Nodes appear with various labels and badges to help you identify what each node is contributing to the overall grade. How long a label and how many badges appear depends on the size of each node, as set by the Node Editor’s Zoom slider.

- **Node number**: Nodes are numbered in the order in which they appear in the node graph, making it possible for you to select specific nodes by number via the DaVinci control panel.

- **Adjustment badges**: As you apply various operations within a node, small badges appear underneath the thumbnail that indicate which palettes have been used to adjust that node. How many badges are visible depends on how far in or out you’re zoomed into the Node Editor, and whether or not there are Color Space or HDR labels already taking some of this room. At larger node sizes, more badges can appear within the width of the node. Each palette in the Color page has a unique badge. If you apply more operations than a node has area to display, a single “downward arrow” badge appears.

- **Animation badge**: Nodes with animated parameters display a keyframe badge.

Labeling Nodes

Nodes can be labeled to identify a particular node’s function in your grade. This can make it easier to revise a grade months later. Node labels are also saved when you save a still, so labels can also make it easier to decipher a saved grade down the road. At each node’s default size in the Node Editor, nodes can appear with up to 12 characters of text, although larger nodes can accommodate more text.

To label a node:

1. Right-click a node and choose Change Label.
2. Type the label text you want and press Return.

   The label you entered appears above the node in the Node Editor.

To edit a node’s label:

- Once a node has a label, you can change the label at any time by double-clicking it.

Selecting Nodes

The node that’s currently selected in the Node Editor is highlighted in orange, and is referred to as the current node. When you adjust any of the parameters or settings in the Color page, you’re adjusting parameters within the current node. You can only select one node at a time.
To select a node, making it the current node, do one of the following:

— Click any node in the node graph.
— Choose Color > Nodes > Previous Node (Option-Shift-Semicolon) or Color > Nodes > Next Node (Option-Shift-Apostrophe). When you do this, the last node loops around to the first one, and vice versa.

The selected node appears highlighted in orange. You also have the ability to select multiple nodes, in preparation for doing things like moving them or creating compound nodes (covered later in this chapter).

To select multiple nodes:

— Command-click each of the nodes you want to simultaneously select.
— With the Node Editor Selection tool chosen (at the upper left-hand corner of the Node Editor) simply drag to select multiple nodes using a bounding box.

When you select multiple nodes, each one appears highlighted in white, with the exception of the current node, which remains orange.

When you select another clip in the Timeline, the default behavior is that the last node that was selected when you worked on that clip is the one that’s selected when you move to that clip again. However, a setting in the option menu of the Node Editor and the Color panel of the User Preferences, called “Switching clips,” lets you change this behavior. For more information on this option, see Chapter 4, “System and User Preferences.”

Disabling Nodes

In the process of creating a node tree, it’s often useful to turn one or more selected nodes off to disable their effect on your grade. It’s also useful to turn the entire node tree off and on in order to see “before and after” views of the current clip. Disabled nodes are not processed during rendering, and they remain disabled when you save that grade along with a still in the Gallery and then apply that grade to another shot.
Disabling Individual Nodes
Disabling a single node is useful for temporarily disabling adjustments that you don’t think you want to use but don’t want to discard (however you should remember that it’s alarmingly easy to inadvertently turn these nodes back on again). It’s also good for giving your client a before and after preview of the last adjustment.

To toggle individual nodes off and on, do one of the following:
— Click the number of any node in the node graph to disable that node by itself.
— Select a single node, and choose Color > Nodes > Enable/Disable Selected Nodes (Command-D).

Disabling Multiple Nodes All At Once
If you select more than one node in the node tree, using any of the methods of turning nodes off and on described above (including Command-D) will toggle Enable/Disable Selected Nodes. Please note that the current node outlined in orange is always considered to be part of the selection.

This makes it easy to do before/after comparisons of any combination of nodes doing complicated adjustments by selecting them, while leaving un-selected nodes doing base adjustments that you want to leave enabled alone.

Disabling All Nodes
In addition to the Bypass All Grades command, disabling all nodes of a grade at once is another easy way of disabling a grade to provide a before and after of the original state of the clip (or the color managed state of the clip if Resolve Color Management (RCM) is enabled). More importantly, it’s a good way to disable all nodes of a grade in preparation for walking your client through each operation in that grade node by node, as you turn each node on in turn while narrating how it’s improving the image.

To turn every node off and on at once, do one of the following:
— Choose Color > Nodes > Enable/Disable All Nodes (Option-D) to toggle all nodes off and on.

IMPORTANT
When you turn every node off and then on again, every node is re-enabled, even nodes that had previously been individually disabled.

Turning Grades and/or Fusion Effects Off
The Bypass Color Grades and Fusion Effects button/drop-down commands in the Viewer’s title bar are also available via View > Bypass Color and Fusion menu commands. Turning off Fusion effects in the Color page is an easy way to improve playback performance on low power systems when you just need to make a quick set of grading adjustments. Toggling grades off and on is also a convenient way to quickly get a before and after look at a shot where the before goes all the way back to the source.
If you choose Toggle Bypass or click the Viewer control, you’ll turn off whatever is checked in the optional menu, which lets you choose whether or not you want to bypass both Color and Fusion, or just one or the other.

(Left) Menu commands for bypassing Color and Fusion, (Right) Edit page Timeline Viewer controls

### Resetting Nodes

If you’re dissatisfied with your current operations and want to start over, there are three ways you can reset nodes in the Node Editor. These are available as items in the Color menu.

- **Reset Selected Node Grade:** Resets the currently selected node, eliminating all keyframes, to the default parameter settings.
- **Reset Grades and Keep Nodes:** Resets every node in the current node tree, without affecting the node tree’s structure; all nodes remain where they were. However, each node has been reset to the default parameter settings.
- **Reset All Grades and Nodes:** Deletes every node and keyframe, and restores a single node set to the default parameter settings.

You can also reset nodes using the mouse, which can be a quick thing to do if you’re already working in the Node Editor to accomplish other things.

**Methods of resetting nodes with the mouse:**

- **To reset a selected node:** Right-click that node and choose Reset Node Grade from the contextual menu.
- **To reset all grades and nodes:** Right-click anywhere in the background of the Node Editor, and choose Reset All Grades and Nodes from the contextual menu.

**Methods of resetting nodes with the keyboard:**

- **To reset a selected node:** Press (Shift-home).
- **To reset all grades and nodes:** Press (Command-home).
- **To reset all grades and keep nodes:** Press (Shift-Command-home).
Previewing and Restoring Node Trees

There are two other methods of quickly dealing with unwanted changes you’ve made to node trees, without needing to use undo.

— **Preview Memory**: Lets you preview the effect of any saved grade on the current clip. To preview, choose Color > Preview Memory (Option-Shift-P), and then right-click any saved still in the Gallery (or Memory) and choose Add Correction. In fact, you can use Add Correction to try out as many stills as you like. If you like any still’s effect, then you can leave it be. If you don’t like any of the stills you previewed, then choosing Color > Preview Memory again reverts the clip to the original grade.

— **Original Memory**: This command lets you quickly revert a clip’s grade to its original state when you first selected that clip. It is accessed by choosing Color > Original Memory (Option-Shift-O). This is useful for getting immediately back to a clip’s original grade if you’ve made a series of changes that you then regret. Selecting another clip in the Timeline and then reselecting the clip you made changes to resets what is considered to be the current grade.

Caching Specific Nodes to Improve Performance

You can flag specific nodes to be cached, along with all nodes appearing upstream in that node tree. By caching nodes using processor-intensive effects, you free up real time capability for the remaining downstream nodes in a grade. Choosing Playback > Render Cache > User only caches nodes that you’ve flagged for caching.

When you choose Playback > Render Cache > Smart mode, DaVinci Resolve automatically caches any nodes that use Motion Blur, Noise Reduction, or OFX plug-ins, without you needing to do anything.

**To flag a node and all corrections made in upstream nodes for caching:**

— Right-click any node and choose Node Cache > On from the contextual menu.

Editing Node Trees

There is no limit to the number of nodes you can create and connect to one another, and you can make as many or as few parameter adjustments as you like within each node. The following procedures describe the ways you can add nodes to the node graph as you build each grade’s node tree.

**Adding Nodes**

The simplest thing you can do to add to the complexity of a node tree is to add additional nodes, in order to add more adjustments to the current grade. You can add nodes so that they’re automatically attached to nodes that are already in the node tree, for immediate adjustment, or you can add unattached nodes to empty areas of the node tree in preparation for assembling a particularly complicated and specific node tree to accomplish a difficult task.
Methods of adding nodes to the tree using a mouse, tablet, or trackpad:

— **To add any kind of node to the node graph using the mouse:** Right-click any node in the node tree, and choose the type of node you want to add from the Add Node submenu of the contextual menu.

— **To add a disconnected node to the node graph:** Right-click anywhere within the node graph’s background, then choose Add Node > Corrector from the contextual menu. Disconnected nodes have no effect on a node tree until they’re connected.

Methods of adding nodes to a currently selected node in the tree using the keyboard:

— **To add a serial node after the currently selected node:** Press Option-S key, choose Color > Nodes > Add Serial from the menu.

— **To append a serial node to the very end of the node tree:** Press Option-K, choose Color > Nodes > Append Node from the menu.

— **To add a serial node before the currently selected node:** Press Shift-S, or choose Color > Nodes > Add Before Current.

— **To add nodes in parallel to the currently selected node:** Press Option-P, choose Color > Nodes > Add Parallel from the menu.

— **To layer nodes with the currently selected node:** Press Option-L, choose Color > Nodes > Add Layer from the menu.

— **To add an outside node to the currently selected node:** Press Option-O, choose Color > Nodes > Add Outside Node from the menu.

**Adding Nodes with Windows Turned On**

There are also dedicated commands for adding serial nodes with Circular/Linear/Polygon/Curve windows automatically turned on, for convenience.

**To add a node to the tree with a Window automatically enabled:**

Choose an item from the Nodes menu that corresponds to the following:

— **Node + CPW:** Circular Power window (Option-C)

— **Node + LPW:** Linear Power window (Option-Q)

— **Node + PPW:** Polygonal Power window (Option-G)

— **Node + PCW:** PowerCurve window (Option-B)

Whenever you add a node to a tree, it’s numbered consecutively to come after the next most recent node you’d added, regardless of the order in which it appears in the node tree. For example, if you’ve already added three nodes, and then you decide to add another node in between Nodes 1 and 2, the new node will be Node 4, and the order of the nodes will be 1, 4, 2, and 3.

**Deleting Nodes**

If there’s a node that you no longer need, you can choose to remove it completely from the node tree to remove its effect permanently.
To delete a node, do one of the following:

— Select a node, then press the Forward-Delete key.
— Right-click a node, and choose Delete Node.

After you’ve deleted a node, the node to the left and right of the node you deleted are automatically connected so that the node tree is unbroken. Also, all the nodes in a tree are renumbered after the deletion of any node, so there’s no discontinuity in node order. For example, if you have three consecutively numbered nodes in a tree and you delete the second one, the node that was formerly number 3 is renumbered to be 2.

Connecting and Disconnecting Nodes

For a node tree to work, every node in the Node Editor must be connected into a working node tree, from the Source input, through each node in the tree, to the Node Tree output. Any disconnected node will result in that clip’s grade being disabled. However, you may find the need to disconnect some parts of a node tree in order to reconnect them in different ways.

To connect two disconnected nodes:

— Click and drag a connection from the RGB or key output of one node to the corresponding RGB or key input of another, and when the line highlights, release the mouse button.

To change the connection from one node to another:

— Move the pointer over the second half of any connection line between two nodes until it highlights blue, then click and drag it to reconnect it to another input, on that node or another.

To disconnect two nodes, do one of the following:

— Position the pointer over the right-hand side of a node connection so it highlights, and click it to delete it.
— Click a link to select it (selected links turn orange), and then press the Delete or Forward-Delete key.
— Right-click a link and choose Delete Link.

To overwrite a node’s previous connection:

— You can drag a connection to a node input or output that’s already connected, which will overwrite the previous connection with the new one you’re dragging. When you do this, the connection that’s about to be overwritten appears highlighted in orange.
— You can connect any node’s RGB or Key output to as many inputs as you want, but you can only have one connection going to a node’s input. The exception to this is a node with multiple inputs, designed to combine the output of multiple nodes. These include the Parallel, Mixer, and Key Mixer nodes.
Extracting a Node

Sometimes you need to remove a node from its current position in the node tree, such that the nodes to the left and right of it automatically reconnect to one another, saving you from having to reconnect them manually. This is called extracting a node.

To extract a node, do one of the following:
— Select a node, and choose Color > Nodes > Extract Current Node.
— Select a node, and press E.

Keep in mind that disconnected nodes in the node tree suspend grading altogether, so you’ll want to either reconnect that node to another part of the node tree, or delete it; you cannot leave it disconnected in the Node Editor.

Inserting a Node

If there’s a disconnected node in the Node Editor, there’s a simple way you can insert it into the node tree between any two other nodes. This also works for nodes that you’re dragging into a node tree from another source, for example, from the exposed node tree of a still in the Gallery.

To insert a disconnected node between two other nodes:
— Drag a disconnected node, or a node from another node tree, onto the connection between any two other nodes in a node tree; when a plus icon appears over the node you’re dragging, drop it to insert the node.

Rearranging Node Order

The order in which nodes are connected in your tree affects the result of a grade. For example, if you boost the highlights in the first node, and then you try to isolate a portion of the picture in a second node that you now realize has been clipped, you may to need to change your order of operations to optimize your corrections.

To swap the contents of two nodes:
— Command-drag any node and drop it onto another node to swap the operations within each node. The nodes won’t appear to have moved, but you should be able to tell from the node badges underneath that the operations have been reversed.

To move a node to any other position in the node tree:
1. Double-click any node in the node tree and press E to extract it, removing it from the tree so that it becomes unattached.
2. Drag the now-unattached node to the connection line between any two other nodes in the tree, and when a small plus icon appears, drop it to automatically connect that node at that position in the node tree.
Copying and Pasting All Settings From One Node to Another

The simplest thing you can do is to copy all of a node’s settings and paste them into another node. This makes it easy to duplicate things like windows, qualifier settings, keyframing, or motion tracking that you want to reuse in another node as the basis for another operation. This is also a quick way to manually ripple a change you make in a node to that same node in another clip’s grade.

To copy a node’s settings from one clip to another, do one of the following:

— Option-drag one node onto another. When you drop it, the settings of the node you dragged overwrite those of the node you dropped onto.

— Select a node with settings you want to copy and choose Edit > Copy (Command-C). Then, select a node you want to paste these settings to either in the current grade or in the grade of another clip, or create a new node, and choose Edit > Paste (Command-V) to paste the settings you copied. These pasted node settings overwrite any other settings that node previously used.

**NOTE:** There are additional methods of copying nodes and individual node settings. For more information, see Chapter 138, “Grade Management.”

Keeping Node Trees Organized

It’s a good idea to keep the arrangement of your nodes in the node graph clean and neat. It’ll make it easier to read your tree if you need to revisit a grade later on, and it will also make it easier for other colorists working on the same project to figure out what you’re doing. The following procedures describe how to rearrange the nodes in your tree, and the node tree working area, to help you keep on top of your grades.

To move nodes within the Node Editor:

— Drag any node to a new position.

— Command-click or drag a bounding box around multiple nodes that you want to move, and drag them all to a new position.

Of course, it’s easy to get carried away. If you’ve been working furiously on a complex grade and you find yourself staring at a riot of disorganized nodes, it’s easy to quickly reorganize your node graph using a pair of commands in the Node Editor contextual menu.

To clean up the node graph, right-click the Node Editor and choose:

— **Cleanup Node Graph:** Moves all nodes in the node graph so they appear in an evenly spaced grid. Connection lines are routed around nodes to minimize clutter.
Before/after using "Cleanup Node Graph"
Using Compound Nodes

Another node structure you can use to keep complex node trees organized is the compound node. You can Command-click to select any number of nodes in the node tree (selected nodes are highlighted white), and then use the “Create Compound Node” command to nest all selected nodes inside of a single node.

The resulting compound node that’s created has as many inputs and outputs as are necessary to accommodate the connection lines that attached the nodes you selected to the rest of the node tree.

You can use compound nodes to organize complicated node trees by nesting sets of nodes that work together to do a specific thing within a single node. You can also turn a set of nodes that you’re using to create a specific effect into a compound node in preparation for saving to the Gallery. Creating a library of effects in this way makes it easy to reuse them via the Append Grade command, without the undue burden of adding lots more nodes to your grade later on.

Methods for creating and working with compound nodes:

— **To create a compound node:** Command-click each node you want to nest inside of a compound node to select them with a white highlight, or drag a bounding box around a group of nodes. Then, right-click one of the selected nodes, and choose Create Compound Node from the contextual menu.
To edit a compound node: Either hold the Command key down while double-clicking the compound node you want to open, or right-click any compound node and choose Show Compound Node from the contextual menu. The contents of that node appear in the Node Editor, taking the place of the overall node tree.

To exit a compound node you’re editing: To return to the top level node tree, double-click the leftmost item in the path control at the bottom of the Node Editor, or click the name of the compound node. You can also right-click in the compound Node Editor and choose “Exit Compound Node” from the contextual menu.

To label a compound node: Right-click a compound node, choose Change Label from the contextual menu, and type a new label for that node. Press the Return key when you’re finished.

To decompose a compound node: Right-click the compound node you want to decompose, and choose “Decompose Compound Node” from the contextual menu. The compound node disappears, replaced by the original nodes within. Please note, if you had applied an adjustment to the compound node itself, that adjustment is lost when you decompose it back into its constituent nodes. If you want to preserve the compound node adjustment itself, you can copy it, then decompose the node, and then create a new node and paste the adjustment you’d copied.

Adding Inputs and Outputs to Compound Nodes

When you open the contents of a compound node using the Show Compound Node command, you can make whatever adjustments you like to the node tree within, but you also have the option of right-clicking within the Node Editor and choosing Add Source to add an input to the compound node, or Add Output to add an output. Adding more inputs and outputs lets you set up the node to connect to the rest of your node tree in more complicated ways. Disconnected inputs and outputs have no effect on your grade.

Furthermore, you can also use the Add Alpha Source and Add Alpha Output contextual menu commands to add KEY inputs and outputs to a compound node, making it easy to route key or alpha channel data to other connections in the enclosing node tree.

Nesting Compound Nodes

Compound nodes can also be nested within other compound nodes, if necessary.

Grading Compound Nodes

After you’ve created a compound node, you can select it to make one or more adjustments using the compound node itself, which effectively adds those adjustments after all other adjustments that take place via the nodes that are inside of the compound node. This gives you the opportunity to “trim” the effect that compound node is having on your grade, or to limit it using a qualifier or window.

To adjust the individual nodes nested within a compound node, you need to first open the compound node. Then, you can select and adjust any node as you ordinarily would.
Identifying Nodes

As you make various adjustments to nodes, small badges appear underneath that indicate what each node is actually doing. Since nodes are capable of holding multiple adjustments, any given node may have multiple badges; how many badges a node can show depends on the zoom level of the Node Editor. Larger nodes will show more badges, whereas smaller nodes will show fewer badges, hiding whichever badges don’t fit.

![Badges underneath each node indicate which adjustments it contains](image)

Another nice organizational feature of the Node Editor is an automatic tooltip that appears whenever you hover the pointer over a particular node, that shows you a concise list of all the operations applied to that particular node.

Putting Nodes into HDR Mode

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR mode of the node you’re working on by right-clicking that node in the Node Editor and choosing HDR Mode from the contextual menu.

![Using a node's contextual menu to put that node into HDR mode](image)

This setting adapts that node’s controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.
Clip vs. Timeline Grading

Ordinarily, the Node Editor has two modes. The default Clip mode lets you create individual grades for each clip or group in the Timeline. However, the Timeline grade mode lets you apply a single grade simultaneously to every clip in the Timeline, as seen in the Thumbnail timeline in the following screenshot.

There are a variety of reasons you might want to do this. For example, if you’re working on a commercial spot, you might elect to use Clip grades to do general correcting and scene-to-scene balancing, and then use the Timeline grade to apply a single stylistic grade to the entire spot simultaneously. That way, any changes the client wants made to the style of the grade can be instantly applied to the whole spot.

Another example would be using the Timeline grade to apply corrections meant to address QC issues running throughout a program, desaturating highlights or selectively darkening a specific shade of red wherever it appears.

To switch between Clip and Timeline grading modes:

— Choose the mode from the drop-down menu at the top right of the Node Editor.

— Click the dot in the Node Editor toolbar that corresponds to the Clip or Timeline mode.

NOTE: When you reset the Timeline grade using the Color > Reset All Grades and Nodes command, the Output Sizing parameters are reset as well.
Two dots at the top of the Node Editor let you switch between Clip and Timeline modes via a single click. If you’re working on a clip that’s part of a group, four dots will be displayed to allow fast access to the Pre-Clip and Post-Clip Group modes as well. For more information about group grading, see Chapter 138, “Grade Management.”

**Timeline Grades and Saved Stills**

When you save a Gallery still, the Clip and Timeline grades are both saved. However, when you apply a grade from that still, you only apply either the Clip grade, or the Timeline grade, depending on which mode the Node Editor is in. For more information on saving and applying grades, see Chapter 138, “Grade Management.”
Chapter 140

Image Processing Order of Operations

The addition of the HDR palette and Color Warper in DaVinci Resolve 17 necessitated an updated diagram of the order of all image processing operations in DaVinci Resolve, from input through output. A truly detailed breakdown now requires two charts as detailed in this chapter; the first chart details the overall order of operations taking place on every page, while the second zooms into the specific order of operations occurring within each node of the Pre-Clip, Clip, Post-Clip, and Timeline grades that you create on the Color page. Understanding the order of operations presented here will make it easier for you to control the power of the full DaVinci Resolve toolset.

Contents

| Overall Image Processing | 3053 |
| Image Processing Within Grades | 3054 |
Overall Image Processing

In the following chart, each image processing operation in DaVinci Resolve is shown in the order in which it’s processed. Operations are color-coded to indicate the page on which those controls appear, because in many cases page order does not determine image processing order. Why? Either to make sure each operation is processed as cleanly as possible, or to give the user the maximum control over the image. For both of these reasons, image processing order is carefully considered, and in some cases the best result requires operations on different pages to alternate with one another.

Most of the time, this order of operations is irrelevant to the user who’s only interested in the end result. However, if you’re trying to achieve something very specific, or if you’re wondering why you see a particular result when you use the features of the Cut, Edit, Fusion, and Color pages together all at once, this chart should help make things clear. Finishing artists in particular should find this chart illuminating.

The overall order of image processing operations in DaVinci Resolve, from input through output
Image Processing Within Grades

For Pre-Clip, Clip, Post-Clip, and Timeline grades on the Color page, most Color page operations are available within each Corrector node you add to the Node Editor. Within each node, these operations take place in the following specific order.

![Operations Within Corrector Nodes](image.png)

The order of image processing operations that takes place within each Corrector node in the Color page.

Thanks to the modular operation of the Node Editor, if a pair of image processing operations you need to use isn’t in the ideal order for what you’re trying to do, you can apply each operation using two different nodes in order to force those operations into the order you want. Similarly, when using Layer, Parallel, or Key mixer nodes, the order of operations can be seen in the visible arrangement of nodes in your node graph.

That said, most colorists tend to spread different operations across multiple nodes, whether they need to or not, for organizational purposes or to “sandbox” certain volatile decisions that might need to be independently revised later. However, nothing’s keeping you from using multiple operations within a single node if you prefer a simpler node structure for your grading. Thanks to the flexibility of the Color page, it’s your choice.
Serial, Parallel, and Layer Nodes

This chapter covers the four fundamental node structures you can use to combine Color page adjustments in even more detailed ways. These methods let you control your order of operations and re-combine multiple versions of the graded image in much more specific ways.

Contents

Serial, Parallel, and Layer Node Tree Structures 3056

Adjusting Layer Node Strength Using Key Output Gain 3061
Converting Layer Mixers to Parallel Mixers 3062
Serial, Parallel, and Layer Node Tree Structures

There are several ways you can organize nodes in a tree. Each method lets you control a group of image processing operations in different ways to achieve specific results. This section covers how to use Serial nodes, Parallel nodes, and Layer nodes, as well as how to use LUTs, work with HDR media that lets you combine two different exposures using two different Source inputs, and apply additional project-wide adjustments using the Timeline grade.

Serial Node Structures

The simplest, and most common node structure is a serial cascade of nodes, where a linear series of nodes is connected, one after another.

Controlling What Feeds a Node’s RGB Input

When you create a grade using serially arranged nodes, each node’s output is used as the next node’s input, so the order in which the nodes are arranged determines the order of image processing operations.

In the following screenshot, the node tree shows a series of three operations that are applied to a log-exposed, low-contrast clip. The first node expands clip contrast and increases saturation. The second node isolates the sky to intensify its color. The third desaturates and warms the image. At right, you can see the result of this node tree.

Node 2 pulls a clean key from the image data fed it by Node 1

If, instead, we reversed the order of Nodes 2 and 3, the result will be a less effective key.
By comparison, Node 3 pulls a less than optimal key from the image data fed it by Node 2.

Because the secondary operation is sampling the desaturated image, rather than the source, the HSL Qualifier’s key has less image data to work with, and thus you may get an inferior result.

## Parallel Node Structures

Another way to organize your corrections is to use a Parallel node structure, which lets you apply two or more overlapping adjustments at a single stage of a node tree. You can use the Parallel node structure for organizational reasons when there is a group of secondary corrections that you want to apply all at once. You can also use this structure for the unique way it blends overlapping image adjustments.

The Parallel Mixer node that makes this possible has multiple RGB inputs and a single RGB output. This lets the Parallel Mixer mix together multiple Corrector nodes, outputting a single image as a result.

When you add a Parallel node to an existing node, DaVinci Resolve automatically adds one Corrector node below the current node, and adds a Parallel Mixer node to its output.

If you want to create a series of Parallel nodes that connect to the output of the currently selected node, create a Serial node before you create your first Parallel node.

If you’re manually connecting another node to a Parallel Mixer node, you can drag from the output of the node to the Parallel Mixer node, and it will automatically add an input for you.

**Tip:** To create an additional, unconnected input on a Parallel Mixer node:

- Right-click a Parallel Mixer node and choose Add One Input.
Ordinarily, the RGB input of every Corrector node that’s connected to a Parallel node is connected to the output of the same node. This results in a stack of nodes that take the same state of the image as their input. This makes it easy to apply multiple secondary operations without worrying about whether or not a change to one will affect the keys of the others.

Further Parallel nodes can be added as you wish with each using a common source.

If you add another node in parallel, the Parallel Mixer automatically adds another input. You can have as many nodes in parallel as you need.

The adjustments made by all nodes that are connected to a Parallel Mixer are combined equally, regardless of which nodes are highest. In the following example, a separate overlapping window is applied by each of three nodes in parallel.

As you can see in the image at right, the three tints created by the overlapping windows are all mixed together equally; the colors blend with one another as if they are optically mixed. Most of the time, this is exactly what you want when you’re blending overlapping naturalistic color adjustments.
Converting Parallel Mixers to Layer Mixers

On the other hand, if you need your overlapping color adjustments to have priority over one another, or if you want to combine multiple adjustments using composite modes, then you may want to use the Layer Mixer node instead. If you’ve created a Parallel Mixer structure and you want to convert it to a Layer Mixer, you can.

**To change a Parallel Mixer node into a Layer Mixer node:**

— Right-click a Parallel Mixer node and choose Morph Into Layer Mixer Node.

Layer Mixer Node Structures

The Layer Mixer is structurally quite similar to the layout used by the Parallel Mixer. However, there are two key differences. First, the Layer Mixer node combines multiple adjustments with priority given to the image adjustment in the lowest overlapping node input. Second, you have the option of combining all of the Corrector nodes that are connected to a Layer Mixer using one of several different composite modes, to create a wide variety of visual effects.

Because of their similarities, layering nodes with the Layer Mixer works in much the same way as creating a Parallel node structure.

Layer Mixer Prioritization

In the following example, the same node structure from the Parallel Mixer example is shown, this time with the three overlapping color adjustments mixed together using the Layer Mixer.

The Layer Mixer prioritizes nodes connected to lower inputs such that each node’s output completely obscures whatever is behind it.

Now, instead of the three adjusted color tints being blended, you can see that the blue tint, which is connected to the lowest input of the Layer Mixer, is dominant and covers the overlapping regions of the two other adjustments. Meanwhile, the green tint, which is connected to the middle input of the Layer Mixer, covers the overlapping portion of the orange tint, which is connected to the highest input of the Layer Mixer.
Rearranging which connections are attached to which Layer Mixer inputs changes each node’s priority, and like the Parallel Mixer, you can add more inputs manually, or by dragging the output of a node to the Layer Mixer.

The Layer Mixer’s prioritization is most useful when you have an overlapping adjustment that you need to override any other adjustments happening on that stack. In the following example, two nodes are connected to the Layer Mixer node. Node 2 is applying a high-contrast, cool look to the entire clip. Node 3 isolates the skin tone, which is unflattering with the background stylization, and applies a different, more naturalistic adjustment.

Using the layer mixer, grades on Node 3 will have a greater priority over Node 2, so the final grade combines the high contrast from Node 2 with the adjusted skin tone from Node 4.

Because of the Layer Mixer’s prioritization, the adjustment made to the woman’s skin tone completely covers the adjustment made to the node that comes above it, providing the best of both worlds with one simple adjustment.

**TIP:** If you want to “solo” overlapping nodes that are connected to the Layer Mixer to see their individual adjustment, turn on Highlight (Shift-H, or the HILITE button on the DaVinci Resolve Mini Panel, or at the bottom of the T-bar panel of the DaVinci control panel). This lets you view just that node’s effect, regardless of what other node adjustments are overlapping.

**Using Composite Modes With the Layer Mixer**

You have the option of combining the adjustments made by all nodes connected to a Layer Mixer node using the same Composite modes that are available when compositing clips in the Timeline. This lets you combine different overlapping image adjustments using compositing math to achieve creative effects or utilitarian fixes.
The following simple example shows two overlapping Corrector nodes connected to a Layer Mixer node that’s set to the Add composite mode. Node 3 has no adjustment, but Node 5 has an extremely high-contrast curve adjustment applied, along with a blur, that effectively isolates the highlights of the image and feathers them out.

By adding both treatments together, a hot glow has been created, blowing out the highlights of the image. Many, many other effects are possible using the different composite modes that are available. For more information on composite modes, see Chapter 50, “Compositing and Transforms in the Timeline.”

**Adjusting Layer Node Strength Using Key Output Gain**

Whether you’re combining overlapping corrections, or mixing different adjustments using Composite modes, you’ll run into situations where you want to reduce the influence of one overlapping adjustment relative to the other nodes that are connected to the Layer Mixer node. This can be accomplished using each overlapping node’s Key Output Gain parameter, located in the Key palette.

Key Output Gain defaults to 1.00, but lowering this value reduces the strength of that node’s contribution to the Layer Mixer. Using the previous example, selecting Node 4 (the high-contrast image used to create the glow), opening the Key palette, and reducing the Key Output Gain parameter to 0.50 reduces the intensity of the Glow effect by half.
You can use Key Output Gain to mix the proportion of any number of overlapping adjustments in order to create the perfect combination for your purposes.

**TIP:** You can also use the Key Output Gain parameter to mix the proportion of adjustments being combined using the Parallel Mixer node.

## Converting Layer Mixers to Parallel Mixers

You can easily convert a Layer Mixer to a Parallel Mixer should you discover that you need to mix your overlapping corrections evenly rather than combine them with priority. Keep in mind that you’ll lose the ability to use Composite modes.

**To change a Layer Mixer node into a Parallel Mixer node:**

— Right-click a Parallel Mixer node and choose Morph Into Parallel Node.
A key is the actual image channel that’s generated by different secondary operations to isolate specific portions of images to work on.

This chapter covers different ways you can manipulate and combine keys from multiple nodes, or propagate keys among nodes. It also shows different ways you can use mattes that are imported from other applications, as well as how to use the Key palette to further manipulate keys in different ways.

Introduction to Manipulating and Combining Keys

Each node’s key input and key output makes it possible to route key channel data from one node to another so you can apply isolated corrections. Furthermore, the Key Mixer lets you combine a variety of keys from different nodes to create more detailed keys with which to tackle complex operations. This section covers all the ways you can recombine key data, as well as how keys can be used in conjunction with the Alpha output to create regions of transparency in a clip for compositing right within DaVinci Resolve.

Outside Nodes

Whenever you use a Power Window or HSL Qualifier to limit a correction within one node, a special node structure lets you automatically create a second node, called an Outside node, to apply additional adjustments to the inverse of the region you isolated in the previous node. Outside nodes are really just Corrector nodes with the Key Palette’s Key Input Invert control enabled, which makes it easy to apply separate corrections to an isolated subject and to its surroundings.

The Key Input Invert button, in the Key palette, that inverts any key fed to that node’s Key Input.

In the following example, the sky has been isolated using a Power Window, and an Outside node has been added to make an additional correction to everything else within the shot.

The Outside node automatically has its key input inverted.

To add an Outside node to a node, creating a secondary correction:

1. Select a node that has been limited using a Power Window or HSL Qualifier.
2. Do one of the following:
   - Choose Nodes > Add Outside (Option-O).
   - Right-click a node choose Add Outside Node.

A new node is created immediately after the selected node, with the RGB and key outputs of the first node automatically connected to those of the new node.
When selecting the new node and opening the Key palette, you can see that the Key Input’s Invert control is on by default, which is what inverts the key from the previous node.

![Key Input Invert control is on by default for each node.](image)

If, instead of using the Outside node to invert the incoming key, you want to copy the existing key in order to perform another operation to the same isolated region, you can disable the key input’s Invert control.

### Feeding Keys From One Node to Another

One of the most powerful aspects of the Node Editor is the ability to create keys based on a specific part of the node tree, and feed the result into a completely different correction somewhere else in the node tree. This is one of the reasons for the separate key input and output on every Corrector node.

The key that’s created whenever you use the HSL Qualifier, create one or more windows, or use an external matte can be output from one node’s key output and fed to the key input of any other node in a tree. There are many reasons to do this, but the following example shows a common problem you can solve with this technique.

**Using a key from one node to make an adjustment with a different node:**

1. Use Node 1 to apply a basic primary correction, increasing contrast and balancing the color to achieve a pleasing ambient color temperature.

2. Add a Serial node (Node 2), followed by a Layer Mixer node which also adds Node 4 (as seen in the following screenshots). Then, completely desaturate Node 4 and add contrast to make it super-high contrast black and white, desaturate Node 2 just a bit, and right-click the Layer Mixer node to choose the Overlay blend mode with which to combine these two layers.

![A group of nodes to create a stylized image](image)
The result is a highly stylized image, but the skin tone on the actor’s face and hands in the resulting image are too monochromatic, and you want to give them some differentiation. Simply adding another node after the Layer Mixer and keying the skin tone may not work well because the low level of saturation will make a key difficult to pull.

3 Add another node after the Layer Mixer (Node 5 in the screenshot), and then right-click in the gray background area of the Node Editor, and choose Add Node > Corrector to create an unattached node, (Node 6).

4 Connect the RGB output of Node 1 to the RGB input of Node 6, and then connect the key output of Node 6 to the key input of Node 5. Now you’re ready to pull a high-quality key from the very first correction in Node 1, skipping all the complication coming afterwards.

5 Use the HSL Qualifier in Node 6 to pull a good strong skin tone key based on the primary image. Given the way the node tree is now set up, that key is fed to Node 5, and will limit whatever adjustments you make there.

6 Now, you can make your adjustment to Node 6’s grade, to lower the contrast, brighten, and increase the saturation of the actor’s skin tone. As a result of this operation, the background remains desaturated and contrasty, while the actor’s skin tone has the brighter quality we need for the shot.
This example could have been handled in a variety of different ways, but the point is that you can add nodes that connect to the state of the image at any part of a node tree, and use them to generate keys to feed to any other node, regardless of what’s happening to the picture in between.

**Connecting Key Outputs to RGB Inputs, and Vice Versa**

There’s another way you can manipulate a key from one node using another in the Node Editor, and that’s to connect the key output from one node to the RGB input of another node. When you do this, you can use any of the controls of the second node to manipulate the key, and you can then use the result by connecting the RGB output of the second node to the key input of a third node.

In the node tree shown above, Node 2 pulls a key, Node 4 manipulates the key, and Node 3 uses the key to make a color adjustment.

Keep in mind that a key is just a grayscale image. Setting up this kind of node structure lets you use any of the second node’s controls, such as the Custom Curves, Noise Reduction or Motion Blur controls, Sharpen, Midtone Contrast, Lift/Gamma/Gain, Contrast, or Log controls, to manipulate the key in ways you couldn’t do using only the Matte Finesse controls.

While this technique may not be necessary for conventional color isolations, it can come in very handy when making tricky isolations with hard to key subjects, or when using one of the Qualifier modes to pull a key to create transparency for compositing using the Node Editor’s Alpha output. In this instance, you can connect the RGB output of a node used for key manipulation directly to the Alpha output. In
the example, Node 1 pulls a key, and the RGB is connected to Node 3 which is used to color correct the foreground image. The key from Node 1 is connected to the RGB of Node 2, which manipulates the key to clean it up prior to connecting it to the Alpha output block at the bottom right of the Node Editor.

Furthermore, this capability also lets you create keys in other ways besides using the Qualifier palette controls. In the following example, the Contrast and Custom Curve controls in Node 3 create a high-contrast matte of the windows which is blurred. The RGB output of Node 3 is then connected to the KEY input of Node 2, where the resulting key can be used for a variety of adjustments; in this case, to tint the product within the image green. Alternately, this technique could be also be used to create transparency via the Alpha output.

You can manually connect RGB inputs and outputs to Key inputs and outputs by dragging links between them. Alternatively, you can drag and hover a node over an RGB or Key link to insert it. Interconnecting key and RGB inputs and outputs is a powerful capability that lets you create many kinds of workarounds for uncommon situations.

**Using External Mattes**

The External Matte node has evolved over the years. What was once purely a means for importing matte channels for defining opacity and limiting adjustments has expanded to become a way to import the RGB channels of a media file to be used for overlaying grain, texture, and stylized distress onto an image, and even as a way to use the channels of a clip itself as a matte.
Matte clips can be added to your project in one of two ways:

— You can add mattes using the Media page, either by attaching them to a clip so a particular matte is only available to a particular clip as part of a Clip grade, or you can add timeline mattes that stand alone in the Media Pool, which are then available to any Track grade.

— You can also add a matte to a clip using the Media Pool in the Color page, by dragging a clip from the Media Pool to the Node Editor. When you do so, that clip is turned into an external matte in the current grade, which you can use as a matte for secondary adjustments, or as a compositing layer (in conjunction with the Layer mixer) for mixing textures or images with your grade. That clip is also automatically attached to the Media Pool clip that corresponds to the clip you’re grading, as a clip matte, to help you keep track of which clips are using other clips as mattes.

For more information about adding matte clips in the Media page, see “Adding and Removing External Mattes” in Chapter 18, “Adding and Organizing Media with the Media Pool.”

Whether attached or unattached, mattes operate within a grade using EXT MATTE (external matte) nodes. EXT MATTE nodes have the following outputs:

— **EXT MATTE Outputs:** Four blue square key outputs let you output the channels contained within the EXT MATTE node, but which channels are available affects what is output. If the EXT MATTE node’s source clip has RGBA channels, then these are available as Alpha, Red, Green, and Blue key outputs that you can attach to any other node’s key input. On the other hand, if the EXT MATTE node’s source clip only has RGB channels, then the key outputs that are made available are Y (luma), Red, Green, and Blue, and a “Use Lum for Alpha Output” setting in the Node Editor contextual menu lets you use the Y channel as a matte.

An interesting aspect of these four outputs is that each one is dedicated to individual A, R, G, and B color channels. Ordinarily, External Matte clips are written with matte data written simultaneously to all three RGB channels. However, you could also render separate pure primary-colored mattes to each color channel (a so-called “disco” matte), so that the Red channel has one matte, the Green channel another, and the Blue channels still another, thereby exporting three separate mattes within a single media file, for convenience. If you add another matte to the Alpha channel, you can even export four mattes within a single file. You can then use each one of these mattes individually by connecting the correct output of the EXT MATTE node. (Note: For backward compatibility, projects from versions of DaVinci Resolve previous to 12.5 continue to output RGBY from the square outputs, not YRGB.)

— **RGB Output:** A square green RGB output lets you connect the RGB image data of a matte clip to any other clip’s RGB input. This is especially useful when you’re combining a matte clip with the current clip using a Layer Mixer node, to create a textured composite of some kind.
External Mattes to Limit Adjustments

Going back to the External Matte node's original use, mattes are typically grayscale media files that represent image opacity, and are meant to be used either as alpha channels for creating opacity within a corresponding RGB clip, or as a matte for limiting effects.

An example of a matte channel would be the key created by a green screen keyer. If you output just the key, that would be an external matte. If you receive an external matte along with an effects clip, you can attach the matte to its corresponding RGB clip in the Media page. Then, you can access that matte via an External Matte node in the Node Editor, so you can use the key it outputs to limit different kinds of corrections you want to apply.

In the following example, the keyed matte of a green screen composite clip is used to apply different corrections to the inside and outside of a keyed composite, in order to make the subject match the background more convincingly.

A matte attached to clip Makeup_Green.mov, as seen in the Media Pool

To use a clip matte to limit an adjustment within a Clip grade:

1 Right-click any node, and choose the attached matte you want to use from the Add Matte submenu of the contextual menu.

   By default, the EXT MATTE node that appears has its first output connected to the Connect one of the EXT MATTE node's triangular key outputs to the key input of a node you want it to limit.

2 Select the node to which the EXT MATTE node is attached, and add an Outside node to make it possible to add adjustments on either side of the matte.

3 If necessary, select Node 1, and use the Key palette controls to modify the incoming key, inverting or blurring it as necessary to create the isolation you need.
NOTE: Don’t select the EXT MATTE node, because it exposes different controls in the Key palette for transforming, flipping, looping, and freezing the matte.

At this point, you can add adjustments to the inside and the outside of this composited shot to improve the composite.

(Before/After) An external matte is used to apply separate grades to the foreground and background of a previously composited clip.

Ideally, external mattes are exported so that they match the size and duration of the RGB clip they’re supposed to accompany. If they don’t match or if you’re using some other grayscale clip as an external matte to create some sort of effect, then there are parameters in the Key palette that you can use to retime or transform a matte so it works better in your grade.

To slip the sync of a matte relative to the clip it’s attached to:
1. Select the Ext Matte node you want to slip.
2. Open the Key palette, and turn off the Lock Matte checkbox.
3. Raise or lower the Offset parameter until the matte is perfectly aligned with the clip it’s supposed to match.

To transform a matte:
1. Select the Ext Matte you want to transform.
2. Open the Key palette, and turn off the Lock Matte checkbox.
3. Use the Pan, Tilt, Zoom, Rotate, Width, Height, HFlip, or VFlip parameters to adjust the matte so it has the correct geometry.

It’s worth mentioning that you can attach as many external mattes to a single clip in DaVinci Resolve as you like. For example, if a CGI shot has been delivered with a set of isolation mattes for each of three characters in the scene, you can import all three mattes and use them to isolate adjustments that you want to make in the Node Editor.

**Extracting External Mattes from OpenEXR Layers**

OpenEXR media is capable of containing multiple layers and multiple alpha channels, which can also be accessed from EXT MATTE nodes. As a result, DaVinci Resolve uses a slightly different but related procedure for accessing these mattes.
To extract OpenEXR layers as external matte nodes:

1. Right-click any node, and choose the .exr clip name from the Add Matte submenu of the contextual menu.
   
   By default, the EXT MATTE node that appears has its first output connected to the Connect one of the EXT MATTE node’s triangular key outputs to the key input of a node you want it to limit.

2. Double-click the EXT MATTE node to select it, then right-click it and choose which layer you want to use from the Select Matte submenu.

   ![Right-clicking an OpenEXR file’s EXT MATTE node to choose which layer to use](image)

OpenEXR files with multiple RGBA layers (or passes) embedded within them (RGBA + RGBA + RGBA and so on) or OpenEXR files with multiple alpha channels (RGBA + A + A) expose multiple entries in this submenu. Whichever one you choose is the layer that will be used as a matte by that EXT MATTE node.

Once you’ve extracted an OpenEXR layer, you can use it as you would any other EXT MATTE node described in this section, to limit adjustments (as seen above), or to add texture or transparency (as seen in the following sections).

**Using External Mattes to Add Texture**

You can also use external mattes as creative tools, to add grain and texture. For example, you might use a more abstract animated matte, or a grayscale film scan of dirt and dust, to apply correction for effect.

![Light leak and dirt and dust images From Warren Eagles’ Scratch FX collection (FXPHD), designed to add texture to your grades](image)
Once attached to a clip, external mattes can be exposed in the Node Editor, and their key output can be used just like any other key in a node tree.

**To use a clip matte to create texture for a Clip or Timeline grade:**

1. When applying a matte as part of a Clip or Timeline grade, right-click any node and choose the attached or timeline matte you want to use from the Add Matte submenu of the contextual menu. Unattached mattes appear in the Add Matte > Timeline Mattes submenu.

2. Disconnect the EXT MATTE node’s key output connection to the Key input of the node it’s connected to by default.

3. Add a Layer Mixer to the end of the node tree.

4. Disconnect the bottom Corrector node’s RGB input, and then connect it to the EXT MATTE node’s square RGB output.

5. Right-click the Layer Mixer node, and choose Overlay from the Composite Mode submenu to blend the Ext Matte node most effectively with the grade.

6. If necessary, you can use the grading controls of the Corrector node to which you’ve attached the EXT MATTE node to change the characteristics of the texture clip, desaturating it for instance. You can also select the EXT MATTE node itself, open the Key palette, and use the Transform, Offset, Loop, or Freeze controls described later to change how the matte appears.

The resulting texture effect, blended with the grade using the Overlay composite mode.
**TIP:** If you want the texture you create to be unaffected by blur or sharpening operations within the grade, be sure to add it to the very end of the node tree.

### Using External Mattes to Create Transparency

You can also use an EXT MATTE node to create transparency in a clip, for compositing with clips underneath it on the Timeline.

#### To use a clip matte to create transparency in a clip:

1. Right-click any node, and choose the attached matte you want to use from the Add Matte submenu of the contextual menu.
   
   Adding an EXT MATTE node to a Clip grade applies the effect to only that clip, whereas adding an EXT MATTE node to a Track grade applies the effect to the entire Timeline.

2. Right-click any empty area of the Node Editor, and choose Add Alpha Output to reveal the Node Tree output on the right that lets you assign a key to be used to define clip transparency.

3. Connect one of the EXT MATTE node’s triangular key outputs to the Alpha output at the right of the Node Editor.

![The node setup for using an external matte to composite two layer](image)

The areas of the matte defined by the key are now rendered transparent.

![The final composite created using the external matte node](image)
**Key Palette Controls for the External Matte Node**

When you select an EXT MATTE node, the Key palette displays different parameters only for mattes. Be aware that you must turn off the Lock Matte checkbox before you can make adjustments to transform the matte.

![Key Palette showing a texture layer added as an EXT MATTE node](image)

- **Transform**: Standard Pan, Tilt, Zoom, Rotate, Width, and Height parameters let you transform a matte to fit the image better.
- **Flip Image**: Two buttons let you flip the matte clip horizontally or vertically.
- **Offset**: Adjust this parameter to offset the start point of a matte clip.
- **Freeze**: Turning on this checkbox freezes the matte clip on a single frame. Adjust the Offset parameter to choose which frame to freeze on.
- **Loop**: Turning on this checkbox enables matte clips to loop endlessly, which lets shorter matte clips cover longer durations.
- **Lock Matte**: When turned on, locks the sizing of a matte to whatever changes are made to the Input Sizing of that clip, so the matte transforms to follow the clip.

You can also use external mattes as creative tools. For example, you might use a more abstract animated matte, or a grayscale film scan of dirt and dust, to apply correction for effect.

**Using Mattes From the Fusion Page**

If you’re grading a composite that’s been created in the Fusion page, you can feed mattes created in different parts of a Fusion composition to the Color page to use in the grade as well. For example, if you’re grading a composite of a foreground actor who’s green screen keyed against a background layer, you might want to use the matte generated for the key to protect the foreground subject from an operation in your grade that you only want to affect the background. Happily, this is easy to set up.

In the following Fusion composition, two DeltaKeyer nodes (one to create an overall matte, and one to create a solid matte protecting the core) and one BSpline node (to create a garbage matte) work together to create a finely-tuned matte. This matte is used by the Merge1 node to preserve the subject’s hair and composite them in front of a gently blurred (using the LensBlur node) planet, with the final
result connected to the MediaOut1 node, which feeds this image to the Edit page and Color page for continued adjustment.

A green screen composition in the Fusion page, outputting the RGB in MediaOut1, and the foreground matte in MediaOut2

Because the Merge1 node outputs the entire composition as a single image, a second MediaOut node (highlighted) is added to output the matte, just in case the colorist might want to use it later.

**TIP:** In this composition, the foreground and background images are different sizes, so outputting the alpha channel of the DeltaKeyer1 node would result in a matte sized to match the foreground image, but that doesn’t fit the composition, which is cropping the top and bottom of the foreground image based on the frame size of the widescreen background image. To get around this, the foreground and background images are composited a second time using the Merge2 node, which has the Operator parameter set to “In” to output just the foreground image and matte, as resized by the Merge operation. The resulting MediaOut2 node thus outputs a foreground matte that’s properly sized to fit the composition.
On the Color page, the grade in node 1 is applied to the overall final result, which is a single image. After grading, it’s decided that the woman appears a bit warm relative to the cool blue of the planet behind.

Right-clicking the background of the Node Editor and choosing Add Source adds a second source at the left of the Node Editor.

This second source corresponds to the second MediaOut node you added to the Fusion page composition, which outputs the Matte as a key in the Color page, usable just like any other key. If you hover your pointer over each source, a tooltip appears letting you know which output corresponds to which node.

Generally, sources are arranged from top to bottom from the first MediaOut node appearing in a Fusion composition to the last. At this point, you can connect the second Source to the Key input of a second corrector node, using that key to selectively grade just the woman in the foreground (grade exaggerated...
for effect), without affecting the background. The Viewer is shown with Splitscreen set to Highlight Modes, so you can see the result as well as the key from the Fusion page that’s being used by Node 2.

Connecting the second source to a second Corrector node’s KEY input to use the matte to limit a correction made to the foreground character.

Using the Key Mixer

The Key Mixer node lets you mix keys output from multiple Corrector nodes, combining them in different ways to create a single key output. This makes it possible to build much more intricate keys than you can with a single qualifier or set of four windows. In particular, the Key Mixer node is the only way to combine multiple keys made using qualifiers and windows, adding, subtracting, or intersecting them to create a highly specific result.

Adding Two Keys Together

In the following example, you’ll learn how to set up a Key Mixer to combine the keys output by two Corrector nodes in a node tree. Then you’ll learn how to change the way the input keys are combined using the Key palette.

To combine two or more keys using the Key Mixer:

1. Right-click anywhere on the gray area of the Node Editor, and choose Add Node > Key Mixer.
2. Create two Corrector nodes, then attach their RGB inputs to the RGB output from an appropriate node in the main part of the tree, and attach their key outputs to the key inputs of the Key Mixer.
3. Next, attach the key output of the Key Mixer node to the key input of the node you want to use to make the correction. Remember, the objective is to use the key that’s output by the Key Mixer to limit the adjustment being made using another node, in this case Node 3.
Keep in mind, especially since this is a significant reordering of nodes in the Node Editor, that every node needs to be connected properly for the overall grade to work.

4  Now that the node structure is fully connected, use windows, qualifiers, or both to create keys in each of the nodes that you connected to the Key Mixer. In this example, Node 2 is isolating the main skin tone, and Node 5 is isolating the blue of his jeans and hood.

By default, all keys connected to the Key Mixer are added together, as you can see in the Key Mixer’s thumbnail.

By default, all keys connected to the Key Mixer are added together, as you can see in the Key Mixer’s thumbnail.

Combining multiple keys with the Key Mixer

If you wanted, you can use the controls in the Key palette to change this, in order to isolate the intersection of two keys, or to subtract one key from another. This is covered in the next section.

5  Continuing with the previous setup where both keys are added together by default, selecting Node 3 and dropping the saturation to be very faint stylizes the entire background, while leaving the various hues of the man we’ve isolated alone.

Final grade, the talent in color with a B&W background

**Subtracting One Key from Another**

The way multiple keys are combined within the Key Mixer depends on a pair of Key Input buttons you can toggle using the Key palette. In the following example, a partial green tint is washed throughout the midtones of the image using a qualifier, but you want to exclude the man’s skin tone from this operation.

Using the Key Mixer, you can subtract one key from another to accomplish this with ease.
A selective blue tint added to the midtones of the image includes the red sign.

To change the Key Input settings for a node connected to a Key Mixer:

1. In this example, Node 2 is isolating part of the midtones of the image, and feeding its key through the Key Mixer to Node 4, which is using it to apply a partial blue tint. However, in preparation for subtracting the skin tone from this operation, Node 3 is isolating the man’s skin tone.

A node setup in preparation of subtracting the Bar sign from the midtone isolation being used to add a partial blue tint

2. To reveal the controls you’ll use to change how the key from Node 3 interacts with the key from Node 2, double-click the Key Mixer node to select it.

3. Open the Key palette; a list of all input links that are connected to the Key Mixer appears at the right.

The input list of the Key Mixer node

4. Within each list entry is the input name (Input Link 1, Input Link 2, etc.), a Matte control, a Mask control, a gain parameter, and an offset parameter.
— **To subtract Node 3’s key from that of Node 2:** Turn on both the Key Input Matte button and the Key Input Invert button for Input Link 2.

![Key Mixer](image1)

Turning on Matte and Invert for Input Link 2 to Output Node 3 subtracted from Node 2

— **To subtract Node 2’s key from that of Node 3:** Turn on both the Key Input Matte button and the Key Input Invert button for Input Link 1.

![Key Mixer](image2)

Turning on Matte and Invert for Input Link 1 to Output Node 2 subtracted from Node 3

— **To limit the output to the intersection of both keys:** Turn on the Key Input Matte button for either Input Link 1 or Input Link 2.

![Key Mixer](image3)

Turning on Matte for Input Link 1 to output the intersection of two mattes

— **To invert the resulting matte you’ve created:** Turn on the Output Link Invert button.
When you're finished, if you choose to subtract Node 3’s key from that of Node 2, the result should resemble the following screenshot.

![Screenshot Example](image)

The result of subtracting a key of the man’s face from a key of the overall midtones of the image, and using that to add a selective green tint

---

**Adding Inputs to Key Mixer Nodes**

New Key Mixer nodes have two key inputs by default. If necessary, additional inputs can be added in order to combine even more keys with one another.

**To add inputs to the Key Mixer:**

- Drag the Key Output from a corrector node to the Key Mixer.
- Right-click a Key Mixer node, and choose Add One Input.

When combining three or more keys, the interaction of keys using the Key palette controls becomes even more complex, but the rules outlined above still apply.

---

**Using the Key Palette**

For example, the Key Input Invert control is always enabled when you add an Outside node, which is why the Outside node applies adjustments to the inverse area of the previous node. If you turn this control off, that node's key will exactly mirror the original key being fed to it from the previous node.

The controls that are available in the Key palette vary depending on what kind of node you have selected:
— **Corrector Nodes**: Have three sets of parameters. Key Input parameters let you make adjustments to keys being fed through a node’s Key Input connection. The Key Output parameters let you make adjustments to the key data being output by a node’s Key Output connection, and includes the incredibly powerful Offset Gain parameter that governs the strength of that node’s contribution to the overall grade. Finally, the Qualifier parameters let you make adjustments to the internal key created with the HSL Qualifier or Window controls. This functionality is covered more extensively in the next section.

— **Ext Mattes**: Have two sets of parameters. Transform parameters let you make geometric transformations to a matte so it fits the clip it’s being applied to better. An Offset control lets you slip the sync between an external matte and the clip to which it’s applied. This functionality is covered in the section on external mattes.

— **Key Mixer Nodes**: Have two sets of parameters that are dependent on which of the connections attached to a Key Mixer’s key inputs is selected. Input parameters let you adjust how much of a contribution a key makes to the total key mix, and whether the contribution is additive or subtractive.

The Output parameters let you adjust the inversion and strength of the key that’s output by the Key Mixer. This functionality is described more extensively in the Key Mixer section.

Layer Mixer and Parallel Mixer nodes have no adjustable controls in the Key palette.

**Using the Key Palette to Affect Corrector Nodes**

When you open the Key palette for a selected Corrector node, you can adjust the following parameters:

![Key palette showing controls when a node is selected](image)

**Key Input Controls**

— **Input invert**: Inverts the key being fed into the key input. Off by default.
— **Input matte**: Lets you switch the key input between Matte and Mask modes. In Matte mode (on by default) the key input combines via intersection with keys generated internally using the Qualifier or Windows palette. In Mask mode, the key input is added to the internal key instead.
— **Gain**: Controls the strength of the key connected to the key input.
— **Offset**: Controls the contrast of the key connected to the key input.
— **Blur Radius**: Blurs the key connected to the key input.
— **Blur H/V Ratio**: Alters the horizontal/vertical ratio of the blur that’s being applied to the key input.
Key Output Controls

- **Qualifier invert**: Inverts the overall key.
- **Gain**: Using the key output, this parameter governs the strength of that node’s contribution to the overall grade. Setting Gain to 0 results in that node having no effect at all, while the default setting of 1.00 applies the full strength of any adjustments made with that node. The maximum setting of 2.00 increases the intensity of any part of the key output that’s less than 100 percent white. You can also use this parameter to keyframe the key output to fade that node’s contribution in or out with one set of keyframes.
- **Offset**: Lets you adjust the contrast of the Output key. This has no effect if the entire key is 100 percent white (a solid key).

Qualifier Controls

- **Qualifier invert**: Inverts the key created by that node’s Qualifier palette.
- **Qualifier matte**: Lets you switch the interaction of the keys generated by the Qualifier and Window palettes between Matte and Mask modes. In Matte mode (the default), the Qualifier and Windows palettes combine via intersection. In Mask mode, they’re added together instead.
- **Gain**: Lets you raise or lower the strength of the key generated by the Qualifier palette.
- **Offset**: Lets you adjust the contrast of the key generated by the Qualifier palette.

Using the Key Palette to Adjust Key Mixer Controls

When you open the Key palette for a selected Key Mixer node, you can adjust the following controls:

- **Input list**: A list of every input that’s connected to the Key Mixer. Each entry on the list has the following controls:
  - **Input name**: The name of each node connection attached to that key mixer, such as Input Link 1, Input Link 2, and so on.
  - **Input invert**: Inverts the key being fed into this particular input. Off by default.
  - **Input mask**: Lets you switch the key input between Matte and Mask modes. In Matte mode (on) the key input combines via intersection with other inputs connected to the Key mixer. In Mask mode (off by default), the key input is added to the other key inputs connected to the Key mixer.
  - **Gain parameter**: Decreases or increases the intensity of that input matte’s contribution to the resulting output matte.
  - **Offset parameter**: Adjusts the contrast of that input matte’s contribution to the resulting output matte.
— **Output invert**: Inverts the overall result of the various Input Link interactions.

— **Gain**: This parameter increases or reduces the strength of the resulting output key. Setting Gain to 0 results in all inputs being set to black, while the default setting of 1.00 outputs the combined mattes at full strength. The maximum setting of 2.00 increases the intensity of any part of the key output that’s less than 100 percent white, which can have the practical effect of “growing” soft edges. You can also use this parameter to keyframe the key output to fade that node’s contribution in or out with one set of keyframes.

— **Offset**: Lets you adjust the contrast of the Output key.

### The Many Uses of Key Output Gain

Several of the techniques discussed in here and in “Secondary Qualifiers,” can be further customized using the Key Output Gain parameter, which makes it easy to control the strength of a node’s effect on your grade with a single adjustment. In the following example, two simple Serial nodes are applied to a clip, with the first one expanding image contrast, and the second one using a variety of controls to add some extreme warmth to the highlights.

![A tint applied only to the highlights of the image](image)

If you decided that you want to reduce the amount of warmth added by the second node without readjusting the controls you used to create the effect, you could open the Key palette and lower the Key Output Gain parameter to fade the effect with a single adjustment.

![Four versions of this grade shown using the Versions option of the Split Screen controls, with Output Gain set to 1, .75, .5, and .25 for comparison](image)

This principle also works for controlling the strength of individual nodes that are being combined in parallel, that are combined using the Layer node, or for simply fading out the effect of any node in the node tree you want to “turn down” a bit.
Chapter 143

Channel Splitting and Image Compositing

This chapter begins by showing node structures you can use to isolate, split apart, convert, and recombine the image channels of clip in different ways. This includes ways of using the additional image channels that are provided in some types of media.

The second part of the chapter shows ways that you can do image compositing right in the Color page, with techniques for using external mattes for compositing, and using qualifier keys to do green- and blue-screen compositing against other layers in the Timeline.

Isolating, Splitting, and Converting Color Channels

DaVinci Resolve provides two different methods of making channel-specific adjustments, depending on whether you need to apply an adjustment to just one channel within a single node, or apply separate adjustments to all three channels across several nodes.

Enabling, Disabling, and Converting Node Channels

Within the contextual menu of each node in the Node Editor is a series of four options:

![Menu options]

Expanded choices for choosing a color space and gamma for image processing within a node, and for disabling channels.

While the ability to change the color space in which a particular node’s operations work from the RGB default has been available for many versions, the list of available color spaces was greatly expanded in DaVinci Resolve 15 (all the previous options such as Lab (CIE), HSL, and YUV are still there). Additionally, you have the option of choosing the gamma that node works with as well, with a similarly long list of options.

Choosing a node-specific color space and gamma does not directly alter the image, as with the Color Space Transform ResolveFX plug-in. Instead, changing a node’s color space and gamma alters what type of image channels the red, green, and blue controls affect, and how the adjustments you make within that node are applied. For example, this lets you make a temperature adjustment with a node’s gamma set to Linear, which in some instances may be mathematically advantageous.

Additionally, three checked Enable Channel 1–3 options let you turn individual channels off or on, limiting which channel that node’s adjustments will actually affect.

In the following example, you’ll see how to use these features to selectively sharpen just the Y’ (luma) of an image without affecting the chroma, which can be a more subtle effect than simply sharpening the entire image.
To use channel disabling and color space conversion to sharpen luma only:

1. Add a node with which to apply the sharpening you want to the current clip.
2. Right-click the new node, and choose YUV from the Color Space submenu of the contextual menu.
3. Apply sharpening by doing one of the following:
   - Using that node’s contextual menu, uncheck Enable Channel 2 and Enable Channel 3, which correspond to the U (Cb) and V (Cr) channels, leaving only Channel 1 (Y) enabled. Then, open the Blur palette, and drag the ganged Radius sliders down to sharpen the Y channel.
   - You can also just open the Blur palette, ungang the Radius sliders, and drag the red slider down to sharpen the Y channel, since any control with three gangable sliders will automatically assign those sliders to whichever channels are used by the currently selected Color Space.

As you can see, while the Blur palette ordinarily provides separate R, G, and B controls that can be unganged from one another, the Color Space submenu lets you apply sharpening to the channel definitions of other colorspaces, providing many other corrective and creative possibilities with the same controls.

**Supported Color Spaces for Conversion**

The Color space submenu available when you right-click a node in the Node Editor supports four different color spaces that you can set each node to work within. When you choose a color space other than RGB, all channel-specific controls (the Custom curves, Soft curves, RGB Lift/Gamma/Gain sliders, and RGB mixer) operate on the particular channels of that color space, rather than the default YRGB channels. By switching color spaces, you can achieve very different kinds of adjustments by swinging values among mathematically different axes.

YUV converts the image into Y’, Cb, and Cr channels. The Y’ channel governs luminance, while the Cb and Cr are color difference channels that work within the broadcast model of color.
HSL converts the image into Hue, Saturation, and Lightness channels. Lightness is identical to Luminance, while Hue and Saturation are exactly as described.

LAB operates on the L, A, and B channels. The L channel governs luminance, while the A and B channels are color difference channels; A adjusts color on an axis from magenta to green, B adjusts color on an axis from yellow to blue.

Splitting Channels with the Splitter/Combiner Nodes

Another method of applying corrections to individual color channels is using the Splitter/Combiner nodes, which break the Red, Green, and Blue channels apart into separate node tree branches, each capable of accepting multiple serial and parallel nodes of image adjustment. There are two ways you can create a Splitter/Combiner node structure.

Methods of adding Splitter/Combiner nodes:

— **To add a premade Splitter/Combiner node structure:** Choose Color > Nodes > Add Splitter/Combiner Nodes (Option-Y). A Splitter and Combiner node appear already connected to three Corrector nodes, one for each color channel.

— **To manually construct a Splitter/Combiner node structure:** Right-click in any empty area of the Node Editor, and choose from the Add Node submenu to create a Splitter node, a Combiner node, and three Corrector nodes, wiring them together as necessary to create the desired effect.

The Splitter Combiner node structure

The Splitter node takes an incoming image and provides individual outputs for each color channel (top/red, middle/green, bottom/blue). When you connect each of these outputs to a Corrector node, that color channel automatically connects to all three internal channels of that node, so that the default three nodes in a Splitter/Combiner structure are internally processing red/red/red, green/green/green, blue/blue/blue. The Combiner then pulls the Red, Green, and Blue channels out of each node connected
to its three inputs, and reassembles them into a single RGB image again. Of course, what happens in between the Splitter and Combiner is entirely up to you.

One of the simplest ways of showing the possibilities of this node structure is to combine it with Node Sizing in the Sizing palette. Using Node Sizing, you can correct for misaligned channels in older archived video, or create channel misalignments for creative looks. In the following example, a simple Node Sizing adjustment to a split Blue channel will create an interesting “prism vignette” effect.

**To use Node Sizing on individually split channels:**

1. Choose Nodes > Add Splitter/Combiner Node (or press Option-Y) to add a premade Splitter/Combiner node structure to the Node Editor.

2. Select the middle of the three Corrector nodes appearing in between the Splitter and Combiner nodes (Node 5 in the following screenshot).

3. Open the Sizing palette, choose Node Sizing from the Mode drop-down, and then raise the zoom parameter by a small amount; this example uses 1.014.

![Zooming just one color channel using the Splitter/Combiner nodes](image)

As you can see in the screenshot, just the Green channel has been zoomed in on across the entire image. This is only possible using Node Sizing. This is cool, but not quite what you need.

4. Open the Window palette, add a Circular window, turn on its Invert control, and transform it to be a very soft, horizontally aligned vignette. This limits the individual scaling done to the Green channel to just the outer edge of the image, similar to a lens with excessive chromatic aberration.

![The resulting channel split effect](image)

You could easily keep going, applying varying amounts of zoom with different window shapes to each of the other color channels, and perhaps adding some blur to enhance the effect, but this example should show the creative potential available when using this technique.
Multi-Channel RED HDRx Support

The RED EPIC, SCARLET, DRAGON, and WEAPON cameras are all capable of shooting in an HDR mode that effectively "brackets" two different exposures of each frame. The resulting image data stores two channels of image data: the regular exposure, and a "highlight exposure" that’s underexposed by a user-selectable margin (+3, +4, +5, or +6 f-stops difference).

By default, the Input bar in the node graph feeds the regular exposure to your grade’s node tree. To take advantage of the additional “highlight” exposure, you can add an additional Source input to the node graph that feeds a second stream of image data that you can mix with the regular exposure in different ways.

**NOTE:** You can also take advantage of the highlight exposure of RED HDRx media by enabling and adjusting the Magic Motion controls in the Camera Raw palette.

To set up a node tree combining the normal and highlight HDR versions:

1. Using the first default node (Node 1), grade the image to see if you even need to use the alternate exposure that’s available. We’ll assume for this example that you do. In this example, the sky of the default exposure is pretty blown out, but there may be detail that can be retrieved using the highlight exposure.

2. Create a Layer Mixer node by choosing Nodes > Add Layer (Option-L).
   Two nodes are created, a Layer Mixer node that’s added after Node 1, and a third node (Node 3) that’s connected to a second RGB input of the Layer Mixer node in parallel to Node 1.

   ![Using HDRx images with the Layer Mixer](image-url)

   The Source currently supplies two input, but you can add a second source, which is the short exposure in the HDR image.
3 Right-click anywhere within the node graph (except on a node) and choose Add Source from the contextual menu.

A second Source input appears underneath the first, which outputs the highlight exposure of the image as a separate image stream.

A node tree that uses a Layer Mixer node to mix two Corrector nodes, each connected to separate outputs for the regular and highlight exposures

4 Delete the connection between the top Source input and Node 3, and then connect the bottom Source input to the RGB input of Node 3.

Immediately, the image in the node thumbnail and Viewer updates to show the darker, underexposed version of the HDR image. This is because, by default, the Layer Mixer is mixing 100% of Node 3 over Node 1.

5 Select Node 3 and use one of the following two procedures to create a useful combination of the two exposures:

To create a mix of the two exposures, open the Key tab, and drag the Key Output Gain slider to lower the contribution of Node 3 to the overall image. Using dynamics (keyframing), this is a good way to animate a dissolve from the regular exposure to the highlight exposure if you’re going from a dark environment to a bright environment in the same take and you want to create a smooth transition between both exposures.

Dissolving between the regular and highlight exposures of RED HDRx media using the Key Output Gain slider of a Corrector node connected to a Layer Mixer node

**TIP:** You can also use the Blend Type and Blend Bias parameters in the Camera Raw palette to blend the two exposures without building a dedicated node tree.

To use the highlight exposure to selectively put detail back into the image (for example, to retrieve blown-out windows), use a Power Window, HSL Qualification, or a combination of the two to isolate the region you want to retrieve in Node 3. (Be careful if you’re using HSL Qualification to combine both exposures, as keyed edges can be tricky to blend.)
Isolating a region of the image to replace using the highlight exposure image of a RED HDRx clip

Final node display with isolations

A Note About RED HDRx Media and Performance

Since RED HDRx media records two complete streams of image data, DaVinci Resolve must simultaneously decode two separate tracks whenever you add a second Source input. (If you don’t add the second Source input, only the first stream is decoded.)

Because of this, whether you’re relying on your computer’s CPU or GPU to decode RED media, you’ll get half the performance when using the highlight stream of an HDR clip.

To improve performance, you can enable the Smart Cache by choosing Playback > Render Cache > Smart. This automatically caches all raw source clips to the current codec set in the Render Cache Format parameter of the Master Settings panel of the Project Settings. Alternatively, you can enable the User Cache, and cache all HDRx clips manually by right-clicking them and choosing Render Cache Fusion Output > On. DaVinci Resolve renders all cached clips while you’re paused, so the next time you play a cached clip, it will play at full speed.

If you regularly use RED HDRx media, multiple high-end GPU cards are recommended for optimal decoding performance.
Introduction to Compositing

Using the Alpha Output

While DaVinci Resolve can use the alpha channel of imported media for compositing, the Alpha Output in the Node Editor is an optional output that you can turn on to create clip transparency using operations inside DaVinci Resolve to create composites against other clips on lower video tracks. There are many ways of using the Alpha Output, but this section will focus on three examples.

Using a Qualifier Key to Create Transparency

In this first example, the Alpha Output will be used to composite a green screen clip with a background plate.

In preparation for this composite, the background plate is on track V1 of the Timeline, and the green screen clip has been superimposed on track V2.

A superimposed green screen clip on track V2 of the Timeline, above a background plate on track V1, ready for compositing
To create a chroma-key composite in the Color page:

1. Right-click anywhere within the gray area of the Node Editor and choose Add Alpha Output to add the Alpha Output at the right of the node graph.

   An Alpha Output appears underneath the Node Tree output at the right of the Node Editor.

2. You’ll want to use Node 1 to color correct the image to optimize it for keying. In this example, the foreground plate is log-encoded, so a LUT is added to Node 1 to normalize it.

3. Add a Serial node after Node 1 and connect its key output to the Alpha Output. This is a fast way to build this composite if you’re confident that the corrections you’ve made in Node 1 won’t adversely affect the key (or if you know they’ll improve it by expanding the contrast of a flat-contrast source clip).

   Alternately, you could create a second processing branch by adding a disconnected node (Node 2), connecting the Source node to its RGB input, and then connecting its key output to the Alpha Output you just added. Creating a second image processing branch from which to pull your key lets you key directly from the source (assuming the source is fit to key without adjustment), avoiding any problems that grading the first node could introduce to the key.

4. Use the Qualifier controls of Node 2 to key out the green background, and then turn on the Invert checkbox to create the proper composite. In this example, we’re using the 3D Qualifier mode to pull a high-quality key.
An HSL Qualification to key the green feeding the Alpha Output to create transparency

5 If there’s green spill in the composite (or blue in cases where you’re keying a bluescreen) you can turn on the Despill checkbox to eliminate it.

6 You can also use a Power Window to garbage matte out any elements you don’t want intruding into the shot, using the Tracker palette if necessary to make the window follow the motion of the foreground subject.

7 If necessary, you can add another node to the output of Node 2 to make whatever corrections are necessary to the background plate clip to make the composite blend more seamlessly. For example, with this additional node selected, you could right-click the background clip and choose “Shot Match to This Clip” to use the automatic shot matching in DaVinci Resolve to adjust the foreground to match the background.
Adding more color adjustments to a node added after the qualifier

With all this set up, you end up with a nice green screen composite that’s visible in both the Color and Edit pages.

The result, with a window garbage matte cropping out the equipment, ready for further refinement

Using a Matte to Create Transparency

If you’ve been provided with a separate Matte clip for defining clip transparency, you can use that Matte clip within the node tree of a superimposed clip to create a composite using the Alpha Output.

To create a composite using an external matte:

1. To associate an external matte with a clip, open the Media page, select the clip you want to add a matte to in the Media Pool, navigate to the matte file using the Library browser, and then right-click the matte file and choose Add as Matte. For more information on importing mattes, see Chapter 142, “Combining Keys and Using Mattes.”

2. Open the Color page and select the foreground clip in the Thumbnail timeline, then right-click Node 1 in the Node Editor and choose the matte you added from the Add Matte submenu.

   An EXT MATTE node appears underneath Node 1, with the first of its four key outputs connected to Node 1’s key input. (Working with external mattes is covered in more detail in a prior section of this chapter.)
3 Now, right-click anywhere within the node graph (other than on a node) and choose Add Alpha Output from the contextual menu. An Alpha output appears underneath the Node Tree output.

4 Drag a connection line from the second key output of the EXT MATTE node to the Alpha output.

Using an external matte in the grade and to the Alpha output

You should now see a successful composite, with the external matte creating a region of transparency in the foreground clip through which the background clip shows through.

Before and after the final composite, created by connecting an EXT MATTE node to the Alpha output in the node graph

Use an OFX Plug-in to Create Transparency

If you’ve installed an OFX plug-in capable of keying, you can right-click the node you’ve applied it to and choose Use OFX Alpha to route the key created by the plug-in out the key output of that node. When Use OFX Alpha is enabled, the HSL Qualifier and Window palette output is ignored, the only key that’s output is from the OFX plug-in.
Choosing Use OFX Alpha in the Node Editor

Once Use OFX Alpha is enabled, and you've created a key using your OFX plug-in of choice, you can right-click anywhere within the node graph (other than on a node) and choose Add Alpha Output from the contextual menu to make the Alpha output appear, and you can then connect the key output from the node with the OFX plug-in to the Alpha output to use it to create transparency.

Setting up a composite using an OFX plug-in

**NOTE:** When Use OFX Alpha is enabled for a node, you cannot use a window to create a garbage matte within that node as you would when keying with the HSL Qualifier. To create a garbage matte with which to exclude unwanted and unkeyable elements from the edges of the picture, you'll need to combine the key from a window in another node with the key output by the OFX plug-in using a Key Mixer node.
Compositing Entirely Within an OFX Plug-In

Certain OFX plug-ins that are capable of combining two image streams to create a composite can be used as of DaVinci Resolve version 11.1 by exposing a “second layer input” on the node to which that plug-in has been applied. This makes it possible to composite the image you’re grading with the RGB output from an EXT MATTE node.

To create a composite using an OFX plug-in:

1. Open the Open FX panel, use the Library to find the OFX compositing plug-in that you want to use, and drag it onto the appropriate node to apply it. The above example shows the Boris Effects plug-in “BCC Composite,” which mathematically combines two image streams using one of a long list of blending modes.

2. Right-click the node with the Open FX plug-in applied to it, and choose Second Layer Input from the contextual menu. A second RGB input should appear on the left of the node, underneath the first.
3 Open the Media page, locate the clip you want to composite in the Library, and import it as an unassigned matte.

4 Open the Color page again, right-click the node with the OpenFX plug-in applied to it, and choose Add Matte > Track Mattes > "name of matte imported in step 3" from the contextual menu.

5 By default, the EXT MATTE node that appears is connected via one of its key outputs. Delete the key connection, and drag a new connection line from the EXT MATTE node’s RGB output to the second RGB input of the node with the OpenFX plug-in.

6 At this point, the node tree is wired up to composite the clip with the EXT MATTE image, and you need only adjust the parameters of the OpenFX plug-in to achieve the result you desire.
Chapter 144

Keyframing in the Color Page

The Color page has a dedicated Keyframe Editor, found at the right of the palette area, that you can use to animate grading changes from one frame to another. Because grading is a fundamentally different task than editing, the Color page Keyframe Editor operates somewhat differently from the Curve Editor in the Edit page.

Introduction to Keyframing

Whether it’s referred to as keyframing, dynamics, or marks, DaVinci Resolve provides an interface for automatically interpolating color adjustment parameters in various ways from one setting to another. For example, if you have a clip with varying exposure settings, you can animate a series of contrast adjustments using Dynamic keyframes to make the changes in exposure less distracting.

The Keyframe Editor with dynamic keyframes animating the parameters of Node 2

In another example, suppose you’re grading a documentary, and an archival clip that’s edited in the middle of the Timeline actually consists of six different shots from a program in the eighties. If you’re in a hurry, you can insert Static keyframes (marks) at the cut points of each of these shots, creating instant one-frame transitions between different adjustments made to that clip’s grade, which allows you to create unique adjustments for each shot within the clip.

Round static keyframes added to all parameters, enabling individual adjustment of shots merged together within a single clip

In both cases, you use the Keyframe Editor to create a series of keyframes with which to change parameters from one value to another. In this section, you’ll learn how to work with the Keyframe Editor to set up these kinds of animated changes.

The Keyframe Editor Interface

The Keyframe Editor has all the controls necessary to create and modify keyframes for the currently selected clip. If necessary, you can even make it wider in a single screen layout by clicking its expand button (at the top right of the Keyframe Editor). If you have two computer displays, you can use the Color page’s Dual Screen layout which places the Keyframe Editor on a second screen and uses the entire width of the monitor, for even more room.
The Keyframe Editor consists of the following components:

- **Timeline Ruler:** Mirrors the record timecode of the currently selected clip; dragging within the Timeline Ruler moves the playhead, and a timecode display to the left shows the current frame.

- **Keyframe track header:** Each node in the current grade has a corresponding keyframe track, Sizing has its own keyframe track, and the track header contains controls you can use to manage the keyframing.

  - **Enable/Disable button:** A round white button lets you enable or disable that track’s corresponding node.
  
  - **Lock button:** Lets you prevent any changes from being made to that track’s corresponding node. Nodes that have been locked show a lock icon. You can also lock or unlock nodes by right-clicking a node in the Node Editor and choosing Lock Node from the contextual menu.

- **Auto-Keyframe button:** Turn this button on to automatically create a Dynamic keyframe every time you adjust any parameter within that node.

- **Track disclosure triangle:** Exposes individually keyframable groups of parameters underneath the main keyframe track.
— **Keyframe tracks:** To the right of the track header, the keyframe tracks are where you create and edit the keyframes that animate parameter changes. A topmost “master keyframe track” shows every keyframe applied on every keyframe track in the Keyframe Editor, even keyframes applied to a keyframing track hidden inside a track with a closed disclosure triangle.

— **Keyframes:** Each keyframe appears as a small diamond for a Dynamic keyframe or as a circle for a Static keyframe. Dynamic keyframes are associated with dissolves while Static keyframes (marks) act instantly. Grades are linked to the preceding keyframe, which may be a default one on the first frame of the master clip. Keyframes can be selected by clicking on them, or moved by dragging them to another position in the keyframe track.

— **FX track:** Resolve FX or OFX plug-ins that have been added to a grade as a standalone node have a separate track for creating animated effects. Every parameter of that track is keyframed via a single consolidated keyframe track. If you apply multiple plug-ins as multiple nodes, each has a separate FX track.

— **Sizing track:** The Pan, Tilt, Zoom, Rotate, and Convergence (in Stereo 3D projects) parameter have an entirely separate track for creating animated pan and scan adjustments.

— **Track selection drop-down:** A colored bar shows the currently selected scope of keyframing: all tracks at once, just the current correction node, or the Sizing settings, as defined by the Keyframe Timeline mode discussed in the next section.

Ordinarily, the Keyframe Editor takes up the rightmost bottom third of the Color page. However, you can make it wider to have more room to work if you have a scene requiring complex keyframing.

**To expand and collapse the Keyframe Editor:**

— Click the Expand/Collapse button at the top right corner of the Keyframe Editor. The Keyframe Editor widens or narrows accordingly.

**To zoom into and out of the keyframe tracks:**

— Use the Zoom slider to zoom into or out of the Keyframe Editor.
— Right-click any keyframe track and choose Maximum Zoom to zoom all the way in.
— Right-click any keyframe track and choose Reset Zoom to fit the entire clip into the available width of the Keyframe Editor.

**All/Color/Sizing**

Perhaps the most important control for keyframing, the Keyframe Timeline mode, lets you switch the scope of what tracks get keyframed when you use the Start Dynamic or Add Static Keyframe commands, either from the keyboard or via the buttons of your control panel. This command alternates among three modes:

— **All:** The default mode. Adds keyframes to every track in the Keyframe Editor, keyframing every parameter in every node all at once, including the Sizing settings. In this mode, an orange bar appears highlighting the topmost “master keyframe track.”

— **Color:** Only adds keyframes to the node currently selected in the Node Editor. In this mode, a green bar appears highlighting the keyframe track corresponding to the node currently selected.
— **Sizing:** Only adds keyframes to the Sizing track, which is useful when you’re keyframing “pan and scan” style transforms. In this mode, a blue bar appears highlighting the Sizing track.

— **EXT MATTE:** Only appears if there’s an external matte node in the node tree. Lets you keyframe external matte-specific parameters in the Key palette.

Even though All is the default setting, it may be to your advantage to switch to the Color or Sizing keyframing modes to avoid creating a lot of unnecessary keyframes. Even though keyframing everything all at once is a fast way to work, the extra keyframes may slow you down when you later need to make adjustments to nodes that didn’t need to be keyframed in the first place.

**To change the keyframing mode, do one of the following:**

— Choose an option from the Keyframe mode drop-down at the top right of the Keyframe Editor.

— Choose an option from the Mark > Keyframe Timeline mode submenu.

**TIP:** This control has one other function. Choosing a mode also affects what is copied when you use the various grade management tools in DaVinci Resolve. For example, if you choose Color, then you can copy a clip's color grade without copying its sizing. If you choose Sizing, then you can copy the sizing without copying the color grade. For more information, see “Copying Grades” in Chapter 138, “Grade Management.”

## Keyframing Methods

There are two different types of keyframes used by DaVinci Resolve to create automated changes. Each type of keyframe interpolates parameters differently.

### Dynamic Keyframes (Dynamics)

Dynamic keyframes are the most conventional type of keyframe you’ll use, and are the type of keyframe used for creating animated changes from one state to another. For example, if you need a grade to become brighter over time to compensate for a change in lighting conditions, you’ll use Dynamic keyframes.

Nearly every parameter and control in the Color page can be keyframed, but it’s important to understand that the Interface controls do not animate to match whatever dynamically keyframed changes are taking place. Instead, visible Interface controls that correspond to keyframed changes will jump from their initial position at one keyframe to their final position when the playhead reaches the next keyframe.

This can be most confusing with Curves, which can be interpolated using Dynamic keyframes just like any other control or parameter. Just keep in mind that the actual settings are animating, even though the controls are not.
To animate a node using Dynamic keyframes:

1. Move the playhead in the Keyframe Editor’s Timeline ruler to the frame where you want to begin a change.

2. Do one of the following to place a Dynamic keyframe at that frame:
   - Choose Mark > Add Keyframe (Command-[).  
   - Turn on the Auto Keyframe button for the track you want to animate in the Keyframe Editor.

   Dynamic keyframes are diamond-shaped.

3. If necessary, adjust your clip at this first position of your animated change. If you’re using Auto Keyframe, then you have to make an adjustment for a keyframe to be created.

4. Now, move the playhead to the frame that is at the second position of the animated change you’re making, and create another Dynamic keyframe if you’re creating keyframes manually, or make another adjustment if Auto Keyframe is on.

5. After you’ve created this second keyframe, make whatever adjustments are necessary to the clip to create the final look you need.

   At this point, playing from the first keyframe to the second keyframe should show a smoothly animated change from the first adjustment to the second. When you’re finished, make sure you turn Auto Keyframe off if it was enabled.

Static Keyframes (Marks)

Static keyframes, or marks, are keyframes that are used to create abrupt, one frame changes from one state to another. They’re typically used to mark edit points separating one shot from another when multiple shots appear within a single clip. However, Static keyframes are also useful in any situation where you need a sudden change from one setting to another, such as when creating a lightning effect.

Static keyframes are round.

To automate a node using Static keyframes:

1. Find the frame at which you want the abrupt change to take place, and place a keyframe at that frame by doing one of the following:
   - Choose Mark > Make Static Keyframe (Command-]).
   - Static keyframes (marks) are round.

2. Move the playhead to any frame before the keyframe to make changes to the entire segment of the clip leading up to the keyframe, or move the playhead to any frame after the keyframe to make changes to the entire segment of the clip appearing after the keyframe. The playhead does not need to be on top of the keyframe, but if it is, you’ll be adjusting the second portion of the clip.
NOTE: If you’re using Static keyframes to automate grading changes between multiple shots appearing within a single clip, keep in mind that you can’t add nodes from one keyframe to the next as you would if you had split the clip in the Edit page.

Mixing and Converting Dynamic and Static Keyframes

Typically, if you’re creating multiple animated changes within a clip, you’ll want to use all Dynamic keyframes. Similarly, if you’re creating a series of abrupt changes, you’ll use all Static keyframes. However, you can mix Dynamic and Static keyframes together, so long as you keep in mind the following rules:

— If you add a Dynamic keyframe to the right of a Static keyframe: There will be no interpolation from the Static keyframe to the Dynamic keyframe. However, if you add a Static keyframe to the right of a Dynamic keyframe, there will be interpolation.

![No dynamic interpolation following the static keyframe](image)

— If you accidentally create the wrong kind of keyframe, it’s easy to convert it into the type of keyframe you need.

To change one kind of keyframe into another:

1. Click the keyframe you want to convert to select it.
2. Right-click the selected keyframe, and choose either Change to Dynamic Keyframe or Change to Static Keyframe.

Try Creating Keyframed Changes in a Separate Node

One tip to keep in mind is that you don’t have to create keyframed changes within the same nodes you’re using to create other adjustments. If you want to create some automated changes without altering the nodes you’ve already adjusted, you can simply create a new node in which to make your keyframed changes. That way, if you don’t like the result, or you somehow find yourself hopelessly tangled up in a needlessly complicated set of keyframes, it’s easy to reset either just the keyframes or the entire node without affecting the rest of your grade.

Keyframed Nodes Have a Badge

Nodes with keyframed parameters display a keyframe badge in the Node Editor, to make them easy to find. Note that keyframe badges won’t appear when you simply add a keyframe but only once there’s an actual keyframed adjustment being made.
Using Specific Keyframing Tracks

If you’re simply using the Color mode of the All/Color/Sizing command to do keyframing, then you’ll be adding keyframes to every parameter of the currently selected node whenever you apply a single keyframe. However, often that’s overkill in situations where you only need to keyframe a single setting or group of settings.

For example, you may find that you need to keyframe a color adjustment in order to change the color temperature and brightness when the camera pans across a window, but you don’t want to keyframe the Windows palette controls because you want to adjust them independently. This can be done by opening a Corrector track to expose the keyframing tracks within.

Keyframing tracks let you keyframe different sets of similarly functioning parameters separately from one another. For example, there’s one keyframing track for all the color adjustment parameters, and another keyframing track governing the parameters found within the Qualifier palette.

To reveal a node’s keyframing tracks:
— Click the disclosure triangle next to the number of the node you’re keyframing.

To keyframe an individual keyframing track manually:
1. Make whatever adjustments you need to the currently selected node, and click its disclosure triangle to reveal its keyframing tracks.
2 Move the playhead in the Keyframe Editor to where you want to add the first keyframe, then right-click within the keyframing track you want to animate, and choose Add Static Keyframe or Add Dynamic Keyframe (this example shows a Dynamic keyframe).

A keyframe appears at the position of the playhead in that keyframing track.

3 Move the playhead in the Keyframe Editor to where you want to add the next keyframe, then right-click within the keyframing track and again choose either Add Static Keyframe or Add Dynamic Keyframe (this example shows a Dynamic keyframe).

![Keyframing just the Circular Power Window using its individual keyframe track](image)

Now, you can make whatever changes you need to the controls governed by the keyframing track you keyframed, in order to create the necessary animated effect.

**TIP:** You can also animate individual keyframing tracks using automatic keyframing, explained in more detail later in this chapter.

### Corrector Keyframing Tracks

All of the parameters governing the adjustment of color and contrast controls, as well as various effects, Power Windows, and other adjustments are sorted into various sub-tracks within the Corrector track.

- **Linear Win:** Controls parameters corresponding to the Linear window.
- **Circ Win:** Controls parameters corresponding to the Circular window.
- **Polygon Win:** Controls parameters corresponding to the Polygon window.
- **PowerCurve:** Controls parameters corresponding to the PowerCurve window.
- **Gradient Win:** Controls parameters corresponding to the Gradient window.
- **Color Corrector:** Controls all parameters found in the Camera Raw, Color Wheels, Primary Controls, RGB Mixer, and Curves palettes.
- **Qualifier:** Controls all parameters in the Qualifier palette.
- **Defocus:** Controls all parameters in the Blur and Key palettes.
- **NR:** Controls the Spatial and Temporal Noise Reduction and Motion Blur parameters found in the Motion Effects palette.
- **Open FX:** Controls all parameters of whichever OFX plug-in is applied to the current node.
- **Node Format:** Controls all parameters of the node sizing mode of the Sizing palette for the current node.
ResolveFX Keyframe Tracks

The Color Page Keyframe Editor supports viewing and editing keyframes for ResolveFX and OpenFX plug-ins in the Color page in one of two ways:

— Plug-ins that have been added to a Corrector node appear within the hierarchical list of keyframe tracks that appear within that node’s top-level keyframe track.

— Plug-ins that have been added as standalone nodes appear within a new FX track of the Keyframe Editor. Each plug-in that’s added as a separate node has a separate FX track.

The Sizing Keyframing Tracks

The Sizing keyframing tracks govern sizing transforms and stereoscopic adjustments separately from the color controls.

— **Input Sizing**: Controls the Input Sizing parameters found within the Sizing palette.
— **Convergence**: Controls the Convergence parameter in the Stereo 3D palette.
— **Float Window**: Controls the Left, Right, Top, and Bottom Position/Rotate/Softness Floating Windows parameters.
— **Auto Align**: Controls the Pitch and Yaw parameters in the Stereo 3D palette.

**TIP**: Output Sizing can only be keyframed when you choose Timeline mode in the Node Editor.
The Ext Matte Node’s Freeform Isolation Track

If your node tree has an External Matte, the EXT MATTE node exposes a Freeform Isolation track in the Keyframe Editor. This is useful for time offsets or Sizing repositioning of the Ext Matte image.

Automatic Keyframing

Every track in the Keyframe Editor has an Auto-Keyframing button that can be turned on or off. When auto-keyframing is enabled for a particular track, every change made to a parameter or control associated with that keyframe track automatically generates a keyframe. There are two ways you can use this:

— Used with a keyframing track, auto-keyframing makes it simple to set up animated changes to specific adjustments within a node. This is a lot easier than manually placing keyframes one by one.

— On the other hand, turning on auto-keyframing for the Corrector track correspondingly enables auto-keyframing for every keyframing track belonging to that node. In this case, keyframes will automatically be placed on whatever keyframing track corresponds to the parameters or controls you adjust.

Auto-keyframing selected for Circular window on Node 1

When auto-keyframing is disabled, changes you make alter existing keyframes. How this alteration works depends on the location of the playhead, and the type of keyframes in the Keyframe Editor. For more information, see the next section.

Modifying Keyframes

Once you’ve started adding keyframes to animate changes to a grade, there are a variety of methods available to navigate and edit these keyframes to further customize these effects. This section covers the different ways you can navigate among, alter, and remove keyframes.

Navigating Among Keyframes

For many operations, it’s necessary to move the playhead directly on top of the keyframe you want to modify. While you can always use the transport controls or pointer to move the playhead, there are also commands for jumping to a specific keyframe.

To move the playhead among a series of keyframes:

— Choose Playback > Next > Keyframe (the right bracket key) or Playback > Previous > Keyframe (the left bracket key).
Moving Keyframes

If you need to change the timing of a series of keyframes, you can move the position of any keyframe, along with whatever values that keyframe contains.

**To move a single keyframe using the onscreen interface:**
- Use the pointer to drag any keyframe to another location.
- Drag keyframes in a top-level Corrector or Sizing track to simultaneously move all other keyframes on the same frame within that corrector.

**To move multiple keyframes at the same time:**

1. If necessary, open the keyframe track with the keyframes you want to move.
2. Drag a bounding box around the keyframes you want to move. Selected keyframes appear highlighted in red.
3. Drag any of the selected keyframes to move them to the left or right.

Changing Keyframe Values

Unlike many other applications, DaVinci Resolve lets you alter keyframe values when the playhead isn’t directly on an existing keyframe. How this works depends on the location of the playhead relative to the keyframes that are in the Keyframe Editor, and what kind of keyframes you’re editing.

- **If the playhead is to the left or on the first Dynamic keyframe:** The Dynamic keyframe at or to the right of the playhead updates with the new adjusted values.
- **If the playhead is to the left or on the last Dynamic keyframe:** The Dynamic keyframe at or to the left of the playhead updates with the new adjusted values.
- **If the playhead is between two Dynamic keyframes:** The Dynamic keyframe to the left of the playhead updates with the new adjusted values, but the Dynamic keyframe to the right is unaffected.
- **If the playhead is between two Static keyframes (marks):** Adjustments made between two Static keyframes always affect the keyframe to the left of the playhead. The entire segment of the clip between that keyframe and the next is affected equally.

Changing Dynamic Attributes

By default, the transition from one Dynamic keyframe to the next is linear. However, if you need to alter the acceleration of value interpolation from one Dynamic keyframe to the next, then you can change that keyframe’s dynamic attributes.

**To change a keyframe’s dynamic attributes:**

1. Click to select a keyframe in the Keyframe Editor.
2. Right-click the selected keyframe, and choose Change Dynamic Attributes.
3. When the Dynamic Attributes window appears, do one or both of the following:
   - Choose a new outgoing acceleration curve using the Start slider, affecting the interpolation occurring to the right of that keyframe.
   - Choose a new incoming acceleration curve using the End slider, affecting the interpolation occurring to the left of that keyframe.
As you choose different acceleration curves, the display to the right shows the resulting curve graph.

![Image of dissolve profile](image.png)

Changing the dissolve profile

4 When you're happy with the curve, click OK.

By using different Start and End values, you can make animated adjustments “ease in” or “ease out” of a particular keyframe, to create a more gradual or abrupt transition.

**TIP:** The default dynamic profile start and end of each new keyframe can be set via the Dynamics Profile values in the General Options panel of the Project Settings.

### Deleting Keyframes

You have the option to delete individual keyframes, or to delete all the keyframes within a particular grade at once.

**To delete individual keyframes, do one of the following:**

- Move the playhead on top of the keyframe you want to delete, then choose Mark > Delete Keyframe (Option-`). Every keyframe at the position of the playhead is deleted.
- Using the pointer, click a keyframe in the Keyframe Editor to select it, then right-click that keyframe and choose Delete Selected Keyframe. Only the selected keyframe is deleted.

**To delete every keyframe for the current clip:**

- Choose Mark > Delete All Keyframes.
Copying Keyframes

It’s possible to copy a set of keyframes from one node to another, either within the current grade, or in another clip entirely. It’s also possible to copy an entire grade with keyframes from one clip to another.

To copy a set of keyframes from one node to another:

1. Select a node to copy keyframes from, and choose Edit > Copy (Command-C).
2. Do one of the following:
   - To copy all keyframes, select another node to paste keyframes and other adjustments to, and choose Edit > Paste (Command-V).
   - If you want to just copy only the keyframe information from a specific keyframe track, choose Edit > Paste Attributes (Option-V), then click the “Copy Keyframes and Align Using” checkbox, and select the appropriate parameters to copy.

   **TIP:** This procedure also works for tracking data that you want to copy from one node to another, either in the current clip, or another clip altogether.

To copy an entire grade with keyframes from one clip to another:

1. Click the thumbnail of the clip you want to copy to in the Thumbnail timeline.
2. Right-click the thumbnail of the clip you want to copy from, and choose Apply Grade from the contextual menu.

   **NOTE:** When copying a grade with keyframes from one clip to another, the keyframes will automatically be placed at matching frames that correspond to the source timecode of the originating clip. This makes it easy to copy a grade with keyframes to the same clip elsewhere in the Timeline, but it may not provide the desired results if you’re applying a grade with keyframes from one clip to a completely different one.

Keyframes and Saved Stills

If you save a still from a clip using keyframes within the grade, by default keyframes are not saved. However, the still and grade that are saved reflect whatever parameter values are contained by the next keyframe to the left of the position of the playhead. For example, if a clip has a dynamically keyframed transition from a saturation of 50 to a saturation of 0, and you place the playhead right in the middle of both keyframes when you save a still, the grade and still that are saved have a saturation of 50.

However, if you right-click the background of the Gallery, choose one of the options within the “Apply Grades Using” submenu, and choose the appropriate “Keyframes Aligning…” options, then grades saved within a still are saved with the keyframes, which reference the source timecode, or start frame of the original clips. This means that if you apply a saved grade with keyframes to a clip, the keyframes...
will automatically be placed at matching frames that correspond to the source timecode or start frame of the original clip. This makes it easy to copy a grade with keyframes to the same clip elsewhere in the Timeline, but it may not provide the desired results if you’re applying a grade with keyframes from one clip to a completely different one.

### Adding EDL Marks

Just as clip grades are separate from the timeline grade that can be applied to the entire Timeline, so clip keyframes are separate from timeline keyframes. Keyframes you apply to the timeline grade work exactly the same as clip keyframes. However, there is one extra option you have when keyframing the timeline grade.

If you find yourself wanting to adjust a timeline grade individually to take into account variations from one clip to the next, you can use the Add EDL Marks on Tracks command to add a Static keyframe (mark) to the Keyframe Editor at the position of every edit point in the entire Timeline.

**To add EDL marks:**

1. Choose Timeline from the Node Editor’s mode drop-down menu.
2. If you want to keyframe a grade, then create whatever grade you need to apply to the entire Timeline. If you want to keyframe Sizing settings, you don’t need to do anything else.
3. Right-click the Corrector track or the Sizing track in the Keyframe Editor, and choose Add EDL Marks on Tracks.

   Marks appear at the frame of every edit point in the Timeline. You may want to widen the Keyframe Editor to make it easier to work with all these keyframes.

After you’ve added EDL marks, you can delete them if you decide you don’t want them any more.

**To delete EDL marks:**

   — Right-click the Corrector track in the Keyframe Editor, and choose Delete EDL Marks on Tracks.

If you’ve added your own keyframes in addition to the EDL marks, then the Delete EDL Marks on Tracks command only eliminates the EDL marks. Your custom marks are left alone.
Chapter 145

Copying and Importing Grades Using ColorTrace

ColorTrace is a key feature of DaVinci Resolve, which lets you copy grades quickly and easily from the clips of one timeline to those within another, based on the source timecode of each clip (or using clip names when in Automatic mode). You can even use ColorTrace to copy grades between timelines within the same project, and ColorTrace one stereo timeline to another.

Contents

Copying Grades Using ColorTrace 3118
Using ColorTrace in Automatic Mode 3119
Using ColorTrace in Manual Mode 3122
Importing CDL Data Using ColorTrace 3125
Using CDL Adjustments 3126
Calculating CDL Functions 3126
Copying Grades Using ColorTrace

ColorTrace copies whichever version of a clip’s grade was applied in the Source timeline you’re copying from, either local or remote, depending on which grades each clip in the Source timeline is set to use. Furthermore, ColorTrace copies Group Pre-Clip and Group Post-Clip grades, as well as Fusion compositions. These improvements make this an extremely reliable tool for copying grades from one timeline to another in a wide variety of situations.

To use ColorTrace:

1. Open the Edit page and select the Timeline you want to use ColorTrace with from the Media Pool, then open it and choose Timelines > ColorTrace > ColorTrace From Timeline.

Choosing ColorTrace for a selected Timeline

The ColorTrace Setup window appears, which shows every project library, user, project, and timeline within a single hierarchical list.

2. Using the Project List browser, select the specific Timeline you want to copy grades from. You’ll need to click the disclosure triangle to the left of the project library, user name, and project that contains that Timeline in order to select it.

ColorTrace project and Timeline selection window
(Optional) If you’re using ColorTrace with a project that has numerous VFX clips in a workflow where all VFX clips have specific reel names that identify them, you can enter these names (with asterisks (*) used as wildcards that indicate text in each reel name that can vary) in the “Effects Shot Definitions” field.

This speeds automatic ColorTrace operations by enabling DaVinci Resolve to use fuzzy string matching when a clip’s reel number qualifies it as a VFX shot so that the best match is displayed first on the list. You can enter multiple VFX reel names with wildcards, one per line, for simultaneous string matching. You can use whatever reel name text makes sense for your workflow, some examples of VFX reel names are as follows:

* _COMP_*
  
  VFX*
  
  EFFECTS*

Click Continue.

The ColorTrace window appears with two tabs that let you choose how to work.

Choose which mode to work in by clicking the Automatic or Manual tab:

— In Automatic mode, ColorTrace automatically searches for matching clips between the selected Timeline and the current Timeline. Each clip is color coded depending on the correspondence that’s been identified.

— In Manual mode, you copy grades yourself, using the Copy and Paste procedures, or by dragging and dropping using your mouse.

The ColorTrace window is complex; details about the operation of each mode are covered separately in the following sections.

When you’re finished using ColorTrace, click Close.

Using ColorTrace in Automatic Mode

In Automatic mode, ColorTrace automatically finds the correspondences between clips in the selected Timeline that you want to copy grades from (the Source timeline), and those in the current Timeline that you want to copy grades to (the Target timeline).

Each clip in the Target Timeline Thumbnail timeline is outlined with a color that indicates its status.

— **Red:** No match was found at all. Generally true for clips in the current Timeline that weren’t used in the Timeline you’re ColorTrace matching to.

— **Blue:** Due to overlapping timecode and reel names, multiple correspondences have been found (similar to a reel conflict), and you must select the correct one for each clip. This often happens with VFX and motion graphics clips that you’ve imported with timecode starting at 00:00:00:00.
— **Green**: A match has been found.

![ColorTrace Thumbnail outlines indicate matching, overlapping, and non matching clips.](image1)

In Automatic mode the correspondence between each clip in the Source timeline and each clip in the Target timeline should be automatically made. However, overlapping timecode and reel names can cause problems. The other controls in the ColorTrace window help you deal with the subset of clips that can't be automatically matched, or are matched in error. These controls are:

- **Matching Source Clips list**: Shows a scrollable collection of thumbnails that might correspond to the selected clip in the Target timeline.
- **Target Timeline**: Shows each clip in the Timeline you want to copy grades to, color coded according to how good a match it is.
- **Clip Info pane**: Displays two columns of properties for the source clip and the target clips that you've selected. These properties include the reel, source timecode, record timecode, clip name, project names, and timeline names of each clip, for easy comparison.
- **Attributes and options checkboxes**: A series of checkboxes lets you specify which clip attributes are copied as part of the ColorTrace operation.
- **Color**: Enables the copying of grades.
- **Preserve Num Nodes**: When copying grades, lets you prevent the first X nodes of the target clip grades from being overwritten by the first X nodes of the source clip grades.
- **Input Sizing**: Enables the copying of Input Sizing attributes.
- **Convergence**: Enables the copying of Convergence for Stereo 3D projects.
- **Floating Windows**: Enables the copying of Floating Windows for Stereo 3D projects.
- **Auto Align**: Enables the copying of Auto Align settings for Stereo 3D projects.
- **All Versions**: Copies all versions, rather than just the current version, from the source to the target clips. The currently selected version of each source clip is always correctly copied.
— Version Camera Raw Settings: Enables the copying of versioned Raw settings, rather than just the current Raw setting.
— Track Marks: Enables the copying of keyframes.
— Flags and Markers: Enables copying of all flags and markers.
— Hide Matching Clips: Hides all clips which have been successfully matched, and only show the clips with multiple or no matches. This lets you focus on the subset of problem clips within a potentially long timeline.
— Ignore Reel Names: If you believe the reel names are in error, you can turn this checkbox on to ignore them, matching all source and target clips by timecode alone.

— Copy Grades: Copies the matched source grades to each green and purple target clip.
— Copy Grades & Exit: Once you’ve finished making all the grade matches you can, click this button to copy the matched source grades to each green and purple target clip, and close the ColorTrace window.

Here’s how to use these controls to sort out which source clips to copy from for each blue and red target clip in the Target timeline.

**To manually choose which source grades should be copied to which target clips:**

1. Click any blue clip thumbnail in the Target timeline.

A collection of clips with overlapping timecode and reel names appears. If you want to ignore the reel names because you believe they might be in error, turn on the Ignore Reel Names checkbox.

2. If a comparison of the Source and Target thumbnails doesn’t make the choice obvious, then click any of the clips in the Matching Source Clips timeline to view its metadata for comparison in the source/target columns below.
Once you’ve decided on a clip correspondence, double-click the Matching Source Clip thumbnail you want to copy from. If no clip in the Matching Source Clip pane is a good match, double-click the “Set As New Shot” box.

The Source and Target thumbnails both turn purple, to show that you’ve created a correspondence.

The matching Source and Target clips now both marked with purple outline

Continue working your way through every thumbnail with Blue and Red Xs until you’ve found matches for every clip in the Timeline for which it’s possible.

4 When you’re finished, click Copy Grades & Exit.

Using ColorTrace in Manual Mode

Manual mode is ideal for situations where you want to copy grades between programs with clips that have no timecode or reel name correspondence at all. The Manual ColorTrace interface is designed to let you move through two different timelines, either a clip at a time, or in matching multiples of clips, copying grades from the Source timeline to the Target timeline.

For example, if you’re trying to copy grades from a timeline that was conformed from individual media files, to another timeline that was conformed from a flattened master media file, you can use the ColorTrace Manual mode to accomplish this.
The manual interface consists of two sets of controls that correspond to the Source timeline (labeled “Timeline to copy from”), and the Target timeline (labeled “Timeline to paste to”). The general idea is that you move through both sets of timelines one clip at a time, or in matching multiples of clips at a time, and copy grades from the “Copy from” timeline to the “Paste to” timeline.

ColorTrace Manual window

Manual mode has the following controls:

— **Source timeline**: Shows all clips in the Source timeline you selected; the clips you’re copying grades from. Click any one clip thumbnail to select it, or click a thumbnail, and then Shift-click another thumbnail to select a contiguous range of clips. You cannot select a noncontiguous range of clips.

— **Copy Range controls**: Two fields show the range of clips in the current selection that you’ll be copying from, referred to by their numeric position in the Source timeline. You can change the range numerically by either entering new numbers in the fields, or by using the up/down arrow buttons to alter the value by one. The First button automatically adds all clips from the first one in the Timeline into the current selection. The Last button automatically adds every clip going to the last one in the Timeline to the current selection.

— **Target timeline**: Shows all clips in the Target timeline you selected; the clips you’re pasting grades to. Selecting clips works identically as with the Source timeline.

— **Paste Range controls**: Two fields show the range of clips in the current selection that you’ll be pasting to, referred to by their numeric position in the Source timeline. All controls work identically to the Copy Range controls.

— **Attributes and options checkboxes**: Turn off the checkboxes of any clip characteristics that you don’t want to copy as part of the ColorTrace operation. A more complete description of these options appears in the section on the Automatic ColorTrace mode.

— **Paste button**: Once you’ve selected one or more source clips and a matching number of target clips, clicking Paste copies the grades, PTZR settings, and marks (depending on the corresponding checkboxes).

— **Undo Last**: Lets you undo the most recent paste action.

— **Undo All**: Lets you undo all paste actions in Manual mode.

— **Done**: Finishes the operation and closes the ColorTrace window.

If you’re cherry picking individual grades from one timeline to paste into shots in another, you can copy grades one at a time.
To copy one source grade to one target clip:

— Click a thumbnail in the Source timeline (on top) to copy from, then click a thumbnail in the Target timeline (on the bottom), and click Paste.

You can also simultaneously copy the grades of entire scenes of clips from one timeline to another. For example, if you’re copying grades from an originally graded timeline to a re-edited version of the same program, you can copy every grade from a 10-clip scene in the Source timeline to the same 10 clips in the Target timeline which have been pushed back later in the Timeline.

To copy a group of source grades to a group of target clips:

1 Choose a continuous range of source clips by doing one of the following:
   — Click the first clip in the range, and then Shift-click the last clip in the range.
   — Enter the clip number of the first clip in the left “Copy Range” field, and then enter the clip number of the last clip in the right field.
   — Click a clip, and then click First to select every clip from that one to the first clip in the Timeline.
   — Click a clip, and then click Last to select every clip from that one to the last clip in the Timeline.

2 Choose a continuous range of Target clips by using the same procedures as in the previous step, but using the “Paste Range” controls.

IMPORTANT

You must select the same number of target clips as you did source clips for the Paste button to become enabled.

3 When you’ve made your selections, click Paste.

The grade settings from the source clips are pasted to the destination clips, in order. In other words, if you copy from clips 5 through 9 to clips 11 through 15, then grade 5 is copied to shot 11, grade 6 is copied to shot 12, grade 7 is copied to shot 13, and so on.
Importing CDL Data Using ColorTrace

The ColorTrace CDL command lets you import ASC CDL file formats from other applications into DaVinci Resolve. DaVinci Resolve also has the ability to read DRX filenames from CDL files, allowing a CDL to load exported DaVinci Resolve grades.

There are three supported file formats:

- **CMX EDL:** An EDL with comments referring to CCC/CDL XML files, or even Slope, Offset, and Power (SOP) data within the comment area.
- **CCC and CDL XML:** A file format that contains various color correction looks, and even references.

**To import CDL data into DaVinci Resolve:**

1. If you're importing CCC/CDL XML correction looks:
   - Open the Gallery page, right-click anywhere within the Stills tab, and choose Import from the contextual menu.
   - When the Import Stills dialog appears, open the CDL/CCC files. When these are finished importing into the Gallery, an ASC logo will appear along with them.

2. Open the Edit page and select the Timeline you want to use ColorTrace with in the Timeline list.

3. Right-click anywhere within the Timeline, and choose ColorTrace from CDL.

4. Select an EDL using the Select EDL dialog, and click Open.

5. Select its corresponding CDL and CCC files using the Select CDL Files dialog. If there are no CDL or CCC files (which is the case if there are inline SOP comments within the EDL), you should click Cancel.

6. Using the ColorTrace With CDL window, copy the source grades from the CMX EDL/CCC & CDL XML files to the Target timeline.

   At this point, the ColorTrace window works identically as previously described.

For formatting reference, here are some examples of CMX, CCC, and CDL files.

**Example CMX EDL File**

```
TITLE: Final EDL FCM: NON-DROP FRAME
01:19:28:16 01:19:28:16
01:00:41:18 01:00:42:18 ASC_CC_XML test_cc.102
01:00:00:00 01:19:28:16 01:00:42:18 01:00:43:18 ASC_SOP (0.9 1.2 0.5)(0.4 -0.5 0.6)(1.0 0.8 1.5)
```

**Example CCC File**

```
<ColorCorrectionCollection xmlns="urn:ASC:CDL:v0.5" >
<InputDescription> test corrections for ref_input_image.1920
</InputDescription> <ViewingDescription>
for mathematical analysis only </ViewingDescription>
<ColorCorrection id="test_cc.100"> <SOPNode>
<Description> for ref_output_image.0100 </Description> <Slope> 1.0 1.0 1.0 </Slope> <Offset> 0.0 0.0 0.0 </Offset> <Power> 1.0 1.0 1.0 </Power>
</SOPNode> </ColorCorrection>
<ColorCorrection id="test_cc.101"> <SOPNode>
```

Chapter 145  Copying and Importing Grades Using ColorTrace
Example CDL File

<pre><code>&lt;ColorDecisionList xmlns="urn:ASC:CDL:v0.5"&gt;
  &lt;InputDescription&gt; GeneralProducts M1 std thru GP M1 LUT4 &lt;/InputDescription&gt;
  &lt;ViewingDescription&gt; GP P1, DCI P3, Pathe color emul &lt;/ViewingDescription&gt;
  &lt;MediaRef ref="/some/Project/frame%250900-0954%5B.dpx"&gt;
    &lt;ColorCorrection id="cc03340"&gt;
      &lt;SOPNode&gt;
        &lt;Description&gt;change +1 red, contrast boost&lt;/Description&gt;
        &lt;Slope&gt;1.2 1.3 1.4&lt;/Slope&gt; &lt;Offset&gt;0.3 0.0 0.0&lt;/Offset&gt; &lt;Power&gt;1.0 1.0 1.0&lt;/Power&gt;
      &lt;/SOPNode&gt;
    &lt;/ColorCorrection&gt;
  &lt;/MediaRef&gt;
&lt;/ColorDecisionList&gt;</code></pre>

Using CDL Adjustments

Once you’ve imported a CDL (Color Decision List), then the CDL adjustment for each clip is made available to you via a contextual menu command in the Thumbnail timeline of the Color page.

Calculating CDL Functions

To turn the SOP values into a primary correction, the following math is used by DaVinci Resolve:

\[
\text{Output} = (\text{Input} \times \text{Slope} + \text{Offset})^{\text{Power}}
\]

Output refers to the final grade. Input is the value of each pixel within each color channel (on a scale from 0–1). The detent value for Slope is 1. The detent value for Offset is 0. The detent value for Power is 1.
Chapter 146

Using LUTs

Lookup Tables, also known as LUTs, are one of the most ubiquitous means of creating, exchanging, and applying image processing operations there is for purposes of color management, display calibration, look management, and general-purpose processing of image color and contrast. DaVinci Resolve has robust support for LUTs throughout its image processing pipeline.

What is a LUT?

LUTs are simply files, similar to plug-ins but far more focused and with no user interface, that specify image processing operations. These operations are accomplished in a variety of ways. The traditional approach is to use a 1D table or 3D “cube” of pre-calculated values to perform an image color transform. However, newer LUT formats including CLF and DCTL let you use mathematical scripts to process an image.

Whatever type of LUT you use, these files can be loaded into DaVinci Resolve and applied at different points of the image processing pipeline to apply image processing operations for different purposes. There are several well-known uses of LUTs, but the important thing you should take away is that LUTs are simply color transform operations that can be used for many things, and there’s no single use of a LUT that’s more or less important than any other.

Here are some frequent uses for LUTs:

— While optionally superseded by Resolve Color Management (RCM), lookup tables (LUTs) have been frequently used to create a starting point adjustment for media acquired with some logarithmic encoding. DPX log film scans, digital media using the ARRI ALEXA’s Log-C encoding, Sony’s S-Log exposure setting, or RED R3D media that is debayered using the REDFilmLog setting are all examples of media using a logarithmic exposure curve, designed to protect as much detail in the highlights and shadows of a digitally encoded image as possible. While log-encoded media retains a lot of image data, the picture is initially flat and unsuitable for use without grading. The exposure and color must be adjusted to “normalize” the media, making it look closer to the way it’s supposed to, in order to start grading. While you can do this manually, it’s usually faster to use a LUT that’s tailored to your type of media and the exposures you’re using. Alternately, you can also use Resolve Color Management to accomplish this.

— LUTs are commonly used in onset workflows where dailies for different scenes are managed with corresponding LUTs. These LUTs were used to monitor the media as it was being recorded to define a baseline reference for how each scene is meant to look, at least so far as field monitoring is concerned. In more advanced workflows, LUTs are used as a baseline look, defined prior to the shoot and used during the shoot, that then defines the creative starting point for different scenes once grading begins after the shoot.

— LUTs are frequently used as a stylistic component of a grade, or “look” that gives users a quick start when desiring some manner of creative adjustment. Over the years, companies and individuals have created an ecosystem of such looks that are disseminated and sold in various LUT formats supported by DaVinci Resolve.

In all of these instances, LUTs are simply image processing adjustments that are applied to affect the color and contrast of a clip, in much the same way as you’d make adjustments using any of the contrast or color controls in the Color page.
Supported LUT Formats

DaVinci Resolve uses both 1D and 3D LUTs, and supports LUTs in a variety of formats.

— **.cube**: DaVinci Resolve uses both 1D and 3D LUTs in the .cube format. 3D LUTs can be exported as 17x17x17, 33x33x33, or 65x65x65 cubes with 32-bit floating point processing. DaVinci Resolve can also read and use Shaper LUTs in the .cube format, but these must also be created outside of DaVinci Resolve. You should note that while 17-point LUTs are not recommended to use for grading, they are useful when exporting LUTs for on-set monitoring, to accommodate different display, calibration, and signal conversion devices.

— **Panasonic VLUT format**: DaVinci Resolve can both read and generate this LUT format, designed for use in the Panasonic VariCam camera ecosystem.

— **Video Range LUTs**: Beginning with DaVinci Resolve 17, support was added for importing LUTs that include additional metadata specifying them as processing image data in Video Range, rather than Full Range. More information about how to format LUTs as Video Range is included in the Developer Documentation available from the Help menu. Being able to specify whether a LUT is meant to be Video or Full Range allows LUT processing to automatically accommodate DaVinci Resolve’s data range setting pipeline for clip attributes, project settings, and output settings.

— **CLF (common LUT format)**: CLFs use an XML format that is capable of encompassing a limited number of mathematical transforms in addition to traditional lookup-tables to do image processing. Promoted by the academy as the ideal LUT format for use with ACES, LMTs for ACES are recommended to be in the CLF format due to its increased precision and flexibility.

— **DCTL**: DCTL files are actually color transformation scripts that DaVinci Resolve sees and applies just like any other LUT. Unlike other LUTs, which are 1D or 3D lookup tables of values that approximate image transformations using interpolation, DCTL files are actually comprised of computer code that directly transforms images using combinations of math functions that you devise. Additionally, DCTL files run natively on the GPU of your workstation, so they can be fast. For more information on DCTL, see Chapter 191, “Creating DCTL LUTs.”

### What’s the Difference Between a LUT and a Shaper LUT?

DaVinci Resolve is capable of importing and using LUTs within its 32-bit floating point image processing pipeline. The .cube format can be used as either a simple 33x33x33 3D LUT, or as a shaper LUT, which is actually a method of using two LUTs, a 1D LUT and a 3D LUT together, that addresses signal processing issues that 3D LUTs alone can’t handle.

For processor efficiency, 3D LUTs are designed with reasonable lower and upper limits for the data they will handle. It’s well known that when a 3D LUT is fed values that are outside of the range that LUT is designed to handle, the out-of-range data will be clipped. Since many LUTs are designed with digital cinema workflows in mind, the practical result is that feeding a video signal with super-white in it to a 3D LUT that’s designed for full-range data (0–1) will clip the super-white part of the signal.

Shaper LUTs handle this issue by first using a 1D LUT to process video signals with out-of-range data, fitting the signal into a range that the 3D LUT won’t clamp. The output of the 3D LUT includes the reverse transformation, to effectively zero out the 1D LUTs transform, while retaining whatever processing the 3D LUT was meant to apply.
Shaper LUTs are also useful for dealing with extremely large data sets, such as OpenEXR files that can theoretically handle an image data range of \(-\infty\) to \(+\infty\). Using a Shaper LUT, you can remap the incoming data to fit more precision in the 0–1 range, leaving less important data outside the range.

**LUTs and ACES**

The academy that promotes the correct use of ACES strongly recommends that LUTs be processed in the ACES color space. For this reason, two project settings let you choose how this will be done:

— **ACEScc AP1 Timeline Space**: This setting works for either the ACEScc or ACEScct Color Science settings depending on what you've selected in the Color Science pop-up at the top of the Color Management panel in the Project Settings. This setting lets you use LUTs that were created for ACES workflows that are similar to (but not the same as) LUTs you would create and use in a traditional log-encoded workflow. LUTs designed for working with this setting should have a range of \(-0.358\) to \(1.468\) so that grading operations that clip an image from 0 to 1 won’t destroy the look being applied. The “ACEScc AP1 Timeline Space” setting is also good for workflows where you want to use conventional LUTs that were designed for Rec. 709 workflows using the ResolveFX “ACES Transform” plug-in, which over a series of three nodes lets you transform the image from ACES to 709, apply a Rec. 709-designed LUT, and then convert the image from 709 back to ACES.

— **ACES AP0 Linear**: This setting requires you to apply an LMT LUT that has been specifically created for ACES image data. Only use this setting if you’re using CLFs that are designed for ACES using a range of \(-65504\) to \(65504\), as specified by SMPTE 2065.

**Adding Lookup Tables of Your Own**

The menus in the Color Management panel of the Project settings include a series of factory preset LUTs that were installed with DaVinci Resolve, along with any LUTs that have been generated by DaVinci Resolve, or that you've imported into the proper directory for your operating system for your own use.

By default, LUTs are saved to the following locations:

— **On OS X**: Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/
— **On Windows**: C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT
— **On Linux**: /home/resolve/LUT

**Custom LUT Paths**

A list in the General panel of the DaVinci Resolve System Preferences lets you add multiple file paths for loading LUTs that you want to use in DaVinci Resolve. This works for network volumes for facilities where multiple workstations are accessing a central collection of LUTs to be shared among multiple artists.
Clicking the Add button lets you add a file path to this table from a dialog. Selecting a location in this list and clicking Remove removes that location.

A list in the General panel of the System Preferences lets you add multiple locations where LUTs you want to use from within DaVinci Resolve are located.

**LUT Paths for the macOS App Store Version of DaVinci Resolve**

If you downloaded the non-studio version of DaVinci Resolve from the Apple App Store, LUTs are saved in a different location in order for DaVinci Resolve to remain totally self-contained. In this case, you can click the Open LUT Folder button in the Lookup Tables panel of the Project Settings, to open up a Finder window at the location these LUTs are stored. You can use this window to copy LUTs that you want DaVinci Resolve to have access to, or delete LUTs that you no longer need.

If you add a LUT to one of these directories after DaVinci Resolve has been opened, you can click the Update Lists button to refresh the contents of the pop-up menus.

**LUT Controls in the Project Settings**

While there’s an entire group of LUT controls in the Color Management panel of the Project Settings, those are designed to apply LUTs, at different parts of the image processing pipeline, to the entire Timeline. This is useful when you want to apply a single color and contrast transformation to the entire program at once, but less so if you want to apply different LUTs on a per clip basis. For more information on using the Lookup Table settings, see Chapter 4, “System and User Preferences.”

**Applying LUTs to Source Clips**

Another way of applying a LUT to a clip is to apply it directly to the source clip, which you can do to any clip in the Media Pool, or in the Thumbnail Timeline of the Color page. This can be convenient, but keep in mind that source clip LUTs cannot be copied from one timeline to another using ColorTrace, so using source clip LUTs limits your potential workflows. For most workflows, it’s better to apply LUTs directly in the Node Editor so they live in each clip’s grade.
To apply a LUT to one or more selected clips in the Media Pool:
— Right-click one of the selected clips, and choose a LUT from the 1D LUT or 3D LUT submenus.

To apply a LUT to one or more selected clips in the Thumbnail Timeline of the Color page:
— Right-click one of the selected thumbnails, and choose a LUT from the 1D LUT or 3D LUT submenus.

**TIP:** If you’re wanting to apply an image transformation to normalize log-encoded source clips, you may also consider using Resolve Color Management (RCM). Depending on your source media, it may be an easier and more automated process. For more information, see Chapter 8, “Data Levels, Color Management, and ACES.”

### Using the Color Page LUT Browser

The LUT Browser on the Color page provides a centralized area for browsing and previewing all of the LUTs installed on your workstation. All LUTs appear in the sidebar, by category.

By default, all LUTs appear with a test thumbnail that give a preview of that LUT’s effect, but you can also get a live preview of how the current clip looks with that LUT by hover scrubbing with the pointer over a particular LUT’s thumbnail (this is described in more detail below).

![The LUT Browser](image)

**To open the LUT Browser:**
— Click the LUT Browser button in the UI Toolbar at the top of the Color page.

**Methods of working with the LUT Browser:**
— **To see the LUTs in any category:** Click on a LUT category to select it in the sidebar, and its LUTs will appear in the browser area.
— **To make a LUT a favorite:** Hover the mouse over a LUT and click the star badge that appears at the upper right-hand corner, or right-click any LUT and choose Add to Favorites. That LUT will then appear when you select the Favorites category in the Node Editor contextual menu for nodes.
— **To search or filter for specific LUTs:** Open a bin that has the LUT you’re looking for, then click the magnifying glass icon to open the search field, and type text that will identify the LUTs you’re looking for.

— **To see LUTs in Column or Thumbnail view:** Click the Column or Thumbnail buttons at the top right of the LUT Browser to choose how to view LUTs in the browser area.

— **To sort LUTs in Thumbnail view:** Click the Thumbnail Sort pop-up menu and choose which criteria you want to sort LUTs by. The options are filename, type, relative path, file path, usage, date modified. There are also options for ascending and descending sort modes.

— **To sort LUTs in Column view:** Click the column header to sort by that column. Click a header repeatedly to toggle between ascending and descending modes.

— **To update the thumbnail of a LUT with an image from a clip:** Choose a clip and frame that you want to use as the new thumbnail for a particular LUT, then right-click that LUT and choose Update Thumbnail With Timeline Frame.

— **To reset the thumbnail of a LUT to use the standard thumbnail:** Right-click a LUT and choose Reset Thumbnail to go back to using the standard test image.

— **To refresh a LUT category with new LUTs that may have been installed:** Select a LUT category, then right-click anywhere within the browser area and choose Refresh to refresh the contents of that category from disk.

### Enabling and Disabling the LUT Viewer live preview:

1. Open the LUT Viewer’s option menu and choose Live Preview.

   ![Live Preview option for the LUT browser](image)

   The Live Preview option for the LUT browser lets you hover over a LUT to preview it on the current clip in the Viewer.

2. Click a node in the Node Editor you want to preview applying a LUT to. The live preview will display how the current clip will appear with the LUT you select applied to the currently selected node of the current grade, which will affect the result.

3. Move the pointer over the LUT you want to preview.

   The Viewer image updates to show how that clip would look with that LUT applied to the currently selected node.

### To apply a LUT from the LUT Browser to a specific node, do one of the following:

— Right-click a LUT and choose Apply LUT to current node.

— Drag a LUT from the LUT Browser and drop it onto the node you want to apply a LUT to. If you drag a LUT onto a node that already has a LUT, the previous LUT will be overwritten by the new one.
Applying a LUT Within a Node

DaVinci Resolve lets you apply LUTs within a grade by connecting a LUT to a particular node in the Node Editor. This gives you the greatest amount of control over where the LUT is applied in your image processing pipeline, and it also gives you the opportunity to apply image adjustments prior to the LUT, and after the LUT, as you require.

To apply a LUT within a node, do one of the following:

— Right-click any node, and choose a LUT from the 1D Input LUT, 1D Output LUT, 3D LUT, DCTL, or CLF (common LUT format) submenus of the LUT submenu. The LUT submenus list whichever LUTs have been installed on your workstation. For more information on installing LUTs, see Chapter 4, “System and User Preferences.”

— Right-click any node, and choose a LUT from the LUT > Favorites submenu.

— Use the LUT Browser to find a LUT you want to use, and then drag and drop that LUT onto the node you want to apply it to.

**TIP:** If you hold down the Option key while scrolling through the submenu of LUTs in a Corrector node’s contextual menu, you’ll get a live update in the Viewer of how each LUT affects the image.

To reveal a selected node’s LUT:

For any node in the Node Editor with a LUT applied to it, you can right-click that node and choose Reveal Selected LUT to automatically open the LUT viewer and select that LUT.

LUTs Are the Last Operation Within a Node

Each node in the Node Editor is capable of performing multiple operations, and these operations occur in a specific order. LUTs that you add to a node impose their transformation as the last operation within that node, after all other Color page adjustments applied by that node.

Practically, this means that you can use a node’s Color and Contrast controls to trim the image data that will be fed into a LUT applied to that same node. For example, if a LUT’s contrast adjustment clips the highlights of the image too much, you can use that node’s Contrast controls to lower the highlights of the image prior to the LUT, restoring detail to the image.

Favorite LUTs Submenu in Node Editor

When you “star” a LUT as a favorite in the LUT Browser, those favorite LUTs appear in a submenu of the contextual menu that appears when you right-click on a node in the Node Editor. This makes it easy to create a short list of your go-to LUTs for various situations, for rapid application right in the Node Editor.
Exporting LUTs

If you find it necessary to exchange image adjustments with other grading applications, compositing applications, or NLEs, often the easiest inter-application solution is to export a LUT. This can be done whether your grade consists of one node or several nodes, so long as they contain only Primaries palette adjustments, Custom Curves palette adjustments, and compatible ResolveFX plug-ins that include Color Space Transform, ACES Transform, and Gamut Mapping. All nodes with compatible functions will be mathematically combined and translated into a LUT.

Keep in mind that any nodes that use Qualifiers, Windows, incompatible filtering operations (such as sharpening or blurring), or incompatible Resolve FX or Open FX will be completely ignored, as will all other correction operations made within these nodes.

To export a LUT:

1. Right-click a clip thumbnail in the Timeline of the Color page, and choose an option from the Generate LUT submenu:
   - Generate 3D LUT (17 Point Cube): A DaVinci-developed LUT format
   - Generate 3D LUT (33 Point Cube): A DaVinci-developed LUT format
   - Generate 3D LUT (65 Point Cube): A DaVinci-developed LUT format
   - Generate 3D LUT (Panasonic VLUT): A LUT format associated with Panasonic VariCam cameras

2. Choose a location for the resulting LUT file in the file dialog. The default file path depends on your operating system; saving it here will make it available to DaVinci Resolve for future use.
   - On OS X: Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/
   - On Windows: C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT
   - On Linux: /home/resolve/LUT

   If you like, you can create a new folder in which to save your custom LUTs.

3. Enter a name into the Save As field, and click Save. A LUT file is saved.

   Once created, you can use an exported LUT from within DaVinci Resolve, applying it to a clip or node directly, or applying it to the entire project using the settings found in the Color Management panel of the Project Settings. You can also copy the LUT to a memory stick to give to someone for monitoring or previewing in an onset workflow, or to someone using another grading application that can read this LUT format.
DaVinci Resolve Control Panels

The DaVinci Resolve control panels make it easier to make more adjustments in the same amount of time than using a mouse, pen, or trackpad with the on-screen interface.

Additionally, using a DaVinci Resolve control panel to control the Color page provides vastly superior ergonomic comfort to clutching a mouse or pen all day, which is important when you’re potentially grading a thousand shots per day.

This chapter covers details about the three DaVinci Resolve control panels that are available, and how they work with DaVinci Resolve.

About The DaVinci Resolve Control Panels

There are three DaVinci Resolve control panel options available and each are designed to meet modern workflow ergonomics and ease of use so colorists can quickly and accurately construct both simple and complex creative grades with minimal fatigue.

This chapter provides details of the each of the panel functions and should be read in conjunction with the previous grading chapters to get the best from your panel.
The DaVinci Micro Panel

The DaVinci Resolve Micro Panel is ideal for edit suites that need a professional grading panel for occasional grades or quick adjustments to shots. You will also find it on DIT carts and in video village situations on set where its small size, portability, and low power needs are ideal for teams on the move.

The DaVinci Resolve Mini Panel

For many facilities and individual operators, the DaVinci Resolve Mini Panel is a compact yet powerful grading panel that’s fully featured despite its small size. The bottom half of this panel is identical to the Micro Panel, making it easy for people upgrading from the Micro to leverage their existing muscle memory. However, the top half of this panel adds direct-selection palette keys, dynamically remapped soft knobs and buttons, and a paged menu system that offers considerably more flexibility than the Micro Panel, and a better overall grading experience as a result.
The DaVinci Resolve Advanced Panel

The ultimate grading panel to give you the speed for long and complex grading sessions, and to make a lasting impact on clients visiting your suite or looking in on you as they’re videoconferencing during a remote grading session. The DaVinci Resolve Advanced control panels features dozens of fixed palette keys and menu driven soft knobs and buttons so most grading operations are just a keystroke or two away. High resolution liquid crystal displays (LCD) and backlit keys accommodate a typical darkened grading environment, with LCD panel and key color and intensity being user customizable, so each colorist can set up their preferred panel configuration.

DaVinci Resolve Advanced Panel

The original key configuration for the DaVinci Resolve Advanced Panel was updated in late 2020 to add new features and capabilities, while eliminating redundancy and making better use of the full complement of available buttons. Owners of the original panel can update to the new layout, but both the original and new layout are described in separate sections of this chapter.

Updating the Control Panels Firmware

From time to time, Blackmagic updates the functionality of the Control Panels through firmware changes. New firmware for the Micro and Mini Panels can be checked for and installed by opening the separate DaVinci Control Panels Setup utility that is installed by default with DaVinci Resolve. Firmware for the Advanced Panel is updated directly from DaVinci Resolve automatically.
Using the DaVinci Resolve Micro Panel

The Micro Panel features a row of direct control knobs at the top of the panel, three trackballs with rings for color grading, and to the right, transport and commonly used keys to speed up your grading session. Above the trackballs are reset buttons and also mode selection buttons for Log, Offset, and the Viewer selector. When selecting the Viewer mode, the full display will switch to the Cinema Viewer, which is ideal for playback and review of clips. The Log and Offset selections are described below.

Primary Trackball Mode

This is the default mode for the panels with the Log, Offset, and Viewer keys off (unlit). The three trackballs, from left to right, are in the traditional DaVinci format of Lift, Gamma, and Gain when DaVinci Resolve is set for Primary grading. Rotating the trackball performs a color balance adjustment for the range, changing its RGB parameters. The colors are set by moving the trackball in the direction corresponding to the color rings in the Primaries Wheels interface. Rotating the ring around each trackball adjusts the range’s Master Wheel, which allows you to control the contrast via YRGB adjustments.

Primary Trackball Mode controls

Log Trackball Mode

Log Trackball mode can be entered using the Log key just above the center trackball. When in Log grading, the trackballs shift to the Log Control’s Shadow, Midtone, and Highlights parameters. Rotating the trackball performs a color balance adjustment for the range, changing its RGB parameters. The colors are set by moving the trackball in the direction corresponding to the color rings in the Primaries Log interface. Rotating the ring around each trackball adjusts the range’s Master Wheel, which allows you to control the contrast via RGB adjustments.
Log Trackball Mode controls

Offset Trackball Mode controls

Offset Trackball Mode

You can also select the Offset button whether in Primary or Log modes. This is a toggle operation, and when selected, the left hand side ring surrounding the trackball controls the color temperature of the image, the center trackball ring the color tint, and the right hand side trackball controls the image offset balance and master exposure with the ring.
Above the three trackballs are three buttons for resetting the grade:

- **RGB**: This key only resets the RGB balance to default detent.
- **All**: Select All to reset both RGB and level.
- **Level**: Select the Level key to reset the level while maintaining RGB differential.

**Control Knobs**

The top of the panel features 12 high-resolution endless turn optical encoder control knobs with detent resets. These are spaced in groups of three for fast operation in dark suites. From left to right, the knobs control:

- **Y Lift**: This knob is for adjusting the contrast of the image in the darker areas. The midtone, and to a lesser amount the brighter areas of an image, will also change.
- **Y Gamma**: Use the gamma knob for primarily midtone contrast changes with some influence on the darker and brighter sections.
- **Y Gain**: The Y Gain control influences the brighter parts of the image at a greater extent to the mid and darker portions.
— **Contrast**: This one parameter lets you increase or reduce the distance between the darkest and lightest values of an image, raising or lowering image contrast. The effect is similar to using the Lift and Gain master controls to make simultaneous opposing adjustments.

— **Contrast Pivot**: Changes the center of tonality about which dark and bright parts of the image are stretched or narrowed during a contrast adjustment.

— **Midtone Detail**: When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high detail are left alone.

— **Color Boost**: Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation.

— **Shadow**: Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity.

— **Highlight**: Makes it easy to selectively retrieve blown-out highlight detail in high dynamic range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result.

— **Saturation**: Increases or decreases overall image saturation. At higher values, colors appear more intense, while at lower values, color intensity diminishes until, at 0, all color is gone, leaving you with a grayscale image.

— **Hue Rotation**: Rotates all hues of the image around the full perimeter of the color wheel. The default setting of 50 shows the original distribution of hues.

— **Luminance Mix**: Lets you control the balance between YRGB contrast adjustments you’ve made using the Master Wheels or ganged Custom curves, and Y-only adjustments to contrast made using the Y channel Lift/Gamma/Gain controls of the Primaries palette or the unganged Luma curve.

Additional detail can be found in the Color page basics chapter, and each of these operations can be seen on the Primary palette of the user interface.

**Control Buttons**

On the right-hand side of the trackballs there are three groups of control buttons.
The top group includes:

- **Grab Still**: At any time when you are grading, selecting the Grab Still key automatically grabs a full resolution frame from the Timeline and attaches the node graph metadata for later display and use.
- **Undo**: Undo is one of the favorite keys of colorists. Try any grade, and if you don’t like it, simply undo. There are multiple steps of undo available within the page.
- **Redo**: Sometimes you hit undo once too many times. Redo will put back into effect the last item you undid. As with undo, there are multiple levels of redo.
- **Play Still**: Using Play Still, DaVinci Resolve will automatically display a wipe on the Viewer between the current scene and the current still. You can use your mouse on the Viewer to move the wipe position. Selecting Play Still a second time will toggle this mode off.
- **Prev Mem**: Each clip, by default, has a memory of its grade, sizing, and so on, which is saved in reference to the source timecode. If you are grading a clip and move from it to another clip, the grade is saved automatically in a memory for that clip. If you come back to the clip and make a change to the grade, then decide you don’t like the change, select Prev Mem to return to the previous grade status you found when selecting the clip.
- **Reset**: This key resets the grade of the current node. Holding down this key deletes all nodes in the clip except for the first node, resets the grades to default, and clears the keyframes.
- **Loop**: You may wish to repeat a review of a grade of a clip, or a selection of clips on the Timeline; this Loop toggle key selects or deselects the Loop operation.
- **Bypass**: This toggle selects the Node Graph Bypass mode.
- **Disable**: This toggle enables or disables the current node.

The middle group of buttons include:

- **Prev Node**: Within the Node Editor on the Color page, you are likely to have a number of nodes. These are numbered based on the order that you added them. DaVinci Resolve node graphs are completely user configurable, so you can add nodes anywhere and in any order you like. Thus, the Previous Node key selects the node one lower in numerical order.
- **Next Node**: Similar to the Previous Node key, this selects the node adjacent to the current node, in this case the next higher numerical position.
- **Prev Frame**: To step the Viewer one frame in reverse along the Timeline. Press and hold the Prev Frame button to go to the first frame of the clip.
- **Next Frame**: A single frame step forward for each key press. Press and hold the Next Frame button to go to the last frame of the clip.
- **Prev Clip**: Selects the first frame of the previous clip.
- **Next Clip**: Selects the first frame of the next clip.

The bottom group includes the Timeline Transport buttons for reverse play, stop, and play.

- **Left Arrow**: Select this key to play the clip/Timeline in reverse. Press the Left Arrow key multiple times to play in reverse at a faster speed.
- **Stop**: You guessed it. This stops the playback.
- **Right Arrow**: The forward key plays the clip/Timeline forward. Press the Right Arrow key multiple times to play forward at a faster speed.
Using the DaVinci Resolve Mini Panel

The Mini Panel has an identical feature set and controls as the Micro Panel for the lower trackball deck. In addition, the panel has an upper sloped desk with dual high resolution LCD displays with eight soft knobs and keys that are menu driven. There are also two banks of control buttons, on the left-hand side for palette selection and on the right-hand side for commonly used operations.

Please refer to the Micro Panel details above for the lower deck features.

Data and Power Connections

The DaVinci Resolve Mini Panel has multiple ways to connect data and power in order for easy install in a wide variety of post-production environments. There is no power switch, and the panel is always on when connected to a power source. When DaVinci Resolve is closed, the LCD will display “No connection to DaVinci Resolve” and will turn off the LEDs and go dormant after approximately 10 minutes.

Data Connections to the Computer

— **USB-C**: The Mini Panel can be connected directly to the computer via a USB type C connection. It cannot be powered by USB-C, however. If connected directly via USB C, DaVinci Resolve should see the panel automatically.

— **Ethernet**: The Mini Panel can be connected to computer via an Ethernet network. This requires setting the up the panel to be on the same subnet as the host computer in the Network Settings. You will also need to connect to the panel using the DaVinci Resolve Mini Panel (Ethernet) option in the Color Grading section of the Control Panels pane of the System Preferences.

Power Connections

— **AC Power**: The Mini Panel can be powered directly from a wall socket.

— **DC Power**: The Mini Panel can be powered using a 12V battery and 4-pin XLR power connector

— **PoE**: The Mini Panel can be connected and powered with a single cable via Power over Ethernet (PoE) if your router supports this function.

---

The power and connection ports of the Mini Panel
Palette Selection Buttons

On the left-hand side of the top deck you will find 15 palette selection buttons. To quickly select the main palette toolsets in DaVinci Resolve, simply select the appropriate button and the menus on the LCD screens will update to the correct display.

— **Home**: This key is used for the initial setup of the panel and also selects the top-most menu.
— **Network**: Exposes the Network Settings controls to set up the Mini Panel over Ethernet.
— **About**: Displays the currently installed firmware version.

— **Left Arrow**: A number of menus have multiple pages as indicated by the small dots in the center of the LCD displays. The Left Arrow moves the menu display left.
— **Right Arrow**: The Right Arrow moves the menu display right.
— **Raw**: This palette contains groups of parameters that correspond to every camera raw media format that’s supported by DaVinci Resolve.

— **Primary**: The first grade for every clip will be likely be a primary. This is where you balance the clip and correct for offsets in the black and white balance. Selecting Primary switches DaVinci Resolve from other grading modes and automatically selects the Primary menus for the LCD displays. For more information on using these controls, see Chapter 128, “Primaries Palette.”
— **Primary**: Exposes the Primary grading controls and opens the Primaries Wheels palette in the DaVinci Resolve interface.
— **Log**: Exposes the Log grading controls and opens the Primaries Log palette in the DaVinci Resolve interface.
— **Offset**: Exposes the Offset adjustment controls.
— **RGB Mixer**: Exposes the RGB Mixer controls and opens the RGB Mixer palette in the DaVinci Resolve interface.
— **Motion:** The Motion Effects palette (only available in the Studio version) contains two sets of controls for applying optical-flow-calculated effects to clips in your program. These include enhanced Temporal and Spatial noise reduction, and motion-estimated artificial motion blur.

— **Curves:** The Curves palette has modes that provide different curve-based methods of manipulating the color and contrast of an image. Each curve lets you adjust a customizable region of the image based either on image tonality (zones of lightness or darkness), hue (specific colors), or saturation (intensity of color). For more information on the specifics of curves, see Chapter 131, “Curves.”

— **Custom:** Exposes the Custom curve controls and opens the Custom curve palette in DaVinci Resolve. In Custom mode, the first 6 knobs represent control points along the curve in 20% increments. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value. Using the arrow keys, you can also navigate to the Intensity and Soft Clip controls.

— **Tools:** Allows you to gang or split the YRGB components of the curves, as well as provides access to the YSFX controls.

— **Hue vs Hue:** Exposes the Hue vs Hue curve controls and opens the Hue vs Hue curve palette in DaVinci Resolve. In this mode, the first 6 knobs represent specific colors along the curve. The eighth knob (Input Hue) allows you to fine tune the selected color. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value.

— **Hue vs Sat:** Exposes the Hue vs Sat curve controls and opens the Hue vs Sat curve palette in DaVinci Resolve. In this mode, the first 6 knobs represent specific colors along the curve. The eighth knob (Input Hue) allows you to fine tune the selected color. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value.

— **Hue vs Lum:** Exposes the Hue vs Lum curve controls and opens the Hue vs Lum curve palette in DaVinci Resolve. In this mode, the first 6 knobs represent specific colors along the curve. The eighth knob (Input Hue) allows you to fine tune the selected color. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value.

— **Lum vs Sat:** Exposes the Lum vs Sat curve controls and opens the Lum vs Sat curve palette in DaVinci Resolve. In this mode, the first 4 knobs represent Black, Shadow, Highlights, and White along the curve. The eighth knob (Input Lum) allows you to fine tune the selected level. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value.

— **Sat vs Sat:** Exposes the Sat vs Sat curve controls and opens the Sat vs Sat curve palette in DaVinci Resolve. In this mode, the first 4 knobs represent Black, Shadow, Highlights, and White along the curve. The eighth knob (Input Sat) allows you to fine tune the selected level. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value.

— **Sat vs Lum:** Exposes the Sat vs Lum curve controls and opens the Sat vs Lum curve palette in DaVinci Resolve. In this mode, the first 4 knobs represent Black, Shadow, Highlights, and White along the curve. The eighth knob (Input Sat) allows you to fine tune the selected level. Rotating the knobs increases or decreases the position of the control point, and pressing in on the knob resets the control point to its default value.
— **Qualifier:** When you select and isolate a particular color, and change that color, you are making a secondary correction. The qualifier key updates the menus to provide all the Secondary controls, including the 3D, HSL, RGB, or Luma key, with which to isolate the correction you need. For more information on Qualifiers, see Chapter 133, “Secondary Qualifiers.”

— **HSL:** Exposes the HSL qualifier controls and opens up the HSL Qualifier in DaVinci Resolve. The arrow keys cycle through all available controls of the qualifier including the Matte Finesse tools, and the knobs are used to make adjustments.

— **RGB:** Exposes the RGB qualifier controls and opens up the RGB Qualifier in DaVinci Resolve. The arrow keys cycle through all available controls of the qualifier including the Matte Finesse tools, and the knobs are used to make adjustments.

— **LUM:** Exposes the LUM qualifier controls and opens up the LUM Qualifier in DaVinci Resolve. The arrow keys cycle through all available controls of the qualifier including the Matte Finesse tools, and the knobs are used to make adjustments.

— **3D:** Exposes the 3D qualifier controls and opens up the 3D Qualifier in DaVinci Resolve. The panel controls give you access to the full parameters of the 3D qualifier. However, the unique nature of the 3D qualifier requires pointer input to select the color paths to key. The arrow keys will expose the Matte Finesse tools, and the knobs are used to make adjustments.

— **Tools:** Exposes additional tools for all qualifiers, including Picker, Picker Subtract/Add, Feather Subtract/Add, and Invert.

— **Window:** Power Windows are another way of making secondary correction, being essentially shapes you can use to isolate regions of the image. Different controls let you use oval, rectangular, polygonal, or custom curved shapes. Because you can isolate regions of the image by drawing, Power Windows produce exceptionally clean results, with edges that can be precisely positioned and feathered to achieve a variety of effects. For more information on Windows, see Chapter 134, “Secondary Windows and Tracking.”

— **Linear:** Exposes the Linear Window adjustment controls. It is possible to shape the window to your specifications using the eight control knobs. Pressing the knob resets the parameter.

— **Circle:** Exposes the Circle Window adjustment controls. It is possible to shape the window to your specifications using the eight control knobs. Pressing the knob resets the parameter.

— **Polygon:** Exposes the Polygon Window adjustment controls. The Polygon Window must first be created using the pointer in the Viewer; it is then possible to move the window to your specifications using the eight control knobs. Pressing the knob resets the parameter.

— **Curve:** Exposes the Curve Window adjustment controls. The Curve Window must first be created using the pointer in the Viewer; it is then possible to move the window to your specifications using the eight control knobs. Pressing the knob resets the parameter.

— **Gradient:** Exposes the Gradient Window adjustment controls. It is possible to shape the window to your specifications using the five control knobs. Pressing the knob resets the parameter.

— **Add Window:** If you need to add another window of the same type (linear, circle, etc.) in the same node, you can press this button to add another one. Each specific window’s parameters can then be accessed by using the Left/Right Arrow keys on the Mini Panel.

— **Window On:** Toggles the selected window on or off. The correct order to create a window using the Mini Panel is to select the window type first, and then press the Window On button to activate it.

— **Tools:** Exposes a common set of Window-related tools, including Invert, Mask Control, Window Copy/Paste, Convert to Curve, and a Delete button to remove a specific window from a set of window types created by the Add Window function.
— **Tracker:** The Tracker palette operates in Window mode, where the tracking controls let you match the motion of a window to that of a moving feature in the frame. The tracking controls are all accessed by the soft keys on top of the LCD panels; the knobs have no functionality in the tracker. You can track forward, reverse, and forward/reverse. You can access the Clip and Frame modes, as well as add and delete keyframes, copy and paste tracks, and select the included spatial parameters of the track. Toggling between the Tracker in frame mode and the Window panels allow you to manually track a window solely on the Mini Panel if necessary.

— **Blur:** With the Blur palette controls you can apply an exceptionally high-quality Gaussian blur, or another equally high-quality sharpening operation to your image. For more information on how to use the Blur controls, see Chapter 150, “The Motion Effects and Blur Palettes.”

— **Blur:** Exposes the Blur controls and opens the Blur palette in the DaVinci Resolve interface. The Radius and H/V Ratio amounts can be adjusted either simultaneously or on a per color basis by using the control knobs.

— **Sharpen:** Exposes the Sharpen controls and opens the Blur palette in the DaVinci Resolve interface. The Radius and H/V Ratio, and Scaling amounts can be adjusted either simultaneously or on a per color basis by using the control knobs. Coring controls are accessible via the Left/Right arrows.

— **Mist:** Exposes the Mist controls and opens the Blur palette in the DaVinci Resolve interface. The Radius and H/V Ratio, and Scaling amounts can be adjusted either simultaneously or on a per color basis by using the control knobs. Mix controls are accessible via the Left/Right arrows.

— **Keyer:** Each color correction node’s key input and key output makes it possible to route key channel data from one node to another, so you can apply isolated corrections. These key levels are controlled in the Keyer palette and include the Key Input, Key Output, and Qualifier tools.

— **Sizing:** DaVinci Resolve has a powerful toolset for making geometric transforms, using advanced algorithms for optical-quality sizing operations, and they are found in this palette.

— **Edit:** Exposes the sizing controls to affect a specific clip on the Edit or Cut page and are linked to the transform values set in the Video Inspector.

— **Input:** Exposes the sizing controls to affect a specific clip on the Color page only. The changes made here will be seen in the Timeline but will not be linked to the clip’s Video Inspector.

— **Output:** Exposes the sizing controls to affect the entire timeline.

— **Node:** Exposes the sizing controls to affect a specific node.

— **Reference:** Exposes the sizing controls to affect the Gallery Still that is being used in a reference wipe.

— **Fx:** This palette allows the control of Resolve FX plug-ins. Resolve FX plug-ins span the gamut from blurs and complex color adjustments to stylized image treatments and lighting effects to sharpen and repair operations that are too complex to accomplish using the palette controls of the Color page. Several of the most commonly used Resolve FX plug-ins are mapped to the soft buttons above the LCD panels. Pressing one of these buttons applies the plug-in to the selected node. If the specific plug-in you want is not assigned to the soft buttons, you can manually drag the Resolve FX to your node from the Open FX Library. Once placed, the parameters of that plug-in will be available in the panel interface. For more information on specific Resolve FX controls, see Chapter 148, “Using Open FX and Resolve FX.”

— **User:** Additional palettes introduced in newer versions of DaVinci Resolve without their own direct access buttons will appear here.
— **Stereoscopic:** Exposes DaVinci Resolve’s extensive set of stereoscopic controls to use with 3D images, including convergence, stereo alignment, and floating windows. If no clips have been marked as Stereo, this palette is inactive. For more information on the Stereoscopic tools, see Chapter 15, “Stereoscopic Workflows.”

— **HDR:** Exposes the High Dynamic Range toolset and opens the High Dynamic Range palette in DaVinci Resolve. The HDR toolset provides a more nuanced, zone-based primary grading that is especially suited for HDR deliverables. The six default zones being Black, Dark, Shadow, Light, Highlight, and Specular. However, using the HDR palette with the Mini Panel creates some unique interface conventions to keep in mind:

  Each zone is mapped to an LCD panel, and a trackball and its ring.
  — The LCD Panel shows the Zone Name, and the four knobs control saturation, exposure, zone pivot, and zone falloff.
  — The Trackball controls the zone’s color balance showing angle and strength or XY coordinates.
  — The Ring controls the zone’s exposure.

  There are six default zones (and the user can add more), but only three sets of trackballs, and two LCD panels, so the trackballs now shift zones up or down depending on the selected active zones, instead of being dedicated to a single zone like with lift, gamma, and gain.

  Zones are shifted using the Prev Zone and Next Zone soft keys above the LCD panels. The current active zones are shown in the High Dynamic Range palette in DaVinci Resolve, and they are also indicated by the colored Zone bank controls on the top of the palette.

  The left trackball is mapped to the left LCD panel.
  — The center trackball is mapped to the right LCD panel.

  The right trackball is still active, but has no corresponding LCD, so the saturation, exposure, zone pivot, and zone falloff controls are not adjustable until you shift the zones down using the Previous Zone soft button. Then the zone that was on the right trackball is now remapped to the center trackball and the right LCD screen.

  To access the highest zone’s LCD panel, you must navigate to the furthest zone bank to the right by using the Next Zone button until it reaches the end. Then you must press the Right Arrow key on the Mini Panel. The highest zone controls (by default specular) are now available in the Left LCD panel but are still linked to the right trackball.

  Global is accessed via the Right arrows, the LCD is changed to allow the knobs control of the Black/Offset, Color Balance, Exposure, Temperature, and Tint, but the trackballs are still actively controlling the zones set in the zone bank.

For more information on using the HDR toolset, see Chapter 129, “HDR Palette.”

**TIP:** The trackballs and rings are always active in their selected zones in the HDR palette, regardless of what is on the LCD screens at the time.
Quick Selection Buttons

On the right-hand side of the top deck, you will find 15 quick selection buttons. These are for very commonly used selections that a colorist might use many times for each clip.

— **Serial**: The most common node to use on the node graph is a Serial node. A Serial node is a full-featured color correction processor offering primaries, secondaries, windows, tracking, image stabilization, sharpening and blur, matte blur, and so on. Serial nodes are added one after the other in a cascade mode, similar to adding one layer of correction on top of the last. All grades in a preceding node(s) will impact the source image and therefore the grades in following nodes.

— **Parallel**: Unlike adding a Serial node, adding a Parallel node first actually adds two nodes. One behaves like a Serial node with full color correction capabilities. The second is a Parallel Mixer node. This mixer accepts the image from the original Serial node and from the new Serial node and the output is a mix of these two. If the current node is one of the Serial nodes immediately preceding the Parallel Mixer node and you select Add Parallel again, another input to the mixer will be created as will another preceding Serial node. In each case, the input to these Serial nodes will be common, effectively making them in parallel to each other. The key advantage is that the source image is available to many nodes, whereas in a straight Serial node graph, each time you restrict a color in a node the following nodes have little ability or limited range to use that color.

— **Layer**: The Layer node is similar to the Parallel node in that it accepts the image inputs from more than one node. The key difference to a Parallel node is that the mixing of the inputs in a Layer node is prioritized towards the latest additions to the input list. For example, select Add Layer and DaVinci Resolve will add a node in parallel to the current node and link the output of the current and the newly made Parallel node to the two inputs of the Layer Mixer node. The previous current node will have the lowest priority in the mix, and the newly made Parallel node the highest priority. Add one more Layer node, a third input node will be created with a higher mix priority than the first two nodes.
— **Node + Linear**: Adds a Serial node after the current node on the node graph and simultaneously adds a Linear Power Window, thus reducing the number of keystrokes.

— **Node + Circle**: Adds a node after the current node on the node graph and simultaneously adds a Circular Power Window.

— **Append**: Often when navigating around the Node Editor and making correction trims, the colorist decides he/she needs an additional node for more correction. Using the Append Node key will always add a Serial node to the very end of the node graph, regardless of which node in the graph is the current node.

— **Copy**: Used to copy a selected nodes grade to another node.

— **Paste**: Use this key to complete the copy/paste of node grade.

— **Full Viewer**: The Full Viewer display shows an enlarged Viewer and this includes transport controls at the bottom, timecodes and the selections for Reference Still modes, split screens, and Highlight modes.

— **Prev Still**: If you have a still selected, the Previous Still key selects the one preceding.

— **Next Still**: The next still is selected if this key is used.

— **Highlight**: When in the Qualifier menus making secondary qualifiers, it’s common to select the Highlight key to show a high contrast separation of the qualified color and all other parts of the image. Toggle this key to turn off.

— **Prev KF**: This key steps backward one keyframe on the Clip/Track Timeline display.

— **Next KF**: For keyframe steps forward on the Clip/Track Timeline display.

— **Ref**: This toggle key changes the reference wipe mode between Gallery, Timeline, and Offline sources.

### Using the DaVinci Resolve Advanced Control Panel (Legacy Layout)

**IMPORTANT**

For information on the new version of the DaVinci Resolve Advanced control panel, see the next section. This section covers the previous version of the Advanced Panel for legacy owners.

There are three panels in the Advanced control panel set. The center Trackball panel is where the majority of controls and feedback for the colorist are found and it includes a slide-out keyboard.

On either side of the Trackball panel are two interchangeable panels, the position of which is determined by operator preference. The T-bar panel, shown above on the left, has a T-bar Mix/ Wipe control and a number of menu and function keys. The Search Dial panel, shown above on the right, has the Timeline Transport controls and a Jog/Shuttle control as well as a numerical keypad and associated function keys.

All panels have soft keys and variable control knobs within the LCD panel, which provide an accurate visual reference to the control without the risk of parallax errors.
A key feature of the panel design is real-time feedback, provided to the colorist via the full color LCD panels where you can see, at a glance, the relative settings of the controls and a highlight of the last control touched. For example, if a control is out of its default reset, the panels show this with a selectable color highlight.

**Menus, Soft Keys, and Soft Knob Controls**

The soft menu structure is designed to offer simultaneous control over multiple functions and a fast, logical, and efficient way to move between the menus. These soft menus, the soft keys, and the operation of these in conjunction with the variable knobs are covered in the preceding chapters of this manual as their state changes depending on the operation being performed.

You will find the LCD on each of the panels has a two-line title description of the menu’s main function and there are two lines of text above each pot or switch describing the control. The T-bar and Search Dial panels also have a “More” key to the bottom right of the LCD which will select a second layer of menus.

The T-bar and Search Dial panels have quite independent controls compared to the Trackball panel. For example, the T-bar panel’s default menu is for Windows adjustment while the default menu for the Search Dial panel is Sizing. This allows users to control windows or sizing at any time, regardless of the Trackball panel mode and eliminates the need to change the work surface to adjust window position or input sizing.

While the menus change with the UI, the hard keys, trackballs, T-bar, and shuttle control remain relatively constant, so the majority of this chapter describes groups and individual key functions. At the end of this chapter are details on copying forward, scrolling, and rippling changes using the Advanced control panel.

**Shift Key Convention**

Before describing the hard key operation, it is important to understand two keys on the left and right panels. These keys, Shift Up and Shift Down, provide access to potentially two more functions on each of the next key selected.

For example, on the T-bar panel, next to the Shift Up key is the Base Mem key. The term “Base Mem” is a legacy DaVinci colorist description to revert to the default memory, so there is no grade or sizing on that node. (There is an exception discussed later in this chapter.)

If you select Shift Up and then Base Mem, the All operation is to Base Mem All or reset the current color correction of every node in the node graph for the current clip, leaving the nodes in place. To “Reset” the selected node graph or “Reset Grades and Nodes,” first select Shift Down, then Base Mem.

To permit a fast and single-handed operation, this function does not require you to hold the Shift Up or Shift Down key while selecting the second key; just select them sequentially, first the Shift key, then the function.

**Trackball Panel**

The Center panel has the traditional four trackballs, each with a surrounding control ring and no end stop in either direction. Three variable knob controls are on each side of the panel, three keys above the trackballs, three below the leftmost and rightmost trackballs. On the LCD panel, there are three LCD displays, each with eight knob controls and four keys. The LCD screens are menu driven and thus the knobs, soft keys, and the display itself depends on the application’s current operation. The Center
panel also offers a slide-out keyboard for naming files, stills, and nodes, as well as for a number of other operations.

The three trackballs, from left to right, are in the traditional DaVinci format of Lift, Gamma, and Gain when DaVinci Resolve is set for Primary grading; when in Log grading they are Lowlights, Midtones, and Highlights.

By rotating the trackball the colorist can alter the balance between the red, green, and blue levels of the image. Using the vectorscope as a rough guide, moving the trackball towards the three-thirty clock position adds more blue while reducing the red and green.

The control ring surrounding these trackballs provides a master amplitude control of the associated trackball.

![The Trackball panel includes a slide-out keyboard](image)

**Above the three leftmost trackballs you will see three buttons for resetting the grade:**

- **RGB:** This key only resets the RGB balance to default detent.
- **All:** Select All to reset both RGB and level.
- **Level:** Select the Level key to reset the level while maintaining RGB differential.

The rightmost (fourth) trackball has a number of modes. It operates similar to a mouse for moving the onscreen cursors, Color curve control point position, and Power Windows position, and can also act as a primary grade Offset control.

Under the leftmost and rightmost trackballs there are three unmarked buttons.

On the left hand side of the panel, the right-most of the three unlabelled buttons below the trackball toggles the right hand side (fourth) trackball in and out of offset adjust mode.

The keys under the right-hand side trackball provide left, center, and right mouse buttons.

Above the rightmost trackball, the three keys have two modes.
When used in conjunction with the Shift Down button, the three buttons above the trackball function as
resets, as per the buttons above the other trackballs.

- **Shift Down Adjust Window:** Only resets the RGB balance to default detent.
- **Shift Down Modes:** To reset both RGB and level.
- **Shift Down Cursor:** To reset the level while maintaining RGB differential.

**In their normal operation they select:**

- **Adjust Window:** Selection turns on the Viewer Shape cursors for the current node and allows the
  trackball to position the current window.
- **Modes:** This key allows access to a number of menus and acts as an on/off toggle.
- **Display (Shift Up Cursor):** This shift function changes the cursor views on the main monitor. The
  user can select the cursor display, including: Windows, Off, On the UI but not the main SDI monitor,
  or displayed on both.
- **Cursor:** The Cursor is used for the color picker when in Curves and Vector/Secondary modes. This
  key also controls the Window display.

On the left side of the panel are three luminance knobs. From top to bottom they are Luminance Gain,
Gamma, and Lift.

On the right side there are three more controls, from top to bottom: Saturation, Hue (has the effect of
hue rotation), and Luminance Mix.

**T-bar Panel**

The T-bar panel, typically located on the left for a right-handed colorist, has an LCD display with four
variable controls and nine soft keys. The lower section of the panel houses the T-bar and six groups of
hard keys. Each group and their keys are described below.

**Mode Control Group**

The Mode Control group provides navigation to a number of the GUI pages and a few
commonly used functions.

- **Config:** This key opens the Project Setting window where you will set up DaVinci Resolve for each
  project. Select again to close the window without saving.
- **Browse:** Select Browse to call the Media page where you can review files on attached storage and
  review the Media Pool.
- **VSR (Shift Down Browse):** This selection is reserved for future use.
- **Conform:** Selects the Lightbox display on the Color page.
- **Shift Up Conform:** Toggles the display of the Lightbox on the SDI output.
- **Deck (Shift Up Revival):** The Deck key selects the Capture mode for importing a batch
  list from an EDL.
- **Revival:** This key opens the Revival Dirt and Dust-busting window.
- **Scene (Shift Down Revival):** To select the Scene Cut Detection window, select the Shift Down key
  followed by the Revival key.
- **Current ~ Viewer:** This key toggles between the Color page and the Enhanced Viewer page.
- **Object Track Mode:** This key selects the Tracking menus.
— **Clip/Track/Unmix:** This is a toggle key between the Clip/Timeline modes of the node graph and the Unmix mode.

— **User (Shift Up Cache Mode):** This marks a clip for render cache of the clip output.

— **Cache:** This key is a toggle function to turn the render cache on or off.

— **Editor:** Selects the Edit page where you can edit the Timeline, import AAF, EDL or XMLs and apply speed changes, Composite and Dissolve/Wipe effects, and so on.

— **Proxy On/Off:** This key toggles the proxy mode on and off.

— **Auto Color:** This is a popular key. Using this key, DaVinci Resolve will automatically make a basic primary color correction to balance the blacks and whites of your image.

— **Page Up (Shift Up Gallery):** In larger projects you may have a number of gallery albums holding stills. This key changes the Gallery page to the next higher album on the list.

— **Gallery:** Used to select the Gallery UI page where you can manage, import, and export your stills.

— **Page Down (Shift Down Gallery):** The inverse of the Shift Up Gallery function, this selects the Gallery album one lower than the current.

— **A/C Mode:** This toggle key displays the clips in the Timeline in the order of the EDL (the record order, often referred to as C Mode), or the ascending order of the source clip timecode, called A Mode.

— **Handles Mode:** This selection exposes the handles of the selected clip to allow tracking and grading outside the I/O selections of the current edit.

**Timeline Management Group**

When grading clips, colorists often try different looks. This group of keys offers a quick way to navigate through these versions and to split and join clips on the Timeline.

— **Split (Shift Up Undo):** This key splits the clip at the position of the cursor on the Timeline.

— **Undo:** Undo is one of the favorite keys of colorists. Try any grade, and if you don’t like it, simply undo. There are multiple steps of undo available within the page.

— **Join (Shift Up Redo):** The reverse of split. Place the Timeline cursor at the junction of two clips that have sequential timecode and select Join to make just one clip.

— **Redo:** Sometimes you hit undo once too many times. Redo will put back into effect the last item you undid. As with undo, there are multiple levels of redo.

— **Restore Point:** This selection is reserved for future use.

— **Save:** Remember this key; it’s your friend. Save often, and also consider the auto save options found in the User Preferences.

— **Add Version:** When you make a grade on any clip, DaVinci Resolve stores the parameters for that clip. If you want to try different grades, don’t lose your good grades, just use the Add Version feature. This key makes a second, third, or higher version of the grade for that clip.

— **Default Version:** If you have multiple versions of grades for a clip, this key is used to select the Default version, regardless of which version is currently displayed.

— **Previous Version:** This selects the grade one version lower in order. For example, if you are on version three, select Previous Version to get to version two. Once the Default version is reached, selecting Previous Version again will select the highest version.

— **Next Version:** Use this key to select the next higher version of the grade. Once the top version is reached, selecting Next Version again will select the lower version.
Keyframing Group

On the bottom right of the Color page is the Keyframe timeline for the current clip. The Keyframing group of keys is used in association with the Keyframe timeline and controls the selection of marks for the start and end of dynamic transitions of the grade.

— Start Dynamic: Use Start Dynamic to select the first keyframe in a transition. The transition may be a grade change, resizing, the addition of a matte, or any number of 100 variables, all of which are associated with the node graph and the Clip or Track timeline.
— Ripple Value: If you have a grade or effect, or just an adjustment, and you would like to ripple this effect over another effect or over a large number of other clips, use Ripple Value.
— Delete: This key deletes the selected keyframe.
— Lift Mark: If you place a keyframe in the wrong spot, put your cursor on the keyframe and use Lift Mark to remove it.
— Trim: This key is used with the numerical keypad to trim a keyframe’s position.
— Mark: Like the Start Dynamic key, Mark is a major key. It places a Static keyframe on the Keyframe timeline.
— Scene (Shift Down Mark): This selection opens the Scene Cut Detector.

Memory Access Group

DaVinci Resolve has a number of hot keys, called Mems, where you can store a grade for quick reference. In fact, every time you make a grade for a clip, a memory of the grade is kept. While you could save a still for each clip, having thousands of stills to scroll through would take time, so there are 26 quick and easy memory locations to store a grade, called A–Z Mems.

Every clip has its own metadata for the grade that is stored by DaVinci Resolve as a memory. There are a number of keys available to select or revert to these stored metadata memories, or to clear the metadata to revert to a base grade or no grade state.

— All (Shift Up Base Mem): This is used to reset the current color correction of every node in the node graph for the current clip, leaving the nodes in place.
— Base Mem: Used to reset the grade of the current node.
— Reset (Shift Down Base Mem): Used to reset the grades of the current clip.
— Please note that there is an exception to the rule to clear the Base Mem. It is possible, in fact very helpful sometimes, to have a clip preset that is not cleared when you select Base Mem. For example, when a film is over scanned and the frame edges are shown as well as the image. Instead of making an input resize adjustment for every clip to remove the framing, a preset resize can be made and stored, with a label, and this preset is not deleted when using Base Mem.
— Preview Mem: To preview one of the Memory grades on any clip, select the clip on the Timeline, select Preview Mem and then the Memory letter. This key is a toggle so if you do not like the grade on the memory for that clip, select Preview Mem again and the grade will revert to the original.
— Original Mem: Each clip by default has a memory of its grade and sizing, etc. If you are grading a clip and move from it to another clip, the grade for the first clip is saved automatically in a memory for that clip. If you come back to that clip and make a change to the grade, then decide you don't like the change, select Original Mem to return to the grade status you found originally.
— Scroll: When you select Scroll you can navigate up and down the Timeline to find and select a clip and its grade to recall to the current clip.
— **View (Shift Up Current):** The Color page has two display modes. The normal mode includes the viewer, stills, and node graph on the top of the page. Selecting View toggles to the alternate page with a wide Node Graph view and stills but no viewer. Select View again to toggle back to the normal mode.

— **Crt:** Select Current before selecting a Mem key (A, B, C to Z) and the current grade on the active Timeline clip will be stored in the memory selected.

— **Shift Up:** The Shift Up key permits the operator to select the upper secondary function of keys on the control panel. This operation does not require you to hold the Shift Up key, just select it prior to the second key.

— **Shift Down:** The Shift Down key permits the operator to select the lower secondary function of keys on the control panel. This operation does not require you to hold the Shift Down key, just select it prior to the second key.

— **Macro:** This key displays the Split Screen controls on the T-bar panel LCD display.

— **Memory Keys:** The A, B, C to Z keys, selected directly or with the appropriate Shift Up or Shift Down preselection will recall the grade stored in this memory and will apply it automatically to the clip that is active on the Timeline.

### Menu Navigation and Node Control Group

DaVinci Resolve is a nodal-based color enhancement system. Grades are not stored in layers, but in nodes. In operation they can appear to be in layers if you select the Serial nodes, but greater grading flexibility is available by using the Parallel and Layer nodes.

This group also gives you quick access to the main menus to control primaries, secondaries (known here as Vectors), image sizing, and windows. It also offers a quick way to add and manage nodes.

— **Primary:** The first grade for every clip will be likely be a primary. This is where you balance the clip and correct for offsets in the black and white balance. Selecting Primary switches DaVinci Resolve from other grading modes and automatically selects the Primary and Custom Curve menus for the LCD displays.

— **Vectors:** When you select and isolate a particular color, and change that color, you are making a secondary correction. The Vectors key updates the menus to provide all the Secondary controls, including the hue selection and control.
— **Sizing:** The input and output image resizing engines are controlled using the menus selected by Sizing.

— **Windows:** The Windows key opens the menus for Circular, Linear, Polygon, PowerCurve, and Gradient windows that can be used as a matte or mask for primary and secondary grades.

— **Outside Node:** Selecting the Outside Node key adds another node after the current node and automatically link both image and key paths. If the original node has a grade within the matte shape the new Outside node would control the grade in the inverse (i.e., outside the matte).

— **Add Matte:** Selecting this key displays the Matte node on the node graph for the selected node and the default matte selected.

— **Disable Current:** This key is a toggle key and it disables or enables the grade on the current node.

— **Delete Current:** To delete the current node. Remember to use undo if you had the wrong node selected.

— **Bypass (Shift Up Disable Current):** This toggle selects the bypass mode.

— **Enable/Disable All (Shift Down Disable Current):** This toggle enables or disables all nodes.

— **Node + CPW:** Adding a Serial node is a one button selection, Add Serial, but to also add a window requires a number of extra key selections. The Node + CPW key adds a node after the current node on the node graph and simultaneously adds a Circular Power Window, thus reducing the number of keystrokes.

— **Node + LPW:** As above, adds a Serial node after the current node with a Linear Power Window.

— **Node + PPW:** A Polygon Power Window is also selected when adding a Serial node.

— **Node + PCW:** This key, like the others above, adds a Serial node after the current node, but also sets up the PowerCurve Window to permit the marking of freeform shape points and Bezier spline curves on the viewer to construct a freeform window.

— **Add Serial:** The most common node to use on the node graph is a Serial node. A Serial node is a full-featured color correction processor offering primaries, secondaries, windows, tracking, image stabilization, sharpening and blur, matte blur, and so on. Serial nodes are added one after the other in a cascade mode, similar to adding one layer of correction on top of the last. All grades in a preceding node(s) will impact the source image and therefore the grades in following nodes.

— **Shift Down Add Serial (Add Serial Before):** This adds a serial node before the current node.

— **Add Parallel:** Unlike adding a Serial node, adding a Parallel node first actually adds two nodes. One behaves like a Serial node with full color correction capabilities. The second is a Parallel Mixer node. This mixer accepts the image from the original Serial node and from the new Serial node and the output is a mix of these two. If the current node is one of the Serial nodes immediately preceding the Parallel Mixer node and you select Add Parallel again, another input to the mixer will be created as will another preceding Serial node. In each case, the input to these Serial nodes will be common, effectively making them in parallel to each other. The key advantage is that the source image is available to many nodes, whereas in a straight Serial node graph, each time you restrict a color in a node the following nodes have little ability or limited range to use that color.

— **Add Layer:** The Layer node is similar to the Parallel node in that it accepts the image inputs from more than one node. The key difference to a Parallel node is that the mixing of the inputs in a Layer node is prioritized towards the latest additions to the input list. For example, select Add Layer and DaVinci Resolve will add a node in parallel to the current node and link the output of the current and the newly made Parallel node to the two inputs of the Layer Mixer node. The previous current node will have the lowest priority in the mix, and the newly made Parallel node the highest priority. Add one more Layer node, and a third input node will be created with a higher mix priority than the first two nodes.
— **Append Node**: Often when navigating around the Node Editor and making correction trims, the colorist decides he/she needs an additional node for more correction. Using the Append Node key will always add a Serial node to the very end of the node graph, regardless of which node in the graph is the current node.

**Reference Configuration Group**

This area of the T-bar panel includes six keys and the fader T-bar. It is primarily used for control of stills display with and without reference wipes. The fader bar controls the mix or wipe position when the appropriate mode is active.

— **Key**: This key adds and Alpha output on the node graph.

— **Circle**: This key is not yet implemented.

— **Wipe**: The Wipe key selects a wipe for reference comparison with the current image.

— **H/V**: This key toggles the wipe between horizontal and vertical.

— **Box**: This key is not yet implemented.

— **Mix**: Select this key to mix in preference to wipe.

— **Still**: The Still key permits comparison of the current clip with the selected still.

— **Memory**: Use this key to compare the current clip with a memory.

— **Highlight**: When in the Qualifier (Vector) menus making secondary qualifiers, it’s common to select the Highlight key to show a high contrast separation of the qualified color and all other parts of the image. Toggle this key to turn off. Highlight is used so often it’s also on the T-bar panel and, when in Vectors mode, on the Trackball panel.

— **Mode (ShiftDownHighlight)**: Used to toggle the Highlight mode from gray to high contrast.

— **Timeline**: Select the Timeline key when you want to compare the current to the Timeline image.

— **Offline**: Select the Offline key when you want to compare the current to the Offline image.

— **Reference On/Off**: This toggle key will turn the reference view on or off. When on, you can see the current clip in comparison to a reference.

**Search Dial panel**

The Search Dial panel, typically located on the right for a right-handed colorist, has an LCD display with four variable controls and nine soft keys. The lower section of the panel houses the Jog/Shuttle knob and six groups of hard keys. Each group and their keys are described below.

**Reference Configuration Group**

Located at the top left-hand side of the Search Dial panel are the Deck and Still selection keys. These are all related to controlling the tape deck and to grabbing and selecting stills. There is also an Undo and Redo key, a Shift Up and a Save key.

— **Split (Shift Up In)**: DaVinci Resolve associates grading information based on source timecode so it’s important to have each source clip identified as a different clip from the others. The Split key will split one clip into two on the frame selected. Each can therefore have its own grade. This is a quick, accurate, and easy way to split a long image sequence into multiple clips.

— **In**: When marking an In point you can use the UI, a keyboard shortcut, or this key.
— **Join (Shift Up Out):** Join is the reverse of the Split key. If you have clips with contiguous timecode, place the playhead on the first frame of a clip and select Join to merge the preceding clip.

— **Out:** The Out key is used to select an Out point on the Timeline or deck.

— **Duration:** To define a duration, first select the time using the numerical keypad (the colon separates the hours, minutes, seconds, and frames), and then select Duration.

— **Gang:** This key is not implemented.

— **Undo:** The colorist’s friend. DaVinci Resolve has virtually unlimited undo steps available within the page you are working in.

— **Redo:** If you want to redo a step, use redo. Ideal when used with undo to compare two grades quickly.

— **Source (L):** This key is not implemented.

— **Place (Shift Up A ( R )):** This key is not implemented.

— **A ( R ):** This key is not implemented.

— **F:** This key is not implemented.

— **Place (Shift Up B):** This key is not implemented.

— **B:** This key is not implemented.

— **G:** This key is not implemented.

— **Place (Shift Up C):** This key is not implemented.

— **C:** This key is not implemented.

— **H:** This key is not implemented.

— **D:** This key is not implemented.

— **I:** This key is not implemented.

— **E:** This key is not implemented.

— **J:** This key is not implemented.

— **Shift Up:** Use the Shift Up key as a pre-selector for the keys with an upper option. Select the keys sequentially and do not hold the Shift Up key while selecting the second key.

— **Preroll:** The Preroll key is used in conjunction with the numerical keypad to select a preroll time for tape operations.

— **Cue:** Selecting Cue will force the transport to the preroll position.

— **Previous Still:** If you have a still selected, the Previous Still key selects the one preceding.

— **Next Still:** The next still is selected if this key is used.

— **Play Still:** Using Play Still, DaVinci Resolve will automatically display a wipe on the Viewer between the current scene and the current still. You can use the fader T-bar to move the wipe position and in the Reference Wipe menus change the reference image as required by moving or resizing. Selecting Play Still a second time will toggle this mode off.

— **Save:** The most important key on the panel. Besides using the auto-save feature, you can and should consistently save your project with this key. It only takes a few seconds and can save you hours.

— **Grab Still:** At any time when you are grading, selecting the Grab Still key will automatically grab a full resolution frame from the Timeline and attach the node graph metadata for later display and use.
Transport Control Keys Group

Most colorists will use the Transport Control keys every minute of every grade, so they are located for quick and easy access. While not technically within this key group, the Jog/Shuttle knob is directly above these keys.

— **Jog**: Rotate the Jog control to step forward or backward a few frames at a time.

— **Shuttle**: On the outside of the Jog rotary control is the Shuttle knob. This knob has a detent at the null position and is turned clockwise or counter clockwise to shuttle the Transport/Timeline forward or reverse at the rate selected by the rotation of the Shuttle knob.

— **Loop**: You may wish to repeat a review of a grade of a clip, or a selection of clips on the Timeline; this Loop toggle key selects or deselects the Loop operation.

— **Render**: Once you have finished your grade, the Render key selects the Deliver page used for configuring the render parameters for your project and starting the render.

— **Rec**: (Shift Down Render) This key is not yet implemented.

— **Previous Node**: Within the Node Editor on the Color page you are likely to have a number of nodes. These are numbered based on the order that you added them. DaVinci Resolve node graphs are completely user configurable, so you can add nodes anywhere and in any order you like. Thus, the Previous Node key selects the node one lower in numerical order.

— **Next Node**: Similar to the Previous Node key, this selects the node adjacent to the current node, in this case the next higher numerical position.

— **Highlight**: When in the Qualifier palette making secondary qualifiers, it’s common to select the Highlight key to show a high contrast separation of the qualified color and all other parts of the image. Toggle this key to turn on or off. Highlight is used so often it’s also on the T-bar panel.

— **Mode**: (Shift Down Highlight) Used to toggle the Highlight mode from gray to high contrast.

— **Shift Down**: This is the preselection key for functions indicated on the lower portion of the second keys legend.

— **First Frame**: Selects the first frame of the current clip.

— **Last Frame**: Selects the last frame of the current clip.

— **Step Reverse**: To step the viewer one frame in reverse along the Timeline.

— **Step Reverse Keyframe**: (Shift Down Step Reverse) This key steps backward one keyframe on the Clip/Track Timeline display.

— **Step Forward**: A single frame step forward for each key press.

— **Step Forward Keyframe**: (Shift Down Step Forward) For keyframe steps forward on the Clip/Track Timeline display.

— **Previous Scene**: Selects the first frame of the previous scene.

— **Next Scene**: Selects the first frame of the next scene.

— **Rewind**: Places the Transport, or Timeline, in rewind.

— **Reverse**: Select this key to play the Clip/Timeline in reverse.

— **Stop**: You guessed it. This stops the current transport operation.

— **Forward**: The Forward key will play the Clip/Timeline forward.

— **Fast Forward**: The inverse of the Rewind key; fast forward shuttles along the Timeline/Transport.
Memory Access Keys Group

For fast and direct access to A to Z Memories, or Mems, use this section of the Search Dial panel. This is an extremely powerful feature. With any clip selected on the Timeline, with a single key press, for example "A," the grading parameters stored in memory A, including the node structure, sizing, and so on are automatically applied to the current clip.

- **O (Shift Up A):** Selects memory O.
- **A:** Selects memory A.
- **I (Shift Down A):** Selects Memory I.
- **R (Shift Up B):** Selects memory R.
- **B:** Selects memory B.
- **J (Shift Down B):** Selects Memory J (and so forth).
- **All (Shift Up Base Mem):** This function returns all grades for all nodes on the clip to the default grade/settings and clears dynamic keyframes.
- **Base Mem:** The Base Mem key clears the current node of all its grades and keyframes. Again, with the preset exception noted above.
- **Reset (Shift Down Base Mem Crnt):** This key deletes all nodes in the clip except for the first node and resets the grades to default and clears the keyframes.
- **Preview Mem:** To preview one of the memory grades on any clip, select the clip on the Timeline, select Preview Memory and then the memory. This key is a toggle, so if you do not like the grade on the memory for that clip, select Preview Mem again and the clip’s grade reverts to the original.
- **Original Mem:** Each clip, by default, has a memory of its grade, sizing, and so on. which is saved in reference to the source timecode. If you are grading a clip and move from it to another clip, the grade is saved automatically in a memory for that clip. If you come back to the clip and make a change to the grade, then decide you don’t like the change, select Original Mem to return to the previous grade status you found when selecting the clip.
- **Scroll:** The Scroll key selects a soft menu on the Trackball panel so clips or frames can be scrolled via the rotary control in the soft menu.

Numerical Entry Key Group

On the center right-hand side of the Search Dial panel is the Numerical Entry key group. Here you will find numbers 0 to 9 and associated keys for entering timecode and clip numbers. You will notice the numbers you type are displayed in a scratchpad area at the bottom of the Keyframe palette.

- **Current:** To store a new grade in any memory, first select the Current key and then the memory of your choice.
- **All Color PTZR:** This key is a toggle that selects the parameters that will be copied when updating a grade. Generally, all aspects of the grade are copied, including the pan, tilt, zoom, and rotation sizing transforms, but on occasion you may wish to copy only the grade and not the sizing parameters. In this case, use the All/Color/PTZR to select the mode you need. You can see the Keyframe Timeline toggle between the master or the node selected and the input PTZR parameters.
- **Select Node:** Use this key in conjunction with the numerical keys to select any node on the current node graph. First, select the node number, and then Select Node. The current node changes to the selected node.
- **Backspace:** The Backspace key moves you one item left in the numerical scratch pad display. This permits correction of your numerical entries.
— 0 to 9: You guessed it. These are the numbers!
— >, (Comma): The comma is used just before the frame count if you wish to indicate a drop frame timecode.
— : (Colon): When typing in timecode, the convention is to type the hours followed by a colon, then the minutes, a colon, the seconds, a colon, and finally the frames. DaVinci Resolve does not need to have leading numbers entered where they offer no value and the default value is 0, so to type one hour, three minutes, zero seconds, and sixteen frames, you do not need to type 01:03:00:16. Simply type 1:3::16 and then press Enter. This speeds timecode entry.
— Clear: Clears the scratchpad number.
— - (Minus): Select the Minus key prior to the number to reduce the number.
— + (Plus): Select the Plus key prior to a number to increase the number.
— Take/Enter: Select the Take/Enter key to accept or enter any input.

Keyframing Group
The Keyframe keys are on the bottom right-hand side of the Search Dial panel. The functions are replicated on the T-bar panel. On the bottom right of the Color page is the Keyframe timeline for the current clip in the Timeline. The Keyframe group of keys is used in association with the Keyframe timeline and controls the selection of keyframes for the start and end of dynamic transitions of the grade.

— Start Dynamic: This key is used to select the first point in a transition, a Dynamic keyframe. The transition may be a grade change, a sizing or reposition, or the addition of a matte or any number of 100 variables, all of which are associated with the Node Editor and the Clip or Track Keyframe timeline.
— Ripple Value: If you have a grade or effect, or just an adjustment and you would like to ripple this effect over another effect or a large number of other clips, use Ripple Value.
— Delete: This key deletes the keyframe.
— Lift Mark: If you place a keyframe in the wrong spot, put your cursor on the keyframe and use Lift Mark to remove it.
— Trim: This key is used with the numerical keypad to trim a keyframe position.
— Mark: Like the Start Dynamic key, Mark is a major key. It places a Static keyframe on the Clip timeline.
— Scene (Shift Down Mark): This selection is reserved for future use.

Copying Grades Using the Advanced Control Panel
There are a number of methods of copying grades that are exclusive to the Advanced control panel.

Copy Forward Keys
The simplest way of copying grades using the control panel is to use the comma and colon keys on the keypad of the Search Dial panel to copy grades from one or two clips behind the currently selected clip. This is a great way to copy grades in scenes with a shot-reverse-shot structure, where you’re cutting between two angles of coverage, each of which uses the same grade.

— To copy a grade from one clip back: Press Comma (,).
— To copy a grade from two clips back: Press Colon (:).
Scroll

Scroll mode lets you quickly preview the effects of many different grades applied to clips in the Timeline on the currently selected clip, with the option to either accept or reject the previewed grade to which you’ve “scrolled.” This can be useful for checking to see if any of the previous grades you’ve created in a scene will work for the currently selected clip.

To use Scroll mode:

1. Move the playhead to the clip to which you potentially want to copy a new grade. You can use the PREV SCENE and NEXT SCENE buttons to move quickly.

2. Do one of the following to enter Scroll mode:
   — Press SCROLL on the Search Dial panel.
   — Press MODES, above the fourth trackball on the Center panel, then press the SCROLL MODE soft key.

3. Now, do one of the following to preview different grades from other clips:
   — Press the PREVIOUS SCENE and NEXT SCENE soft keys to move from clip to clip in the Timeline, previewing each grade to the current clip.
   — Turn the SCROLL SCENES knob to scroll smoothly along multiple clips in the Timeline.
   — Turn the SCROLL FRAMES knob to scroll along different frames of any clip, previewing the effects of keyframed grades at different points in time.
   — Press the TOGGLE DECK KEYS soft key to use the transport controls on the Search Dial panel to play through the Timeline, previewing grades as you go.
   — Press a number on the keypad of the Search Dial panel, and then the SCENE NUMBER soft key, to jump to a clip and preview its grade.
   — As you scroll from clip to clip, a red outline indicates the clip with the grade being previewed, and an orange outline indicates the current clip to which you’re previewing each scrolled grade.

4. When you’re finished, do one of the following to either accept or reject a scrolled grade:
   — Press EXIT AS WAS if none of the grades you scrolled through was suitable. This exits Scroll mode and leaves the clip as it was previously.
   — Press EXIT AS IS if you’ve found a grade that works for the current clip. This exits Scroll mode and copies the scrolled grade.

When you press the TOGGLE DECK KEYS soft key in Scroll mode, each of the Transport Control buttons on the Search Dial panel functions as a means of previewing the grades of other clips in the Timeline.

   — **STEP FWD**: Move to the next clip and preview its grade.
   — **STEP REV**: Move to the previous clip and preview its grade.
   — **FWD**: Plays (scrolls) forward at 1 scene per second, previewing each new grade as it appears.
   — **REV**: Play (scrolls) the clips in reverse at 1 scene per second, previewing each new grade as it appears.
   — **FFWD**: Shuttles (scrolls) forward through the Timeline at 4 scenes per second, previewing each new grade as it appears.
   — **RWD**: Shuttles (scrolls) reverse through the Timeline at 4 scenes per second, previewing each new grade as it appears.
Rippling Changes Using the Advanced Control Panel

DaVinci Resolve has a mechanism for rippling specific changes made to one clip to a range of other clips in the Timeline. This is only possible using the controls of the DaVinci Resolve Advanced control panel.

The general idea of the ripple function is that you select a clip, make a change, and then ripple that change to a range of other clips. This rippled change can be applied to the same node in each clip, or the change can be added as an appended node within each rippled clip.

The Ripple mode that’s used when you press the RIPPLE VALUE button can be changed in the Color panel of the User Preferences. There are four options.

— **Exact values changed**: Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if Lift in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain setting of 0.75. Only parameters you adjust are rippled.

— **Percent value changed**: Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Lift level of 1.00 and is changed to 0.90 units, then the Lift setting of each clip you ripple will have a relative reduction of 10% relative to its previous value.

— **Unit value changed**: Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the affected parameter. For example, if the current clip had a Lift of 0.80 and you increased it to 0.90, each rippled scene’s master gain level increases by 0.10.

— **All values are copied**: The current clip’s grade is rippled to the specified clips in its entirety. No comparison is made with the original clip’s parameters, and all memory parameters are rippled.

The following procedure describes in detail how you can use the control panel to ripple a change to a range of other clips. While this procedure may appear complicated, it’s just that there are several options. Once you learn the sequence of commands, this process is actually quite fast.

**To ripple a change using the Ripple Mode soft key commands:**

1. **(Optional)** Press MODES, then press RIPPLE MODES. Four commands appear mapped to the middle soft keys of the Center panel, which can be used later to execute different types of ripple operations.

2. Move the playhead to the clip you want to adjust.

3. Adjust the current clip that you want to ripple to other clips in the Timeline.

4. Define the range of clips you want to ripple to using the number pad on the Search Dial panel. The following combinations will work:
   - An absolute range of clips is defined by entering two clip numbers separated by a comma. For example, if you want to ripple the current change to clips 10 through 15, you’d press “10, 15”
   - To specify every clip from the beginning of the Timeline, use the Minus (–) key. For example, to specify a range of clips from the beginning to clip 20, you’d press “–, 20”
   - To specify every clip to the end of the Timeline, use the Plus (+) key. For example, to specify a range of clips from the clip 50 to the end, you’d press “50, +”
   - To specify every clip in the whole Timeline, press “–, +”

5. **(Optional)** You can control whether the rippled change is applied in an appended node, or an existing node, in every rippled clip:
If you want to apply the rippled change as a new node that’s appended to the end of every rippled clip’s grade, press SHIFT DOWN.

Otherwise, the rippled change will be applied to the same node in every rippled clip that you made your adjustment to in the current clip. In other words, if you made a change to Node 2, it would be ripped to Node 2 of all the clips you specified. If one of the rippled clips doesn’t have the same number of nodes, you may get an error.

6 To execute the ripple, do one of the following:
Press RIPPLE VALUE on the Search Dial panel to ripple a change using the currently selected Ripple Mode in the Color panel of the User Preferences.

Press one of the Center panel soft keys corresponding to the ripple function you want to perform. There are four soft keys:

— **Static Ripple:** Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if Lift in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain setting of 0.75. Only parameters you adjust are rippled. Identical to the “Exact values changed” ripple setting.

— **Relative Ripple:** Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Lift level of 1.00 and is changed to 0.90 units, then the Lift setting of each clip you ripple will have a relative reduction of 10% relative to its previous value. Identical to the “Percent value changed” ripple setting.

— **Absolute Ripple:** Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the affected parameter. For example, if the current clip had a Lift of 0.80 and you increased it to 0.90, each rippled scene’s master gain level increases by 0.10. Identical to the “Unit value changed” ripple setting.

— **Forced Ripple:** The current clip’s grade is rippled to the specified clips in its entirety, overwriting all previous nodes and parameters in the rippled clips.

The adjustment you made in step 4 is applied to the designated range of clips.

Admittedly, that was a long and detailed procedure, but the actual button sequences are straightforward once you put them together. Here are some examples of button sequences that ripple an adjustment you’ve just made in different ways:

— “10, 15” then SHIFT DOWN then RIPPLE VALUE: Copies the change you’ve made to the current clip, and applies it as a new node that’s appended to the end of clips ten through fifteen.

— MODES then RIPPLE MODES then “34, 45” then FORCED RIPPLE: Copies the entire grade of the current clip, using it to overwrite the grade of clips 34 through 45.

— MODES then RIPPLE MODES then “–, +” then SHIFT DOWN then RELATIVE RIPPLE: Copies the change you’ve made to the current clip as a relative percentage, and applies it as a new node appended to the end of every single clip in the entire Timeline.

**WARNING**

Once you ripple a change in this manner, there is no going back. Since undo is a per-clip operation, there is no global undo for changes made to the entire Timeline. Proceed with caution.
Using the DaVinci Resolve Advanced Control Panel (2020 Layout)

In late 2020, an updated and radically re-imagined key layout was introduced for the DaVinci Resolve Advanced Control Panel. This updated layout accounts for new features and controls, updates command terminology, eliminates redundancy, and takes fuller advantage of every key on every panel. The result is to provide maximum functionality, so you can work faster and more efficiently.

1. **T-bar panel**
   - Located at the left, this smaller panel has a greater concentration of fixed keys and a T-bar Mix/Wipe control that can be used for a variety of different functions on the bottom portion, and a smaller set of soft keys and rotary knobs on the top angled portion.

2. **Trackball panel**
   - This central panel is where the majority of controls for the colorist are found. In addition to the trackballs, fixed keys, and fixed rotary knobs on the bottom portion, there are soft keys and rotary knobs on the top angled portion. The Trackball panel also includes a slide-out keyboard underneath.

3. **Search Dial panel**
   - Shown at the right, the bottom portion of this smaller panel also has a greater concentration of fixed keys, a Jog/ Shuttle control with fixed Timeline Transport buttons underneath, and a fixed button numeric keypad that can be used for node and shot navigation, timecode entry, and which can also be used for whole, half, and quarter Printer Points adjustments when the P/Lite mode is activated. The top angled portion has a smaller set of soft keys and rotary knobs.

All three panels have LCD panels that display menus for the soft knobs and buttons.

**Three Panels Working Together**

The Advanced control panel set consists of three modular panels that work together to provide full functionality. The biggest panel with the trackballs is meant to sit in the center, while the two smaller panels are interchangeable depending on operator preference. These three panels are:

- **Trackball panel**: This central panel is where the majority of controls for the colorist are found. In addition to the trackballs, fixed keys, and fixed rotary knobs on the bottom portion, there are soft keys and rotary knobs on the top angled portion. The Trackball panel also includes a slide-out keyboard underneath.

- **T-bar panel**: Shown at the left, this smaller panel has a greater concentration of fixed keys and a T-bar Mix/Wipe control that can be used for a variety of different functions on the bottom portion, and a smaller set of soft keys and rotary knobs on the top angled portion.

- **Search Dial panel**: Shown at the right, the bottom portion of this smaller panel also has a greater concentration of fixed keys, a Jog/ Shuttle control with fixed Timeline Transport buttons underneath, and a fixed button numeric keypad that can be used for node and shot navigation, timecode entry, and which can also be used for whole, half, and quarter Printer Points adjustments when the P/Lite mode is activated. The top angled portion has a smaller set of soft keys and rotary knobs.
The smaller two panels connect to the Center panel via an integrated USB hub, and the Center panel connects to your workstation via USB 2.

On all three panels, the fixed keys and specialized mechanical/optical controls are located on the bottom flat area. The operator-facing top area has all of the dynamically assigned soft keys and rotary controls, located atop an LCD panel which provides dynamic labeling and visual references for each soft control, all angled to be visible to the operator without parallax errors. These soft control displays also provide real-time feedback where you can see the relative settings of each variable control knob at a glance.

Using Fixed Keys and Shift Up/Shift Down Functions

As the name implies, fixed keys offer unchanging functionality for frequently used functions. They’re arranged in clusters of like-minded functionality in an effort to make it easy to access a variety of related controls in one place that’s easier to remember. For example, all the keyframing controls are clustered together at the bottom-right of the Search Dial panel, next to the fixed transport controls which are clustered together at the bottom-left of the Search Dial panel (under the Jog/Shuttle wheel).

However, just because they’re fixed doesn’t mean they’re limited. Many, if not most, of the fixed keys offer one or two alternate functions, appearing above and below the primary function.
Each fixed key can list as many as three different functions; the main function appears at the center, the SHIFT-UP function appears at the top of the key, and the SHIFT-DOWN function appears at the bottom of the key.

The primary function of each fixed key, which is what happens when you simply press it, is displayed at the center in slightly larger text. Every key has at minimum one primary function. In the key shown above, ADD GROUP is the primary function that will be executed when you press the key once, so selecting a number of clips in the Thumbnail Timeline and then pressing this key would create a new group containing all selected clips.

For keys that have them, the alternate commands of fixed keys are accessed using SHIFT UP and SHIFT DOWN keys, a pair of which are located on each of the three panels.
Shift keys shown under the left-most trackball let you access secondary functions; the T-Bar and Jog/Shuttle panels each have shift keys.

Pressing SHIFT UP gives you access to whichever alternate fixed key commands are displayed at the top. To help you see which keys have SHIFT UP functionality, pressing SHIFT UP illuminates all keys having an alternate function with a different color. In the key shown previously, pressing SHIFT UP will illuminate this key with another color to let you know it’s ready to use, and then pressing this key executes the JOIN function, adding the currently selected clip in the Thumbnail Timeline to the current group.

Pressing SHIFT DOWN works similarly, to illuminate and give access to alternate fixed key commands displayed at the bottom of buttons that have them. In the key shown previously, pressing SHIFT DOWN and then this key would execute the REMOVE function, removing the currently selected clip in the Thumbnail timeline from whichever group it belonged to.
(Top) The default lit keys of the Search Dial panel. (Bottom) Pressing SHIFT DOWN highlights all keys with alternate SHIFT DOWN functions so you can instantly see which keys are selectable.
In many cases, including the previous examples, the multiple functions assigned to a particular fixed key are related to one another to make them easier to remember. The primary function of each key is usually the most common function you’d want to perform, while the alternate functions are related to it.

In other cases, alternate functions aren’t directly related to the primary function, but they’re in the same general category of activity. This is true of the “Pages and Layout” group of buttons at the top-left of the T-bar panel, for which the primary function of each button gives access to the main pages of DaVinci Resolve you might want to switch among (this is particularly useful if you’re hiding the bottom button bar of the user interface in order to get more screen real estate while working), while the SHIFT UP and SHIFT DOWN functions let you access specific GUI panels or page customization options that are related to those pages.

Soft Menus, Including Soft Keys and Soft Rotary Controls

Each of the three panels have soft controls. These controls appear on top of an LCD display that provides a top-most two-line title/description of each soft menu’s main function, along with two lines of text above each soft rotary control or soft key that describes that control’s specific function.

The soft controls on the center Trackball panel typically update to show context-specific controls for whichever mode and palette is currently selected. The buttons and rotary controls are designed to offer simultaneous control over multiple related functions in each palette. They also provide a logical way to navigate among multiple sets of controls in palettes that have many modes or in modes that have more controls than can be represented on the Center panel’s 24 rotary and 12 key controls.

(Top) The Trackball panel’s soft menu controls corresponding to the Primaries palette, (Bottom) the soft menu controls corresponding to the Motion Effects palette; note how all the controls update to be contextual to the palette that’s currently in use.
The T-bar and Search Dial panels each have soft controls consisting of four rotary and eight key controls, plus one additional unlabeled “More” key at the bottom right of the LCD. Ordinarily, the More key toggles between the default layout for that panel and additional sets of controls that there isn’t room for.

One of the nicest aspects of the soft controls is that the T-bar and Search Dial panels provide simultaneous access to the controls of other palettes than the currently selected palette displayed in the Trackball panel. For example, the T-bar panel’s default soft menu is the Sizing palette, while the default soft menu for the Search Dial panel is the Curves palette. These defaults let you make adjustments to image sizing or contrast curves at any time, regardless of what’s currently displayed on the Trackball panel’s soft controls, giving you access to multiple palettes’ worth of controls at once for the ultimate in efficiency.

### Changing Which Palettes Appear in the Side Panel Soft Controls

However, there’s another benefit to the soft controls on these side panels; you can choose which Color page palette’s controls appear on each side panel, directly from the control surface.

**To change a side panel’s soft controls to another palette:**

1. Press SHIFT UP on any panel.
2. Press the MORE key on the T-Bar panel or the Search Dial panel.
   
   Once you do so, the fixed keys corresponding to palettes that can be displayed on the side panels are highlighted on the Trackball and T-bar panels. This shows you which palettes can be assigned.
3. Press the key corresponding to the palette you want to assign. For example, if you want to expose the controls of the Qualifier palette, press the QUALIFIER button.

The selected side panel soft menu updates to show the controls of the palette that you assigned. If there are more controls on that palette than can be displayed at once (which is likely), press the MORE key to cycle among all of the available controls in that palette.

For example, if you want to assign the Motion palette’s controls to the T-bar panel because you’re adding a lot of noise reduction to the clips of the program you’re working on, simply press SHIFT UP, then the T-bar panel’s MORE key, then the MOTION key on the Trackball panel. Now the Motion palette’s controls appear on the soft menu of the T-bar panel, and you can use the MORE button to cycle among each page of available controls. If you want to go back the the default arrangement, the two default assignments are the Sizing palette on the T-bar panel, and the Curves palette on the Search Dial panel.
Why Aren’t the Soft Panels Specifically Documented

Because of their dynamically remappable nature, the soft controls will continue to evolve over subsequent versions of DaVinci Resolve along with the palettes and functions they control. For this reason, soft control assignments are not presented in-depth as the fixed keys are. Instead, you’re best off referring to the Color page documentation in the Color Page section of the DaVinci Resolve User Manual to figure out what each identically named control is used for. All you need to know for now is that the soft controls change depending on which palette is selected, the mode of each palette, and the operation being performed.

The Trackball Panel

The focus of the Center panel is four trackballs that work as color balance controls in various palettes of the DaVinci Resolve Color page. Their functionality depends on which palette is currently open. Each trackball has a surrounding control ring that has no end stop in either direction, letting you do continuous rotary adjustment. The rings typically are for adjusting image lightness and contrast in different ways but are sometimes used for other functions, depending on which Color page palette you have selected.

Additional buttons above and below the trackballs, and fixed-function rotary controls to the left and right, complete the center control cluster that provide a predictable set of central controls for making color and contrast adjustments.
Using Trackballs

The principal palettes you’ll use the trackballs with are the Color Wheels and Log Wheels modes of the Primaries palette, and the Global and Zones controls of the HDR palette. Whichever of these modes and palettes is selected will determine the functionality of the trackballs and rings.

However, keep in mind that whichever color controls the trackballs are assigned to, the topmost soft controls on the Trackball palette can be switched to work with other palettes, such as the Motion, Curves, or Qualifier palettes, for example. This means you can adjust the controls of a second palette while simultaneously making color and contrast adjustments with the trackballs and ring controls. This is exceptionally useful when making two kinds of adjustments that interact with one another.

Summarizing the Top Fixed Keys

Each of the four trackball/ring controls has three fixed keys above it. Individually, these keys provide separate Y and RGB reset controls for each trackball/ring pair. However, the first nine of these keys also collectively serve as a fast and convenient way of navigating the principal panels of grading functionality in the Color page.

Additionally, the left-most trackball has a pair of shift keys underneath it for choosing which button function to trigger, giving you fast access.
**Trackball and Ring Reset Controls**

Each trackball’s reset controls are protected by having to press SHIFT UP to use them. This may feel like an extra step at first, but now that this top row of keys is also used to quickly switch among different palettes on the Color page, using SHIFT UP protects you from accidentally pressing a reset when you meant to switch to another palette. If you’re used to the prior layout, this will take a bit if getting used to, but it isn’t so bad once you’ve built up the muscle memory.

**Reset controls above each trackball when pressing SHIFT UP:**
- **RGB:** Resets red, green, and blue channel adjustments while leaving master level (luminance or Y) adjustments alone.
- **All:** Resets both RGB channel and master level adjustments.
- **Level:** Resets master level adjustments while maintaining the differential between the RGB channels (aka color balance).

**Navigation controls above each trackball (primary and SHIFT DOWN functions)**

One of the biggest departures from the previous layout is the introduction of palette switching functions on the top row of fixed keys. This makes it faster to switch among different sets of controls as you work, and frees up additional buttons on the T-bar panel to do other things, adding to the utility of the DaVinci Resolve Advanced panel.

</tr>
</tbody>
</table>
The Tools Button

A TOOLS button at the bottom center of the left-most trackball provides fast access to a soft menu that provides additional options using the soft controls. This is a future-proofing feature and exposes no additional functionality at the time of this writing.

The Fourth Trackball

Depending on which palette you’re using in the Color page, the rightmost (fourth) trackball can be used for color adjustment in conjunction with the first three when acting as an Offset control in the Color Wheels and Log Wheel mode of the Primaries palette, or it can be toggled between Global controls or being the fourth Zone color control in the HDR palette.

However, the fourth trackball can also be set to perform many other functions using the three keys above and three keys below it. By choosing the appropriate palette and mode, it can be used as an eyedropper when sampling colors for qualification, it can be used to create, select, and adjust the control points of adjustment curves, or it can be used to adjust the position and rotation of Power Windows. All of these functions are described in the following table.
The fourth trackball gives access to additional functionality via the fixed keys above and below it.

</tr>
<tr>
<td><strong>AFTER/ENABLE/BYPASS</strong></td>
<td><img src="image" alt="Diagram" /></td>
<td>(AFTER) Disables/re-enables all nodes after the currently selected node</td>
<td>(BYPASS) Toggles Bypass Grade on and off</td>
</tr>
</tbody>
</table>

### Hard-Coded Rotary Knobs

There are an additional six rotary knob controls to either side of the trackballs, arranged three to the left and three to the right.

— On the left side, from top to bottom, the rotaries control Y-only luminance Gain, Gamma, and Lift settings of the Color Wheels and Color Bars modes of the Primaries palette that control lift, gamma, and gain. If you have any other palettes or modes open, using these three knobs will continue to affect the Lift, Gamma, and Gain controls of the currently selected node.
— On the right side, from top to bottom, the rotaries control Saturation, Hue, and Luminance mix. If you have any other palettes or modes open, using these two knobs will continue to affect the Saturation and Luminance Mix controls of the Color Wheels and Color Bars modes of the Primaries palette. The Hue knob will affect the hue of either the Primaries Palette mode or HDR palette, whichever was selected last.

Two sets of three rotary controls to the left and right of the trackballs provide additional functionality.

**Keyboard**

The Center panel also offers a slide-out keyboard for naming files, stills, and nodes, triggering keyboard shortcuts, and writing novels about the innocence of newly hired colorists lost in the maelstrom of the film, television, and streaming industries.

**The T-bar Panel**

The T-bar panel, typically located on the left for a right-handed colorist, has an LCD display with four variable controls and nine soft keys. The lower section of the panel houses the T-bar control and six groups of hard keys. Each group and their keys are described below.
Pages and Layout Group

The Pages and Layout control group at left provides navigation to a number of the GUI pages and a few commonly used methods of opening and closing different panels to customize the Color page UI.

The Pages and Layout keys make it easy to open different pages and panels of the graphical interface.

</table>
Node Control Group

This group of keys, at the bottom center of the T-bar panel, lets you quickly create the many different kinds of nodes that are available with which to organize your grades in the Node Editor of the Color page.

The DaVinci Resolve Color page is a node-based grading system, where the adjustments you make appear as nodes in the Node Editor. Each node contains one or more adjustments that work together. This is similar to the layers that appear in other applications, however nodes provide the flexibility to route image data nonlinearly within a grade, connecting the output of one node to the input of any other node farther down the tree of nodes, branching image processing operations or recombining them via parallel or serial layer nodes to combine Color page functions in creative ways to create sophisticated operations.

<tbody>
<tr>
<td>SWAP/&gt;SHARED/KEY MIXER</td>
<td>(SWAP)</td>
<td>Does “Morph into Layer Mixer Node” or “Morph into Parallel Mixer Node”</td>
<td>(KEY MIXER) Adds a Key Mixer node with its first KEY input attached to the currently selected node’s KEY output; Key Mixer nodes let you combine multiple keys.</td>
</tr>
<tr>
<td>–/NODE+POLYGON/+POLY</td>
<td>–</td>
<td>(NODE+POLYGON) Adds a Corrector node in serial with a polygon window automatically enabled for fast isolation; you can begin drawing a polygon immediately in the Viewer.</td>
<td>(+POLY) Turns on the polygon window for the currently selected node.</td>
</tr>
<tr>
<td>PRECLIP/CLIP/TL/POSTCLIP</td>
<td>(PRECLIP)</td>
<td>Opens the Pre-Clip group grade mode of the Node Editor; only works when a clip is part of a group</td>
<td>(POSTCLIP) Opens the Post-Clip group grade mode of the Node Editor; only works when a clip is part of a group</td>
</tr>
<tr>
<td>NODE+CIRCLE/+CIRCLE</td>
<td>–</td>
<td>(NODE+CIRCLE) Adds a Corrector node in serial with a circular window automatically enabled for fast isolation</td>
<td>(+CIRCLE) Turns on the circular window for the currently selected node</td>
</tr>
<tr>
<td>NODE+LINEAR/+LINEAR</td>
<td>–</td>
<td>(NODE+LINEAR) Adds a Corrector node in serial with a linear window automatically enabled for fast isolation</td>
<td>(+LINEAR) Turns on the linear window for the currently selected node</td>
</tr>
<tr>
<td>NODE+CURVE/+CURVE</td>
<td>–</td>
<td>(NODE+CURVE) Adds a Corrector node in serial with a circular window automatically enabled for fast isolation. You can begin drawing a custom curve shape immediately in the Viewer.</td>
<td>(+CURVE) Turns on the curve window for the currently selected node</td>
</tr>
<tr>
<td>NODE+GRADIENT/+GRAD</td>
<td>–</td>
<td>(NODE+GRADIENT) Adds a Corrector node in serial with a gradient window automatically enabled for fast isolation</td>
<td>(+GRAD) Turns on the gradient window for the currently selected node</td>
</tr>
<tr>
<td>–/APPEND CIRCLE/LABEL</td>
<td>–</td>
<td>(APPEND CIRCLE) Appends a Corrector node in serial with a circular window enabled at the end of your node tree</td>
<td>(LABEL) Lets you type a label above the selected node to identify what it does</td>
</tr>
<tr>
<td>+SPLIT/APPEND LINEAR/–</td>
<td>(+SPLIT)</td>
<td>Adds a Splitter node to your node tree, which splits the red, green, and blue image channels into separate outputs for separate processing</td>
<td>(APPEND LINEAR) Appends a Corrector node in serial with a linear window enabled at the end of your node tree</td>
</tr>
<tr>

<td>Primary Function</td>
<td>Shift Down</td>
</tr>
<tr>
<td>-----</td>
<td>----------</td>
<td>------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>+COMB/APPEND CURVE/POLY</td>
<td>(+COMB)</td>
<td>Adds a Combiner node to your node tree, which combines red, green, and blue image channels that have been split back into a single image</td>
<td>(APPEND CURVE) Adds a Corrector node in serial with a Custom Curve window enabled at the end of your node tree. You can begin drawing a custom curve shape immediately in the Viewer.</td>
</tr>
<tr>
<td>APPEND GRADIENT</td>
<td>–</td>
<td>(APPEND GRADIENT) Adds a Corrector node in serial with a gradient window enabled at the end of your node tree</td>
<td>–</td>
</tr>
<tr>
<td>ADD SERIAL/+BEFORE</td>
<td>–</td>
<td>(ADD SERIAL) The most common way of adding Corrector nodes is in serial, where each new node’s input is connected to the previous node’s output, one after another. Adjustments in preceding nodes will be the starting point for subsequent nodes, so they all work together to combine different sets of adjustments in serial order, similar to layers in a layer-oriented system.</td>
<td>(+BEFORE) Adds a corrector node in serial prior to (before) the currently selected node</td>
</tr>
<tr>
<td>ADD PARALLEL/+FIRST</td>
<td>–</td>
<td>(ADD PARALLEL) Adds a Corrector node in parallel underneath the currently selected node, with both connected to a multi-input Parallel Mixer node (creating one if necessary) so that all input images are mixed together. Each node in parallel shares the same input image, so you can perform multiple operations to the same image and combine them back together.</td>
<td>(+FIRST) Adds a Corrector node before the currently selected parallel node, so that both nodes sit within the same parallel branch of the node tree, with the new node preceding the original one.</td>
</tr>
<tr>
<td>ADD LAYER</td>
<td>–</td>
<td>(ADD LAYER) Adds a Corrector node as a layer underneath the currently selected node, connected to a multi-input Layer Mixer node (creating one if necessary) so that its output has higher mix priority than any other nodes previously connected to the same Layer Mixer. The Layer Mixer node combines the outputs of multiple nodes such that the image output by lower nodes takes priority over images output by higher nodes. Layer Mixer nodes can also be set to use different composite modes to combine images together in different ways.</td>
<td>–</td>
</tr>
<tr>
<td>APPEND NODE</td>
<td>–</td>
<td>(APPEND NODE) Adds a corrector node serially to the very end of the node graph.</td>
<td>–</td>
</tr>
</tbody>
</table>
The T-Bar Control

The T-bar control is a vertical lever that you can push and pull up and down. Functioning as a fader, it’s mainly used to control the mix or wipe of a reference image against the current clip being evaluated.

Which reference is being compared, and the method of comparison, is controlled by the Viewer and Reference Group of fixed keys immediately below it.

![The T-Bar Control](image)

The T-bar control is a vertical lever that controls Reference Wipes or Split Screen comparisons. The Viewer and Reference keys let you choose how to set up comparison wipes and split-screen effects to help you grade.

### Viewer and Reference Group

This area below the T-bar includes six keys that let you choose among different reference modes for the Viewer, different Viewer modes, and the Highlight mode. When an appropriate mode is active, the fader bar controls the mix or wipe position for that mode.

</tbody>
</table>

**The Search Dial panel**

The Search Dial panel, typically located on the right for a right-handed colorist, has an LCD display with four variable controls and nine soft keys. The lower section of the panel houses the Jog/Shuttle knob and six groups of hard keys. Each group and their keys are described below.

**Memories Group**

The first group of keys is the Memories group. These include the grade reset controls, buttons for storing and recalling memories (by letter), and controls for grabbing and browsing stills, applying grades, and controlling looping for playback.
The letter keys in this group are called “memories” or MEMs, which save stills and grades that you can
quickly apply to another clip to overwrite its previous grade. There are 26 MEMs, labeled with letters
from A to Z. To apply a MEM to another clip, simply press the letter corresponding to the MEM with the
grade you want to apply. To save a grade to a MEM, press CRNT and then the letter of the MEM you want
to save to. More information appears in the table of key functionality below.

The Memories keys let you save and recall memories for quick grade propagation,
grade reset buttons, and other grade management functions.

</tr>
<tr>
<td>P/PONG/LOOP/PLAYHEAD</td>
<td>(P/PONG) Toggles looping mode between ping-pong and loop forward</td>
<td>(LOOP) Toggles playback looping on and off</td>
<td>(PLAYHEAD) Press to add an Active Playhead to the Mini Timeline using the highlighted the A/B/C/D keys above; once added, pressing PLAYHEAD and a letter switches playback control to that playhead</td>
</tr>
</tbody>
</table>
— **Duration:** To define a duration, first select the time using the numerical keypad (the colon separates the hours, minutes, seconds, and frames), and then select Duration.
— **Cue:** Selecting Cue will force the transport to the preroll position.

**Management and Modes Group**

This group of keys gives access to a wide variety of functions that, due to their diversity, are difficult to generalize. They include everything from the all-important Undo and Redo commands, to splitting and rejoining clips, setting and clearing In and Out points to control playback and looping, and commands for reverting to the Original Memory, using Preview Memory, and using Scroll (which is described in more detail later in this chapter).

The Management and Modes Keys

- **SCENE/UNDO/NEXT CLIP**
  - **Shift Up:** (SCENE) Opens the Scene Detect Window
  - **Primary Function:** (UNDO) Triggers one step of undo; DaVinci Resolve supports unlimited steps of undo
  - **Shift Down:** (NEXT CLIP) Not yet implemented at the time of this writing

- **SPLIT/REDO/JOIN**
  - **Shift Up:** (SPLIT) Splits one clip into two at the frame under the playhead, so each split clip can be graded independently
  - **Primary Function:** (REDO) Triggers one step of redo; DaVinci Resolve supports unlimited steps of redo
  - **Shift Down:** (JOIN) The reverse of the Split key; move the playhead to an edit point with contiguous timecode, and press JOIN to merge the clips into one.

</tbody>
</table>

**Jog/Shuttle Control**

The Jog/Shuttle control is actually two controls in one. The Shuttle control is the outer knob, which rocks to the left and right and controls real-time or fast playback. The Jog control is an inner wheel that spins freely and controls the playhead in slow motion, a frame or two at a time.

- **Shuttle:** The Shuttle control is the outer knob, which rocks to the left and right. This knob has a detent at the center position which stops playback. Turning this control counter-clockwise shuttles among a variety of reverse speeds, with reverse playback going faster the farther left you turn. Turning this control clockwise shuttles among a variety of forward speeds, with playback going faster the farther right you turn.

- **Jog:** The Jog control is an inner wheel that spins freely. Rotate the Jog control to step forward or backward a few frames at a time.
The Jog/Shuttle control lets you control playback and playhead position. The Transport Control keys let you control playback, navigate stills in galleries, and navigate nodes in the Node Editor.

**Transport Control Keys Group**

This group of keys is found beneath the Jog/Shuttle control. These keys are all about controlling playback and moving the playhead around your timeline.

**Numeric Entry Group**

On the center right-hand side of the Search Dial panel is the Numerical Entry key group. Here you will find numbers 0 to 9 and associated keys for entering timecode and clip numbers. You will notice the numbers you type are displayed in a scratchpad area at the bottom of the Keyframe palette.

The number keys group provides access to multiple overlapping functions, including Printer Points adjustment when the P/LITE mode is enabled.

**Keyframing Group**

The Keyframe keys are on the bottom right-hand side of the Search Dial panel. The functions are replicated on the T-bar panel. On the bottom right of the Color page is the Keyframe timeline for the current clip in the Timeline. The Keyframe group of keys is used in association with the Keyframe timeline and controls the selection of keyframes for the start and end of dynamic transitions of the grade.

The number keys group provides access to multiple overlapping functions, including Printer Points adjustment when the P/LITE mode is enabled.

Auto Color Using the DaVinci Resolve Advanced Control Panel

To make an automatic correction to a clip, you can simply press SHIFT UP and then AUTO/MODE/SEARCH on the T-bar panel. This will use the advanced algorithms of the DaVinci Neural Engine to automatically analyze the image and adjust color balance and contrast to produce a nice, neutral starting point.

However, if you crave a bit more control over how the automatic color adjustment is made, and you have a DaVinci control panel, you can use the cursor to choose which color values to sample when making an automatic color balancing and contrast adjustment. It’s like a cross between the Auto Color control and the White and Black Point controls found in the GUI. This additional bit of guidance can make the results a lot more predictable.

To use Auto Grade to sample a feature using the DaVinci control panel:

1. Press the CURSOR button on the Trackball panel.
2. Use the fourth trackball to move the cursor to a feature you want to use to define the automatic correction. Whichever color you move the cursor over will be sampled to form the basis of the resulting color and contrast adjustment. Ideally, you should place the cursor over a feature that’s supposed to be neutral, such as a black shadow, gray wall, or white T-shirt. Don’t place the cursor over a feature that actually consists of saturated color, or that happens to be overexposed, as DaVinci Resolve will overcompensate and you’ll get poor results.
3. With the cursor placed over the desired neutral feature, press SHIFT UP and AUTO/MODE/SEARCH on the T-bar panel.

DaVinci Resolve calculates an appropriate correction, which is applied to the selected node.

Legacy Auto Color

The previous methods for doing Auto Color and Shot Match are available from the Color panel of the User Preferences, via two checkboxes named “Use Legacy Auto Color/Shot Match.” With these enabled, DaVinci Resolve looks for the darkest levels in the image to neutralize the RGB color balance in the blacks, and the brightest levels to neutralize the RGB color balance in the highlights. Furthermore, Master Lift and Master Gain are adjusted to maximize image contrast at the outer boundaries of 0 and 100 percent. Using this control with the Primaries Bars mode open makes it easier to see what’s been changed after these automatic adjustments are made.

Adjusting Curves using the DaVinci Resolve Advanced Control Panel

The DaVinci Resolve Advanced Panel can be used to adjust curves in many different ways, keeping your hands on the control panel for fast and efficient adjustment.

Custom Curves Adjustments

The controls that correspond to the Custom curves on the DaVinci control panel are available when you press the CURVES button on the Trackball panel. They’re also the default mapping of the right-hand side Search Dial panel soft menu.
To open the Primary Curve controls of the DaVinci Resolve Advanced control panel:
— Press the CURVES soft key on the Trackball panel.

The rotary knobs on the Center panel update to show the 0% LUM, 20% LUM, 40% LUM, 60% LUM, 80% LUM, and 100% LUM rotary knobs. These controls correspond to the following default control point positions on the Curve controls.

Each rotary curve control on the DaVinci control surface corresponds to one of these six default control point positions by default, all adjustments you make using these controls are ganged across all four YRGB curve controls. However, if you turn Custom curve ganging off by pressing the GANG soft key, then these controls only affect the curve you select using the LUM CURVE, RED CURVE, GREEN CURVE, and BLUE CURVE soft keys.

You also have the option of using the fourth trackball from the left to adjust individual control points on curves to any position you like. This works for all curves in DaVinci Resolve that have control surface mappings.

**Methods of selecting and adjusting curve points using the fourth trackball:**

1. Press SHIFT DOWN and LEVEL/CURSOR/CURVE.
2. Do one of the following to make adjustments:
   — **To select a control point to adjust:** Spin the fourth ring control to the left or right to select the next control point in that direction (it takes about half of a turn to select another control point). Selected control points are highlighted in cyan.
   — **To move a selected control point:** Adjust the fourth trackball to move the control point up, down, left, or right. Selected control points are constrained between whichever control points are to the left and right.

**To adjust the Curve Intensity sliders:**
— Adjust the MASTER INTENSITY, RED INTENSITY, GREEN INTENSITY, or BLUE INTENSITY soft knobs.

**To make YSFX adjustments:**
1. Press the SOFT CLIP soft key.
2. Adjust the LUM YSFX, RED YSFX, GREEN YSFX, or BLUE YSFX soft knobs.
**Soft Clipping Adjustments**

The soft clipping controls can also be manipulated using the DaVinci Resolve Advanced control panel, which provides separate controls for ganged and individual color channels.

**To open the soft clipping control on the DaVinci Resolve Advanced control panel:**

— Press the CURVES key on the Trackball panel, then press the SOFT CLIP soft key.

**To exit the soft clipping controls:**

— Press the MAIN soft key on the Center panel.

**To make a ganged soft clipping adjustment:**

— Adjust the MASTER CLIP or MASTER SOFT soft knobs of the SCENE BLACK CLIPS or SCENE WHITE CLIPS control groups.
— These controls adjust all four corresponding Master-RGB High Soft, High Clip, Low Soft, or Low Clip parameters simultaneously.

**To adjust soft clipping for individual color channels:**

— Adjust the MASTER/RED/GREEN/BLUE CLIP or MASTER/RED/GREEN/BLUE SOFT rotary knobs of the SCENE WHITE CLIPS or SCENE BLACK CLIPS control groups (there are 12 individual knobs).

**HSL Curves Controls**

The HSL curves can also be adjusted using the DaVinci Resolve Advanced Panel.

**To open the soft clipping control on the DaVinci Resolve Advanced Panel:**

1. Press the CURVES key on the Trackball panel.
2. Press the CURVES soft key on the soft menu.
3. Press the soft key that corresponds to the HSL curve you want to adjust, HUE•HUE, HUE•SAT, HUE•LUM, LUM•SAT, SAT•SAT, SAT•LUM.
4. Use the RED, YELLOW, GREEN CYAN, BLUE, and MAGENTA, or the LOW, LOW-MID, MID-HIGH, and HIGH soft knobs to adjust the particular slice of hue or image tonality you want, using the method you’ve selected.

**The Advanced Panel Number Pad Does Many Things**

The number keys serve a wide number of uses. This section describes them all in one place.

**Navigating Clips by Clip Number**

You can move the playhead to the first frame of any clip in the Timeline by typing that clip’s number (listed above the upper left-hand corner of each thumbnail in the Thumbnail Timeline) using the number keys, and then pressing ENTER.

**Navigating Clips by Timecode**

To type timecode instead of a clip number, you need to add colons to signify that you’re entering hours followed by a colon, then the minutes followed by a colon, the seconds with a colon, and finally the frames followed by the ENTER key. As you enter timecode on the Color page, the timecode values you
type appear in the lower right-hand corner of the DaVinci Resolve window, to the left of the Project Manager and Project Settings buttons.

DaVinci Resolve does not need to have leading numbers entered where they offer no value and the default value is 0, so to type one hour, three minutes, zero seconds, and sixteen frames, you do not need to type 01:03:00:16. Simply type 1:3:16 and then press Enter. This speeds timecode entry.

Moving the Playhead Using Relative Frame Numbers
If you type a + or – and a number of frames, the playhead will move forward or backward by that number of frames relative to its prior position.

Selecting Specific Nodes in the Node Editor
You can select specific nodes in the current node tree by typing the node’s number and then pressing SELECT NODE.

Making Printer Points Adjustments
You can use the number keys to make controlled Printer Points adjustments by pressing the P/LITE button (found in the group of keys just above the number keys). The P/LITE button remains highlighted as long as printer points adjustment using the number keys is active. Press P/LITE again to toggle printer points mode off.

The P/LITE button toggles printer points mode on and off in the default “whole point” mode. You can also press SHIFT UP P/LITE 1/2 to work in “half point” mode, or SHIFT DOWN P/LITE 1/4 to work in “quarter point” mode.

In Printer Points mode, you have three sets of controls:
— Plus and minus Red, Green, and Blue to adjust color balance in the additive manner, by raising or lowering specific color channels
— Plus and minus Master to raise or lower RGB equally to adjust luminance
— Plus and minus Cyan, Magenta, and Yellow to adjust color balance in the subtractive manner, by raising or lowering pairs of color channels corresponding to Cyan (Blue and Green), Magenta (Red and Blue), and Yellow (Red and Green)

Viewing Individual Red, Green, and Blue Channels in the Viewer
You can use the number keys to choose individual channels to evaluate in the Viewer, in order to more closely evaluate noise or image quality on a per-channel basis.

First, press SHIFT DOWN, then press the GALLERY/REF INVERT/RGB button on the T-bar panel to trigger the RGB function. Three number keys are then highlighted, 1 (labeled GREEN), 3 (labeled BLUE), AND 5 (labeled RED). Pressing any of these keys sets the Viewer to show only that channel as a grayscale image.

To go back to viewing full-color RGB, press REF INVERT.

Adding Tracking Points in Interactive Mode
The DaVinci Resolve Advanced control panel has a full set of tracking controls. However, there’s also the ability to manually add tracking points one by one while in Interactive Object Tracking mode.
To add a single tracking point:
1. Select a window you want to track.
2. Press SHIFT DOWN and ALL/WINDOW/TRACKER.
3. Press the INTERACTIVE soft key.
4. Using the DaVinci Resolve Advanced control panel, press the CURSOR button above the fourth trackball of the Center panel, and move the onscreen cursor to the detail of the image that you want to add a tracking point to.
5. Click the SET TRACK POINT soft key, within the Interactive mode controls of the Tracker palette. This adds a tracking point corresponding to the feature of the image that you clicked, and you’re ready to start tracking.

Copying Grades Using the Advanced Control Panel

There are a number of procedures for copying grades that have specific implementations on the Advanced control panel.

Copy Forward Keys

The simplest way of copying grades using the control panel is to use the comma and colon keys on the keypad of the Search Dial panel, or the –1 and –2 SHIFT UP functions on the memory keys area of the Search Dial panel, to copy grades from one or two clips behind the currently selected clip. This is a great way to copy grades in scenes with a shot-reverse-shot structure, where you’re cutting between two angles of coverage, each of which uses the same grade.

— To copy a grade from one clip back: Press the Comma (,) or –1 buttons.
— To copy a grade from two clips back: Press Colon (:) or –2 buttons.

Scroll

Scroll mode lets you quickly preview how different grades on a variety of other clips in the Timeline would look on the currently selected clip. As you preview the grade of each other clip, you have the option to either accept or reject the previewed grade to which you’ve “scrolled.” Accepted grades (EXIT AS IS) overwrite the previous grade of the current clip, while rejecting the scrolled grade (EXIT AS WAS) cancels the entire operation.

Scroll mode can be useful for checking to see if any of the previous grades you’ve created in a scene will work for the currently selected clip.

To use the Scroll mode:
1. Move the playhead to the clip to which you potentially want to copy a new grade. You can use the PREV SCENE and NEXT SCENE buttons to move around neighboring clips, or you can use the number keys to jump to a specific clip number or timecode value of the Timeline.
2. Do one of the following to enter Scroll mode:
   — Press SCROLL on the Search Dial panel.
   — Press MODE on the T-bar panel, then press the SCROLL MODE soft key.
   — Once you’re in Scroll mode, the Center panel soft menu displays a row of commands with which to control scrolling through previews of possible grades to copy.
Now, do one of the following to preview different grades from other clips:

— Press the PREVIOUS SCENE and NEXT SCENE soft keys to move from clip to clip in the Timeline, previewing each grade to the current clip.

— Turn the SCROLL SCENES knob to scroll smoothly along multiple clips in the Timeline.

— Turn the SCROLL FRAMES knob to scroll along different frames of any clip, previewing the effects of keyframed grades at different points in time.

— Press the TOGGLE DECK KEYS soft key to use the transport controls on the Search Dial panel to play through the Timeline, previewing grades as you go.

— Enter a number on the keypad of the Search Dial panel, and then the SCENE # soft key, to jump to a clip and preview its grade.

As you scroll from clip to clip, a purple outline indicates the clip with the grade being previewed and an orange outline indicates the current clip to which you’re previewing each scrolled grade.

When you’re finished, do one of the following to either accept or reject the currently previewed grade that you’ve scrolled to:

— Press EXIT AS WAS if none of the grades you scrolled through was suitable. This exits Scroll mode and leaves the clip as it was previously.

— Press EXIT AS IS if you’ve found a grade that works for the current clip. This exits Scroll mode and copies the scrolled grade.

When you press the TOGGLE DECK KEYS soft key in Scroll mode, each of the Transport Control buttons on the Search Dial panel functions as a means of previewing the grades of other clips in the Timeline.

— **NEXT CLIP:** Move to the next clip and preview its grade.

— **PREV CLIP:** Move to the previous clip and preview its grade.

— **FWD:** Plays (scrolls) forward at 1 scene per second, previewing each new grade as it appears.

— **REV:** Play (scrolls) the clips in reverse at 1 scene per second, previewing each new grade as it appears.

— **FFWD:** Shuttles (scrolls) forward through the Timeline at 4 scenes per second, previewing each new grade as it appears.

— **RWD:** Shuttles (scrolls) reverse through the Timeline at 4 scenes per second, previewing each new grade as it appears.

**Rippling Changes Using the Advanced Control Panel**

DaVinci Resolve has a mechanism for rippling specific changes made to one clip to a range of other clips in the Timeline. This is only possible using the controls of the DaVinci Resolve Advanced control panel.

The general idea of the ripple function is that you select a clip, make a change to one or more nodes in its grade, and then ripple that change to a range of other clips. This rippled change can be applied to the same node in each clip, or the change can be applied as an appended node within each rippled clip.

The following procedure describes in detail how you can use the control panel to ripple a change to a range of other clips. While this procedure may appear complicated, it’s just that there are several options. Once you learn the sequence of commands, this process is actually quite fast.
To ripple a change using the Ripple Mode soft key commands:

1. (Optional) On the T-Bar panel, press MODES, then in the soft menu of the Trackball panel press RIPPLE MODES. Four selectable modes appear mapped to the soft keys of the Trackball panel, which can be used later to execute different types of ripple operations. Press the mode you want to use for rippling.

   — **Ripple Static:** (Exact values changed) Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if Lift in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain setting of 0.75. Only parameters you adjust are rippled.

   — **Ripple Relative:** (Percent value changed) Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Lift level of 1.00 and is changed to 0.90 units, then the Lift setting of each clip you ripple will have a relative reduction of 10% relative to its previous value.

   — **Ripple Absolute:** (Unit value changed) Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the affected parameter. For example, if the current clip had a Lift of 0.80 and you increased it to 0.90, each rippled scene’s master gain level increases by 0.10.

   — **Ripple Forced:** (All values are copied) The current clip’s grade is rippled to the specified clips in its entirety. No comparison is made with the original clip’s parameters, and all memory parameters are rippled.

2. Move the playhead to the clip you want to adjust.

3. Adjust the grade of the current clip in the manner you want to ripple to other clips in the Timeline.

4. Now, you must define the range of clips you want to ripple to using the number pad on the Search Dial panel. The following combinations will work:

   — An absolute range of clips is defined by entering two clip numbers separated by a comma. For example, if you want to ripple the current change to clips 10 through 15, you’d press “10, 15”

   — To specify every clip from the beginning of the Timeline, use the Minus (–) key. For example, to specify a range of clips from the beginning to clip 20, you’d press “–, 20”

   — To specify every clip to the end of the Timeline, use the Plus (+) key. For example, to specify a range of clips from the clip 50 to the end, you’d press “50, +”

   — To specify every clip in the whole Timeline, press “–, +”

5. (Optional) You can control whether the rippled change is applied in an appended node, or an existing node, in every rippled clip by pressing the SHIFT DOWN key of any panel. If you don’t press SHIFT DOWN, the rippled change will be applied to the same node in every rippled clip that was adjusted in the current clip. In other words, if you made a change to Node 4, it will be rippled to Node 4 of all clips specified for rippling to. If one of the rippled clips doesn’t have the same number of nodes (in this case if there’s no node 4), you may get an error.

6. To execute the ripple, do one of the following:

   — Press RIPPLE VALUE on the Search Dial panel to ripple a change to the selected node in each clip’s grade, using the currently selected Ripple Mode in the Color panel of the User Preferences.

   — Press SHIFT DOWN and APPEND to ripple to add the change via an appended node at the end of each clip’s grade

   — Press one of the Center panel soft keys corresponding to the ripple function you want to perform.
There are four soft keys:

a. Static Ripple: Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if Lift in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain setting of 0.75. Only parameters you adjust are rippled. Identical to the “Exact values changed”ripple setting.

b. Relative Ripple: Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Lift level of 1.00 and is changed to 0.90 units, then the Lift setting of each clip you ripple will have a relative reduction of 10% relative to its previous value. Identical to the “Percent value changed”ripple setting.

c. Absolute Ripple: Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the affected parameter. For example, if the current clip had a Lift of 0.80 and you increased it to 0.90, each rippled scene’s master gain level increases by 0.10. Identical to the “Unit value changed”ripple setting.

d. Forced Ripple: The current clip’s grade is rippled to the specified clips in its entirety, overwriting all previous nodes and parameters in the rippled clips.

Now, the adjustment you made in step 4 is applied to the designated range of clips.

Admittedly, that was a long and detailed procedure when spelled out in text, but the actual button sequences are straightforward once you put them together. Here are some examples of button sequences that ripple an adjustment you’ve just made in different ways:

— “10, 15” then SHIFT DOWN then RIPPLE VALUE: Copies the change you’ve made to the current clip and applies it as a new node that’s appended to the end of clips ten through fifteen.

— MODES then RIPPLE MODES then “34, 45” then FORCED RIPPLE: Copies the entire grade of the current clip, using it to overwrite the grade of clips 34 through 45.

— MODES then RIPPLE MODES then “–, +” then SHIFT DOWN then RELATIVE RIPPLE: Copies the change you’ve made to the current clip as a relative percentage and applies it as a new node appended to the end of every single clip in the entire Timeline.

**WARNING**

Since undo is a per-clip operation, there is no global undo for changes made to the entire Timeline. This means that once you ripple a change in this manner, there is no going back. Proceed with caution.

Chapter 148

Using Open FX and Resolve FX

This chapter covers the use of Resolve FX and Open FX plug-ins, that allow you to use the built-in filters that come with DaVinci Resolve, as well as third-party filters from a variety of companies, to create complex effects and adjustments that aren’t possible using the ordinary palette tools in the Color page.

Contents

Resolve FX

Resolve FX are the built-in plug-ins that come with DaVinci Resolve. These plug-ins span the gamut from
blurs and complex color adjustments to stylized image treatments and lighting effects to sharpen and
repair operations that are too complex to accomplish using the palette controls of the Color page.

Most Resolve FX plug-ins have been optimized for real-time playback, making it possible to apply
complex effects such as Lens Flares, Light Rays, Film Grain, or Warping, and make adjustments while
getting immediate, high-quality feedback, and enabling you to play each variation of your effect as
you work without the need to wait for rendering or caching to happen first. Of course, if you’re working
with extremely high-resolution or raw source media, if your workstation is particularly old, or if you’re
applying many Resolve FX all at once, your performance may slow, necessitating the use of either the
Smart Cache or User Cache.

Open FX

Open FX (OFX) is an open plug-in standard intended to enable easier development of cross-platform
visual effects plug-ins for a variety of applications. Popular plug-in packages include BorisFX Sapphire
and Continuum Complete, Red Giant Universe, and NewBlue TotalFX, all of which are ubiquitous tools for
feature and broadcast work. The available Open FX plug-in packages are also growing every year as this
format becomes more widely adopted among developers.

With Open FX support, you can use plug-ins to do many stylized operations that would be difficult or
impossible to do using the other tools in DaVinci Resolve. Everything from lens flares, optical blinds and
prism effects, lens warp correction, film and video grain and damage effects, dead-pixel corrections,
and more can be accomplished with the right plug-in collection.
The installation and licensing of Open FX plug-ins is handled by a vendor’s own installer. Once installed, Open FX plug-ins appear within the Library of the Open FX panel, which can be opened by clicking the FX button at the top right of the Color page or Edit page Interface toolbar.

**Where are OFX Installed?**

According to the standard governing how OFX work, all OFX plug-ins on a particular workstation are installed into a standardized location to foster plug-in compatibility with multiple applications. These locations are:

- **On macOS:** /Library/OFX/Plugins
- **On Windows:** C:/Program Files/Common Files/OFX/Plugins
- **On Linux:** /usr/OFX/Plugins

**Open FX Plug-Ins Can Be Processor Intensive**

Because they create such a wide variety of effects, some third-party Open FX plug-ins can be extremely processor intensive, all the more if you add multiple plug-ins to a single grade. If you find your playback performance dropping because of a particularly expensive effects operation, you can use the Smart Cache to automatically cache nodes and clips that have Open FX plug-ins applied to them. Once fully cached, you can play these clips back in real time, at least until you change that clip’s grade again. For more information on caching and on improving performance in DaVinci Resolve overall, see Chapter 8, “Improving Performance, Proxies, and the Render Cache.”

**Browsing the Open FX Library**

All of these built-in plug-ins appear within categories at the top of the Open FX Library.

When you click the FX button, the Open FX panel opens out of the right side of the Node Editor to show the Library, resizing the Viewer, Gallery, and Node Editor to make room. The Open FX Library is organized hierarchically. Each vendor’s plug-ins appear under a header with the name of that plug-in collection, and possibly organized into categories, separated by headers with Open or Close arrows that appear to the right of the category name, which let you show or hide the contents so that you can make the hierarchy as compact or spread out as you like.

**To open and close Open FX categories, do one of the following:**

- Move the pointer over the header you want to open or close, and click the Close or Open arrow to the right of the category name.
- To open or close all headers at once, Option-click the Open or Close arrow.
Since many Open FX plug-in collections are quite large, an optional Search field can be opened at the top of the Library that lets you quickly find plug-ins by name or partial name.

**To search for an Open FX filter by name:**

1. Click the magnifying glass button at the upper right-hand corner of the Open FX panel.
2. Type your search string into the Search field that appears. A few letters should be enough to isolate only those plug-ins that have that character string within their name.

**Open FX Library Favorites**

You can click on the far right of any Resolve FX or OFX filter to flag it with a star as a favorite filter. When you do so, choosing Favorites from the Effects Library option menu filters out all clips that are not favorites, letting you see only effects you most commonly use. To “de-favorite” any effect, click its star to turn it off.
Using Resolve FX and Open FX in the Color Page

This section provides an overview of procedures that describe how you can work with Open FX plug-ins within the Color page.

Methods of working with Open FX:

— **To add an Open FX plug-in to a node:** Drag a plug-in from the Open FX Library onto a node. If you drag a plug-in onto a node that already has a plug-in, the previous plug-in will be overwritten.

— **To remove an Open FX plug-in from a node:** Right-click a node showing the FX badge, and choose Remove OFX Plug-in from the contextual menu.

— **To add an Open FX plug-in as a separate node:** Drag a plug-in from the Open FX Library onto a connection line in the Node Editor. A new node is created and labeled with the name of the Open FX plug-in.

— **To edit the parameters of an Open FX plug-in:** Select any node with an FX badge, and open the Open FX Panel to show the Settings list. You can switch to the Library by clicking the Library button.
— **To sample a color parameter within an Open FX plug-in:** Some OFX plug-ins have a color swatch parameter, which exposes an eyedropper button in the Settings. Clicking the eyedropper turns the pointer into an eyedropper you can use to sample the contents of the Viewer.

— **To use Open FX onscreen controls in the Viewer:** Select any node with an FX badge, and the onscreen controls, if there are any, should appear in the Viewer. If not, make sure the Viewer mode drop-down is set to FX.

**Applying Resolve FX and Open FX Plug-Ins**

Once you’ve found an Open FX plug-in you want to use in the Library, there are two ways of applying it within the Node Editor of the Color page. Which method you use depends on how you want to use that plug-in.

**Adding a Plug-In to a Corrector Node**

If you want to combine an Open FX plug-in with a grade within a single node, simply drag and drop it onto a new corrector node to apply that plug-in’s effect to that node. Nodes with an Open FX plug-in applied have an FX badge in the bottom left-hand corner.

You can only apply one Open FX plug-in to a node at a time, but by using multiple nodes you can add as many Open FX plug-ins to your grade as you need.

When added to a corrector node, Open FX are applied after Motion Blur and Noise Reduction, but before anything else. This means you can use Motion Blur and Noise Reduction to pre-process the image before it’s handed off to the Open FX plug-in. This also means that all other adjustments you make within that node are applied to the Open FX plug-in’s output.

However, the principal advantage of adding plug-ins to corrector nodes is that you can use secondary operations such as a window, a qualifier, or a key to limit that plug-in’s effect, much as you would limit any other kind of adjustment you’d make with a corrector node.
Adding a Plug-In as a Stand-Alone OFX Node

If you want to add an Open FX plug-in to your grade as a stand-alone effect, you can simply drag any plug-in from the Open FX Library onto a connection line of your grade, and an Open FX node will be created.

(Left) A node with an OFX filter applied to it, (Right) A stand-alone Open FX node

The advantage of this is that it’s fast to apply plug-ins in this way, and this can be an easier way for you to add plug-ins that are more complicated, such as those having multiple inputs for creating compositing effects.

For example, the Lens Blur plug-in lets you connect a black and white image that’s been added to the node tree as an external matte to a Lens Blur node’s second RGB input to use to create custom bokeh effects when you set the Shape Type drop-down to External Input.

Resolve FX and Open FX Settings

When you select a node with a Resolve FX or Open FX plug-in applied to it, the Open FX panel switches to the Settings, which show you every single parameter associated with that plug-in, ready for customization.
Adjust any of the standard controls to manipulate that plug-in’s effect on the image.

**Editing Effects Using the Full Screen Viewer**

Because the Open FX panel can often be too short to present the full controls of more complicated filters, it remains visible when you switch to the Full Screen Viewer mode in the Color page. Jump into this mode by choosing Workspace > Viewer Mode > Full Screen Viewer (Shift-F).

This control layout makes it considerably easier to do detailed work while viewing a larger image and having all of your effects visible in a taller panel off to the side.
TIP: You can also open and close the Node Editor while in Full Screen Viewer mode, if you need to switch nodes while doing effects work.

**Resolve FX and Open FX Onscreen Controls**

In the Edit page, Fusion page, and Color page, Resolve FX and Open FX display on-screen controls that you can use to visually edit an effect. In the Edit and Color pages, selecting an Open FX plug-in node or a plug-in in the Inspector that has onscreen controls automatically changes the Viewer’s mode to Open FX Overlay mode, with the available controls ready to use. Different plug-ins expose different custom controls, letting you control the effect or manipulate the image, depending on that plug-in’s function.

Adjusting the onscreen controls exposed by the GenArts Sapphire Glint Rainbow plug-in

If for whatever reason you switch the Viewer to another onscreen control mode (for example, showing the Window or Image Wipe controls), you can always switch back to the Open FX controls by choosing the Open FX Overlay mode from the onscreen control drop-down menu underneath the Viewer.

TIP: You may find that as you work you want to temporarily hide or show the onscreen controls in the Viewer so you can get an uncluttered look at the image you’re adjusting. You can quickly toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).
Keyframing Resolve FX and OFX in the Inspector

Resolve FX and Open FX can be keyframed in the Edit, Fusion, and Color pages. However, they can only be keyframed in the Edit and Color pages using the keyframing controls found in the Inspector (at the time of this writing). Happily, most simple keyframing tasks can be performed using three buttons that appear to the right of any parameter that’s capable of being keyframed. It takes two keyframes at minimum to create an animated effect.

The three keyframe controls that appear in the Inspector, from left to right: Previous keyframe, Create/Delete keyframe, Next keyframe

Methods of keyframing parameters in the Inspector:

— **To add a keyframe:** Select a clip, open the Inspector, then move the Timeline playhead to the frame where you want to place a keyframe, and click the Keyframe button next to the parameter of the Inspector you want to animate. Once you’ve added at least one keyframe to a parameter, all other adjustments you make to parameters in the Inspector, or using the onscreen Transform/Crop controls in the Timeline Viewer, add new keyframes automatically if the playhead is at another frame.

— **To move the playhead to the next or previous keyframe:** Click the small left- or right-hand arrow to either side of a parameter’s keyframe control, or press Right-Bracket (]) or Left-Bracket ([), to jump the playhead to the next or previous keyframe.

— **To edit an existing keyframe of a parameter:** Move the playhead to be on top of the keyframe you want to edit, and then change that parameter, either in the Inspector, or using the onscreen controls of the Timeline Viewer.

— **Methods of changing keyframe interpolation in the Inspector:**

  - **To change a keyframe to Static:** (Color page only) Static keyframes create abrupt one-frame changes at the keyframe to which they’re applied, which is good for creating sudden effects. Move the playhead to a frame with a keyframe using the next/previous keyframe controls, then right-click the orange keyframe button and choose “Change to Static Keyframe.” The keyframe control changes to a round button to show that keyframe is now Static.

  - **To change a keyframe to Dynamic:** Move the playhead to a frame with a keyframe using the next/previous keyframe controls, then right-click the orange keyframe button and choose “Change to Dynamic Keyframe.” The keyframe control changes to a diamond button to show that keyframe is now Dynamic.
Methods of deleting keyframes and disabling keyframed effects:

— **To delete a single keyframe:** Open the Inspector, move the Timeline playhead to a frame with a keyframe, and click the orange Keyframe button in the Inspector to delete it.

— **To delete all keyframes for one parameter:** Click the reset button to the right of a parameter’s keyframe control in the Inspector.

— **To delete all keyframes in a group of parameters in the Inspector:** Click the reset button to the right of a parameter group’s title bar in the Inspector.

— **To disable or enable a single parameter’s keyframed effect:** In the Timeline, click the toggle control at the left of a parameter’s keyframe track. A white dot means it’s enabled, while no dot means it’s grayed-out and disabled.

— **To disable or enable a group of parameters in the Inspector:** Click the toggle control at the left of a parameter group’s title bar in the Inspector. Orange means that group is enabled. Gray is disabled.

### Motion Tracking Resolve FX and Compatible OFX Plug-Ins

When using Resolve FX in the Color page, Resolve FX that have position parameters, including Dent, Lens Flare, Light Rays (when “From a Location” is selected), Mirrors, Radial Blur, Ripples, Vortex, and Zoom Blur can all be motion tracked to follow the position of a moving subject in the frame using the point-based tracking in the FX mode of the Tracker palette.

**To match move Resolve FX to a feature using the FX tracker:**

1. Create a new node, and drag the Resolve FX filter you want to apply onto that node to apply the effect. In this example, we’re adding a Lens Flare effect, that has the position parameters necessary to be match moved to follow the motion of the shot, and we’re choosing the MIR-I 2.8/37 preset, which looks like a sun.

![Applying a Lens Flare to the shot](image)

2. If necessary, use the onscreen controls in the Viewer or the X Position and Y Position sliders to move the Resolve FX effect to where you want it.
3. Next, open the Tracker Palette and choose FX from the mode drop-down.

4. Click the Add Tracker Point button, at the bottom left-hand side of the Tracker palette, to add tracker crosshairs to the center of the Viewer.

5. Drag the crosshairs to a high-contrast detail (such as a small object or corner), and click the Track Forward button. In this example, there’s a rock out at sea that will make a good plane of motion for tracking a far-away sun. There is no inner or outer box to position or resize while you do this; you just need to drag the crosshairs to center on the feature you want to track.
6 Now, click the Track Forward button, and DaVinci Resolve will track the feature. The Resolve FX applied to that node will simultaneously move to follow the track, and when the tracking is done, you’re finished.

A successful track

7 After you’ve finished tracking, you can freely reposition the Resolve FX to offset it from the track.

For more information about single-point tracking, see the “Point Tracker Workflows” section of Chapter 136, “Motion Tracking Windows.”
Chapter 149

Sizing and Image Stabilization

DaVinci Resolve has a powerful toolset for making geometric transforms, using advanced algorithms for optical-quality sizing operations. This section covers the nuts and bolts of resolution independence in DaVinci Resolve, and how to use the Sizing palette. This chapter also covers how to use the Stabilizer mode of the Tracker palette to subdue unwanted camera wiggle.

The Five Color Page Sizing Modes

The Sizing Palette on the Color page can be put into one of five modes, each of which accomplishes a different task.

— **Edit Sizing**: These controls mirror those found in the Inspector of the Edit page.

— **Input Sizing**: These controls let you make sizing adjustments to individual clips that affect their overall geometry (pan, tilt, zoom, and rotation). These controls are useful for doing clip-by-clip pan and scan adjustments.

— **Output Sizing**: These controls are nearly identical, except that they affect every clip in the entire timeline, all at once. Output sizing is useful for making a formatting adjustment to an entire timeline, such as changing an HD timeline to an SD timeline with simple adjustments to crop and pan the resulting framing.

— **Node Sizing**: Lets you add targeted sizing adjustments at any point within the node tree. Like Input Sizing, Node Sizing is specific to a particular clip. Unlike Input Sizing, Node Sizing is affected by operations that split color channels (such as the splitter/combiner nodes) and limit the image (such as qualifiers and windows). You can also add as many node sizing adjustments to a clip’s grade as you need.

— **Reference Sizing**: A set of sizing controls that lets you reposition the still when a wipe comparison is being made. Using these controls, you can move the still image to better compare it to the clip you’re wiping it against. The Reference Sizing controls only work when you have a wipe enabled.

Sizing Order of Processing on the Color Page

Input Sizing adjustments are applied before all image processing that takes place in the node graph, including Node Sizing, while Output Sizing adjustments are applied after image processing in the node graph.

Sizing Controls

Input, Node, and Output Sizing share many of the same controls. When the Sizing palette is set to Input Sizing mode, the controls transform each clip individually. If you’re simply pushing in on one or two clips, or making individual pan and scan adjustments to account for a change in format, these are the controls you want to use.

![The Sizing palette](image-url)
— **Pan**: Moves the clip along the horizontal, X axis. Positive values move the clip right, negative values move the clip left.

— **Tilt**: Moves the clip along the vertical, Y axis. Positive values move the clip up, negative values move the clip down.

— **Zoom**: Adjusts the overall dimensions of the clip. The range is from 0.250 (1/4x size) to 4.000 (4x size). Normal size is 1.000.

— **Rotate**: Positive values rotate the clip clockwise. Negative values rotate the clip counter-clockwise.

— **Width**: Stretches the image wider or narrower. The range is from 0.250 (1/4x width) to 4.000 (4x width). Normal width is 1.000.

— **Height**: Stretches the image taller or shorter. The range is from 0.250 (1/4x height) to 4.000 (4x height). Normal height is 1.000.

— **Pitch**: Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values stretch the image more extremely.

— **Yaw**: Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and push the right of the image forward. Higher values stretch the image more extremely.

— **Key Lock**: (Node Sizing only) Lets you choose how regions of the image that are isolated by one or more windows will be transformed. There are two options:
  — **Off**: While off, the transform controls will move the windowed region to another area of the frame, effectively duplicating the windowed area.
  — **On**: While on, the transform controls will move other areas of the frame into the windowed regions, effectively covering up the windowed area with another portion of the picture.

— **Flip Image**: Two buttons let you flip the image in different dimensions.
  — **Flip Horizontal control**: Reverses the image along the X axis, left to right.
  — **Flip Vertical control**: Reverses the clip along the Y axis, turning it upside down.

— **Lens Correction**: (Edit Sizing only) Two controls let you correct for lens distortion in the image, or add lens distortion of your own (only available in the Studio version).
  — **Analyze**: Automatically analyzes the frame in the Timeline at the position of the playhead for edges that are being distorted by wide angle lens. Clicking the Analyze button modifies the effect of the Distortion slider so that it gives a more accurate result, but it doesn’t perform a correction.
  — **Distortion**: Dragging this slider to the right applies a warp to the image that lets you straighten the bent areas of the picture that can be caused by wide angle lenses. It’s not necessary to click the Analyze button prior to using this slider, but using the Analyze button can improve the accuracy of the result.
Blanking Controls

Output Sizing mode also has a set of Blanking controls that you can use to add custom blanking to a clip or project. For example, you can use these controls to add nonstandard letterboxing or pillarboxing to an image. Along with all other Output Sizing adjustments, blanking is added last in the image processing pipeline, so it’s not affected by any of the color or contrast adjustments you make.

— **Top**: Adjusts the top letterbox.
— **Right**: Adjusts the right pillarbox.
— **Bottom**: Adjusts the bottom letterbox.
— **Left**: Adjusts the left pillarbox.
— **Smooth**: A checkbox that lets you turn on edge anti-aliasing for source blanking. Overrides the Anti-alias Edges drop-down menu found in the Image Scaling panel of the Project Settings.

**NOTE**: It might be necessary to turn anti-aliasing off if you notice black blurring at the edges of blanking being applied to an image.

Blanking presets are also available by choosing from the Timeline > Output Blanking submenu. Choosing one of these options automatically sets the Blanking parameters of the Sizing palette’s Output Sizing mode. The following presets are available:

— **1.33**: SD or 4:3
— **1.66**: European theatrical
— **1.77**: HD or 16:9
— **1.85**: Theatrical flat aspect ratio
— **2.00**: Univisium. Aspect ratio designed to accommodate both theatrical wide-screen and HD delivery.
— **2.35**: Original anamorphic (scope) theatrical wide-screen
— **2.39**: Current 35mm anamorphic (scope) theatrical wide-screen
— **2.40**: Current 35mm anamorphic (scope) theatrical wide-screen (rounded up for Blu-Ray)
— **Reset**: Restores the clip to its original aspect ratio.

Anti-aliasing at the edges of blanking is handled by an Anti-Alias Edges setting in the Image Scaling panel of the Project Settings. For more information, see Chapter 4, “System and User Preferences.”

### Resetting the Sizing Palette

You can reset every control within the Sizing palette at any time by clicking the reset button in the upper right-hand corner of the palette.

### Input and Output Sizing Presets

If there are Input or Output Sizing settings that you find yourself using repeatedly, you can save them as presets for easy recall. For example, if there’s a group of input settings that you use to resize a clip of a particular format to match the current project, you can save it as a preset that you can use whenever.
— **Preset drop-down menu:** Provides access to all the currently saved presets in the current project library.

— **Delete Preset:** To delete a preset, select it from the drop-down menu, click the trash can button, then click OK.

— **Save As New Preset:** To add a preset, make whatever settings adjustments you need, then click the plus button. When the Format Preset dialog appears, enter a name, check that the settings are correct, then click Save in the Format Preset window.

— **Update Preset:** To change a preset, load the preset you want to change, make whatever changes you need, then click Update in the Format Preset window.

The Input and Output Sizing modes save different presets. Each of these sets of presets is available from the “Override input scaling” and “Override output scaling” drop-down menus in the Image Scaling project setting menu.

## Sizing Controls with the DaVinci Control Panel

There are two sets of DaVinci control panel mappings for the sizing controls. The most obvious controls can be seen permanently mapped to the knobs and soft keys of the Transport panel. This makes these controls easy to access for projects where you’re panning and scanning nearly every shot of a film-scanned program.

### To adjust PTZR settings:

1. Press the OUTPUT or INPUT soft key to switch between Output Sizing and Input Sizing modes.
2. Use the PAN, TILT, ZOOM, and ROTATE knobs of the Transport panel, and the H FLIP and V FLIP soft keys.

### To adjust Input and Output Blanking:

1. Press the INPUT BLANKING or OUTPUT BLANKING soft key on the Transport panel.
2. Use the knobs labeled LEFT, RIGHT, TOP, and BOTTOM to make a blanking adjustment.
3. Press SIZING when you’re finished.

Another set of DaVinci control panel mappings appears when you press the SIZING button of the T-bar panel. In this case, the Center panel knobs and soft keys update to a page showing the following:

— **Ref Wipe Sizing Adjustments:** These controls, on the middle screen of the Center panel, let you reposition a still from the Gallery that’s being displayed in a split screen. This can make it easier to compare features that would otherwise be obscured by the still’s position on screen.

— **Input Sizing Adjustments:** The Input Sizing controls are displayed on the right screen of the Center panel. These are similar to the mappings on the Transport panel, but the Center panel’s second row of knobs also exposes PITCH, YAW, H SIZE, and V SIZE controls, and there’s an additional MODIFY PAR button that lets you change the pixel aspect ratio of a clip.
Output Sizing Adjustments: If you press the OUTPUT soft key on the Center panel, the knobs and soft keys change to show the Output Sizing controls. Press BLANKING to expose all the preset aspect ratios on the Transport panel, along with the USER which allows you to expose user definable presets.

To save and recall user definable blanking aspect ratios:
1 Press SIZING on the T-bar panel.
2 Press the OUTPUT soft key on the Center panel.
3 Press the OUTPUT BLANKING soft key on the Transport panel, and then enter the blanking aspect ratio as a number (e.g., 2.4) using the number pad on the Transport panel to set your customized blanking.
4 Press the BLANKING soft key on the Center panel.
5 To apply the new ratio, press the BLANKING soft key on the Center panel, then press USER on the Transport panel, and press one of the USER 1–5 soft keys.

TIP: With the Input Sizing Adjustments controls exposed on the Center panel, you can set the Transport panel to display the Output Sizing controls, for simultaneous presentation of every sizing control that’s available.

Using Node Sizing for Channel and Paint Effects

Using Node Sizing, you can apply individual sizing adjustments on a per-node basis. All Node Sizing adjustments within a grade are cumulative, and any keyframing done to Node Sizing parameters is stored in that node’s Node Format keyframe track in the Keyframe Editor. Two good examples of Node Sizing include realigning color channels individually in conjunction with the Splitter/Combiner nodes, or duplicating windowed regions of an image by moving them around the frame.

Example 1
Using node sizing on individual color channels:
1 Choose Color > Nodes > Add Splitter/Combiner Node to add this node structure to the current grade.
2 Select one of the three Corrector nodes connected between the Splitter and Combiner nodes that corresponds to the color channel you want to transform.
Adding the Splitter/Combiner nodes to use Node Sizing on individual color channels

3 Open the Sizing palette, choose Node Sizing from the mode drop-down, and use the Sizing parameters to transform that channel as necessary. For example, if you have an old video clip with misaligned color components, you could pan a misaligned channel to the left or right to try and improve its alignment.

Before and after panning the green channel

Example 2
Using Node Sizing to duplicate a windowed area of an image to cover a blemish:

1 Create a new node.
2 Open the Window palette, create a Circular window, and then shrink and reposition it to surround a feature you want to remove.
3 Open the Tracking palette, and track the window to follow the feature to be removed.
4 After the track is complete, now move the window to an adjacent area of clean detail that’s right next to the feature you want to remove. This is the area of the image you’re going to duplicate and cover the unwanted feature with.
5 Now, open the Sizing palette, choose Node Sizing from the mode drop-down, check Key Lock, and use the Sizing parameters to move a duplicate of the windowed area to cover up the unwanted feature.
Before/after using Node Sizing to clone an area of the image to cover up the actor with a plant to create a clean background

When you’re done, playing through the clip should show that the duplicated area of the image is still tracking the feature you want to remove.

**Image Stabilization in the Tracker Palette**

The Image Stabilization mode of the Tracker palette lets you smooth out or even steady unwanted camera motion within a clip. The analysis is performed in such a way as to preserve the motion of individual subjects within the frame, as well as the overall direction of desirable camera motion, while correcting for unsteadiness.

**Using the Stabilizer**

DaVinci Resolve uses an advanced stabilizer that’s capable of both warping and translation to minimize unwanted shaking in a clip replaces the classic stabilization tools that were available previously (these tools are still available should you need specific capabilities of the older toolset, and are covered in a later section). With a single click of the Stabilize button, the currently selected clip is analyzed and automatically stabilized using a combination of warping and image translations.

The default Stabilizer controls
**Stabilizer Parameters and Controls**

The default settings yield good results for most situations, but there are ways you can customize stabilization in situations where unique issues arise.

A drop-down menu provides three different options that determine how the selected clip is analyzed and transformed during stabilization. You must choose an option first, before clicking the Stabilize button, because the option you choose changes how the image analysis is performed. If you choose another option, you must click the Stabilize button again to reanalyze the clip.

- **Perspective**: Enables perspective, pan, tilt, zoom, and rotation analysis and stabilization.
- **Similarity**: Enables pan, tilt, zoom, and rotation analysis and stabilization, for instances where perspective analysis results in unwanted motion artifacts.
- **Translation**: Enables pan and tilt analysis and stabilization only, for instances where only X and Y stabilization gives you acceptable results.

The other controls let you customize how aggressively the selected clip is stabilized.

- **Bypass Stabilization**: This checkbox lets you turn stabilization off and on to be able to compare the stabilized and unstabilized image.
- **Cropping Ratio**: This value limits how hard the stabilizer tries to stabilize, by dictating how much blanking or zooming you're willing to accept in exchange for eliminating unwanted motion. A value of 1.0 results in no stabilization being applied. Progressively lower values enable more aggressive stabilization. Changing this value requires you to click the Stabilize button again to reanalyze the clip.
- **Smooth**: Lets you apply mathematical smoothing to the analyzed data used to stabilize the clip, allowing camera motion in the shot while eliminating unwanted jittering. Lower values perform less smoothing, allowing more of the character of the original camera motion to show through, while higher values smooth the shot more aggressively. Changing this value requires you to click the Stabilize button again to reanalyze the clip.
- **Strength**: This value is a multiplier that lets you choose how tightly you want to use the stabilization track to eliminate motion from a shot using the current analysis. With a value of 1.00, stabilization is maximized. Since some clips might look more natural with looser stabilization, choosing a number lower than 100 lets a percentage of the original camera motion show through. Zero (0) disables stabilization altogether. As an additional tip, you can invert the stabilization by choosing –1.00 when pasting a stabilization analysis from another clip to perform a match move based on the overall motion of the scene, and you can use a negative value either lower or higher than –1.00 to under or overcompensate when inverting the stabilization, simulating the effects of parallax where foreground and background planes move together but at different speeds.
- **Camera Lock**: Turning on this checkbox disables Cropping Ratio and Smooth, and enables the stabilizer to focus on eliminating all camera motion from the shot in an effort to create a locked shot.
- **Zoom**: When this checkbox is turned on, the image is resized by a large enough percentage to eliminate the blanking (black edges) that is the result of warping and transforming the image to eliminate unwanted camera motion. The lower a value Cropping Ratio is set to, the more DaVinci Resolve will need to zoom into an image to eliminate these blanked edges. If you turn this off, the image is not zoomed at all, and whatever blanking intrudes into the image is output along with the image, on the assumption that you’ll have dedicated compositing artists deal with eliminating this blanking by filling in the missing image data in a more sophisticated manner. You may also leave this checkbox turned off if you’re planning on animating the Input Sizing Zoom...
parameter to dynamically zoom into and out of a shot being stabilized to eliminate blanking only where it occurs, using only as much zooming as is necessary for each region of the shot.

**Using the Classic Stabilizer**

The “classic” image stabilizer controls available in DaVinci Resolve version 12.5 and earlier are still available, simply select “Classic Stabilizer” from the option menu of the Tracker palette. Classic image stabilization in DaVinci Resolve consists of three steps. First, you analyze the clip. Second, you choose the Stabilization settings you want to use. Third, you click Stabilize to calculate the result.

When analyzing the clip, you can choose to use either the default Cloud Tracker, which automatically finds as many trackable points as possible throughout the image and calculates stabilization based on all of them, or you can use the Point Tracker, which lets you manually place one or more individual crosshairs on image features that you select. For more information on using the Point Tracker for window tracking, see Chapter 136, “Motion Tracking Windows.”

![The Classic Stabilizer mode of the Tracker palette](image)

As with object tracking, you can choose which aspects of motion to stabilize, but this must be done before you do the initial image analysis.

**Analyze Controls**

The Analyze controls automatically scan through the entire clip, identifying trackable features that can be used to stabilize the shot.

A series of four checkboxes let you turn on and off which axes you’d like to stabilize. These checkboxes must be selected before you perform an analysis in order to restrict the data that’s generated.

- **Pan:** Enables horizontal stabilization.
- **Tilt:** Enables vertical stabilization.
- **Zoom:** Enables stabilization of size.
- **Rotate:** Enables stabilization of orientation.

**NOTE:** Once stabilization has been done, disabling these checkboxes does nothing to alter the result. To make changes, you need to enable or disable the necessary checkboxes first, and then reanalyze the clip.
The five direction buttons let you perform the stabilization analysis.

— **Track One Frame Reverse:** Initiates tracking from the current frame backward by a duration of one frame.
— **Track Reverse:** Initiates tracking from the current frame backward, ending at the first frame of the clip.
— **Pause:** Stops tracking (if you’re fast enough to click this button before tracking is finished).
— **Track Forward:** Initiates tracking from the current frame forward, ending at the last frame of the clip.
— **Track One Frame Forward:** Initiates tracking from the current frame forward by a duration of one frame.

**Interactive Mode Controls**
The Interactive controls let you make manual changes to the automatically generated tracking point cloud that DaVinci Resolve creates, so you can try different ways of obtaining better stabilization results in challenging situations.

— **Interactive Mode checkbox:** Turns the Interactive stabilization mode on and off. When you enter Interactive mode, you can manually alter the point cloud that DaVinci Resolve uses to stabilize the image. You’ll then make your analysis while in Interactive mode. When you exit Interactive mode, your manual changes to the point cloud are eliminated, and DaVinci Resolve again uses automatically placed point clouds to do all stabilization.
— **Insert:** Lets you add tracking points to whatever analyzable features exist within a bounding box that you’ve drawn in the Viewer. Inserted stabilization points are automatically placed.
— **Set Point:** Lets you use the cursor (using the DaVinci Resolve control panel), to manually place individual tracking points, one by one, with which to track a feature. If there is no trackable pixel group at the coordinates where you placed the cursor, a tracking point will be placed at the nearest trackable pixel group. You must place at least two tracking points at different pixel groups to track rotation, and at least three to track zoom.
— **Delete:** Eliminates all stabilization points within a bounding box that you’ve drawn in the Viewer.

The procedures for using Interactive mode for stabilization are the same as for tracking. For more information, see Chapter 136, “Motion Tracking Windows.”

**Stabilization Parameters and Controls**
There are five controls in the Stabilization group:

![Stabilization controls](image)

— **Strong:** Lets you choose how tightly you want to use the stabilization track to eliminate motion from a shot. With a value of 100, stabilization is maximized in an effort to “lock” the shot in place and eliminate all camera motion. This value is a multiplier. Since some clips might look more natural with looser stabilization, choosing a number lower than 100 lets a percentage of the original camera motion show through. Zero (0) disables stabilization altogether. Additionally, you can invert the
stabilization by choosing –100, as described in the section on performing a match move below, and you can use a negative value either lower or higher than –100 to under or overcompensate when inverting the stabilization, simulating the effects of parallax where foreground and background planes move together but at different speeds.

— **Smooth**: Lets you apply mathematical smoothing to the analyzed data used to stabilize the clip, and is meant to be used when the Strong parameter is less than 100, allowing camera motion in the shot while eliminating unwanted wiggling. Lower values perform less smoothing, allowing more of the character of the original camera motion to show through, while higher values smooth the shot more aggressively.

— **Zoom**: When this checkbox is turned on, the image is resized by a large enough percentage to eliminate the blanking (black edges) that is the result of repositioning the image to eliminate unwanted camera motion. The higher a value Smooth Frames is set to, the more DaVinci Resolve will need to zoom into an image to eliminate these blanked edges. If you turn this off, the image is not zoomed at all, and whatever blanking intrudes into the image is output along with the image, on the assumption that you’ll have dedicated compositing artists deal with eliminating this blanking by filling in the missing image data in a more sophisticated manner. You may also leave this checkbox turned off if you’re planning on animating the Input Sizing Zoom parameter to dynamically zoom into and out of a shot being stabilized to eliminate blanking only where it occurs, using only as much zooming as is necessary for each region of the shot.

— **Tracker Type**: A drop-down menu below the Tracker graph lets you choose whether to use the Cloud Tracker or the Point Tracker. The default Cloud Tracker automatically finds as many trackable points as possible throughout the image and calculates stabilization based on all of them. This is fast, but can result in problems if there are too many prominent subjects in the frame with different vectors of motion. The Point Tracker, by contrast, lets you manually place one or more individual crosshairs on image features that you select. This involves more steps, but has the advantage of letting you choose exactly which features exhibit the motion you’re trying to stabilize. For more information on using the Point Tracker for window tracking, see Chapter 136, “Motion Tracking Windows.”

— **Stabilize**: After you’ve tracked the clip and adjusted the previous two controls, you need to click Stabilize to calculate the resulting effect of the Strong, Smooth, and Zoom controls on your clip. Whenever you make changes to the Strong, Smooth, or Zoom parameters, you need to click Stabilize to recalculate the resulting effect on your clip.

### Classic Stabilization With the Cloud Tracker

Classic Image stabilization in DaVinci Resolve is easy, but you need to follow a specific series of steps for it to be successful.

**To stabilize an image:**

1. Open the Tracker palette, and choose Stabilizer from the Palette mode drop-down menu. Select Classic Stabilizer in the option menu. Make sure the Tracker Type drop-down menu at the bottom right of the Tracker palette is set to Cloud Tracker.

2. Turn off any of the Analyze checkboxes (Pan, Tilt, Zoom, Rotate, Perspective 3D) that correspond to transform axes you don’t want to smooth.

3. Click the Track Forward button to track the clip forward (or Track Reverse if you’d rather start from the end of the clip and work backward).
Multiple tracking points are automatically placed to analyze the motion of the image for stabilization.

This analyzes the clip, but no stabilization is yet applied.

4 Adjust the Strong parameter to reflect what kind of stabilization you want. If you want to eliminate all possible motion from the shot, leave Strong set to 100. If you want to use stabilization to smooth out the shot but leave some motion in the frame, reduce the strong parameter to be less than 100 but greater than 0. This parameter is a multiplier, so higher numbers reflect a higher percentage of smoothing being applied to the clip’s range of motion, and lower numbers reflect a lower percentage of smoothing being applied to the original range of motion.

5 If you’ve set the Strong parameter to a value less than 100 to calm the motion in the shot, rather than lock the shot completely, you can also adjust the Smooth parameter to mathematically smooth what motion remains in the shot. This lets you even out any “wobbling” that you don’t want, while retaining the camera motion that you do want. The Strong and Smooth parameters work together, so experiment with different values in each parameter to get the result you need.

6 Choose how you want the edges of the stabilized clip to be handled using the Zoom checkbox:
   — If you want DaVinci Resolve to zoom into the image as much as is necessary to prevent blanking (black edges) from intruding into the frame (the result of repositioning the image to steady camera motion), then turn on the Viewer Zoom checkbox.
   — If you want to leave the scale of the image alone, allowing blanking (black edges) to intrude into the frame so that you either (a) have an effects artist deal with filling in these holes later, or (b) manually animate the Input Sizing Zoom parameter to eliminate blanking in a dynamic way, then turn off the Viewer Zoom checkbox.

7 With all of these controls adjusted, click Stabilize. The clip is immediately transformed to apply the amount of stabilization you selected via the Smooth Frames slider.

8 Play the clip and examine the stabilization effect. If you need to make any changes, choose new Strong and Smooth Frames values, then click Stabilize. Any time you change any of the Stabilization parameters, you need to click Stabilize to recalculate the resulting transform to your clip.
Classic Stabilizing Using the Point Tracker

For clips in which there are too many moving subjects for the Cloud Tracker to get a solid lock, you need to track a very specific feature in order to successfully stabilize the image. In these cases, it’s often faster to use the Point Tracker for stabilization.

To stabilize an image using the Point Tracker:

1. Open the Tracker palette, and choose Stabilizer from the Palette mode drop-down menu. Select Classic Stabilizer from the option menu.
2. Choose Point Tracker from the Tracker Type drop-down menu at the bottom right of the Tracker palette. This changes the available controls under the tracker graph.
3. Click the Add Tracker Point button to add a crosshairs to the Viewer, and drag it to a high-contrast, angular feature you want to track that’s indicative of the overall motion of the clip.

4. Click the Track Forward button to track the clip forward (or Track Reverse if you’d rather start from the end of the clip and work backward).

   This analyzes the feature you chose to track with the crosshairs, but no stabilization is yet applied.

5. Adjust the Strong parameter to reflect what kind of stabilization you want. If you want to eliminate all possible motion from the shot, leave Strong set to 100. If you want to use stabilization to smooth out the shot but leave some motion in the frame, reduce the strong parameter to be less than 100 but greater than 0. This parameter is a multiplier, so higher numbers reflect a higher percentage of smoothing being applied to the clip’s range of motion, and lower numbers reflect a lower percentage of smoothing being applied to the original range of motion.

6. If you’ve set the Strong parameter to a value less than 100 to calm the motion in the shot, rather than lock the shot completely, you can also adjust the Smooth parameter to mathematically smooth what motion remains in the shot. This lets you even out any “wobbling” that you don’t want, while retaining the camera motion that you do want. The Strong and Smooth parameters work together, so experiment with different values in each parameter to get the result you need.

7. Choose how you want the edges of the stabilized clip to be handled using the Zoom checkbox:
   - If you want DaVinci Resolve to zoom into the image as much as is necessary to prevent blanking (black edges) from intruding into the frame (the result of repositioning the image to steady camera motion), then turn on the Viewer Zoom checkbox.

   **TIP:** You can optionally add more than one Tracker crosshairs to track multiple features, and DaVinci Resolve will attempt to stabilize as many dimensions as are made possible by the additional trackers. One point lets you stabilize Pan and Tilt. Two points lets you try to stabilize Pan, Tilt, and Rotation. Four points lets you try to stabilize Pan, Tilt, Rotation, and Zoom.
— If you want to leave the scale of the image alone, allowing blanking (black edges) to intrude into the frame so that you either (a) have an effects artist deal with filling in these holes later, or (b) manually animate the Input Sizing Zoom parameter to eliminate blanking in a dynamic way, then turn off the Viewer Zoom checkbox.

8 With all of these controls adjusted, click Stabilize. The clip is immediately transformed to apply the amount of stabilization you selected via the Smooth Frames slider.

9 Play the clip and examine the stabilization effect. If you need to make any changes, choose new Strong and Smooth Frames values, then click Stabilize. Any time you change any of the Stabilization parameters, you need to click Stabilize to recalculate the resulting transform to your clip.

Using Stabilization to Create a Match Move

In some circumstances, such as when you’re using the HSL Qualifier to create transparency for a composite (using the Alpha Output described later in this chapter), you may find you need to apply the motion from a foreground clip to the background clip so that the two clips appear to be moving as one. This is referred to as doing a “match move,” and is a necessary step when creating a composite for purposes of doing a sky replacement, for example. This can be done in a simple way using the Stabilizer mode of the Tracker palette.

To match the motion of a background clip to a foreground clip:

1 First, in the Edit page, edit a foreground clip onto track V2, and a background clip with a more interesting sky onto track V1.

2 With that done, open the Color page and follow the instructions in the section titled “Using a Qualifier Key to Create Transparency” in Chapter 143, “Channel Splitting and Image Compositing,” to key the sky, and use that key to create a region of transparency in the foreground clip that lets the background sky clip in track V1 show through.

Creating transparency to replace the sky in a superimposed clip with a sky image edited into a lower video track

In this example, the plain blue sky is being keyed so that it can be replaced with a more interesting photo of a dramatically cloudy sky.
This procedure works equally well with still images or movie clips. Also, depending on the range of motion you’re going to be matching, you’ll probably need to use a background image that’s somewhat larger than the region you’re keying, to make sure you have full coverage as the layer moves to match the foreground motion. If necessary, you can zoom into the image using the Zoom parameter in the Transform section of the Edit page Inspector.

3 In this example, the foreground clip happens to have a camera pan, which gives the composite away as the sky doesn’t move along with it. To move the compound clip of the sky image to match this pan, open the Tracker pallet.

4 Choose its Stabilizer mode, and then click the Analyze Forward button to analyze the motion of the entire clip. Then, click the Tracker palette’s Option menu, and choose Copy Track Data.

5 Select the clip that you want to match (in this case the sky image), then open the Tracker Palette’s Option menu and choose Paste Track Data.

6 Now, for this to work correctly, you need to set the Strong parameter to –100, and click the Stabilize button. Setting a negative value inverts the tracking data you copied in step 3, which enables it to become a match move. If you’re feeling extra tricky, you can set the Strong parameter to a little less than –100, say –94, which introduces a disparity of foreground and background motion that simulates parallax.

Inverting the Strong parameter with a negative number to create matched motion

At this point, playing through the clip should result in a nicely matched correspondence between the movement of the foreground and background layers.
Tracking and Stabilizing with the DaVinci Control Panel

All of the tracking commands are available via the DaVinci Resolve control panel.

**To open and close tracking controls:**

— Press OBJECT TRACK MODE at the top of the T-bar panel.
— All of the tracking controls appear on the soft keys of the Center and T-bar panels.

**To do simple tracking:**

— Use the TRACK FWD, TRACK REV, and STOP TRACK soft buttons on the left side of the Center panel.
— Press SHOW TRACK if you want to see the resulting motion path.

**To turn tracking on and off for Pan, Tilt, Zoom, and Rotate:**

1. Press the P/T/Z/R ENABLE soft key. The middle four soft keys of the Center panel change to display PAN ON/OFF, TILT ON/OFF, ZOOM ON/OFF, and ROTATE ON/OFF.
2. Use these buttons to toggle any of these checkboxes on or off, then press BACK to go back to the other tracking controls.

**To interpolate between two separately tracked ranges of frames:**

1. Use the transport controls to move the playhead to the first frame you want to place a mark, and press MARK. A Viewer Mark appears on the tracking bar, identifying either the beginning or the end of the gap in that clip’s motion tracking data.
2. If necessary, use the transport controls to move the playhead to the second frame where you want to place a mark, and press MARK. A second Viewer Mark appears in the tracking bar, identifying both the beginning and end of the gap in that clip’s motion tracking data.
3. To perform the interpolation, do one of the following:
   — If you marked both the first and last tracked frames that surround a gap in tracking data, press the INTRPLT BETWEEN soft key.
   — If you marked the last tracked frame in the first half of the clip, then use the transport controls to move the playhead to the first tracked frame of the second half of the clip and press the INTRPLT REV soft key.
— If you marked the first tracked frame in the second half of the clip, then use the transport controls to move the playhead to the last tracked frame of the first half of the clip and press the INTRPLT FWD soft key.

**To move the playhead to different “cue” frames:**
— Press the CUE START, CUE LOWER, CUE UPPER, or CUE END soft keys on the T-bar panel.

**To use Interactive mode:**

1. Press the INTERACTIVE soft key at the left of the Center panel. Additional button controls appear on the soft keys of the Transport panel, including INSERT (POINTS), DELETE (POINTS), CLEAR (POINTS), and SET POINT.

2. Do one of the following:
   — To eliminate all tracking points, press the CLEAR soft key.
   — To add a single tracking point, press CURSOR (above the fourth trackball), use the fourth trackball to position the onscreen cursor over the feature you’d like to add a tracking point to, and then press the SET POINT soft key.
   — To eliminate a range of tracking points in order to prevent the tracking of an undesirable feature, use the mouse to draw a bounding box around the tracking points you want to remove, and press the DELETE soft key.
   — To add a range of tracking points to a specific feature, use the mouse to draw a bounding box around the feature you want to track, and press the INSERT soft key.

3. Use the TRACK FWD, TRACK REV, and STOP TRACK soft buttons on the left side of the Center panel to perform the necessary tracking.

4. Press the INTERACTIVE soft key again to leave Interactive mode.
Chapter 150

The Motion Effects and Blur Palettes

This chapter covers the Noise Reduction and Motion Blur effects found in the Motion Effects palette. It also goes into detail about the Blur, Sharpen, and Mist features of the Blur palette.

Motion Effects Palette

The Motion Effects palette (only available in the Studio version) contains two sets of controls for applying optical-flow-calculated effects to clips in your program. These include enhanced Spatial and Temporal noise reduction, and motion-estimated artificial motion blur.

Noise Reduction Controls

Two sets of parameters let you apply GPU-accelerated Temporal and/or Spatial noise reduction that’s designed to let you subdue noise in problematic clips, in close to real time on workstations with appropriate processing power. Both methods of noise reduction can be used separately or together, in varying amounts depending on the needs of the particular material you’re working on. Furthermore, each set of controls is highly customizable, allowing for varying amounts of noise reduction to the chroma and luma of an image, as well as numerous options for how to apply this noise reduction.

Temporal NR Controls

The Temporal NR controls analyze images across multiple frames in order to isolate noise from detail. Motion estimation settings let you exclude moving subjects from this operation in order to prevent unwanted motion artifacts.

— Number of Frames: The number of frames you want DaVinci Resolve to average in order to separate detail from the noise. You can choose between 0 and 5 frames. 0 applies no frame averaging, higher values apply more frame averaging, at the expense of being significantly more computationally intensive the higher a value you use. Also, a higher frame setting will yield a better analysis, but may yield unwanted artifacts if there are fast-moving images in the frame. A value of 1 may yield better results for fast-moving images. If you need to use higher frame values but you see artifacts, you can also try adjusting the Motion Threshold to fix the issue.

— Motion Est. Type: Picks the method DaVinci Resolve uses to detect motion in the image. The default, Faster, is less processor intensive, but less accurate. Choosing Better can effectively exclude motion more accurately, but is more processor intensive. None lets you disable motion estimation altogether, with the result being the application of Temporal NR to the entire image.
— **Motion Range**: Three settings, Small, Medium, and Large, let you set the speed of motion that Motion Estimation should expect to exclude. A Small setting assumes slow-moving subjects with little or no motion blur, allowing Temporal NR to affect more of the image at a given Motion Threshold setting. A Large setting assumes fast motion with blur occupying a larger area of the image, which excludes more of the image from Temporal NR at the same Motion Threshold setting. Choose the setting that gives you the best compromise between a reduction in noise and the introduction of motion artifacts when adjusting the Motion Threshold parameter.

— **Luma Threshold**: Lets you determine how much or how little Temporal NR to apply to the luma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine detail from the image.

— **Chroma Threshold**: Lets you determine how much or how little Temporal NR to apply to the chroma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine color detail from the image, although you may find you can raise the Chroma Threshold higher than the Luma Threshold with less noticeable artifacting.

— **Luma/Chroma Threshold ganging**: Ordinarily, the Luma and Chroma Threshold parameters are ganged together so that adjusting one adjusts both. However, you can ungang these parameters in order to adjust different amounts of noise reduction to each component of the image, depending on where the noise happens to be worst.

— **Motion Threshold**: Defines the threshold separating which moving pixels are in motion (above this threshold) versus which moving pixels are static (below this threshold). Using Motion Estimation, Temporal Noise Reduction is not applied to regions of the image that fall above this threshold, in order to prevent motion artifacts by not applying frame-averaging to parts of the image that are in motion. Lower values omit more of the image from Temporal NR by considering more subtle movements. Higher values apply Temporal NR to more of the image by requiring faster motion for exclusion. You can choose between 0 and 100, where 0 applies Temporal NR to no pixels, and 100 applies Temporal NR to all pixels. The default value is 50, which is a suitable compromise for many clips. Be aware that if you set too high a Motion Threshold, you may see artifacts in moving parts of the image.

— **NR Blend**: Lets you dissolve between the image as it’s being affected by the Temporal NR parameters (at 0.0) and the image with no noise reduction at all (100.0). This parameter lets you easily split the difference when using aggressive temporal noise reduction.

### Spatial NR Controls

The Spatial NR controls let you smooth out regions of high-frequency noise throughout the image, while attempting to avoid softening by preserving detail. It’s effective for reducing noise that Temporal NR can’t.

— **Mode**: The Mode drop-down lets you switch Spatial NR between three different algorithms. All three modes of operation use exactly the same controls, so you can switch between modes using the same settings to compare your results.

— **Faster**: Uses a computationally lightweight method of noise reduction that’s good at lower settings, but may produce artifacts when applied at higher values.
— **Better:** Switches the Spatial NR controls to use a higher quality algorithm that produces greatly superior results to Faster, at the expense of being more processor intensive to render, as well as not allowing you to decouple the Luma and Chroma Threshold sliders for individual adjustments to each color component.

— **Enhanced:** Does a significantly better job of preserving image sharpness and detail when raising the Spatial Threshold sliders to eliminate noise. This improvement is particularly apparent when the Spatial Threshold sliders are raised to high values (what constitutes “high” varies with the image you’re working on). At lower values, the improvement may be more subtle when compared to the “Better” mode, which is less processor intensive than the computationally expensive “Enhanced” setting. Additionally, “Enhanced” lets you decouple the Luma and Chroma threshold sliders so you can add different amounts of noise reduction to each color component, as the image requires.

— **Radius:** Options include Large, Medium, and Small. A smaller radius offers greater real time performance, and can provide good quality when using low Luma and Chroma Threshold values. However, you may see more aliasing in regions of detail when using low NR Threshold values.

Setting Radius to be progressively larger results in higher quality within areas of greater visual detail at high Luma and Chroma Threshold values, at the expense of slower performance. An NR Radius of Medium should provide suitable quality for most images when using medium NR Threshold settings. As with many operations, there’s an adjustable tradeoff between quality and speed.

— **Luma Threshold:** Lets you determine how much or how little noise reduction to apply to the luma component of the image. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine detail from the image.

— **Chroma Threshold:** Lets you determine how much or how little noise reduction to apply to the chroma component of the image by smoothing out regions of high-frequency noise while attempting to preserve the sharpness of significant edge details. The range is 0–100, where 0 applies no noise reduction at all, and 100 is the maximum amount. Too high a setting may eliminate fine color detail from the image, although you may find you can raise the Chroma Threshold higher than the Luma Threshold with less noticeable artifacting.

— **Luma/Chroma Threshold ganging:** Ordinarily, the Luma and Chroma Threshold parameters are ganged together so that adjusting one adjusts both. However, you can ungang these parameters in order to adjust different amounts of noise reduction to each component of the image. For example, if an image softens too much at a certain level of noise reduction, but you find there’s more color speckling than there is luma noise, you can lower the Luma Threshold to preserve detail while raising the Chroma Threshold to eliminate color noise.

— **NR Blend:** Lets you dissolve between the image as it’s being affected by the Spatial NR parameters (at 0.0) and the image with no noise reduction at all (100.0). This parameter lets you easily split the difference when using aggressive spatial noise reduction.

### Using Noise Reduction

The following procedure suggests a method of using the Noise Reduction (NR) parameters to achieve a controlled result.
Applying noise reduction to an image:

1. Enable Temporal NR by choosing 1 to 5 frames from the Number of Frames drop-down menu. Keep in mind that more frames dramatically increase the render time of this effect, while it may or may not significantly improve the result, depending on your material.

2. Choose options from the Motion Est. Type and Motion Range drop-down menus corresponding to how much motion is in the image. If there’s a lot of motion, you may need to choose Better and Large. If there’s not very much motion, lesser settings may suffice.

3. With Luma and Chroma Threshold linked, slowly raise either parameter until you just start to see a reduction in noise within the nonmoving areas of the image, then make smaller adjustments to determine the maximum amount of Temporal NR you can add without creating motion artifacts, or overly softening image detail you want to preserve.

4. If there’s obviously more chroma than luma noise in the image, you can disable Luma/Chroma linking at a satisfactory level of luma noise reduction, and then raise the Chroma Threshold to apply more aggressive Temporal NR to address color speckling in the picture.

5. If you’re not satisfied with the tradeoff between the maximum possible threshold of noise reduction and the prevention of motion artifacts, you may want to adjust the Motion Threshold setting, lowering it to omit more of the motion from the noise reduction operation, or raising it to include more motion. If you’re still not satisfied, you can also try better Motion Est. Type and Motion Range settings.

(Left) Before and (Right) after Temporal NR to reduce noise in unmoving areas of the image

Keep in mind that the strength of Temporal NR is to reduce noise in unmoving parts of the image. When you’ve achieve the best tradeoff between noise reduction in the still areas and avoidance of motion artifacts in the moving areas of the image, then it’s time to turn to Spatial NR to further eliminate noise throughout the rest of the picture.

6. Enable Spatial NR by raising either the Luma or Chroma Threshold parameters, which are linked by default, until you strike a suitable balance between the reduction of noise, and an unwanted increase in image softness.

7. It’s recommended to choose the Enhanced option from the Spatial NR mode drop-down, as it will yield the best possible results. However, this can be processor-intensive, so if you need better real-time performance, you can switch the mode to Faster and compare results.

8. If there’s obviously more chroma than luma noise in the image, you can disable Luma/Chroma linking at a satisfactory level of luma noise reduction, and then raise the Chroma Threshold to apply more aggressive Spatial NR to address color speckling in the picture.
9 If you’ve had to use a high Spatial NR Luma or Chroma Threshold setting to reduce noise visibly, and areas of detail look a bit chunky or aliased, you can choose a larger setting from the Radius drop-down menu to enable a more detailed analysis of the scene. This will result in higher visual quality, but larger NR Radius settings are more processor intensive, and may reduce real time performance if you don’t have adequate GPU resources available to your system.

10 If you’ve found suitable noise reduction settings, but the result is too aggressive and makes the image appear too processed, you can try raising the Spatial NR and/or Temporal NR Blend parameters to fade between the noise reduction added by each set of controls, and the image as it was before you added noise reduction.

Try Applying Temporal NR First, then Applying Spatial NR

Because Temporal NR analyzes multiple frames for its noise isolation, it tends to be better at preserving detail accurately in regions of the image where there’s little motion. If you try applying Temporal NR first and get a successful result, even if only in part of the image, you may reduce how much Spatial NR you have to apply, thus improving the overall quality of your final result.

Keep in mind that while Temporal NR does a great job in unmoving parts of an image but is less effective when dealing with subjects in motion, Spatial NR is able to reduce noise everywhere in the frame falling below its threshold, even when there’s motion. Ultimately, a combination of the two is almost always going to be a winning combination.

Spatial NR Radius, How Large Should You Go?

Larger NR Radius settings can dramatically improve the quality of high-detail regions in shots where you’re using aggressive Spatial noise reduction, but it’s not necessary to always jump to the large Radius setting, which provides the highest precision. In many cases, when evaluating an image that you’re applying noise reduction to, you may not actually be able to perceive the additional quality, and you’ll waste processing time on an unnecessary level of correction.

It’s a good idea to make sure that you’re evaluating the full-frame image on a large enough display to see the noise you’re working on within the viewing context of the intended audience. Zooming really far into a clip while applying noise reduction may encourage you to use higher quality settings than are necessary, because an excessively enlarged detail of an image lets you see subtle changes that you wouldn’t notice at actual size.
Limiting Noise Reduction in Useful Ways

As with any other correction in the Color page, noise reduction can be limited using HSL Qualification or Power Windows. This means you can focus your efforts on reducing noise in the most problematic areas of an image (for example, in shadows and background regions), while sparing elements that you don’t want to affect (such as faces or better-lit areas of the image).

Furthermore, you can use Spatial NR in lieu of Blur operations to perform a subtler form of complexion smoothing, using the HSL qualifier or a window to isolate an actor’s skin tone for targeted noise reduction.

Controlling the Order of Operations for Noise Reduction

You can apply noise reduction at any point in your image processing tree using a dedicated node. If you have an image with noise that you think might be enhanced by whatever corrections you need to make (increasing the contrast of underexposed clips often increases whatever noise is within an image), there are two approaches to noise reduction:

— **Apply noise reduction at the beginning of a node tree:** This lets you pre-emptively eliminate any noise before it becomes a problem as a result of whatever adjustments you’re planning to make. The result can be smoother, but you may also notice that the edge detail within the image is a bit softer.

— **Apply noise reduction at the end of a node tree:** The alternative is to make your adjustments first, and then apply noise reduction in a separate node afterwards. In this case, you may find that the noise reduced regions of the image aren’t quite as smooth, however the edge detail within the image may be visibly sharper as a result.

— **Apply noise reduction to only one color channel of an image:** Using the Splitter/Combiner nodes, you can also apply noise reduction to only one color component of an image. If you’re grading a video clip with a noisy Blue channel, this can be a way to focus noise reduction where it’s needed. Isolating a single color channel for noise reduction is also possible using the Channels selection when right-clicking a node. By selecting the specific channel numbers in this node corresponding to your color space (RGB, YUV, LAB, etc.), you can limit the noise reduction operation to the appropriate channels only.

Neither result is universally better or worse than the other. Which is preferable depends on the image you’re working on, and the type of result you’re looking for (you might prefer some shots to be a bit softer, while you’d like other shots to be a bit sharper). The real point is that the node-based image processing of DaVinci Resolve lets you choose which technique works best for you.

**NOTE:** If you apply noise reduction and make color adjustments within the same node, noise reduction is processed first, followed by color adjustments.

Using Noise Reduction Controls with the DaVinci Control Panel

— All three Noise Reduction controls are available via knobs on the PRIMARIES, NOISE REDUCTION control group on the Center panel.

To open the Noise Reduction controls on the DaVinci control panel:

— Press the PRIMARIES or MAIN soft key on the Center panel, whichever is visible (depending on which control group is currently displayed).
**Motion Blur**

Motion Blur settings use optical-flow based motion estimation to add artificial motion blur to clips that have none. This can be useful in cases where a program was shot using a fast shutter speed, and you later decide that the resulting video has too much strobing. By analyzing the motion within a clip, the Motion Blur settings can selectively apply blurring to the image based on the speed and direction of each moving element within the scene.

![Motion Blur controls](image)

Three parameters let you set how much motion blur to add, and at what quality:

- **Motion Est. Type**: A setting of Better provides more accurate pixel mapping at the expense of being more processor intensive. Faster provides a more approximate result, but is less processor intensive.
- **Motion Range**: Determines what speed of motion to consider when defining regions being blurred.
- **Motion Blur**: Raise this parameter to add more motion blur to the image, lower it to add less. The range is 0–100, where 0 applies no motion blur, and 100 applies maximum motion blur.

**The Blur Palette**

The Blur palette has three different modes of operation—blur, sharpen, and mist. While the functionality of the Blur and Sharpen modes somewhat overlap, each mode provides dedicated controls that the other ones lack.

As with virtually everything else in the Color page, the operations performed in the Blur palette can be limited as a secondary operation using HSL Qualifiers, Windows, or Imported mattes, which makes it easy to apply these effects to specific portions of the image.

Many of the controls in the Blur palette consist of three ganged sliders, one for red, one for green, and one for blue.

By default, these ganged sliders move together as one, resulting in each color channel of the image being equally affected. A small white button to the left of each control’s name lets you ungang these sliders, in order to apply degrees of adjustment to individual color channels.

**Blur**

The default mode, Blur lets you apply an exceptionally high-quality Gaussian blur, or another equally high-quality sharpening operation to your image. This mode of operation has the simplest controls.

Two sets of linked parameters let you adjust the extent and directionality of blur or sharpening. Which is applied depends on the direction in which you adjust the Radius control.
Blur Radius controls are ganged by default, but can be unganged

— **Radius:** This is the primary control for adding blur or sharpening. The default value of 0.50 results in no effect being applied to the image. Raising the radius slider increases blur, while lowering the radius increases sharpness, with a minimum value of 0.00 providing maximum sharpness.

  **TIP:** If you raise the Radius slider all the way to 1.00 and the image isn’t blurred enough, add another node and use it to add another blur operation. You can also use the scroll wheel on your mouse while hovering over one of the bars to increase the radius.

— **H/V Ratio:** Lets you add directionality to the current operation. At the default value of 0.50, the image is affected in both the horizontal and vertical directions equally. Raising H/V Ratio makes the effect increasingly directional along the horizontal axis, while lowering makes the effect increasingly directional along the vertical axis.

**To adjust the Blur controls using the DaVinci control panel:**

1. Press the VECTORS button on the T-bar panel, or the VECTORS soft key on the Trackball’s main page.
2. Use the BLUR AMOUNT and H/V RATIO knobs to add either blur or sharpening.
3. When you’re finished, press the PRIMARIES soft key to return to the Center panel’s main page.

**Sharpen**

While the Blur controls also let you apply sharpening simply by lowering, rather than raising, the Radius sliders, the actual Sharpen mode provides additional controls specifically for tailoring sharpening operations.
Sharpening with Coring Softness and Level

— **Radius**: This is the primary control for adding blur or sharpening. The default value of 0.50 results in no effect being applied to the image. Raising the radius slider increases blur, to a maximum value of 1.00. Lowering the radius increases sharpness, with a minimum value of 0.00 providing maximum sharpness.

— **H/V Ratio**: Lets you add directionality to the current operation. At the default value of 0.50, the image is affected in both the horizontal and vertical directions equally. Raising H/V Ratio makes the effect increasingly directional along the horizontal axis, while lowering makes the effect increasingly directional along the vertical axis.

— **Scaling**: Multiplies the amount of scaling being applied by the Radius control for sharpening operations. The scaling parameter has no effect if Radius is set to 0.50 or above for blur effects.

The Coring Softness and Level parameters work together to let you limit sharpening to only the most detailed areas of the picture that would most benefit from it, based on a threshold of image detail that you define using the Level and Softness parameters.

— **Level**: The first slider you should use. Raising this value sets the threshold at which image detail is omitted from the sharpening operation. The default setting of 0 sets the threshold low enough to sharpen the entire image. Raising Level gradually omits low-detail areas of the image, which results in sharpening being restricted to well-defined outlines.

— **Coring Softness**: After you’ve set the Level slider to an appropriate amount, raising Coring Softness blends the border between parts of the image that are sharpened and parts of the image that are left alone.

**To adjust the Sharpening controls using the DaVinci control panel:**

1. Press the VECTORS button on the T-bar panel, or the VECTORS soft key on the Center panel’s main page.
2. On the Center panel, press the IMAGE MODE soft key repeatedly to cycle to the RESOLVE IMAGE SHARPENING controls.
3. Use the SHARP AMOUNT, SCALING, LEVELS, and SOFTNESS knobs to create the desired sharpening effect.
4. When you’re finished, press the PRIMARIES soft key to return to the Center panel’s main page.
Mist

The Mist mode lets you combine blur and sharpen operations in such a way as to create effects similar to those achieved via “Vaseline on the lens” or Pro-Mist optical filters.

Unlike the Blur or Sharpen modes, where the Radius sliders provide immediate access to the desired effect, the Mist mode requires you to lower the Radius and Mix sliders together to get a desirable result. By varying the amounts of Radius and Mix, you can create many variations on the mist effect.

— **Radius:** When creating a Mist effect, you first need to lower Radius to sharpen the image. This operation then combines with a lowering of the Mix parameter to provide the combination of detail and blurring that results in a mist effect.

— **H/V Ratio:** Lets you add directionality to the current operation. At the default value of 0.50, the image is affected in both the horizontal and vertical directions equally. Raising H/V Ratio makes the effect increasingly directional along the horizontal axis, while lowering makes the effect increasingly directional along the vertical axis.

— **Scaling:** Multiplies the amount of scaling being applied by the Radius control, and lets you intensify a mist effect beyond the Radius slider’s ordinary range. The scaling parameter has no effect if Radius is set to 0.50 or above for blur effects.

— **Mix:** After you sharpen the image using the Radius slider, decreasing the Mix parameter adds a superimposed blur that mixes with the high-detail areas of the picture to create the mist effect.

To adjust the Mist controls using the DaVinci control panel:

1. Press the VECTORS button on the T-bar panel, or the VECTORS soft key on the Center panel’s main page.
2. On the Center panel, press the IMAGE MODE soft key repeatedly to cycle to the RESOLVE MIST EFFECT controls.
3. Use the RADIUS, H/V RATIO, SCALING, and MIX knobs to create the desired mist effect.
4. When you’re finished, press the PRIMARIES soft key to return to the Center panel’s main page.
Chapter 151

Dust Removal

This chapter shows how you can use the legacy Dust Removal feature that's built into the Color page.

There's also a pair of Resolve FX plug-ins: “Automatic Dirt Removal” and “Dust Buster,” found in the Revival category of the Resolve FX plug-ins. For more information on those, see Chapter 159, “Resolve FX Revival.”

Contents

Introduction to Dust Removal 3263
Dirt and ROI Settings Parameters 3263
Algorithms for Dirt and Dust Removal 3264
Introduction to Dust Removal

The interactive Dirt and Dust Removal tool provides an interface for dustbusting right from within DaVinci Resolve. This is a raster-based effect, and results in a duplicate set of "dustbusted" media being created within a hidden subdirectory.

If, at any point, you’re unsatisfied with the adjustment you’ve made, you need only use the undo command to return the clip you’re working on to its prior state.

**IMPORTANT**

The Dirt and Dust Removal tool only works with DPX image sequences. Media in a raw, ProRes, or DNxHD format should use the Dust Buster Resolve FX filter instead, or be converted to a DPX image sequence before it can be operated on with this tool.

**To use the Dirt and Dust Removal tool:**

— Click the Onscreen Control drop-down menu at the bottom left of the Viewer, and choose Dust Removal.

![Selecting the Dirt and Dust tool in the Viewer OSD menu](image)

**To open the Dirt and Dust Removal tool setup options:**

— Right-click the Dirt and Dust Removal icon showing in the Onscreen Control drop-down to open the setup window.

**Dirt and ROI Settings Parameters**

In the Dirt and ROI Settings window, there are a number of parameters that you can use to optimize this tool for the particular problem you’re trying to solve.
— **Algorithm:** The Algorithm drop-down menu lets you select the method of filtration to use when painting out dirt or dust. Different options provide different methods for replacing the problem pixels with image data copied from other frames in time, or from other regions of the current frame. You’ll want to choose an option that works best for the type of camera and subject motion happening within the clip you need to clean. For more information on the advantages of each algorithm, see the next section.

— **Aggression:** Increase or decrease the Aggression and Blend sliders depending on the degree of correction you want to apply.

— **Blend:** Sets the % of the original image to be feathered at the edges of the repair.

— **Optimize:** Turning this option on provides better-looking results, at the expense of increased processing time.

— **ROI Mode:** Determines whether a correction is applied with a single click, or via a paint stroke. There are three options.

— **Click and Clean:** Applies a correction with one click, and is fast to use on small dust spots.

— **Draw and Clean:** Lets you “paint” over a larger dirty area with the mouse or a pen, with the correction being applied at the conclusion of your paint stroke.

— **CNC Size:** Defines the width of the “brush” that’s used to paint out dirt and dust.

---

**Algorithms for Dirt and Dust Removal**

There are six algorithms you can choose from that determine how the pixels you paint over are automatically replaced.

— **Auto-temporal –/+ 1:** When an ROI is drawn, the previous frame, the next frame and the current frame will all be used for analysis. The best of these 3 will be automatically selected and used for removing the dirt in the current frame.

— **Auto-temporal –/+ 2:** This is the same as the above, but the frames used instead are the current frame, previous-to-previous frame (i.e., 2 frames back), and next-to-next frame (i.e., 2 frames forward). Therefore, if the ROI is drawn on frame 100, frame 98, frame 100, and frame 102 will be used for analysis. The best of these 3 will be used for removing the dirt in the current frame. The advantage of this selection is that it will avoid the appearance of frozen grain, which may be possible in case of dirt against a stationary background.

— **Temporal –/+ 1:** if the ROI is drawn by dragging the mouse from left to right, the next frame will be used for motion-compensated dirt removal. If the ROI is drawn by dragging the mouse from right to left, the previous frame will be used.

— **Temporal –/+ 2:** if the ROI is drawn by dragging the mouse from left to right, the next-to-next frame will be used for motion-compensated dirt removal. If the ROI is drawn by dragging the mouse from right to left, the previous-to-previous frame will be used.

— **Spatial:** In case of fast or blurred motion, using the previous or next frames may give unsatisfactory results. In this case, the same frame itself can be used for removing the dirt. This will use surrounding information in the current frame to remove the dirt.

— **Median:** The Median filter performs a blending of the pixels, smoothing out the region. Use this when other options do not replace the image, or when there is no support information in which to reconstruct the original. Using small boxes will produce better results.
Chapter 152

Resolve FX

This section provides detailed explanations for each Resolve FX filter that's available on the Cut, Edit, Fusion, and Color pages.

For more information on how to apply and adjust Resolve FX on the Cut page, see Chapter 31, “Video and Audio Effects in the Cut Page.”

For more information on how to apply and adjust Resolve FX on the Edit page, see Chapter 46, “Editing, Adding, and Copying Effects and Filters.”

For more information on how to apply and adjust Resolve FX on the Fusion page, see Chapter 84, “Using Open FX, Resolve FX, and Fuse Plug-Ins.”

For more information on how to apply and adjust Resolve FX on the Color page, see Chapter 148, “Using Open FX and Resolve FX.”

Contents

Catalogue of Resolve FX Filters 3267
Catalogue of Resolve FX Filters

DaVinci Resolve comes with a set of Resolve FX filters, many of which have been optimized for real time playback. These are located within their own category in the Effects Library of the Cut, Edit, and Fusion pages, and in the Open FX browser of the Color page. These effects (or filters) work just like any other Open FX plug-in.

Resolve FX are shown as icons depicting each specific filter. Hovering the mouse pointer over the icon previews the filter in the Viewer, and moving the mouse pointer along the icon previews the filter over the length of the clip.

In addition to the different parameters built into each filter, every single Resolve FX filter has a Blend parameter that mixes that filter’s effect against the original image. Each filter’s Blend parameter appears at the bottom of that filter’s settings.
Chapter 153

Resolve FX Blur

The plug-ins in this category offer a wider variety of different blur methods than those found in the Blur palette.

Contents

Box Blur 3269
Directional Blur 3269
Gaussian Blur 3269
Lens Blur (Studio Version Only) 3270
Shape 3270
Speed 3271
Controls 3271
Mosaic Blur 3272
Radial Blur 3272
Zoom Blur 3273
Box Blur

A variable quality blur that ranges from very low quality to very soft.

- **Horizontal and Vertical Strength**: These sliders let you adjust the width and height of blur.
- **Gang**: This checkbox lets you adjust these parameters together or separately.
- **Number of Iterations**: Controls how smooth the resulting blur is, with 0 being the lowest and most “boxy” level of quality and 1 being the highest and smoothest level of quality. At low iteration values, box blurs can appear somewhat similar to lens blurs.
- **Border Type**: Lets you choose how the edges of the image are affected by this blur, options include Black, Replicate, Reflect, and Wrap Around.

Directional Blur

A blur that’s constrained to a single angle.

- **Blur Strength**: How much blur you want.
- **Blur Angle**: The direction of blur.
- **Blur Type**: When Blur Type is set to Realistic, the blur effect emulates a photographic motion blur. When set to Stylized, the blur effect is a simple and smooth digital blur.
- **Symmetric Blur**: When the Symmetric checkbox is turned on, the blur effect appears to be created from both directions, with the result being more of a double-image that’s blurring along the blur angle, simulating motion blur in a camera. When off, the blur effect appears to be moving in a single direction, from the original position out along the blur angle.
- **Border Type**: Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.

Gaussian Blur

Provides a smooth blur that resembles looking at the image through semi-opaque glass, reducing detail and noise.

- **Horizontal and Vertical Strength**: Two sliders let you adjust the Horizontal and Vertical Strength independently.
- **Gang**: This checkbox lets you keep the Horizontal and Vertical Strength values ganged together.
- **Border Type**: Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.
Lens Blur *(Studio Version Only)*

A high-quality simulation of optical lens blurring. Adjustable parameters let you achieve different kinds of “bokeh” effects, which are similar to those produced by different combinations of aperture design and lens spherical aberration corrections that affect the “circle of confusion” that creates visible shapes in areas of the picture with pinpoint highlights.

**Shape**

The Shape group lets you choose what shape of aperture to simulate and affects the shape of the bokeh in this effect.

— **Shape Type**: Lets you choose what type of apertures you want to use. There are three options:
  
  — **Real Apertures**: Lets you choose a realistic option from the Aperture Shape pop-up menu below, with which to influence the shape of the bokeh effect. Aperture Shape options include Triangle, Square, Pentagon, Hexagon, Heptagon, or Octagon shaped aperture.
  
  — **Creative**: Lets you choose a more fanciful option from the Aperture Shape pop-up menu below, with which to influence the shape of the bokeh effect. These options simulate the kind of bokeh you could realistically achieve by placing a blackout filter with a custom shaped hole in the center in front of a lens. Aperture Shape options include Heart, Star, Starfish, Starburst, Petals, Lip, Eye, Droplet, and Leaf.
  
  — **External Input**: Uses any arbitrary graphic with a (preferably small) white shape against a black background to influence the shape of the bokeh effect. This shape must be a graphic or matte clip that’s added to the Node Editor and can be connected in one of two ways. If the plug-in is dragged onto an ordinary corrector node, then you must use the Add OFX Input command to expose an RGB input with which to connect the image. If you’ve added the plug-in as a self-contained OFX node (named “Lens Blur”), then you can attach the image to the second RGB input of the Lens Blur node.

— **Aperture Shape**: Provides different options for aperture shapes that influence the shape of this plug-in’s simulated bokeh blur effect.

— **Preview Shape**: This checkbox lets you see the actual shape you’ve selected to use.
**Speed**

The Speed Options group lets you adjust the quality/speed tradeoff of this plug-in.

- **Quality:** Three options, Full, Half (Faster), and Quarter (Fast), let you choose a suitable tradeoff between image quality and plug-in performance.
- **Horizontal and Vertical Crop:** Crops the shape image being used to influence the bokeh to a smaller size, in the event the large size of the graphic is slowing things down and you can crop out extra black from the edges. You won’t notice a change to the result until you start cropping into the white part of the shape.

**Controls**

The parameters available from the Controls group change depending on the Shape Type you’ve selected.

- **Blur Size/Scale:** Adjusts the overall amount of blur. At higher values, the shape of bokeh can be more clearly seen.
- **Blade Curvature:** (Only available with Real and Creative Apertures) Lets you round off the edges of the Aperture Shape you selected.
- **Rotation:** Lets you adjust the angle the shape appears at.
- **Anamorphism:** Lets you adjust the aspect ratio of this effect in order to match the lens blur created by anamorphic lenses.
- **Chroma Shift:** Lets you simulate chromatic aberration within the blur effect.
- **Highlights:** Lets you adjust how the highlights of the image affect the blur, dilating or eroding the image more or less depending on how high Smooth Strength is.
- **Apodization:** (Only available with Real and Creative Apertures) A slider that lets you adjust the simulated “Airy disk” pattern in the defocused effect being generated. Dragging the slider to the left toward negative values accentuate concentric rings around the bokeh pattern that simulate the effects of optical diffraction and add a pattern to the result, while dragging this slider to the right introduces positive values that gradually filter the edges of the simulated bokeh pattern, resulting in a progressively smoother result.
- **Catadioptric:** (Only available with Real and Creative Apertures) A slider that lets you simulate the effect of a shaped mirror element in a Catadioptric telescope to “improve” focus within the defocused bokeh effect this plug-in produces. At higher and higher values, the underlying image becomes progressively less blurry, while still being distorted by the bokeh shape being used which results in soft image overlays, creating a very different kind of simulated optical defocusing effect.
Mosaic Blur

A simple, pixelated blur suitable for hiding the face of anonymous witnesses.

- **Pixel Frequency:** Lets you adjust the size of each pixel, thus determining the density and resolution of the resulting grid of pixels.
- **Cell Shape:** Lets you adjust the base shape of the mosaic. The options are Square, Hexagon, and Triangle.
- **Aliasing:** Lets you adjust how tightly each cell samples the area underneath it.
- **X Offset:** Shifts the grid left or right.
- **Y Offset:** Shifts the grid up or down.
- **Aspect:** Adjusts the aspect ratio of the cells.
- **Antialias Result:** With this box checked the effect performs extra processing to get cleaner lines between the cells.
- **In Power Windows Only:** Limits the showing of cells to those cells that are completely inside of a window only.

Radial Blur

A blur effect that simulates the motion blur that would occur were the image spinning around its center point.

- **X and Y Position:** Lets you move the center of the blur.
- **Smooth Strength:** Adjusts how much blurring is applied.
- **Blur Type:** When Blur Type is set to Realistic, the blur effect emulates a photographic motion blur. When set to Stylized, the blur effect is a simple and smooth digital blur.
- **Blur Symmetry:** Three options are available.
  - **Symmetric:** The blur effect appears to be created in both directions, with the result being more of a double-image that’s blurring in an arc around the X/Y Position, simulating motion blur in a camera.
  - **Clockwise:** The blur effect appears to be moving in a single, clockwise direction.
  - **Anti-Clockwise:** The blur effect appears to be moving in a single, counter-clockwise direction.
- **Border Type:** Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.
- **Move with Sizing:** Checking this box lets the blur center retain its relative position in the frame if the Input and Editing sizing are changed.
Zoom Blur

A blur effect that simulates the motion blur that would occur were a camera moving toward the image.

— **X and Y Position**: Lets you move the center of the blur.

— **Zoom Amount**: When Blur Type is set to Realistic, this slider becomes bi-directional. The center is 0, or no blur at all. Dragging to the right expands the blur effect outward from the position. Dragging to the left shrinks the image towards the Position, blurring outward from there.

— **Center Exclusion**: Controls the distance from the XY position that the Zoom Blur begins.

— **Blur Type**: When Blur Type is set to Realistic, the blur effect emulates a photographic motion blur. When set to Stylized, the blur effect is a simple and smooth digital blur.

— **Border Type**: Lets you choose how the edges of the image are affected by this blur; options include Black, Replicate, Reflect, and Wrap Around.

— **Move with Sizing**: Checking this box lets the blur center retain its relative position in the frame if the Input and Editing sizing are changed.
Chapter 154

Resolve FX Color

These plug-ins provide color processing methods that aren’t available in any of the Color Page palettes of the Color page and include several color management tools that can be applied outside of Resolve Color Management (RCM).

ACES Transform

Lets you perform the kind of color transforms that the ACES Input Device Transform and ACES Output Device Transform parameters of the Color Management panel do, without the need to have ACEScc or ACEScct enabled.

— **ACES Version:** When you’ve chosen one of the ACES color science options, this pop-up becomes available to let you choose which version of ACES you want to use. As of DaVinci Resolve 15, you can choose from ACES 1.0.3 or ACES 1.1 (the latest version).

— **Input Transform:** This pop-up menu lets you choose which IDT (Input Device Transform) to use to process the image. It presents the same options that are available in the Color Management panel of the Project Settings.

— **Output Transform:** This pop-up menu lets you choose an ODT (Output Device Transform) with which to transform the image data for monitoring on your calibrated display and when exporting a timeline in the Deliver page. It presents the same options that are available in the Color Management panel of the Project Settings.

For more information about the options available in these parameters, see Chapter 9, “Data Levels, Color Management, and ACES."

**NOTE:** This plug-in does ACES transforms correctly using the transforms specified by the Academy, whereas the Color Transform plug-in does transforms to the ACES color space colorimetrically, which is not actually correct for ACES workflows.

Chromatic Adaptation

A Color category plug-in that lets you precisely transform an image that has been lit or processed assuming one specific color temperature to another user-selectable color temperature. This transformation alters the appearance of all colors in the image as perceived by the human vision system in the same way that a new illuminant would, whether that illuminant is a light in the environment being recorded or the color temperature of a display on which the image is shown. This plug-in is useful for performing specific color temperature transformations as part of color management workflows or for setting up precise color temperature adjustments as part of a creative grade.

You control this transformation by using pop-up menus to define the Illuminant Type of the source (typically the color temperature the camera was set to), and that of the target that you want to transform the image to. For both sets of controls, you can choose a Standard Illuminant from a list, a Color Temperature via a slider, or CIE 1931 xy coordinate values. This plug-in also takes into account the current color space and gamma of the clip, which default to the current Timeline Color Space.

This image transform is extremely precise because the image is first transformed from the Timeline Color Space to XYZ, and then it’s transformed to match the LMS (long, medium, short) color space that models the cone response of the human eye to colors lit by different illuminants.
The Method pop-up menu provides a variety of different transform methods to choose from, defaulting to CAT02. Each option in the Method pop-up menu uses different measurement datasets to create individual CAT matrixes to guide this transformation. As a result, each method prioritizes different levels of accuracy for different sets of colors.

For example:

— CAT02 has a non-linear component that compensates for the tendency of extremely saturated blues to go purple, a typical weakness of other methods. It usually gives the best result for the widest variety of measured data sets and works best for emissive sources (displays) and dim viewing environments.

— Bradford Linear is also a commonly used method, albeit one in which extremely saturated blues will go purple during the transform. It works well for both emissive sources in dim environments and for reflective sources (theater screens) and dark environments.

— Von Kries is one of the oldest methods in common use, although it’s also one in which extremely saturated blues will go purple during the transform. This, as well as all other methods, are available if you need to match work done in another image processing application.

**NOTE:** Be aware that all methods listed will match neutral colors perfectly; the only differences lie in how different ranges of saturated color are transformed.

**Color Compressor** *(Studio Version Only)*

This filter lets you compress a range of colors toward a single target color. It works best when applied to similarly colored regions that have been isolated with a secondary qualifier or window. For example, if you’re adjusting an irregularly lit product such as a soda can or a dress that must have a very specific hue, you can isolate that item and use this filter to push the range of Hue, Saturation, and Luminance closer to the ideal color that’s identified using the color picker.

*(Before/After) Using the Even plug-in to compress original range of hues of the jacket into a narrow “target” range within a secondary operation*
— **Target Color:** A color control with an eyedropper button that you choose or sample a single set of Hue/Saturation/Luminance values you want to push all other colors toward.

— **Compress Hue, Compress Saturation, and Compress Luminance:** These sliders let you individually compress the range of colors you’re adjusting in the image to more and more closely match the image. At 0, no compression is applied, at 0.500 the original range of colors in the image have been adjusted to be halfway between their original values and the values of the Target Color, and at 1.000 the original range of colors has been set to be identical to the Target Color.

## Color Space Transform

Lets you perform the kind of color transforms that LUTs do, but instead of using lookup tables, this plug-in uses the same math used by Resolve Color Management (RCM) in order to do extremely clean color transforms without clipping.

### Color Space Transform

Exposes four pop-up menus that let you set an Input Colorspace, Input Gamma, Output Colorspace, and Output Gamma, in order to do controlled transforms from the Input settings to the Output settings, right within a grade. Resolve Color Management does not have to be enabled for you to use this filter.

### Tone Mapping

Tone Mapping Method lets you enable tone mapping to accommodate workflows where you need to transform one color space into another with a dramatically larger or smaller dynamic range by automating an expansion or contraction of image contrast in such a way as to give a pleasing result with no clipping.

— **None:** This setting disables Input DRT Tone Mapping. No tone mapping is applied to the Input to Timeline Color Space conversion at all, resulting in a simple 1:1 mapping to the Timeline Color Space.

— **Clip:** Hard clips all out-of-bounds values.

— **Simple:** Uses a simple curve to perform this transformation, compressing or expanding the highlights and/or shadows of the timeline dynamic range to better fit the output dynamic range. Note that the “Simple” option maps between approximately 5500 nits and 100 nits, so if you’re mapping from an HDR source with more than 5500 nits to an SDR destination there may still be some clipping of the highlights above 5500 nits.

— **Luminance Mapping:** Same as DaVinci, but more accurate when the Input Color Space of all your media is in a single standards-based color space, such as Rec. 709 or Rec. 2020.

— **DaVinci:** This option tone maps the transform with a smooth luminance roll-off in the shadows and highlights, and controlled desaturation of image values in the very brightest and darkest parts of the image. This setting is particularly useful for wide-gamut camera media and is a good setting to use when mixing media from different cameras.

— **Saturation Preserving:** This option has a smooth luminance roll-off in the shadows and highlights, but does so without desaturating dark shadows and bright highlights, so this is an effective option for colorists who like to push color harder. However, because over-saturation in the highlights of the image can look unnatural, two parameters are exposed to provide some user-adjustable automated desaturation.
— **Sat. Rolloff Start:** Lets you set a threshold, in nits (cd/m²), at which saturation will roll off along with highlight luminance. Beginning of the rolloff.

— **Sat. Rolloff Limit:** Lets you set a threshold, in nits (cd/m²), at which the image will be totally desaturated. End of the rolloff.

— **Use Custom Max Input / Output:** Checking these boxes and adjusting the slider below allows you to specify the minimum and maximum luminance of the input image in nits. Using these two sliders together, you can set which value from the Input Gamma is mapped to which value of the Output Gamma.

— **Adaptation:** Used to compensate for large differences in the viewer’s state of visual adaptation when viewing a bright image on an HDR display versus seeing that same image on an SDR display. For most “average” images this setting works best set between 0–10. However, when you’re converting very bright images (for example, a snow scene at noon), then using a higher value will yield more image detail within the highlights.

## Gamut Mapping

The Color Space Transform plug-in provides Gamut Mapping controls to accommodate workflows where you need to transform one color space into another that has a dramatically larger or smaller gamut. These controls are similar to those found in the Color Management panel of the Project Settings.

Tone Mapping Method lets you enable tone mapping to accommodate workflows where you need to transform one color space into another with a dramatically larger or smaller dynamic range by automating an expansion or contraction of image contrast in such a way as to give a pleasing result with no clipping. There are three options, None, Simple, and Luminance Mapping.

— Choosing None results in no tone mapping at all.

— Choosing “Simple” uses a simple curve to perform this transformation, compressing or expanding the highlights and/or shadows of the timeline dynamic range to better fit the output dynamic range. Note that the “Simple” option maps between approximately 5500 nits and 100 nits, so if you’re mapping from an HDR source with more than 5500 nits to an SDR destination there may still be some clipping of the highlights above 5500 nits.

— Choosing “Luminance Mapping” lets you use a customized curve operation to remap the gamma of the image and enables the Max. Input Luminance, Max. Output Luminance, and Avg. Input Luminance sliders.

— The Max. Input (nits) checkbox and slider lets you set the reference maximum Luminance value (in nits) that you want to remap to the value set by the Max. Output (nits) checkbox and slider, which governs the maximum luminance level of the Output color space (in nits). Using these two sliders together, you can set which value from the Input Gamma is mapped to which value of the Output Gamma.

— The Adaptation slider is designed to compensate for large differences in the viewer’s state of visual adaptation when viewing a bright image on an HDR display versus seeing that same image on an SDR display. For most “average” images this setting works best set between 0–10. However, when you’re converting very bright images (for example, a snow scene at noon), then using a higher value will yield more image detail within the highlights.

— Choosing “Clip” hard clips all out-of-bounds values.
— Gamut Mapping Method accommodates workflows where you need to transform one color space into another with a dramatically larger or smaller gamut by helping to automate an expansion or contraction of image saturation in such a way as to give a pleasing and naturalistic result with no clipping.
— Choosing None results in no Gamut mapping at all.
— Choosing Saturation Mapping from this menu enables saturation mapping to fit the range of saturation values from the Input Color Space and Gamma into the Output Color Space and Gamma. It enables the Saturation Knee and Saturation Max. controls.
— The Saturation Knee slider sets the image level at which saturation mapping begins. Below this level, no remapping is applied. All saturation values from this level on up are remapped according to the Saturation Max. slider. A value of 1.0 is maximum saturation in the currently selected output color space.
— The Saturation Max slider sets the new maximum level to which you want to either raise or lower all saturation values that are above the Saturation Knee setting. A value of 1.0 is maximum saturation in the currently selected output color space.
— Choosing "Clip" hard clips all out-of-gamut values.

**NOTE:** While this plug-in has ACES settings, it does transforms to the ACES color space colormetrically, which is not actually correct for ACES workflows. For actual ACES workflows, use the ACES Transform plug-in, which uses transforms specified by the Academy.

**Advanced**
This drop-down menu exposes the advanced features of the Color Space Transform effect.
— **Use white point adaptation:** Applies a chromatic adaptation transform to account for different white points between color spaces.
— Uncheck this box if you simply want to view the input color space’s white point unaltered in the output color space. For example, wanting to use a P3-D60 mastered clip inside a P3-D65 timeline for reference purposes.
— Check this box to apply the chromatic adaptation transform to convert the input white point to match the output color space’s white point. For example, wanting a P3-D60 mastered clip to cut in with other clips mastered in a P3-D65 timeline.

**Color Stabilizer** *(Studio Version Only)*
Designed to deal with clips that have inconsistencies in exposure and color, caused by manual changes to a lens’ aperture setting or by a camera’s auto exposure settings causing unwanted changes to color and brightness in the middle of a shot. The Color Stabilizer plug-in analyzes a frame of the clip that represents the desired exposure and color, and automatically adjusts every other frame of the current clip to match the analyzed levels.
The Color Stabilizer gives you the best results with clips that don’t have clipped highlights. When used in the Color page, it’s recommended to grade the image to bring all the highlights you want somewhere at or under a value of 1023, and then apply the Color Stabilizer to a node after this adjustment.

**There are two ways of using the Color Stabilizer:**

— The easiest way is to choose Entire Frame from the Region For Analysis pop-up menu. Then, move the playhead in the Viewer to the frame that represents the contrast and color you want the entire clip to have, and click the Analyze This Frame. Now, if you play through the clip, changes in contrast and color should be gone. This method works best for clips where the inconsistency you’re trying to eliminate is fairly uniform, affecting the entire picture.

— Another way is to choose Overlay Rectangle from the Region For Analysis pop-up menu. This causes an onscreen rectangle to appear that you can resize and position over a specific region you want to sample for the duration of the clip. If the selected feature you’re analyzing is moving, then you can use the FX Tracker to track the subject so the selection box follows it (this is important for a consistent result). Once this is set up, move the playhead in the Viewer to the frame that represents the contrast and color you want the entire clip to have, and click the Analyze This Frame. Now, if you play through the clip, changes in contrast and color should be gone. This method works best for clips where there are parts of the picture that are supposed to have a change in brightness or color, such as when something moves into the frame, or a reflected highlight comes and goes because of the lighting scheme, at the same time as an otherwise undesirable change in contrast or color. You can use the selection box to specifically analyze the part of the frame that has the unwanted exposure change, while ignoring the desirable exposure change.

Depending on what option you choose from the Region for Analysis pop-up menu, different additional options appear.

**Analysis Region**

If you choose “Entire Frame” from the Region For Analysis pop-up, these controls don’t appear. A set of Source X/Y Position and Source Width/Height parameters let you transform the selection box that defines which part of the image is being analyzed.

**Channels to Stabilize**

Once you’ve analyzed the frame that represents the best contrast and color for that clip, the Channels to Stabilize controls let you choose how you want to handle making the correction. The What to Stabilize pop-up menu lets you choose between stabilizing White Balance and Brightness, or R, G, B Channels Separately.

— If you choose White Balance and Brightness, two checkboxes let you choose whether or not you want to include Stabilize White Balance and Stabilize Brightness independently from one another.

— If you choose R, G, B channels separately, three checkboxes appear letting for Stabilize Red, Green, and Blue Channel, so you can pick which particular channels you want to correct.
The “Stabilize Levels How” pop-up lets you choose how to make the correction, with options to Match Levels and Contrast, Lift to Consistent Level, Gain to Consistent Level, each of which uses a subtly different method to make the necessary correction, so if one method doesn’t work for the particular problem your clip is exhibiting, you can try the other methods to try and get a better result.

**Captured Analysis Values**

Once you’ve analyzed the frame, another set of parameters appear showing the captured analysis values upon which the automated correction is based, so that you can make manual adjustments if necessary to improve the result. The parameters that are shown depend on the option you chose from the What to Stabilize pop-up menu.

- If you chose White Balance and Brightness, then you’ll have a Normalized White Balance color control, and Low Level and High Level sliders.
- If you chose R, G, B Channels Separately, then you’ll have Red, Green, and Blue High and Low Level sliders.

**Contrast Pop (Studio Version Only)**

A more extreme and selective version of the Midtone Detail control found in the Color Wheels palette, designed to add either sharp high-contrast looks, or soft low-contrast looks to a selective portion of the tonal range of the image.

- **Detail Amount:** Lets you choose how much of this effect to apply. At 0, no effect is applied. At positive values progressively sharper contrast is added, while at negative values progressively softer low-contrast is applied.
- **Detail Size:** Lets you choose which structures of the image are affected by this localized contrast adjustment, from smaller to larger.
- **Low and High Threshold:** These values let you define what range of image tonality is affected by this filter, allowing you to omit either shadows or highlights from this operation.
- **Softness:** Lets you soften the transition between the affected and unaffected areas of the image.

**DCTL (Studio Version Only)**

Lets you apply a DCTL wherever you can apply ResolveFX plug-ins. For more information on DCTLs and where they’re installed, see Chapter 191, “Creating DCTL LUTs.”

- **DCTL List:** A pop-up that lets you choose from the available DCTLs installed on your workstation.
- **Reload DCTL:** A button that lets you refresh the DCTL list pop-up if you’ve installed new DCTLs while DaVinci Resolve is running.
Dehaze (Studio Version Only)

Designed to let you make fast, selective adjustments to color and contrast to reduce the visible effects of smog, airlight, and haze in an image. This filter automatically generates a simulated depth matte which is used to apply more of this corrective color adjustment to faraway parts of the image that would be more affected by haze effects and less color adjustment to closeup parts of the image. However, the simulated depth mask is not going to be perfect, so additional controls exist to let you make adjustments to it to achieve a better result.

— **Dehaze Strength**: This slider applies a simultaneous color and contrast adjustment. Raising Dehaze Strength subtly increases contrast (especially in the shadows) while rebalancing color toward the complement of the currently selected Haze Color and selectively intensifying saturation. Lowering Dehaze Strength decreases contrast and rebalances color toward the selected Haze Color itself while selectively lowering saturation.

— **Haze Color**: A color control with an eyedropper button that you choose or sample the color of smog, airlight, or haze in an image that you want to minimize.

— **Display Depth**: Lets you view the simulated depth matte that’s being generated. It’s useful to turn this on before adjusting the Shadow and Highlight controls below.

— **Shadow**: This slider raises or lowers darkest parts of the simulated depth mask that defines the parts of the image that are supposedly farthest away.

— **Highlight**: This slider lets you raise or lower the lightest parts of the simulated depth mask that defines the parts of the image that are supposedly closest to us.

Despill

Removes the color cast on a subject caused by the reflection of light off the green or blue screen. This color cast remains even though the green screen has been keyed out. This stand alone Despill filter is useful for reducing spill from footage that has already been keyed (matted, rotoscoped, etc.), where you don’t want to redo the key itself. It’s also a useful addition to other keying plug-ins that don’t have a Despill function.
The Despill FX removing a green color cast from the subject’s arms and hair. Above is no despill and below is full despill.

— **Key Color:** Sets the color cast to be removed from the subject. The choices currently are Red, Green, and Blue.
— **Strength:** The amount of Despill to apply. 1.000 is the full despill “on” amount used in the older version of the 3D keyer checkbox. Variable strength comes in handy as you can preserve more of the original color information if the context allows it. For example, depending on your color correction, you may get better despill results at a strength values less than 1.000.

**False Color** *(Studio Version Only)*

False Color is a creative effect that can be used for replicating camera HUDs, infrared sensors, and custom posterization looks by defining a set number of colors for the clip. The color set can either match the False Color setting in a specific Blackmagic Design camera or be picked from a list of creative style presets. The presets can be modified by setting the number of colors used and defining the tonal range each color represents.

Resolve FX False Color thermal preset and legend
General

— **Plugin Mode**: This menu is used to switch between using a specific Blackmagic Design Camera’s False Color setting or accessing creative presets. When Specific Camera Model is chosen, the Camera Model section is displayed for selecting the camera and settings you want to use. When Creative is chosen, the Color bands section is displayed for choosing and customizing the preset.

Camera Model

The Camera Model controls are displayed when Specific Camera Model is chosen from the Plugin Model menu. These menus allow you to match the False Color from a camera configuration.

— **Camera**: Selects the exact Blackmagic Design camera sensor.
— **Camera Mode**: Selects the dynamic range setting.
— **ISO Level**: Sets the ISO or light sensitivity setting.

Color Bands

These controls are displayed when Creative is chosen from the Plugin Model menu. The Color Bands group of controls are used to select and modify the appearance of the False Color presets.

— **Camera**: Selects the exact Blackmagic Design camera sensor.
— **Camera Mode**: Selects the dynamic range setting.
— **ISO Level**: Sets the ISO or light sensitivity setting.

Preprocessing

This group of controls is used to apply tonal and blur processing to the image.

— **Blur**: Applies a blur filter to the False Color.
— **Black Level**: Increases or decreases the shadow range assigned to colors that fall lower on the False Color legend.
— **White Level**: Increases or decreases the highlight range assigned to colors that fall higher on the False Color legend.
— **Gamma**: Shifts the mid-tone range towards colors that fall lower or higher on the False Color legend.

Scale/Legend

This section is used to control the visibility and appearance of the False Color legend. The Legend is displayed to help viewers understand the color representation. Whenever you apply False Color, the Legend is generated and displayed. When you modify a preset, the Legend automatically updates to represent the new color scheme.

— **Show Scale**: Shows or hides the Legend on the left side of the frame.
— **Show Values**: Shows or hides numeric values on the Legend. These numeric values represent different scales based on the Value Style menu.
— **Show Labels**: Shows or hides data point labels on the Legend. The labels identify important data points along the tonal range, such as black clipping, white clipping, and middle gray.
— **Contrast:** Increases or decreases the transparency of the Legend’s background underlay.
— **Value Detail:** Increases or decreases the number of axis value labels displayed on the Legend.
— **Value Style:** This menu includes three options for the scale used for the Legend’s numeric values.
  — **Percentage:** Uses a percentage scale for the Legend, going from 0% at the bottom to 100% at the top.
  — **Hundredths:** Uses a Hundredths scale for the Legend, going from 0 at the bottom to 100 at the top.
  — **Normalized:** Uses a Normalized scale for the Legend, going from 0.0 at the bottom to 1.0 at the top.

**Global Blend**

— **Blend:** Lets you dissolve between the image with no False Color applied (0.0) and the image with False Color fully applied (1.0).

**Flicker Addition**

Why remove flicker with the Resolve FX Flicker Removal plug-in when you can add it instead? Found in the Resolve FX Transform category, the Flicker Addition plug-in adds rapidly animated exposure changes to make the image appear to flicker, creating animated effects that would be difficult to keyframe manually. When applied to an image in different ways, this plug-in can be used to simulate torchlight, firelight, light fixtures with old ballasts or frayed wiring, or any temporally unstable light source. For example, you could key only the highlights of a night-time image, and use Flicker Addition to affect those isolated highlights.

Two groups of controls let you control the quality of this flickering.

**Main Controls**

These controls let you choose how to apply the flicker, and its overall speed and intensity.

— **Flicker Type:** This pop-up menu lets you apply the flicker as a Lift, Gamma, Gain, or Vignette adjustment.
— **Range slider:** This lets you set how widely the flickering will vary.
— **Speed:** This lets you adjust how quickly the flickering is animated.
— **Smoothness:** This slider lets you adjust the temporal quality of the flickering, whether it changes abruptly from one value to another (at lower settings) or whether it makes more continuous transitions from one value to another (at higher settings).
— **Flicker R, G, B Channels:** Three checkboxes let you choose which color channels are affected by this flickering.
**Flicker Quality**

These controls let you adjust the details of how the flickering animates.

— **Randomness Scale**: This slider lets you introduce irregularity to the Horizontal, Vertical, and Rotational motion of the camera shake. The greater this value, the more irregularity will be introduced.

— **Pause Length**: This slider lets you adjust the frequency of intermittent pauses that break up the random motion added by this filter.

— **Pause Interval**: This slider lets you adjust the duration of intermittent pauses that break up the random motion added by this filter.

— **Pause Randomness**: This lets you add a degree of randomness to the intervals that happen.

— **Random Seed**: This slider lets you alter the value that sets what random values are being produced. Identical values result in identical randomness.

**Gamut Limiter**

Lets you limit the gamut to a specified standard. Useful in situations where the delivery color space is a large gamut such as Rec. 2020, but the QC specification requires limiting to a smaller gamut such as P3, in order to limit the amount of saturation allowable in the final output. This is a limiting operation, so out of bounds values are hard clipped. This plug-in can be used regardless of whether or not Resolve Color Management is enabled. Because it’s a limiter, it should probably be one of the last operations in any node tree to prevent useful image data from being clipped.

— **Current Gamut**: Choose the timeline gamut currently being used by the image.

— **Current Gamma**: Choose the timeline gamma currently being used by the image.

— **Limit Gamma to**: Choose the gamut you want to restrict the image to here.

These menus present the same options as the Resolve Color Management menus in the Color Management panel. For more information about the options available in these parameters, see Chapter 9, “Data Levels, Color Management, and ACES.”

**Gamut Mapping (Studio Version Only)**

The Color Space Transform plug-in provides Gamut Mapping controls to accommodate workflows where you need to transform one color space into another that has a dramatically larger or smaller gamut. These controls are identical to those found in the Color Space Transform plug-in’s Gamut Mapping group and are similar to those found in the Color Management panel of the Project Settings.

— **Gamma**: A pop-up menu lets you specify what type of gamma the clip is supposed to have, so set this to whatever matches that image (this may match the timeline color space, but it depends on how you’re working).
— **Tone Mapping Method:** Lets you enable tone mapping, to accommodate workflows where you need to transform one color space into another with a dramatically larger or smaller dynamic range by automating an expansion or contraction of image contrast in such a way as to give a pleasing result with no clipping.

— **None:** This setting disables Input DRT Tone Mapping. No tone mapping is applied to the Input to Timeline Color Space conversion at all, resulting in a simple 1:1 mapping to the Timeline Color Space.

— **Clip:** Hard clips all out-of-bounds values.

— **Simple:** Uses a simple curve to perform this transformation, compressing or expanding the highlights and/or shadows of the timeline dynamic range to better fit the output dynamic range. Note that the "Simple" option maps between approximately 5500 nits and 100 nits, so if you’re mapping from an HDR source with more than 5500 nits to an SDR destination there may still be some clipping of the highlights above 5500 nits.

— **Luminance Mapping:** Same as DaVinci, but more accurate when the Input Color Space of all your media is in a single standards-based color space, such as Rec. 709 or Rec. 2020.

— **DaVinci:** This option tone maps the transform with a smooth luminance roll-off in the shadows and highlights, and controlled desaturation of image values in the very brightest and darkest parts of the image. This setting is particularly useful for wide-gamut camera media and is a good setting to use when mixing media from different cameras.

— **Saturation Preserving:** This option has a smooth luminance roll-off in the shadows and highlights, but does so without desaturating dark shadows and bright highlights, so this is an effective option for colorists who like to push color harder. However, because over-saturation in the highlights of the image can look unnatural, two parameters are exposed to provide some user-adjustable automated desaturation.

— **Sat. Rolloff Start:** Lets you set a threshold, in nits (cd/m2), at which saturation will roll off along with highlight luminance. Beginning of the rolloff.

— **Sat. Rolloff Limit:** Lets you set a threshold, in nits (cd/m2), at which the image will be totally desaturated. End of the rolloff.

— **Use Custom Max Input / Output:** Checking these boxes and adjusting the slider below allows you to specify the minimum and maximum luminance of the input image in nits. Using these two sliders together, you can set which value from the Input Gamma is mapped to which value of the Output Gamma.

— **Avg. Input Luminance:** Used to compensate for large differences in the viewer’s state of visual adaptation when viewing a bright image on an HDR display versus seeing that same image on an SDR display. For most “average” images this setting works best set between 0–10. However, when you’re converting very bright images (for example, a snow scene at noon), then using a higher value will yield more image detail within the highlights.
— **Gamut Mapping Method:** Accommodates workflows where you need to transform one color space into another with a dramatically larger or smaller gamut by helping to automate an expansion or contraction of image saturation in such a way as to give a pleasing and naturalistic result with no clipping. Choosing Saturation Mapping lets you remap the saturation values of the image. It enables the Saturation Knee and Saturation Max. controls.

— The Saturation Knee slider sets the image level at which saturation mapping begins. Below this level, no remapping is applied. All saturation values from this level on up are remapped according to the Saturation Max. slider. A value of 1.0 is maximum saturation in the currently selected output color space.

— The Saturation Max slider sets the new maximum level to which you want to either raise or lower all saturation values that are above the Saturation Knee setting. A value of 1.0 is maximum saturation in the currently selected output color space.

### Invert Color

A Color category plug-in that lets you invert any color channel, including the alpha channel. This little plug-in has 101 uses in advanced workflows, especially when you need to invert Alpha or Key channels to do something specific. This is not a “film negative” plug-in; this is a simple inversion.
Chapter 155

Resolve FX Generate

These plug-ins generate imagery that can be used within grades and composites in different ways.

Contents

Color Generator 3290
Color Palette (Studio Version Only) 3290
Grid 3290
General 3290
Line Properties 3291
Color Generator

Generates a single color using a color picker control. Useful in conjunction with a layer node’s ability to mix a color with an image using different composite modes.

- **Color picker:** You can click the color picker and use the resulting color controls to choose a color to be generated.
- **Eyedropper:** You can also click the eyedropper to sample a color from the image in the Viewer; the eyedropper always samples the image from the input of the current node, regardless of how the current image looks.

Color Palette *(Studio Version Only)*

More of an analysis tool than a creative effect, this plug-in offers four Display modes from the pop-up menu at top: Color Palette, Shadow Region, Midtone Region, and Highlight Region.

- **Display Mode:** A pop-up that provides four different options.
  - **Color Palette:** By default this displays the eight most dominant colors in the image as rectangular swatches along the bottom, and the eight most dominant colors in each of the three main zones of image tonality (shadow, midtone, highlight) are displayed as smaller rectangular patches just above. This lets you see, at a glance, the color palette of any given shot, and this can be output for intrepid art directors who find it useful.
  - **Shadow Region, Midtone Region, or Highlight Region:** Displays a visual preview of which parts of the image fall into which regions (as currently defined by the Shadow and Highlight Threshold sliders). These previews are displayed with the current tonal region appearing saturated and all other parts of the image appearing black.

- **Number of Colors:** Defines the number of isolated colors. This can be set to display anywhere from 8 to 24 patches.
- **Shadow and Highlight Threshold:** The definition of where shadows, midtones, and highlights end and begin is controlled by the Shadow and Highlight Threshold sliders.

Grid

As the name implies, this plug-in generates a grid with two sets of properties.

General

These controls let you adjust the overall density and orientation of the grid.

- **Row Cells and Column Cells:** These sliders let you choose how many cells to divide the grid into, both vertically and horizontally.
- **Pan, Tilt, Zoom, Rotate, Width, Height, ShearX, ShearY, Pitch, and Yaw:** These controls let you transform the grid to serve whatever purpose is necessary.
Line Properties

These controls let you control the properties of the grid lines themselves.

— **Line Color**: This color picker control and accompanying eyedropper let you choose a color with which to draw the grid.

— **Individual Hor. Line Width and Ver. Line Width**: These sliders let you adjust the thickness of all horizontal or all vertical lines.

— **Major Line Spacing**: This slider lets you set every nth line to be thicker, while the Major Line Width control lets you choose how thick to make these major lines.
Chapter 156

Resolve FX Key

DaVinci Resolve includes several Resolve FX dedicated to compositing and keying tasks that are applied directly on the Timeline.

HSL Keyer  3299
3D Keyer

Based on the 3D Qualifier in the Color page, the 3D Keyer offers a fast, simple way of pulling a key to isolate a range of color in the image by dragging your mouse pointer over the parts of the image you want to key. Each time you drag over the image you add to or subtract from the cloud of values you’re carving out of a three-dimensional representation of all available colors; you don’t see this representation, but this “under the hood” functionality is what gives the 3D Keyer its name.

**TIP:** If you’re looking to isolate a range of luma values in the image, you should use the HSL or Luma keyer.

The 3D Keyer is a good one to start with if you’re trying to key a blue screen or green screen background. Its interface of dragging the mouse pointer over the screen color you want to remove, coupled with its high quality and extreme specificity, makes it a fast and accurate tool to use in a variety of circumstances. The 3D Keyer’s greatest strength is the speed with which you can sample areas of the picture to extract from the final key. However, this can also be a weakness if your initial samples aren’t giving you satisfactory results because, unlike the Delta Keyer in the Fusion page, there aren’t many ways to fine-tune the key as it’s being generated. On the other hand, for well-lit subjects you want to key, two or three samples is all you need.

**Selection Range Controls**

The 3D Keyer Selection Range controls

The Selection Range buttons in the Inspector let you define a key by sampling pixels in the Viewer with the mouse pointer.

- **Picker:** Chooses the initial color to qualify. Longer strokes will tend to give you a better key. In the Edit page, the Timeline Viewer Overlay must be set to Open FX.
- **Picker -:** Removes a color region from the qualifier; also available by holding down the Option key.
- **Picker +:** Chooses an additional color region to add to the initial qualifier.
- **Invert:** Inverts the current key; qualified areas are then unqualified and vice versa.
- **Stroke:** Stores the list of picked (+) and unpicked (-) colors, along with their respective RGB values.
- **Delete Stroke:** Deletes the current stroke selected in the Stroke drop-down menu.
- **Reset:** Deletes all strokes and resets the 3D Keyer to its default state.
** Behaviour Options **

These controls adjust the fundamental parameters and modes of the 3D Keyer.

— **Colorspace**: This drop-down menu lets you choose whether you’re sampling colors in YUV, HSL, HSP, or LAB colorspaces. YUV is the default, but if you find you’re not getting satisfactory results, you can choose another colorspace from the drop-down menu to see if that works any better.

— **Soft**: Provides a softer edge to the key that is more forgiving of Chroma and Luma adjustments. The more gentle drop-off is suitable for situations like subtle light changes across a face. Use the Shadow / Midtone / Highlight Matte Finesse controls in conjunction with this mode to fine tune the result.

— **Flat**: The default mode. Each color selected is 100% keyed, and adjustments are made for small color variations. This is the ideal mode for chroma keying a green or blue screen. Additionally, turning up the Pre-Filter setting in the Matte Finesse controls can make for a smoother, flatter key.

— **Tight**: Only keys the exact color picked, and does not apply any softening based on color ranges. You chose that exact color, and only that exact color. Single pixel sharpness levels are expected. This can be used for difficult keying jobs, requiring adjusting the filter and softness manually in the Matte Finesse Controls.

— **Luma**: Functions similar to the Tight setting, but ignores all chroma data. This mode is used for black and white footage.

— **Despill**: If you’re using the 3D qualifier to pull a blue or green screen key to create transparency, this slider lets you adjust an automatic color correction that eliminates blue or green spill from the image, while retaining the image’s original color.

**Usage Options**

The Key Map, shown in the upper left, showing a qualifier that attempts to select the sand in the background (blue lines), while deselecting the pirate’s hats (red lines)

These settings control the user feedback tools from the 3D Keyer in the Viewer. In the Edit page, the Timeline Viewer Overlay must be set to Open FX.
Show Paths: A checkbox that lets you turn the visibility of the lines you’re drawing to sample the image on and off. Turning lines off does not affect the key in any way.

Smart Show Paths: With this checkbox enabled, the lines will only be visible as they are being drawn, and disappear when the mouse button is released.

Auto-B/W Highlight: With this checkbox enabled, the Viewer automatically switches to Highlight B/W mode while drawing a line, to better show you the resulting key in real time. When the button is released the Viewer will switch back to its original viewing mode.

Show Key Map: Check this box to show the Key Map in the Viewer. The Key Map is composed of the Color Space box, and the Brightness Range. The Color Space box is laid out roughly in the same manner as the Color Wheels, with primary colors laid out around its edge. The exact colors and layout is determined by the Color Space that you choose in the 3D Keyer. The Brightness Range is represented as a bar underneath the Color Space, with left being black and right being white. Inside the Color Space and Brightness Range lie the individual colors that you chose with the pickers in the Strokes List.

Key Map Zoom: Controls the zoom level of the Key Map, so you can see finer detail, if necessary.

Key Adjustments

This set of tools allows you to manually adjust the parameters of the actual key. Feedback from these tools can be seen in the Key Map overlay in the Viewer.

Chroma Tolerance: Click and drag left and right to expand or contract the range of colors selected by the key.

Chroma Softness: Click and drag left and right to change the sensitivity to similar colors selected by the key. This determines whether the key is a hard cutoff or a soft selection of similar colors.

Adaptive Chroma Softness: Checking this box allows the keyer to operate consistently in both highly saturated and desaturated regions of the image at the same time. The majority of the time you will want to leave this on. The exception is if you are having difficulty in manually adjusting chroma softness in Soft or Flat mode, then turning Adaptive Chroma Softness off will give you more range to work with. Adaptive Chroma Softness is automatically disabled in Tight and Luma modes as it is contrary to those mode’s functionality.

Luma Dark: Expands or contracts the dark areas of the key in the brightness range.

Luma Light: Expands or contracts the bright areas of the key in the brightness range.

Dark Softness: Controls how well defined the low end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

Light Softness: Controls how well defined the high end of the brightness range is. This determines whether the key is a hard cutoff or a soft selection of similar brightness levels.

Chroma Rotate: Moves your selected color region within the color space, changing its chroma based on its rotation around the central origin point.

Chroma Tilt: Moves your selected color region within the color space, changing its chroma based on its vertical position.

Chroma Shift: Moves your selected color region within the color space, changing its chroma based on its horizontal position.
**TIP:** All of the parameters above are key-framable, allowing you to animate the key over time. For example, you may have qualified a shirt where the actor walks through different colored light in a scene. By key framing the parameters above, you can hold the same key on the shirt as it changes colors in the actual scene.

---

**Matte Finesse**

You may find that sampling the screen color is not enough to overcome some problems. Issues such as chattery edges, holes, or noisy bits can sometimes be easily fixed using the Matte Finesse controls. These controls filter the output of the Keyer and are adjustments that are made to the matte itself, so they may work well in some instances and poorly in others, depending on what you’re trying to do. The Matte Finesse tools are split into two banks of controls labeled 1 and 2.

— **Pre Filter:** This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.

— **Clean Black:** Clean Black is a specialized operation that eliminates noise (seen as white speckling when viewing a high-contrast highlight) in the black area of a key that omits the regions of the image you don't want to isolate, and shrinks the key by making the dark parts of a key darker the higher you raise this parameter, pushing dark gray areas of the key toward black. The practical result is that raising Clean Black lets you “fill holes” in the background portion of a key and erode translucent edges.

— **Clean White:** Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that include areas of the image you’re isolating, and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you “fill holes” in the foreground portion of a key and grow translucent edges.

— **Black Clip:** Raising Black Clip applies a “lift” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward black. The range is 0 to 100, with 0 being the default setting.

— **White Clip:** Lowering White Clip applies a “gain” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward white. The range is 0 to 100, with 100 being the default setting.

— **Blur Radius:** In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you’re keying, with the result being a visible “halo” around your subject, depending on the adjustment you’re making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.

— **In/Out Ratio:** Controls whether the “Blur Radius” is applied equally to the inside and outside of the edge of the matte (zero), applied only within the matte (negative values), or applied only outside the matte (positive values). Using In/Out Ratio can help eliminate fringing when using the Blur Radius parameter. However, you can also use In/Out Ratio even in situations where no Blur Radius is applied at all. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.
— **Morph Operation:** This menu lets you choose how you want to modify the Alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.

— **Morph Radius:** Adjusts how much to shrink, grow, open, or close the key.

— **Shadow:** Adjusts key strength based on the darker parts of the original image.

— **Midtone:** Adjusts key strength based on the midtones of the original image.

— **Highlight:** Adjusts key strength based on the brighter parts of the original image.

— **Post Filter:** Performs a final clean-up of the key, using the original image for reference; useful for bringing back some fine detail in sharp edges or hair.

**Garbage Matte**

These controls let you crop out unwanted things in the frame that are also being keyed, such as lighting fixtures, boom microphones, tracking patches, etc.

— **Matte Shape:** You can choose either a Rectangle or Ellipse with which to crop around the subject you’re keying. Choosing None turns off Garbage Matte. When a garbage matte is enabled, the Open FX Overlay mode of the Viewer shows an on-screen control for adjusting the shape and position of the garbage matte.

— **Edge Softness:** Lets you soften the edges. Defaults to 50; the range is 0 (no softening) to 100 (maximum softening).

— **Invert:** Inverts the garbage matte.

— **Center X and Y:** Lets you adjust and keyframe the position of a garbage matte.

— **Bounding Width and Height:** Lets you adjust the width and height of the garbage matte.

— **Rotation:** Lets you adjust the angle of the garbage matte.

**Output**

The Output controls let you choose how the image is output, composited, and displayed in the Viewer.

— **Output:** This menu offers three options for which channels are output from the effect.

— **Alpha Highlight:** Displays the transparent part of an alpha channel as gray and the solid part of an alpha channel in full color.

— **Alpha Highlight B/W:** Displays the black and white alpha channel, which is often helpful when sampling additional areas to key.

— **Final Composite:** The keyed image is displayed composited over any video track below it.

— **Use Alpha:** A common control in many Resolve FX and 3rd party Open FX plug-ins; this checkbox determines if the alpha channel is used when compositing over another video track. It can be used instead of choosing RGB Only (Blank Alpha) from the Output menu.

**To use the 3D Keyer in the Edit page:**

1. Apply the 3D Keyer to a green screen or blue screen clip that’s on a higher track than the background.

2. In the Inspector, enable the Show Paths checkbox to view the sampled areas once you begin.
3 From the Viewer Overlay menu in the lower-left corner of the Timeline Viewer, choose Open FX Overlays.
4 In the Viewer, click and drag to draw a sampling stroke across the screen color you want to remove.
5 The transparency immediately takes effect, showing the keyed subject against whatever clip appears on the video track underneath it in the Timeline as a composite. To see the matte you created for further adjustment, choose Alpha Highlight or Alpha Highlight B/W from the Output drop-down menu.
6 If necessary, you can add or subtract areas from the screen color selection using the add/subtract Color range controls. Alternatively, with the default Sample eyedropper selected, you can hold down Shift to add to the screen color selection or hold down the Option key to remove from the screen color selection.

Ordinarily, it’s a good idea not to select more than two or three times. If you make too many selections in the image, the result can be a key with hard, jagged edges that can sometimes be more difficult to adjust later on.

**Alpha Matte Shrink and Grow**
*(Studio Version Only)*

This filter lets you refine the edges of alpha and key mattes in a variety of ways, shrinking and growing the edges, and opening and closing holes that appear within a matte. In the Color page, this filter can be applied to Qualifier or Window keys that have been routed to the RGB input of a corrector node, for adjustment and refinement, before connecting the result to the key input of a subsequent node for use isolating an adjustment.

![Applying the Alpha Matte Shrink and Grow filter to a key matte that’s fed to the RGB input of a separate node](image)

— **Operation:** A drop-down menu lets you choose how you want to modify the alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes within the key to clean up a ragged matte.

— **Operator Shape:** A drop-down menu lets you choose how corners and angles in the edges of the key are handled when you grow or shrink it. Circle is the default, and results in even expansion around the surface of the key that eventually averages all angles into a circular shape if you use extreme Radius settings. Square averages all angles into a more rectangular shape if you use extreme Radius settings. Diamond averages all angles into a diamond shape if you use extreme Radius settings.
— **Operator Radius**: A slider adjusts how much to Shrink, Grow, Open, or Close the key.
— **Repeat Operation**: A slider alters the effect of the Operator Radius setting to create more extreme adjustments.

## HSL Keyer

Based on the HSL Qualifier in the Color page, the HSL Keyer is a general-purpose keyer that uses three color components, hue, saturation, and luma, to define a key. In many instances, the HSL Keyer is not as immediately accurate as the 3D Keyer and will include a broader portion of the image for any given sample. On the other hand, if the 3D Keyer is not giving you satisfactory results for a particular shot, the HSL Keyer can sometimes do a better job. The HSL Keyer also gives you the option of disabling color components that you don’t want to contribute to the final key. You can pull a saturation-only key, or a hue-only key, for instances where that may solve the issue at hand.

The most straightforward way to use any keyer is to sample the image in the Viewer. When you sample one or more pixels, the hue, saturation, and luma values are analyzed and set different ranges. There are several eyedropper controls available to sample color and soften the selection.

### Selection Range Controls

The Selection Range buttons in the Inspector let you define a key by sampling and softening pixels in the Viewer with the mouse pointer.

![HSL Keyer Color Range controls](image)

— **Sample Eyedropper**: This is the first control you use whenever sampling the image. It defines the initial range of the qualification; you must use this tool before any of the others. Clicking once with this tool selects a single pixel value, while clicking and dragging selects a range of image values that add together.
— **Add/Subtract Color Range**: These two controls let you add areas of the image to, or subtract them from, the currently selected inner range of values that define the core of the key. As with the eyedropper, you can click on single pixels or drag over a range of color.
— **Add/Subtract Softness**: These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Like the other sampling controls, you can click on single pixels or drag over a range of color.
— **Invert**: Inverts the sampled color to become opaque, and areas not sampled become transparent.
— **Reset**: Resets all the sampled colors while retaining the general control settings.
Keyer Options

One of the HSL Keyer’s strengths, and one of its most underutilized features, is that you can enable or disable each of the three HSL components using the Hue, Sat, and Lum checkboxes. This lets you ignore specific color components while focusing on others that may be more important. For example, if you’re trying to key the saturated parts of an image, regardless of the hue or brightness, you can turn off Hue and Lum so that only Sat is used to sample it.

![HSL Keyer options](image)

Matte Finesse

You may find that sampling the screen color is not enough to overcome some problems. Issues such as chattery edges, holes, or noisy bits can sometimes be easily fixed using the Matte Finesse controls. These controls filter the output of the Keyer and are adjustments that are made to the matte itself, so they may work well in some instances and poorly in others, depending on what you’re trying to do. The Matte Finesse tools are split into two banks of controls labeled 1 and 2.

- **Pre Filter:** This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.

- **Clean Black:** Clean Black is a specialized operation that eliminates noise (seen as white speckling when viewing a high-contrast highlight) in the black area of a key that omits the regions of the image you don’t want to isolate, and shrinks the key by making the dark parts of a key darker the higher you raise this parameter, pushing dark gray areas of the key toward black. The practical result is that raising Clean Black lets you “fill holes” in the background portion of a key and erode translucent edges.

- **Clean White:** Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that include areas of the image you’re isolating, and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you “fill holes” in the foreground portion of a key and grow translucent edges.

- **Black Clip:** Raising Black Clip applies a “lift” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward black. The range is 0 to 100, with 0 being the default setting.

- **White Clip:** Lowering White Clip applies a “gain” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward white. The range is 0 to 100, with 100 being the default setting.
— **Blur Radius**: In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you’re keying, with the result being a visible “halo” around your subject, depending on the adjustment you’re making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.

— **In/Out Ratio**: Controls whether the “Blur Radius” is applied equally to the inside and outside of the edge of the matte (zero), applied only within the matte (negative values), or applied only outside the matte (positive values). Using In/Out Ratio can help eliminate fringing when using the Blur Radius parameter. However, you can also use In/Out Ratio even in situations where no Blur Radius is applied at all. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.

— **Morph Operation**: This menu lets you choose how you want to modify the Alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.

— **Morph Radius**: Adjusts how much to shrink, grow, open, or close the key.

— **Shadow**: Adjusts key strength based on the darker parts of the original image.

— **Midtone**: Adjusts key strength based on the midtones of the original image.

— **Highlight**: Adjusts key strength based on the brighter parts of the original image.

— **Post Filter**: Performs a final clean-up of the key, using the original image for reference; useful for bringing back some fine detail in sharp edges or hair.

### Garbage Matte

These controls let you crop out unwanted things in the frame that are also being keyed, such as lighting fixtures, boom microphones, tracking patches, etc.

— **Matte Shape**: You can choose either a Rectangle or Ellipse with which to crop around the subject you’re keying. Choosing None turns off Garbage Matte. When a garbage matte is enabled, the Open FX Overlay mode of the Viewer shows an on-screen control for adjusting the shape and position of the garbage matte.

— **Edge Softness**: Lets you soften the edges. Defaults to 50; the range is 0 (no softening) to 100 (maximum softening).

— **Invert**: Inverts the garbage matte.

— **Center X and Y**: Lets you adjust and keyframe the position of a garbage matte.

— **Bounding Width and Height**: Lets you adjust the width and height of the garbage matte.

— **Rotation**: Lets you adjust the angle of the garbage matte.

### Output

The Output controls let you choose how the image is output, composited, and displayed in the Viewer.

— **Output**: This menu offers three options for which channels are output from the effect.

— **Alpha Highlight**: Displays the transparent part of an alpha channel as gray and the solid part of an alpha channel in full color.
— **Alpha Highlight B/W:** Displays the black and white alpha channel, which is often helpful when sampling additional areas to key.

— **Final Composite:** The keyed image is displayed composited over any video track below it.

— **Use Alpha:** A common control in many Resolve FX and 3rd party Open FX plug-ins; this checkbox determines if the alpha channel is used when compositing over another video track. It can be used instead of choosing RGB Only [Blank Alpha] from the Output menu.

**To use the HSL Keyer in the Edit page:**

1. Apply the HSL Keyer to a clip on video track 2 or higher.
2. From the Viewer Overlay menu in the lower-left corner of the Timeline Viewer choose Open FX Overlays.
3. Click and drag across the screen color you want to remove.
4. The transparency immediately takes effect, showing the keyed subject against whatever clip appears on the video track underneath it in the Timeline as a composite. To see the matte you created for further adjustment, choose Alpha Highlight or Alpha Highlight B/W from the Output drop-down menu.
5. To add or subtract from the matte, click the plus or minus Color Range control, and click or drag across the portion of the keyed image.
6. To add softness to the outer range of the key you’re creating, click the plus Softness control and then click or drag across the portion of the image you’d like to include as a soft edge.

**Luma Keyer**

Based on the Luma Qualifier in the Color page, the Luma Keyer pulls a key from the luma channel. It’s identical to the HSL Keyer with H and S turned off. Although not often used by itself, the Luma Keyer can produce very dramatic effects when used in conjunction with Composite modes.

**Selection Range Controls**

The Selection Range buttons in the Inspector let you define a key by sampling pixels in the Viewer with the mouse pointer.

— **Sample Eyedropper:** The first control you use whenever sampling the image. It defines the initial range of the keyer; you must use this tool before any of the others. In the Edit page, the Timeline Viewer Overlay must be set to Open FX. Clicking once with this tool selects a single pixel value, while clicking and dragging selects a range of image values that add together.
— **Add/Subtract Luma Range**: These two controls let you add areas of the image to, or subtract them from, the currently selected luma range that defines the core of the key. As with the eyedropper, you can click on single pixels, or drag over a range of color.

— **Add/Subtract Softness**: These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Like the other keying controls, you can click on single pixels, or drag over a range of color.

— **Invert**: Inverts the sampled luma range to become opaque, and areas not sampled become transparent.

— **Reset**: Resets the sampled luma range while retaining the Output control settings.

**Matte Finesse**

You may find that sampling the screen color is not enough to overcome some problems. Issues such as chattery edges, holes, or noisy bits can sometimes be easily fixed using the Matte Finesse controls. These controls filter the output of the Keyer and are adjustments that are made to the matte itself, so they may work well in some instances and poorly in others, depending on what you’re trying to do. The Matte Finesse tools are split into two banks of controls labeled 1 and 2.

— **Pre Filter**: This slider attempts to clean up the image before colors are sampled. This adjustment can be useful when you have footage containing MPEG blocking artifacts.

— **Clean Black**: Clean Black is a specialized operation that eliminates noise (seen as white speckling when viewing a high-contrast highlight) in the black area of a key that omits the regions of the image you don’t want to isolate, and shrinks the key by making the dark parts of a key darker the higher you raise this parameter, pushing dark gray areas of the key toward black. The practical result is that raising Clean Black lets you “fill holes” in the background portion of a key and erode translucent edges.

— **Clean White**: Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that include areas of the image you're isolating, and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you “fill holes” in the foreground portion of a key and grow translucent edges.

— **Black Clip**: Raising Black Clip applies a “lift” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward black. The range is 0 to 100, with 0 being the default setting.

— **White Clip**: Lowering White Clip applies a “gain” adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed toward white. The range is 0 to 100, with 100 being the default setting.

— **Blur Radius**: In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you’re keying, with the result being a visible “halo” around your subject, depending on the adjustment you’re making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.
— **In/Out Ratio:** Controls whether the “Blur Radius” is applied equally to the inside and outside of the edge of the matte (zero), applied only within the matte (negative values), or applied only outside the matte (positive values). Using In/Out Ratio can help eliminate fringing when using the Blur Radius parameter. However, you can also use In/Out Ratio even in situations where no Blur Radius is applied at all. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.

— **Morph Operation:** This menu lets you choose how you want to modify the alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.

— **Morph Radius:** Adjusts how much to shrink, grow, open, or close the key.

— **Shadow:** Adjusts key strength based on the darker parts of the original image.

— **Midtone:** Adjusts key strength based on the midtones of the original image.

— **Highlight:** Adjusts key strength based on the brighter parts of the original image.

— **Post Filter:** Performs a final clean-up of the key, using the original image for reference, useful for bringing back some fine detail in sharp edges or hair.

### Garbage Matte

These controls let you crop out unwanted things in the frame that are also being keyed, such as lighting fixtures, boom microphones, tracking patches, etc.

— **Matte Shape:** You can choose either a Rectangle or Ellipse with which to crop around the subject you’re keying. Choosing None turns off Garbage Matte. When a garbage matte is enabled, the Open FX Overlay mode of the Viewer shows an on-screen control for adjusting the shape and position of the garbage matte.

— **Edge Softness:** Lets you soften the edges. Defaults to 50, the range is 0 (no softening) to 100 (maximum softening).

— **Invert:** Inverts the garbage matte.

— **Center X and Y:** Lets you adjust and keyframe the position of a garbage matte.

— **Bounding Width and Height:** Lets you adjust the width and height of the garbage matte.

— **Rotation:** Lets you adjust the angle of the garbage matte.

### Output

The Output controls let you choose how the image is output, composited, and displayed in the Viewer.

— **Output:** This menu offers three options for which channels are output from the effect.

  — **Alpha Highlight:** Displays the transparent part of an alpha channel as gray and the solid part of an alpha channel in full color.

  — **Alpha Highlight B/W:** Displays the black and white alpha channel, which is often helpful when sampling additional areas to key.

  — **Final Composite:** The keyed image is displayed composited over any video track below it.

— **Use Alpha:** A common control in many Resolve FX and 3rd party Open FX plug-ins; this checkbox determines if the alpha channel is used when compositing over another video track. It can be used instead of choosing RGB Only (Blank Alpha) from the Output menu.
To use the Luma Keyer in the Edit page to key a subject:

1. Apply the Luma Keyer to a clip on video track 2 or higher.

2. From the Viewer Overlay menu in the lower-left corner of the Timeline Viewer choose Open FX Overlays.

3. Either click a pixel in a bright or dark part of the image you want to key out, or click and drag across a range of pixels within that subject.

4. The transparency immediately takes effect, showing the keyed subject against whatever clip appears on the video track underneath it in the Timeline as a composite. To see the matte you created for further adjustment, choose Alpha Highlight or Alpha Highlight B/W from the Output drop-down menu.

5. To add or subtract from the matte, click the plus or minus Luma Range buttons, and then click or drag across the portion of the keyed image.

6. To add softness to the outer range of the key you’re creating, click the plus Softness button and then click or drag across the portion of the image you’d like to include as a soft edge.
Chapter 157

Resolve FX Light

The plug-ins in this category all replicate different optical and lighting effects. While most have been designed to quickly give you realistic results, all can be pushed harder to provide many artistic effects.

Aperture Diffraction (Studio Version Only)

Found in the ResolveFX Light category, Aperture Diffraction models the starburst effect usually seen when shooting bright lights with small apertures, the physical cause of which is light-diffraction on the aperture blades of a lens. This plug-in simulates this, with the result being automatically applied to scene highlights that you can isolate and refine, with customizable virtual apertures.

Small regions of brightness exhibit a star pattern glow, as seen in the following image.

(Left) Original image, (Right) Applying Aperture Diffraction

Large regions of brightness exhibit a more even glow with shaping and texture that look like a natural optical effect. It can be used to create a different type of glow effect with a more realistic look in some situations than the Glow plug-in, though it’s more processor intensive. In other situations, this plug-in opens up many different stylistic possibilities for glowing effects.

(Left) Original image, (Right) Applying Aperture Diffraction

Output

These controls let you choose what image is output by this plug-in.

— Select Output: Lets you preview the image with different stages of the Aperture Diffraction effect applied, viewing the Isolated Source (to help when adjusting the Isolation controls), Preview Aperture (to help when adjusting the Aperture controls), Preview Diffraction Pattern (showing you the resulting diffraction pattern based on the aperture control settings), Diffraction Patterns Alone (showing you the glow effect that will be applied to the image by itself), and the Final Composite.

— Quality: Lets you choose a quality setting to trade off between quality and speed. Choices are Full, Half (Faster), Quarter (Fast).
Isolation Controls

The Isolation controls let you choose which highlights in the scene generate visible glow and patterns. The effect of these controls can be directly monitored by setting Select Output to Isolated Source.

- **Color Mode**: A pop-up menu that lets you either choose to keep the colors of the different highlight regions that generate glow, or treat them all as grayscale brightness only (color controls later can change the effect). Grayscale is faster to process, but Color can result in some brilliant effects.
- **Brightness**: Sets the threshold at which highlights are isolated.
- **Gamma**: Lets you shape the isolated highlights.
- **Smooth**: Lets you blur details in the highlights that you don’t want to be pronounced.
- **Color Filter**: Lets you choose a particular color of highlight to isolate (an eyedropper lets you select a value from the Viewer).
- **Operation**: Lets you adjust the resulting Isolation matte (options include Shrink, Grow, Opening, Closing) with a slider to define how much.

Aperture Controls

The Aperture controls let you define the shape and texture of the resulting glow this plug-in creates.

- **Iris Shape**: Lets you choose a shape that determines how many arms the star pattern will have. Options are Triangle, Square, Pentagon, Hexagon, Heptagon, and Octagon.
- **Aperture Size**: Lets you alter the resulting diffraction pattern alternating between more of a star shape at higher values and a stippled wave pattern at lower values.
- **Blade Curvature and Rotation**: Lets you alter the softness and orientation of the arms of each star.
- **H/V Ratio**: Alters the horizontal/vertical ratio of the aperture, allowing you to replicate an anamorphic glow.
- **Angle**: Sets the angle of the aperture.
- **Chroma Shift**: Lets you introduce some RGB “bleed” into the glow.

Diffraction Controls

- **Result Gamma**: Lets you adjust how pronounced will be the glow that appears between the arms of the star patterns that appear.
- **Result Scale**: Lets you alternate between pronounced star patterns at high values and more diffuse glows at low values.

Compositing Controls

These controls let you adjust how to composite the glow effect against the original image.

- **Normalize Brightness**: This checkbox scales the brightness of the glow to a naturalistic range for the image. Also, when Normalize Brightness is enabled, the Aperture Diffraction effect will keep to a consistent overall brightness as the scene changes.
- **Brightness**: Lets you adjust the intensity of the glow effect.
- **Colorize**: Lets you tint the glow effect using a Color control that appears when Colorize is raised above 0.
**Glow**

A sophisticated, soft glow effect that’s highly customizable with only a few key parameters.

- **Select Output**: Lets you preview the image with different stages of the glow effect applied, viewing the Shiny Regions, the isolated Glow Alone, or the Glowing Image.
- **Shine Threshold**: Defines the luminance level at which glow is triggered to appear on the image.

**Shape and Spread**

- **Spread**: Defines how far out shine extends from areas of the picture that trigger it.
- **H/V Ratio**: Lets you adjust the proportion of horizontal to vertical spread, allowing you to create “streaky” shine that extends farther in a particular dimension.
- **Relative Spread Red/Green/Blue**: Lets you adjust the spread within each color channel by a different amount, simulating a kind of chromatic aberration in the glow.

**Color and Composite**

- **Gain**: Adjusts the brightness of the glow effect.
- **Gamma**: Adjusts the spread of the glow effect.
- **Saturation**: Adjusts the intensity of the glow’s color.
- **Color Filter**: A color picker and eyedropper let you choose a color with which to tint the glow.
- **Glow framing**: Lets you choose what happens when shine hits the edge of the frame, whether it’s amplified by “Reflect in Camera” or whether it’s moderated by a “Vignette” effect.
- **Composite Type**: Lets you choose a composite mode to use to blend the glow effect with the image. Defaults to Screen, which is good for gentle glows. Add lets you create hotter, more intense glows, while other composite modes let you create other varied effects.
- **Opacity**: Lets you adjust the transparency of the glow effect and is a fast way of “easing off” of a glow that you otherwise like, but that’s too intense for the shot at hand.

**Lens Flare** *(Studio Version Only)*

Simulates different kinds of lens flares resulting from the interplay of light through an aperture of selectable shape bouncing within layered optical elements in a lens. Lens flares are completely computer-generated, so they’re always created at your project resolution, whether it’s 1080 or 8K. Four groups of controls give you a lot of ways to customize the presets to create your own effect:

**Lens Flare Preset**

You can choose a type of flare from the Lens Flare Preset pop-up. If you manipulate the controls to create your own effect, this pop-up switches to Custom.
Select Output
The Select Output pop-up lets you switch among the following viewing options:

— **Final Image:** (Default) Shows the lens flare composited against the current clip.
— **Flare Elements Alone:** Shows the isolated flare, making it easier to adjust.
— **Source Mask and Magnified Source Mask:** Let you see the mask created by the Light Source Masking controls below, which is used to limit the lens flare that’s created.

Light Source Masking
Three additional controls at the top let you create a quick and dirty luma key to create a mask that you can use for occluding the lens flare effect behind foreground elements in the scene. For example, if you’re using lens flare to simulate the sun in the sky, these controls let you mask trees in the foreground so that the lens flare appears to be behind the trees, as the sun would be.

— **Enable Light Source Masking:** This checkbox enables the Mask Threshold and Virtual Light Source Size sliders. You can then choose either Source Mask or Magnified Source Mask to see the mask that’s created by raising the Mask Threshold slider.
— **Mask Threshold:** Raising this slider pulls a fast Luma Key that masks off darker foreground elements (such as trees against the horizon) and limits the flare to areas of the picture where the light source of the flaring can “shine through” (In this example, shining between the trees on the horizon.).
— **Virtual Light Source Size:** This slider determines how quickly the center of a flare will disappear behind the luma-keyed mask you’ve created; higher values (simulating bigger light sources) cause a flare to disappear more slowly when passing “behind” a feature of the image that’s being keyed via the Mask Threshold slider.

Position
Position parameters let you adjust the X and Y Position of the simulated light source that’s causing the flare. There are three ways you can adjust the flare position.

— You can Adjust the X and Y Position sliders.
— You can turn on the OpenFX Overlay in the Viewer and drag the on-screen control.
— You can motion track elements within the scene using the FX mode of the Tracker palette.

Checking the Move With Sizing checkbox lets the lens flare retain its relative position in the frame if the Input and Editing sizing are changed.

Global Corrections
The Global Corrections group have parameters that let you quickly adjust the overall quality of the flare effect.

— **Global Scaling:** Lets you make every element of the flare effect larger or smaller at once.
— **Anamorphism:** Lets you stretch all flare elements horizontally to simulate an anamorphic lens’ stretching effect.
— **Lens Center X and Y position:** Lets you offset the center of the simulated lens that’s causing the flaring, about which the various elements of the flare pivot.
— **Global Defocus:** Lets you blur the overall flaring effect being created to soften the effect.
— **Global Brightness:** Lets you raise and lower the overall level of flaring being produced.
— **Global Saturation:** Lets you adjust the overall color intensity of the flaring.
— **Colorise Result:** Lets you choose how much to tint the flare, if at all. At a value of 0 (the default), no colorization is applied at all.
— **Colorization Color:** Lets you choose a color to use to colorize the flare via the Colorize Result slider above. You can use either a color control or eyedropper to sample color from the source RGB image of the current node.

### Aperture

The Aperture parameters let you define the aperture of the simulated camera apparatus through which the flare is being generated. The shape defined by these parameters affects the look of the “starburst element” of each flare, as well as the look of any aperture-shaped “ghost elements” you’re turning on.

— **Aperture Blades:** Defines how many blades make up the aperture. You can choose from 3 to 16 (defaults to 6).
— **Angle:** Sets the angle of the resulting Aperture shape (defaults to 0.183).

### Elements

The Elements pop-up is a deceptively simple set of controls that let you expose the customization controls of each of the layers and elements that combine to create the simulated lens flare. Up to ten levels of elements can contribute to a lens flare effect. Each element and ghost shape has a different set of parameters unique to that type of element. Available elements in this pop-up menu include:

— **Full-Screen Glare:** A simulated overall flaring that covers the entire frame at its most intense. This glare increases as the flare nears the center of the screen and decreases as the flare moves toward the edges of the frame. Recommended for extremely big flaring effects. Parameters include:
  — **Glare Brightness:** A slider; set this to 0 to eliminate glare.
  — **Glare Color:** A color picker and eyedropper combination that lets you tint the glare.

— **Flare Spot:** Simulates the central light source that’s triggering the flare. Parameters include Flare Size (set this to 0 to eliminate the flare spot), Flare Irregularity (which lets you create a more organic-looking, off-balance flare), Flare Softness, and Flare Color.

— **Starburst:** Rays of light stretching out from the center of the flare. Parameters include Starburst Size (set this to 0 to eliminate the starburst), Starburst Softness, Starburst Split Angle (which splits each streak of the starburst into a wider feathered pattern), Starburst Split Balance (which lets you adjust the brightness between each half of split streaks), and Starburst Color.

— **Ghost elements:** Seven available layers of Ghost Elements can be enabled and set to different optional shapes for each lens element you want to simulate. Each of the Ghost element layers can use one of five types of shapes, including:
  — **None:** Turns that particular ghost element off.
  — **Aperture Shape:** A polygonal shape defined by the number of blades in the aperture you’ve selected.
  — **Anamorphic Streak:** A wide horizontal artifact typical of anamorphic lenses.
  — **Disc Shape:** A round ring artifact.
— **Bubble Shape:** An oval with haze within.
— **Corona Rays:** A ring of streaks stretching outward.

Ghost elements share many parameters in common, although specific elements have unique parameters. These parameters are as follows:

— **Color:** A color picker and eyedropper combination that lets you colorize that specific element.
— **Position:** A slider lets you set that element’s position along the optical path that’s defined by the angle from the (Flare) Position X and Y to the Lens Center X and Y parameters. A value of 0 centers that element on the Lens Position, while larger values push that element farther and farther away from the Lens Position.
— **Size:** Sets the size of that flaring element, or in the case of the Anamorphic Streak, the width.
— **Height:** (Anamorphic Streak only) Sets the vertical thickness of the streak.
— **Center Brightness:** (Aperture, Disk, and Anamorphic Streak only) Defines the brightness in the middle of that element, filling it to appear as a solid element. Set this closer to 0 if you want the element to appear hollow.
— **Edge Brightness:** (All but Anamorphic Streak) Defines the brightness of the edge of that element. Raising this value while lowering the Center Brightness lets you create outlined element effects.
— **Softness:** Lets you blur that element.
— **Bristle Density:** (Corona Only) Lets you alter the number and arrangement of the optical bristles that appear. At lower values, fewer bristles appear, at higher values, more bristles appear. As you change the value of this parameter, the placement of bristles shifts, allowing you to change distribution as well as density with a single control.
— **Bristle Scale:** (Corona only) Lets you alter the thickness of the bristles that appear. Smaller values result in thicker bristles, higher values result in smaller bristles more tightly packed together.
— **Ringing:** (All types but Bubble) Simulates a pattern of diffraction artifacts. Higher values increase the number of rings or streaks comprising the element.
— **Chromatic shift:** Simulates chromatic aberration effects.
— **Eclipse Position:** Simulates where the outer (away from the center) or inner (toward the center) side of a Ghost Element doesn’t exist because the light is occluded by the edge of a lens element or some part of the tube housing. Practically, this defines which side of the Ghost Element is affected by the other Eclipse parameters of size, softness, and chromatic shift. Adjusting this results in semi-circular ghost shapes of different kinds. At 0, there is no eclipse. At positive values, the eclipse starts from within the frame and pushes out; at negative values, the eclipse starts from the outside of the frame and pushes in.
— **Eclipse Size:** Defines the size of the eclipse region for that flare element. At higher values, more and more of the flare element is eclipsed.
— **Eclipse Softness:** Defines the softness at the transition from the eclipsed and non-eclipsed regions.
— **Eclipse Chromatic shift:** Lets you create a chromatic aberration effect at the boundary of the eclipsed region. At 0, there is no chromatic shift. At increasingly positive values, there’s a shift toward blue. Toward negative values, there’s a shift toward red.
— **Repeat:** Lets you use this element to spawn many duplicates defined by the following two parameters.
— **Repeat Position Seed and Repeat Size Seed:** At different values, these parameters let you pseudo-randomly redistribute the placement of repeated elements.
Lens Reflections (Studio Version Only)

Found in the ResolveFX Light category, Lens Reflections simulates intense highlights reflecting off the various optical elements within a lens to create flaring and scattering effects based on the shape and motion of highlights you isolate in the scene. It’s an effective simulation that works best when there are light sources or specular reflections in the scene such as the sun, car headlights, light fixtures, fire and flame, or other lighting elements that are plausibly bright enough to cause such flaring.

Also, this plug-in really shines when these light sources move, as each layer of simulated reflections moves according to that element’s position within the virtual lens being simulated, creating organic motion that you don’t have to keyframe. Without intense highlights, the results of this filter will be somewhat abstract.

Output

The Output controls let you preview the image with different stages of the Lens Reflections effect applied.

- **Select Output**: Lets you choose to view the Isolated Source (to help when adjusting the Isolation controls), Reflections Alone (showing you the flaring effect that will be applied to the image by itself), or the Final Composite (the complete effect).
- **Quality**: This pop-up lets you choose how to render the effect. Options are Full, Half (Faster), and Quarter (Fast). The tradeoff is between quality and speed.

Isolation Controls

The Isolation controls let you choose which highlights in the scene will generate lens reflections. The effect of these controls can be directly monitored by setting Select Output to Isolated Source. It’s highly recommended to customize the Isolation controls for the image at hand when using this plug-in, as even more so than other plug-ins, the particular highlights used will have a huge impact on the resulting effect.

- **Color Mode**: A pop-up menu that lets you either choose to keep the colors of the different highlight regions that generate lens reflections, or treat them all as grayscale brightness only (color controls later can change the effect). Grayscale is faster to process, but Color can result in some brilliant effects.
- **Brightness**: Sets the threshold at which highlights are isolated.
— **Gamma:** Lets you shape the isolated highlights.
— **Smooth:** Lets you blur details in the highlights that you don’t want to be pronounced.
— **Color Filter:** Lets you choose a particular color of highlight to isolate (an eyedropper lets you select a value from the Viewer).
— **Operation:** A pop-up lets you adjust the resulting Isolation matte (options include Shrink, Grow, Opening, Closing), and a slider lets you define how much.

### Global Controls

The Global controls let you quickly and easily adjust the overall quality of the Lens Reflections effect using a centralized group of parameters.

— **Global Brightness:** Lets you raise and lower the level of all reflections. Lowering brightness is a good way to make a large lens reflection effect more subtle, although images with small lens reflection effects may benefit from being a little brighter.
— **Global Blur:** Lets you defocus all reflections. This is another good way of making lens reflection effects of all kinds more subtle.
— **Anamorphism:** Lets you deform the reflection elements to simulate an anamorphic lens’ stretching effect.
— **Global Colorize:** Lets you adjust the color intensity of the reflections, either intensifying the color of all reflections or desaturating it.

### Presets

A Presets pop-up provides a number of different settings to get you started. Selecting a preset populates the Reflecting Elements parameters below, at which point you can customize the effect to work best with the image at hand. It’s highly recommended to customize these effects to suit the type of highlights in your image, in order to get the best results.

### Reflecting Elements

There are four groups of Reflecting elements, each with identical controls. This lets you create interactions combining up to four sets of reflections. The controls found within each group are as follows.

— **Brightness:** Lets you adjust the intensity of that reflection.
— **Position in Optical Path:** Lets you shift the reflection according to an element’s position in the lens. Practically, this means that positive values will enlarge an inverted reflection based on the highlights, while reducing values toward 0 will shrink the reflection, and pushing this into negative values will invert the reflection and pull it into the opposite direction as it begins to enlarge again. A value of −1 positions the reflection right over the highlight that creates it.
— **Defocus type:** Lets you choose what kind of blur to use, choices include Box blur, Triangular blur, Lens blur (the most processor intensive), and Gaussian blur (the default).
— **Defocus:** Lets you choose how much to blur that element.
— **Stretch:** Lets you give the flare an anamorphic widescreen look.
— **Stretch Falloff:** Lets you taper the edges for a less uniform stretching effect.
— **Lens Coating:** A pop-up lets you choose common colors such as purple, green, and yellow that correspond to different anti-reflective lens coatings, as well as a selection of other vibrant colors. Defaults to none. When you choose any other option, a color control and eyedropper let you manually choose a color or pick one from the image. A Colorize slider lets you vary how much to tint the reflection by the selected color, although setting Colorize to 0 lets the flare take its color from the source highlights of the image, which can sometimes give you the most interesting look.

---

**Light Rays**

A "rays of light" effect that simulates volumetric lighting emerging from light sources defined by a threshold you define. The effect mimics what are sometimes called "god rays" in the sky, or other highly directional glow effects.

---

**Main Controls**

The Main controls include:

— **Select Output:** Lets you preview the image with different stages of the Lightray effect applied, viewing the Final Image, Lightrays Alone, and Source Regions.

— **Source of Rays:** Lets you choose the emitter of the rays, using Bright Regions or Edges.

— **Source Threshold:** A slider that lets you choose the limit at which light areas of the image emit rays.

---

**Position**

Position parameters let you define the direction rays take.

— **Ray Directions:** A pop-up menu that lets you choose either "From A Location," which exposes controls to let you choose an X or Y position to define a point of origin that defines the angle of the light beams, or "At an Angle," which exposes controls to let you choose an overall orientation for the rays.

---

**Appearance**

Appearance parameters let you customize the ray effect.

— **Ray Dropoff:** A pop-up with four options.
  — **Default (soft):** Produces soft, indistinct rays of light that appear to fade away as they stream out.
  — **Keep Shape of Source:** The edge of the light rays are defined by the shape that emitted them.
  — **CCD Bloom Harsh:** Severely raises the brightness of the part of the image that’s emitting rays as Length is raised, resulting in harsh glow or bloom in the image.
  — **CCD Bloom Soft:** Gently raises the brightness of the part of the image that’s emitting rays as Length is raised, resulting in a very gentle lightning of the image.

— **Length:** Lets you make the rays longer or shorter.

— **Soften:** Lets you blur the rays being emitted.

— **Brightness:** Lets you adjust how bright the rays are.

— **Color:** A color picker and eyedropper let you define a color with which to tint the rays.
Chapter 158

Resolve FX Refine

These plug-ins let you make different kinds of targeted improvements.

Beauty (Studio Version Only)

Beauty is a plug-in that lets you control texture. In Advanced mode, you can selectively smooth image detail that falls above a particular threshold (using the Smoothing Threshold slider), while preserving detail falling below a particular threshold (using the Texture Threshold slider). In this way, you can smooth larger textures you don’t want, while either preserving or exaggerating smaller textures that you do want.

In the case of faces and skin, this plug-in provides another method of smoothing larger, unwanted blemishes, while preserving desirable edge detail and underlying structures such as pores, so you can improve the complexion of subjects on shoots where hair and makeup was not available, without over-softening realistic skin details and creating an overly fake plastic look.

(Left) The original image, (Right) A face with Beauty applied to soften the complexion while retaining fine facial detail

Please note that this plug-in is not only for skin detail, and it’s not only for softening. Once you isolate the fine detail you want to preserve in a subject, you also have the option of exaggerating it to create highly textured results. This plug-in is effective for any subject with textures that need refinement.

**TIP:** This plug-in is best used within a qualification that isolates the particular feature you’re trying to smooth. The default settings apply a moderate amount of smoothing and fine detail recovery that’s appropriate for faces in closeup but will not be universally appropriate for all situations, so some fine-tuning will always be necessary. For naturalistic results, this plug-in produces the best results when used in moderation.

**Operating Mode**

The Beauty plug-in has two operational modes, including an Automatic mode with simpler operation when your objective is to create a maximally smooth or textured result while still preserving important details, and an Advanced mode that provides additional controls that let you preserve fine detail that you want, while smoothing coarse details that you don’t want.
**Auto Controls**

Automatic mode reveals easy-to-use controls for smoothing or coarsening detail.

- **Amount**: Lets you choose how much smoothing or coarsening to apply.
- **Scale**: Lets you reduce or increase the amount of smoothing or coarsening that’s accomplished with the range of the Amount slider.

**Advanced Controls**

Advanced controls reveal the full power of the Beauty plug-in, with preview modes to examine different aspects of this plug-in’s behavior, while specifically adjusting the level of smoothing or coarsening you want, the amount of texture to preserve, and which additional features of the subject you want to recover from this operation to fine tune the result.

- **Show Split View**: Turns on a split-screen view that displays a grid of four images (in clockwise order from upper left): the smoothed or coarsened image, the Texture Recovery mask, the Feature Recovery mask, and the final result. The Split View works best with the Full Screen Viewer enabled (press Shift-F) while the Inspector is shown at right, so each quadrant is large while you make your adjustments.

**Smoothing**

These parameters let you adjust how much smoothing to apply to the image.

- **Smoothing Threshold**: Raising this value increasingly smooths textures above the Texture Threshold (below). Using this control and leaving Diffuse Lighting at 0 preserves the contrast of the lighting on the feature you’re smoothing.
- **Diffuse Lighting**: Another method of softening texture, but in such a way that the lighting of the subject also appears to become more and more diffuse (Similar to setting Midtone Detail to negative values).
- **Preview Smoothed**: Lets you view the image with only smoothing applied by the Smoothing Threshold and Diffuse Lighting sliders, with no texture recovery.

**Texture Recovery**

These parameters let you adjust how much texture to put back into the smoothed result.

- **Texture Threshold**: Lets you set the threshold at which detail is reintroduced to the image. Texture Threshold must always be equal to or lower than Smoothing Threshold, so lowering Smoothing Threshold may also result in lowering Texture Threshold.
- **Add Texture**: Lets you exaggerate recovered texture (at values higher than 1), or minimize recovered texture (at values less than one).
- **Preview Texture**: Lets you view the isolated texture mask that’s being recovered by the Texture Gain and Texture Threshold sliders, so you can fine tune what you want to preserve.
Feature Recovery

These parameters let you recover edge detail.

— **Recovery Amount**: Lets you set the threshold at which detail is reintroduced to the image. Texture Threshold must always be equal to or lower than Smoothing Threshold, so lowering Smoothing Threshold may also result in lowering Texture Threshold.

— **Preview Recovery Area**: Lets you view the mask that’s being generated by the Recovery Amount slider, so you can fine tune what you want to preserve. Preserved detail is white, discarded detail is black.

Custom Mixer

The Custom Mixer is an advanced version of the Layer node. It takes two inputs and combines them based on the Alpha channel of the second input. The Custom Mixer has controls to mix sources, blend effects, and interpolate between grades with per-channel control and mixing options. You can use this tool in a variety of ways to control the relative intensity between the sources, or simply as an alternative to the Layer Node but with slider controls.

The Custom Mixer should be added directly as an FX node, not dragged on top of a Corrector node. To add the Custom Mixer to your Node Graph, drag the Custom Mixer icon from the Resolve FX Refine section of the Effects library, directly into the Node Graph. You can also drag it on top of an existing link in the Node Graph to place it inline.

The Custom Mixer node is connected in the following way. The first and second RGB (Green) inputs are input 1 and input 2 respectively. The alpha of the second input controls the blend of input 2 onto input 1. The alpha of the 1st input does not affect the result; it is passed through the node to the output key.

![Custom Mixer Node connections](image)

The Custom Mixer Node connections: Input 1 (Green triangle above), and Input 2 (Green triangle below). The alpha from Input 2 controls the blend of Input 2 onto Input 1 and is what you modify in the Custom Mixer controls.

The Custom Mixer has two main modes chosen by the Mix mode; both have the same behavior, just different controls to change how the input affects the output.
**Blend**

Blends the second input onto the first input. The normal range is from 0 (fully input 1) to 1 (fully input 2), however you can set the blend factor up to 10 times more or less by typing the numbers directly into the fields. This allows you to enhance the difference between inputs beyond the appearance of either one alone. All the sliders can be keyframed independently.

— **Blend Input 2 onto 1:** Controls the strength of each source, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.

— **Gang:** Check this box to gang the channels of the custom mixer together, or uncheck to adjust separately.

**Combine**

Combines the inputs together, allowing you to change the relative strength of each input’s contribution to the mix. The normal range is from 0 (fully input 1) to 1 (fully input 2), however you can set the blend factor up to 10 times more or less by typing the numbers directly into the fields. This allows you to enhance the difference between inputs beyond the appearance of either one alone. All the sliders can be keyframed independently.

— **Input 1 Contribution:** Controls the strength of input 1’s source, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.

— **Input 2 Contribution:** Controls the strength of input 2’s source, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.

— **Offset:** Controls the offset of the combination, based on the color channels of the selected color space (RGB, YUV, XYZ, etc.). These can be adjusted separately if the Gang checkbox is unchecked.

— **Gang:** Check this box to gang the channels of the custom mixer together, or uncheck to adjust separately.

**Advanced Options**

Sets the composite type, as well as the color space and gamma of the resulting mix.

— **Composite Type:** Sets the composite type used for the mixer from the drop-down menu.

— **Color Space:** Sets the Color Space used for the blend. The default is the current Timeline color space.

— **Gamma:** Sets the Gamma used for the blend. The default is the current Timeline color space.
The initial setup of the Custom Mixer, Node 1 is the original image, Node 2 is identical but with a Noise Reduction effect applied to it.

The final setup of the Custom Mixer, by extending the blend factor by 7, the mixer actually adds noise to the image instead.

For the example above, by applying the Noise Reduction FX to Node 2, and directly connecting the same image from Node 1 to the Custom Mixer, the only difference between the inputs is the noise pattern from the effect itself. By manually turning the blend up past 1, you are blending in more of the noise than you started with. So by using Noise Reduction in conjunction with the Custom Mixer, you can actually add additional noise to an image that perfectly matches the original grain pattern without having to find a similar external grain or noise source.

**Face Refinement** *(Studio Version Only)*

Face Refinement is an incredibly sophisticated yet easy-to-use filter that lets you quickly make very targeted adjustments to people’s complexions. When you apply this filter, imaging techniques are used to automatically detect a face, which is automatically tracked so long as it’s somewhat turned toward the camera.

If multiple faces are present in the frame at the position of the playhead, then clicking the Analyze button once results in boxes being drawn over each detectable face. Click any of these boxes to choose which face you want to refine, and that box will be highlighted to indicate which face you’ll be refining.
When multiple faces are detected, you can click a box to choose which one to work on.

If only one face is present, clicking the Analyze button automatically analyzes that face; no boxes appear and this step is not necessary.

After you’ve selected which face to track (if necessary), you need only click the Analyze button at the top of the Face Refinement controls to “auto-magically” track the face through the trackable range of motion that this plug-in is capable of, and an outline of the face’s major features appears to let you follow its progress.

The Face Refinement filter automatically detecting a performer’s face

Once the face has been tracked, you’re ready to work. This plug-in divides the tracked face into different zones for common operations colorists often perform to quickly eliminate blemishes, adjust the hue and saturation of complexions in regionally appropriate ways, modify lighting, sharpen desirable detail, and refine makeup. Because all adjustments are fit to the proportions of the face that’s been detected and tracked, all you need to do is make the adjustments you need and DaVinci Resolve takes care of the rest.

**Main Controls**

The top two controls let you initiate the Face Refinement process.

- **Analyze**: This button initiates the process of using the facial detection of the Face Refinement plug-in to detect the face you want to make adjustments for, and track its motion throughout the range of the clip. You only need to do this once, and the data will be stored.

- **Show overlay**: To impress your clients and see how well Face Detection is tracking the face you’re working on, you can turn on this checkbox, which turns on the wireframe tracking that shows you which facial details are being detected.
**Skin Mask**

These controls let you adjust the skin mask this plug-in automatically generates in order to limit the effect to only the face of the person you’re targeting.

- **Use mask**: This checkbox enables DaVinci Resolve to sample the dominant skin tone values within the face to create a complexion-focused key to isolate the skin tones of the image. However, since it’s still possible to have blonde hair, wood panelling, or other skin-colored features in the frame that inadvertently get included in this key.
- **Use face mask**: Turning on this checkbox places a circular garbage mask that follows the face to eliminate these accidental inclusions.
- **Face mask size and Face mask softness**: These sliders let you adjust the face mask to better fit the face you’re working on, if necessary.
- **Refine mask**: This slider lets you adjust the face mask to smooth or eliminate gaps in the key.
- **Show mask**: This checkbox makes the face mask being generated visible, which can be helpful to see while you’re tuning it.
- **Show overlay**: To impress your clients and see how well Face Detection is tracking the face you’re working on, you can turn on this checkbox, which turns on the wireframe tracking that shows you which facial details are being detected.

![Limiting the key with the face mask](image)

**Texture**

The Texture controls have three Operating Modes that let you choose the method you want to use to control skin texture. Beauty Automatic and Beauty Advanced provide the texture controls available in the Beauty plug-in, while Smoothing provides the previously available texture adjustment controls.

**Beauty Automatic Controls**

Automatic mode reveals easy-to-use controls for smoothing or coarsening detail.

- **Amount**: Lets you choose how much smoothing or coarsening to apply.
- **Scale**: Lets you reduce or increase the amount of smoothing or coarsening that’s accomplished with the range of the Amount slider.
Smoothing Controls

— **Smoothing**: This slider removes detail from the areas isolated by the Skin Mask controls, smoothing the complexion. Its operation depends on the settings of the Detail Size and Detail sliders below. You may find you can increase Smoothing more dramatically as you increase Detail using the Detail Size and Detail sliders described below.

— **Detail Size and Detail**: Once you’ve used the Smoothing slider, you can then use these sliders to selectively put subtle skin details back into the image; Detail Size determines the maximum size of details you want to put back into the face, and Detail is a sharpening operation that lets you adjust how visible these small details are. By combining smoothing and subtle preservation of small details, you can get a much more naturalistic result than were you to simply leave the entire face unnaturally smooth.

![Top] The original image, [Bottom Left] Only smoothing complexion, [Bottom Right] Using Detail Size and Detail to put natural texture back into the smoothed result (results exaggerated for print)

**Beauty Advanced**

These controls are identical to the Advanced controls of the Beauty plug-in, covered previously in this chapter.
**Color Grading**

These controls let you make color adjustments to the overall face.

— **Contrast:** This slider lets you lighten the face in a natural way by keeping the shadows dark even while you brighten the face, making it easy to bring actors out of the background.

— **Midtone:** Lets you add a more luminous quality to the skin tone.

— **Color boost:** Specifically boosts saturation in the lowest saturated parts of the face.

— **Tint:** Provides a limited range of naturalistic hues emphasizing orange through red (but extending to green and magenta) with which to tweak complexion.

— **Desaturate shadow:** This slider lets you selectively desaturate the darkest shadows on the face to keep things looking natural, or to desaturate more aggressively in order to stylize the face in a different way. Also useful when using the other adjustments of this plug-in makes the shadows too colorful. Moving this slider into negative values will add saturation.

— **Shine Removal:** This slider is an inverse contrast adjustment designed to ameliorate sweat and shine on a person’s face, although moving this slider into negative values will also accentuate shine.

**Eye Retouching**

These controls target just the eyes and surrounding area of the face.

— **Sharpening:** This slider lets you selectively add sharpening just to the eyes and eyelashes, which lets you instantly add focus to any performer.

— **Brightening:** This slider lets you whiten the eyeballs.

— **Eye Light:** This slider lets you brighten the region of the face around the eyes that’s often thrown into shadow by the subject’s forehead in situations with imprudent lighting.

— **Eyebag Removal:** This slider uses a variety of techniques to smooth, color-adjust, and brighten the area under the eyes most susceptible to eye bags with tired talent.

(Left) Eyes with no special adjustment, (Right) Eyes with adjustment

**Lip Retouching**

These controls target just the lips and surrounding area of the mouth.

— **Hue:** This slider lets you adjust the color of a subject’s lips or lipstick.

— **Saturation:** This slider lets you adjust the intensity of lip color.

— **Upper Lip Smooth:** Lets you smooth out fine age lines that can appear above lips.
Blush Retouching

The parameters in this group let you modify the hue of the blush region of a subject’s cheek, letting you correct an unwise makeup choice, or push a subject’s blush color around to add makeup that wasn’t there.

— **Hue:** This slider lets you adjust the hue of the cheeks.
— **Saturation:** This slider then lets you intensify or remove blush color.
— **Size:** This slider lets you adjust the size of the blush area of the cheeks.

About Forehead, Cheek, and Chin Retouching

The next three groups of controls borrow a technique from portrait painters, who’ve long taken advantage of the “traffic light” approach to rendering skin hues, that observes that foreheads are often a bit yellow, the middle of the face is usually a bit red, and chins can be a bit green. A combination of unequal sun exposure, capillary distribution, and follicle growth account for this, but the bottom line is that faces are seldom a single unified hue. This means that there may be a region of the face that would benefit from individual adjustment (cheeks that have gotten too much sun, for example). But it also means that when you allow a bit of hue variation into your face grade, you can achieve a more naturalistic result.

![Image: A face graded with a single hue, and one graded with slight variation in the forehead, blush area, and chin.]

**TIP:** For a variety of reasons, people are extremely sensitive to the hues of skin tone, so tiny variations that can be difficult to identify nevertheless have a significant impact on the resulting visuals. Unless you’re aiming to create a special effect, these controls are meant to be used sparingly.
Forehead Retouching
As the name implies, adjusts color and texture on the forehead.

— **Hue and Saturation:** These sliders let you adjust forehead color.
— **Smooth:** This slider lets you apply a specific smoothing operation to the forehead to ameliorate wrinkles and worry-lines.

Cheek Retouching
Simple color adjustment controls affecting the entire cheek area, and not just the blush area.

— **Hue and Saturation:** These sliders let you adjust the color of the cheek, eye, and nose area.

Chin Retouching
Simple color adjustment controls over the chin of the face.

— **Hue and Saturation:** These sliders let you adjust the color of the chin, running up alongside the sides of the face (the beard area).
Chapter 159

Resolve FX Revival

This category consists of plug-ins that let you fix common technical, damage, and quality problems that bedevil programs being finished, remastered, or restored.

Automatic Dirt Removal
(Studio Version Only)

The Automatic Dirt Removal plug-in uses optical flow technology to target and repair temporally unstable bits of dust, dirt, hair, tape hits, and other unwanted artifacts that last for one or two frames and then disappear. All repairs are made while maintaining structurally consistent detail in the underlying frame, resulting in a high quality restoration of the image. Fortunately, despite its sophistication, this is a relatively easy plug-in to use; just drop the plug-in on a shot, adjust the parameters for the best results, and watch it go.

(Left) Original image, (Right) Using Automatic Dirt Removal

**NOTE:** This plug-in is less successful with vertical scratches that remain in the same position for multiple frames and is completely ineffective for dirt on the lens that remains for the entire shot.

**Main Controls**

The primary controls used to adjust how much dirt is removed from the image.

- **Motion Estimation Type:** Lets you choose from among None, Faster, Normal, and Better. This tunes the tradeoff between performance and quality.

- **Neighbor Frames:** Lets you choose how many frames to compare when detecting dirt. Choosing more frames of comparison takes longer to process, but usually results in finding more dirt and artifacts.

- **Repair Strength:** This slider lets you choose how aggressively to repair dirt and artifacts that are found. Lower settings may let small bits through that may or may not be actual dirt, while higher settings eliminate everything that’s found.

- **Dirt Size Threshold:** This slider lets you tune how large a detected bit of dirt must be to be removed. Raising this parameter lets you omit things like film grain from the operation but may allow smaller bits of dirt through.

- **Show Repair Mask:** This checkbox lets you see the dirt and artifacts that are detected by themselves, so you can see the effectiveness of the results as you fine tune this filter.
**Fine Controls**

These controls let you fine tune the effect in an effort to perfect the tradeoff between removing dirt successfully and preserving true image detail.

- **Motion Threshold:** This slider lets you choose the threshold at which pixels in motion are considered to be dirt and artifacts. At lower values more dirt may escape correction, but you’ll experience fewer motion artifacts. At higher values, more dirt will be eliminated, but you may experience more motion artifacts in footage with camera or subject motion.

- **Edge Ignore:** This slider lets you exclude hard edges in the picture from being affected by dirt or artifacts that are removed. Higher values omit more edges from being affected.

**Chromatic Aberration**

*(Studio Version Only)*

A Revival category plug-in that lets you manually correct the slight color fringing that results from chromatic aberration in a lens. “Estimated Red/Blue Fringes” checkboxes display an “alignment guide” that visually isolates each of two types of fringing against gray.

(Left) The original image in close up, showing chromatic aberration, (Right) The image with Estimated Red Fringes enabled, letting you see the specific problems as differences between red and cyan stripes

This makes it easy to make manual adjustments to correct the problem, using the Scale and Edge controls to individually adjust Red/Cyan and Blue/Yellow fringing.

(Left) The original image in close up, showing chromatic aberration as a cyan fringe along the right of the smokestack and as a red fringe along the closest corner of the building, (Right) The corrected image in close up; this fringe is gone
Advanced Options provide additional parameters for problem shots. Center X and Y parameters let you offset the center of the lens if you’re dealing with a reframed and re-rendered shot. Balance parameters can help exaggerate hard-to-see fringing to make it easier to correct, and the Fringe Magnification parameter enlarges the fringe indicators that are displayed when you turn on either of the Estimated Fringes checkboxes.

**Dead Pixel Fixer (Studio Version Only)**

If you have clips that were shot on a camera with one or more “dead” or “stuck” pixels in the sensor, you may have black or white spots that are fixed in place in the image. This filter is designed to let you place patches on each dead or stuck pixel, identifying them so you can use different methods of fixing the problem.

In many respects, the Dead Pixel Fixer is similar to the Dust Buster, however the Dust Buster effect is designed to repair transient bits of dust and dirt that only last for a frame or two, whereas the Dead Pixel Fixer is designed to work on blemishes that are fixed in place for the duration of a clip.

To fix dead or stuck pixels, apply the Dead Pixel Fixer filter, make sure the OFX onscreen controls are enabled in the viewer, and then click on each pixel you need to fix with the mouse to place a patch on it. You can click anywhere on the image to place as many patches as you like, there’s no limit. You can also Option-click to delete patches you no longer need. To move any patches, simply drag it to another location.

![Multiple dead pixel removal patches](image)

When you place multiple patches, you can click to select whichever patches you want to adjust the controls for. Each patch can have different control settings.
**General**

These top level controls let you choose how to draw patches with which to repair blemishes in the frame, whether or not to show their on-screen controls, and how.

- **Patch Style:** There are three different kinds of patches you can draw to deal with different kinds of blemishes in the frame.
  - **Draw Rect:** Click and drag to place a rectangular patch of any size from one corner to the opposite corner. Once drawn, you can click on any edge of the overlay and drag to reposition it.
  - **Draw Ellipse:** Click and drag to place an elliptical patch of any size from one corner to the opposite corner. Once drawn, you can click on any edge of the overlay and drag to reposition it.
  - **Place Patch:** Lets you place small patches specifically for tiny details such as dead pixels. When you choose this option, a New Patch Size slider appears that lets you adjust the size of the patches you’re about to place prior to placing them. Once drawn, you can click on the edge of any patch and drag to reposition it.

- **New Patch Size:** (only when Place Patch is selected) Lets you choose how large of a patch to place using the Place Patch tool.
