The integration of Fusion into DaVinci Resolve has enabled the ability to use Fusion Titles in the Edit page. Fusion Titles are essentially generators that were created in the Fusion page and which can be edited into the Timeline of the Edit page as clips with custom controls. However, the really exciting thing about this is that you can create your own Fusion Title templates, from nearly any Fusion page composition you can build using Fusion-generated objects such as Text+ layers, Fusion generators, and even 3D geometry and 3D text with texture and lighting effects. This section shows you how it’s done.

Getting Started Creating a Fusion Template

The first part of creating a Fusion template is to create a Fusion composition, consisting of Fusion-generated objects assembled to create nearly any kind of title or generator you can imagine. If you’re really ambitious, it can include animation. In this example, 3D titles and 2D titles have been combined into a show open.

Create a Macro

Macros are basically Fusion compositions that have been turned into self-contained nodes. Ordinarily, these nodes are used as building blocks inside of the Fusion page so that you can turn frequently-made compositing tricks that you use all the time into your own nodes. However, we can also use this macro functionality to build templates for the Edit page.

Having built your composition, select every single node you want to include in that template except for the MediaOut1 node.
Selecting the nodes you want to turn into a template

**TIP:** If you want to control the order in which node controls will be displayed later on, you can Command-click each node you want to include in the macro, one by one, in the order in which you want controls from those nodes to appear. This is an extra step, but it keeps things better organized later on.

Having made this selection, right-click one of the selected nodes and choose Macro > Create Macro from the contextual menu.

Creating a macro from the selected nodes
The Macro Editor window appears, filled to the brim with a hierarchical list of every parameter in the composition you’ve just selected.

The Macro Editor populated with the parameters of all the nodes you selected

This list may look intimidating, but closing the disclosure control of the top Text1 node shows us what’s really going on.

A simple list of all the nodes we’ve selected

Closing the top node’s parameters reveals a simple list of all the nodes we’ve selected. The Macro Editor is designed to let you choose which parameters you want to expose as custom editable controls for that macro. Whichever controls you choose will appear in the Inspector whenever you select that macro, or the node or clip that macro will become.
So all we have to do now is to turn on the checkboxes of all the parameters we’d like to be able to customize. For this example, we’ll check the Text3D node’s Styled Text checkbox, the Cloth node’s Diffuse Color, Green, and Blue checkboxes, and the SpotLight node’s Z Rotation checkbox, so that only the middle word of the template is editable, but we can also change its color and tilt its lighting (making a “swing-on” effect possible).

Once we’ve turned on all the parameters we’d like to use in the eventual template, we click the Close button, and a Save Macro As dialog appears. If we’re using macOS, we navigate to the /Library/Application Support/Blackmagic Design/DaVinci Resolve/Fusion/Templates/Edit/Titles directory, enter a name in the field below, and click Save.
Restart DaVinci Resolve and Use Your New Template

After you’ve saved your macro, you’ll need to quit and re-open DaVinci Resolve. When you open the Effects Library of the Edit page, you should see your new template inside the Titles category, ready to go in the Fusion Titles list.

Editing this template into the Timeline and opening the Inspector, we can see the parameters we enabled for editing, and we can use these to customize the template for our own purposes.

And that’s it!
Chapter 60

Using Viewers

This chapter covers working with viewers in the Fusion page, including using onscreen controls and toolbars, creating groups and subviews, managing Viewer Lookup Tables (LUTs), working with the 3D Viewer, and setting up Viewer preferences and options.

Viewer Overview

Viewers in the Fusion page display the current frame of the current composition in a variety of ways to help you see what you’re doing and evaluate the final result of your compositing artistry. Viewers display 2D images, but they display a 3D environment using a 3D View as well as a special Quad Viewer, to help you effectively work in three dimensions.

Additionally, you can expose “subviews” including color inspectors, magnifiers, waveforms, histograms, and vectorscopes to help you analyze the image as you work.

Single vs. Dual Viewers

By default there are two viewers positioned side by side across the top of the window. However, you can use the Single/Dual Viewer Button to toggle between a single viewer being shown, and two viewers being shown side by side.

Video Output

At the time of this writing, video output is not available from the Fusion page.
Loading Nodes Into Viewers

When you first open the Fusion page, the output of the current empty composition (the MediaOut1 node) is usually showing in Viewer2. If you’re in Dual-viewer mode, Viewer1 remains empty until you assign a node to one of them.

To load specific nodes into specific viewers:
- Hover the pointer over a node, and click one of two buttons that appear at the bottom-left of the node.
- Click once to select a node, and press 1 (for the left Viewer) or 2 (for the right Viewer).
- Right-click a node and choose View On > None/LeftView/RightView in the contextual menu.
- Right-click the control header of a node in the Inspector, and choose View On > None/Left View/Right View from the contextual menu.
- Drag a node and drop it over the Viewer you’d like to load it into (this is great for tablet users).

When a node is being viewed, a View Indicator button appears at the bottom-left. This is the same control that appears when you hover the pointer over a node. Not only does this control let you know which nodes are loaded into which viewer, but they also expose little round buttons for changing which viewer they appear in.

Clearing Viewers

To clear an image from a viewer, click in the Viewer to make it active; a light purple outline is displayed around the active panel. With the Viewer active, press the Tilde (~) key. This key is usually found to the left of the 1 key on U.S. keyboards. The fastest way to remove all the images from all the viewers is to make sure none of the viewers is the active panel, then press the Tilde key.

Position and Layout

When you resize and change the layout of viewers in the composition, that configuration is always saved with the composition. So each time you open the composition, the size and layout is remembered. You can prevent this behavior by disabling the Recall Layout checkbox in the Global Layout preferences.

If you want all new compositions to open with a certain Viewer layout, you can configure the layout of the two primary Viewers, then use the Grab Document Layout button in the Global Layout preferences to remember the layout for any new compositions. To save the position and size of floating viewers, you use the Grab Program Layout button. Finally, if you want to have the floating viewers opened automatically when you open Fusion, enable the Create Floating Views checkbox.
The Viewer Divider

You can change the relative sizes of the left and right Viewers using the horizontal viewer divider that runs between them. Drag the viewer divider to increase or decrease the amount of space used by one viewer. The adjacent viewer will adjust to accommodate the new layout.

The amount of vertical space available for both viewers can be adjusted by dragging the horizontal scroll bar between the Viewers and the Work area below them.

Zooming and Panning into Viewers

There are standardized methods of zooming into and panning around viewers when you need a closer look at the situation. These methods also work with the Node Editor, Spline Editor, and Keyframes Editor.

Methods of panning viewers:
- Middle click and drag to pan around the Viewer.
- Hold Shift and Command down and drag the Viewer to pan.

Methods of scaling viewers:
- Click a viewer, and press the Equals key (=) to zoom in, and the Minus key (-) to zoom out.
- Press the Middle and Left buttons simultaneously and drag left or right to resize the Viewer.
- Hold the Command key down and use your pointer’s scroll control to resize the Viewer.
- Hold the middle mouse button down, then click the left mouse button to zoom in, or click the right button to zoom out. The scaling uses a fixed amount, centered on the position of the cursor.
- Click a viewer and press Command-1 to resize the image in the Viewer to 100 percent.
- Click a viewer and press Command-F or Command-1 to reset the image in the Viewer to fit the Viewer.
• Click the Scale Viewer menu and choose Fit or a percentage.
• Right-click on a viewer and choose an option from the Scale submenu of the contextual menu. This includes a Custom Scale command that lets you type your own scale percentage

**Methods of spinning 3D viewers:**
In 3D Perspective view, hold the Option key down and drag to spin the stage around.

**Flipbook Previews**
As you build more and more complex compositions, and you find yourself needing to preview specific branches of your node tree to get a sense of how various details you’re working on are looking, you may find it useful to create targeted RAM previews at various levels of quality right in the Viewer, by creating a RAM flipbook. RAM Flipbook Previews are preview renders that exist entirely within RAM and allow you to render a node’s output at differing levels of quality for quick processing in order to watch a real-time preview.

**Creating Flipbook Previews**
Creating a flipbook preview is pretty fast, once you know where to look.

**To create a flipbook preview:**
1. Choose the node in your node tree that you want to preview by doing one of the following:
   - Hold the Option key down while dragging a node into the Viewer,
   - Right-click a node and choose an option from the Create/Play Preview submenu in the contextual menu.

2. When the Preview Render dialog opens, choose the quality, resolution, and motion blur settings you want to use for the flipbook preview.

3. When you’ve chosen the settings you want to use, click Start Render.
   The current frame range of the Fusion page Time Ruler is rendered using the settings you’ve selected, and the result is viewable in the Viewer you selected or dragged into.
Once you’ve created a flipbook preview within a particular viewer, right-clicking that viewer presents flipbook-specific commands and options to Play, Loop, Ping-Pong the flipbook, to open it Full Screen, to Show Frame Numbers, and to eliminate it.

**TIP:** If you want to create a flipbook preview and bypass the Render Settings dialog by just using either the default setting or the settings that were chosen last, hold Shift-Option down while you drag a node into the Viewer. The settings dialog will not appear and rendering the preview will start right away.

### Playing Flipbook Previews

While the flipbook preview is loaded into a viewer, or open in fullscreen mode, you can play or scrub through it using the mouse and the keyboard.

**To play back a flipbook using the mouse, do the following:**
- Double click in the Viewer to start playback.

**To scrub through a flipbook using the mouse, do the following:**
- Hold the right mouse button down and drag left or right to scrub through frames.

**To play back a flipbook using the keyboard, do one of the following:**
- Press the Spacebar to start or stop playback.
- Hold Shift and press the Spacebar to play in reverse.

**To scrub through a flipbook frame-by-frame using the keyboard, do one of the following:**
- Press the Left or Right Arrow keys to move to the previous or next frame.
- Hold Shift and press the Left or Right Arrow keys to jump back or forward 10 frames.
- Press Command-Left Arrow to jump to the first frame.
- Press Command-Right Arrow to jump to the last frame.

**TIP:** The mouse and keyboard shortcuts work in Fullscreen mode as well.

### Removing Flipbook Previews

Once you create a flipbook preview, you need to know how to clear it from RAM.

**To eliminate a flipbook you’ve created:**
- Right-click within a viewer containing a flipbook preview, and choose Remove Preview.

### Flipbook Preview Render Settings

This section covers all of the settings available for rendering flipbook previews to RAM.
Settings
The Settings section of the Preview Render dialog include three buttons that determine the overall quality and appearance of your flipbook preview. These buttons also have a significant impact on render times.

- **HiQ:** When enabled, this setting renders the preview in full image quality. If you need to see what the final output of a node would look like, then you would enable the HiQ setting. If you are producing a rough preview to test animation, you can save yourself time by disabling this setting.

- **MB:** The MB in this setting stands for Motion Blur. When enabled, this setting renders with motion blur applied if any node is set to produce motion blur. If you are generating a rough preview and you aren't concerned with the motion blur for animated elements, then you can save yourself time by disabling this setting.

- **Some:** When Some is enabled, only the nodes specifically needed to produce the image of the node you're previewing are rendered.

Size
Since RAM flipbook previews use RAM, it’s helpful to know how many frames you can render into RAM before you run out of memory. The Flipbook Preview dialog calculates the currently available memory and displays how many frames will fit into RAM. If you have a small amount of RAM in your computer and you cannot render the entire range of frames you want, you can choose to lower the resolution to a setting that delivers the best quality/duration ratio for your preview.

Network
Network rendering is not currently available.

Shoot On
Sometimes you may not want to render every single frame, but every second, third or fourth to save render time and get faster feedback. You can use the Step parameter to determine the interval at which frames are rendered.

Frame Range
This field defaults to the current Render In/Out Range set in the Time Ruler to determine the start and end frames for rendering. You can modify the range to render more or fewer frames.

Configurations
Once you’ve created a useful preview configuration, you can save it for later use by clicking the Add button, giving it a name, and clicking OK.

Updating a Preview
An option that is designed for the interactive frame-by-frame work of rotoscoping and paint is to set a Preview to Update from its contextual menu. When active, any frames that are modified on the previewed node are automatically updated in the preview’s playback. This lets you reserve the RAM to do playback. You can keep it playing on a loop or ping-pong while you work in another viewer.
Onscreen Controls

When it comes to adjusting images, the Control Panel provides very precise numerical values, but sometimes visually positioning an element using onscreen controls can get you where you want to go with less tweaking. The Viewers show onscreen controls for manipulating the parameters of the currently selected node. Common onscreen controls include crosshairs, angle indicators, polylines and paint strokes. Each of these controls can be manipulated directly in the Viewer using the mouse or keyboard.

![Image of onscreen controls](image)

The controls that are shown in viewers are determined by which nodes are selected, not by the node displayed in the Viewer. For example, a downstream blur is easily viewed while manipulating the controls for a selected polygon mask or merge. If multiple nodes are selected, the controls for every selected node are shown simultaneously.

Showing and Hiding Onscreen Controls

The onscreen controls for a viewer can be hidden so they don’t interfere with viewing the image.

**To toggle the visibility of onscreen controls, do one of the following:**

- Click a viewer’s Option menu and choose Show Controls to toggle the controls on or off.
- Right-click in a Viewer and choose Options > Show Controls from the contextual menu.
- Select a viewer and press Command-K.

Enabling/Disabling Onscreen Controls in Specific Nodes

Some nodes, like masks, allow disabling of their onscreen controls on a per-node basis, since you often use multiple Polygon nodes to organize and animate masks.

![Image of showing and hiding controls](image)

You can disable some nodes, like the Polygon node, on a per node basis.
Making Fine Adjustments to Onscreen Controls

If you want the visual guidance of onscreen controls with the precision of the Control Panel, you can use different keyboard modifiers.

- The Arrow keys can be used to adjust the position of an onscreen control along the vertical or horizontal axis by small steps.
- Holding the Command key down while using the Arrow keys reduces the scale of each step by a factor of ten. Holding Shift increases the scale of each step by a factor of ten.

Toolbars

There are two toolbars in the Viewer: a Viewer toolbar which always appears at the top of each viewer and gives you control over what that viewer shows, and an optional Node toolbar that appears underneath that gives you contextual controls based on the node you’ve selected in the Node Editor.

Viewer Toolbar

Viewer toolbars run across the top of each Viewer, providing access to many of the most commonly used Viewer-related settings, as well as an indication of the status of many of the most important settings. Most of the menus and buttons found on this toolbar are described in detail throughout this chapter.

Node Toolbars

In addition to the Viewer toolbar, a Node toolbar is displayed underneath, at the top of the Viewer display area, whenever you select a node that exposes special nodes. Examples of nodes that expose a toolbar include the text, masks, paths, paint strokes, and the 3D environment.

Customizing the Node Toolbar

If you want to change the size of the buttons that appear in the Node toolbar, or turn on text names for each node, you can right-click anywhere in the empty area of the toolbar and choose new settings from the Icon Size and Button Style submenus in the contextual menu.
A/B Buffers

Each viewer has two buffers, each of which can contain images from different nodes, enabling easy comparison of two different nodes within the same viewer by either toggling between buffers, or via an adjustable split-wipe. Each buffer can be considered a complete and separate viewer within the same viewer pane. The A buffer is always shown by default, so when you first load a node into a viewer, the image loads into the A buffer.

Flipping Between Buffers

Switching between buffers is easy, either to view a different image while keeping another image handy, or to flip between two different images for comparison.

To switch between buffers, do one of the following:

- Select a viewer and press comma (,) to select the A buffer or press period (.) to select the B buffer.
- Click the buffer menu and choose either Switch to A View or Switch to B View.

TIP: Each buffer can be set to different display settings, for example showing different channels or different viewing LUTs, either applied to different nodes or applied to two buffered versions of the same node.

Split Wipes Between Buffers

You can also wipe between both buffers, providing a more direct means of comparison.

To wipe between buffers, do one of the following:

1. Prepare to wipe between two images by loading different nodes into each buffer, or load the same node with different viewer options into each buffer.
2. To toggle the split wipe on or off, do one of the following:
   - Click the Switch to Split Wipe View button.
   - Press Forward Slash (/).
3. To adjust the wipe, do one of the following:
   - Move the center of the wipe by dragging the center handle of the wipe divider.
   - Press Command-Option and click anywhere in the Viewer to jump the wipe divider to that location.
   - Change the angle or the wipe by dragging the wipe divider of the wipe. Dragging the wipe divider while holding the Shift key snaps it to the nearest 45-degree angle.
   - Panning or zooming the Viewer pans and zooms both buffers together.
(Optional) If you want to change the image that’s displayed on that side of the split, you can drag new nodes onto either half of the Viewer.

To turn the wipe off, click the Switch to Split Wipe View button again (or press /).

The wipe divider can be adjusted for comparing different areas of the A and B images.

Even when you wipe, you can choose different display channels, view LUTs, or other display options for each buffer individually by clicking on the half of the wipe you want to alter, and then choosing the options you want that buffer to use. This allows easy comparison of different channels, LUTs, or other viewer settings while wiping the same image, or different images.

**Moving the Wipe Divider**

Occasionally, you will have either zoomed in or panned so far from the viewer divider that it’s no longer visible in the Viewer. Holding Command-Option down and clicking anywhere in the image will cause the viewer divider to jump to the current position of the pointer.

**Subviews**

A subview is a “mini” viewer that appears within the main Viewer. It’s usually used to show different information about the image.
For example, the RGB channels can be viewed in the main Viewer, while the alpha channel is displayed in a subview. For the most part, the Subview is a fully functional miniature viewer, with its own contextual menu and options. It responds to the same keyboard shortcuts and navigation controls as any other viewer. However, there are several view types that are designed for use only in the Subview, including the Navigator, Magnifier, Color Inspector, and Image Info.

**Showing and Hiding Subviews**

Subviews are easily shown and hidden.

**To enable the currently selected Subview in the Subview menu of a viewer, do one of the following:**

- Click the Subview button in the View toolbar
- Choose Views > Subview > Enabled from the contextual menu.
- Click a viewer, and press the V key.

![The Subview button in the Viewer toolbar](image)

**Changing the Subview Type**

The Subview button enables and disables the Subview, which usually shows the last subview you chose. You can change this at any time.

**To change which subview type is displayed, do one of the following:**

- Click the small arrow to the right of the Subview button to open its menu and choose which subview you want.
- Right-click within a subview to bring up the Subview’s contextual menu.

The Subview popup menu and contextual menu show all the available subview types. Once you choose an option from the list, that is the view that will be displayed in the Subview, and the Subview button will show and hide it as you wish.

**Swapping the Subview with the Main View**

It’s possible to swap the contents of the main Viewer and the Subview for select subview types. However, certain view types, such as the Color Inspector and Magnifier, can only be used in the Subview. In these cases, the swap will not take place.
To swap the contents of the Subview with the main view, do one of the following:

- Press Shift-V
- Right-click in a viewer and choose Views > SubView > Swap from the contextual menu.

**Viewer and Subview Types**

Viewers can be changed to show a variety of different information about the image, but not all view types are available at all times. For example, the 3D Viewer is not available for a 2D node and some of the measurement viewers are only available as subviews. Below is detailed information about the different view types available.

**2D Viewer**

The 2D Viewer is the default type for showing images. When used as a subview, a different node than the one used in the main Viewer can be displayed by dragging the node into the Subview.

This is the only Subview type that is not just a different view of the same node in the main Viewer.

![The Subview used as another viewer](image)

**3D Image Viewer**

The 3D image viewer is available when viewing a node from the 3D category.

![A 3D image viewer as a subview](image)
Histogram

The Histogram is an analysis node that can be used to identify problems with contrast and the dynamic range in an image. The graph shows the frequency distribution of colors in the image, including out of range colors in floating point images. The horizontal axis shows the colors from shadows to highlights. The vertical axis shows the number of pixels in the image that occur at each level.

The Histogram viewer will also display gradient information. You can use the From Image and Perturb modifiers to output gradients. If you need to see the gradient represented in a histogram, drag the modifier’s titlebar into the Viewer.

3D Histogram

This more advanced histogram type shows the color distribution in an image within a 3D cube. One advantage to a 3D Histogram is that it can accurately represent the out of range colors commonly found in floating point and high dynamic range images. It can also be used to look at vector images like position, normal, velocity, and so on.

To rotate within a 3D Histogram, do one of the following:

- Hold the Option key down and drag left or right using the middle mouse button.
- Hold the middle and right mouse buttons down while dragging.
Vectorscope
The Vectorscope duplicates the behavior of a specific type of video test equipment, displaying a circular graph that helps to visualize the intensity of chrominance signals.

Waveform
The Waveform duplicates the behavior of a specific type of video test equipment, displaying a line or bar graph that helps to visualize the voltage or luminance of a broadcast signal.
Navigator

The Navigator can only be used in a subview. It provides a small overview of the entire image, with a rectangle that indicates the portion of the image that is actually visible in the main Viewer. This is useful when zooming in on an image in the main view.

Magnifier

The Magnifier can only be used in a subview. It shows a zoomed in version of the pixels under the cursor in the main Viewer.
Image Info
The Image Info view can only be used in a subview. The Image Info tab shows a horizontal bar across the top of the image with information about the frame size, pixel aspect, and color depth of the viewed image.

Color Inspector
The Color Inspector can only be used in a subview. The Color Inspector shows information about the color channels of the pixel under the cursor. It will show all channels present, even the auxiliary channels such as Z buffer, XYZ normals and UV mapping channels.

Metadata
The contents of this subview is entirely based on the amount of metadata in your image. Most Loaders will give the colorspace and file path for the image. Much more information can be displayed if it exists in the image.
Viewing Selective Channels

When compositing, you often deal with individual color components or channels in an image as much as you deal with the full RGB color of the entire image. The Viewers and Subviews can display the isolated color, alpha, depth channels, and even auxiliary channels that make up the image.

Viewing Color Channels

The default view is the full RGB color channel, but to change the channel that is displayed you can use the Channel toolbar button, the Viewer’s contextual menu, or keyboard shortcuts.

To toggle between RGB and alpha channels in the active Viewer:
Click the Color button, in the Viewer toolbar, to toggle between full RGB color and that image’s alpha channel.

To toggle the channel that’s displayed in the active Viewer:
- Click the arrow to the right of the Color button to choose a specific channel to view of the available channels for the current image.
- Click the Viewer you want to toggle, and press one of the following keyboard shortcuts:
  - C - Full RGB color display
  - R - Display red channel
  - G - Display green channel
  - B - Display blue channel
  - A - Display alpha channel
  - Z - Display Z-buffer channel

Viewing Auxiliary Channels

The Viewers support RGBA and Z channels using keyboard shortcuts, but they support other channels as well. File formats such as Open EXR often include auxiliary image data that provide more control and compositing options when working with rendered 3D images. To view auxiliary image data in a viewer, click the arrow to the right of the RGB button to display the pop up menu or right-click in the Viewer and choose an option from the Channels submenu of the contextual menu.
The 3D Viewer

Building a composite in 3D space has different requirements than traditional 2D compositing. When a node from the 3D category or some particle systems is selected, a 3D Viewer is used to display the scene. The 3D Viewer shows a representation of a composite in a true GPU-accelerated 3D environment.

For more information on 3D controls, see Chapter 68, "3D Compositing."

Panning and Scaling and Rotating a 3D Viewer

For the most part, navigation in the 3D Viewer is similar to the navigation in the 2D Viewer. Panning and zooming work with the same controls even though you're moving within a 3D space. However, when viewing a 3D scene, panning changes the point of view and thus the center point for scaling and rotation, too. A combination of panning and rotation will allow you to move the point of view anywhere in the scene.

Another small change is that there's a lower limit to the scale of a 3D scene. Continuing to zoom in past this limit will instead move ("dolly") the point of view forwards. The mouse wheel will move forward slowly, and the keyboard will move more quickly.

Critically, the 3D Viewer gives you additional control to rotate the Viewer within the three dimensions of the scene, to better see your scene from different angles as you work.

To rotate within a 3D Viewer, do one of the following:

- Hold the Option key down and drag left or right using the middle mouse button.
- Hold the middle and right mouse buttons down while dragging.

The rotation is centered on the middle of the view.

TIP: These rotation controls can be used with the 3D Histogram subview as well.

Viewing Objects Via Wireframe

3D composites not only work with 2D images on image planes, but can also integrate true geometry, such as that generated by the Particle system, Text 3D node, imported FBX meshes, and basic primitives from the 3D toolset. Using a Wireframe view helps to see through a mesh or see the density of the geometry. It is much easier to see a change in the Subdivision level of an ImagePlane3D in wireframe than viewing the rendered image.

To display 3D geometry in wireframe, do the following:

Right-click the 3D Viewer and choose 3D Options > Wireframe from the contextual menu.
Changing the POV of a 3D Viewer

Compositing a 3D scene often requires that you view the scene from different angles to make sure the position and animation are what you want. While the 3D Viewer uses a perspective camera that allows you to look at the 3D scene from any angle, you can also switch the 3D Viewer to view from the front, top, left or right side of the scene; these are collectively called Orthographic views.

Additionally, if you have a camera or spotlight in your scene, you can switch the Viewer to face the scene from the point of view of those objects.

To change the 3D viewpoints:

- Right-click the Viewer and choose an option from the Camera submenu of the contextual menu. The choices include Perspective, Front, Top, Left and Right.

Changing Cameras in a 3D Viewer

If you have one or more camera objects in the 3D scene, they will be listed as options in the contextual menu. Spotlights and other lights or objects in the scene will be listed in the Other submenu. If you choose any one of these objects, the 3D Viewer jumps to display the scene from the point of view of the chosen object. While looking “through” an object, rotating, panning or zooming, the Viewer will instead change the rotation, position and scale of the camera, light, or other object.

Copying a Viewer’s POV to a Camera

There are many times you will have used the default perspective view to set up your scene but now want that point of view to become your main camera’s point of view. You can easily position and orient a camera, light, or other object to match the current point of view shown in the Viewer using the Copy PoV to command.

To copy the point of view in the Viewer to a camera, do the following:

1. Set up a 3D Viewer with the point of view you want by zooming, panning, and rotating the Viewer.
2. Add a camera to your 3D scene.
3. Right-click anywhere within the 3D Viewer, and choose Camera > Copy PoV to > Camera3DNameOfCamera from the contextual menu.

   The Camera3D’s controls will inherit the Viewer’s position and angle values.

   TIP: The Copy PoV to command uses the object’s own coordinate space; any transformations performed downstream by another node are not taken into account.
POV Labels
As you switch the POV of the Viewer, you can keep track of which POV is currently displayed via a text label at the bottom-left corner of the Viewer. Right-clicking directly on this label, or on the axis control above it, acts as a shortcut to the Camera submenu, allowing you to easily choose another viewpoint.

Lighting and Shadows in 3D Viewers
Before you add lights to a 3D scene, default lighting is provided. This basic, flat lighting allows you to see the shading on objects without requiring you to add and set up lights as you work in the 3D viewer. Additionally, shadows are hidden by default. Once you start adding lights of your own, you need to switch modes to see what they affect as you work.

**To see the effects of the default light on the scene:**
Right-click within the 3D Viewer, and choose 3D Options > Default Lights from the contextual menu.

When you’re ready to add your own lighting to a scene, you can connect light nodes in various ways to a Merge 3D node for the scene you’re working on. Once you connect a light to a Merge 3D node, you need to switch the 3D Viewer over to showing the new, proper lighting.

**To toggle Lighting rendering within a 3D scene:**
Right-click within the 3D Viewer, and choose 3D Options > Lighting from the contextual menu.
TIP: Attempting to load a Light node into a viewer all by itself will result in an empty scene, with nothing illuminated. To see the effects of lights, you must view the Merge 3D node the light is connected to.

Similar to lights, the default 3D Viewer has shadows turned off. To see shadows cast from the lighting you’ve created, you have to turn them on.

**To toggle Shadows rendering within a 3D scene:**

Right-click within the 3D Viewer, and choose 3D Options > Shadows from the contextual menu. Enabling shadows will automatically turn on lighting, if it is not already turned on.
NOTE: The shadows shown in the 3D viewer are always hard edged. Soft shadows are available for output to the rest of your composition in the software renderer of the Renderer3D node.

Transparency in 3D Viewers

Image planes and 3D objects are obscured by other objects in a scene depending on the X, Y and Z position coordinates of each object in 3D space. The default method used to determine which polygons are hidden and which are shown based on these coordinates is called Z-buffering.

Z-buffering is extremely fast, but not always accurate, when dealing with multiple transparent layers in a scene. Fortunately, there is another option for more complex 3D scenes with transparency, “Sorted.” The Sorted method can be significantly slower in some scenes but will provide more accurate results no matter how many layers of transparency happen to be in a scene.

The default behavior in the Viewer is to use Z-buffering, but if your scene requires the Sorted method, you can easily change this.

To choose a Sorted method of 3D compositing:
Right-click anywhere within the 3D Viewer and choose one of the options in the Transparency submenu of the contextual menu:

- **Quick Sort**: Reorders the polygons in the scene serially, from back to front, to produce a reasonably accurate rendering of transparency.
- **Full Sort**: Renders every polygon in Z order to produce the most accurate rendering of transparency.

Grid

The 3D Viewer displays a Grid that’s used to provide a plane of reference in the 3D scene. By default, the Grid is 24 x 24 units in size, centered on the origin at (0,0,0), and subdivided into large squares of 2 units with small squares of 0.25 units each. These defaults can be altered in the 3D View panel of the Fusion Settings window, available from the Fusion menu.

To toggle the Grid on and off:
Right-click anywhere within the 3D Viewer and choose 3D Options > Grid from the contextual menu.
Vertex Normals

Normals indicate what direction each vertex of 3D geometry is facing, and they are used when calculating lighting and texturing on an object. When viewing any kind of 3D geometry, including an image plane or a full FBX mesh, you can display the normals for each object in a scene.

To view the Normals in a scene:
Right-click anywhere within the Viewer and choose 3D Options > Vertex Normals from the contextual menu.

Quad View

3D compositing often requires you to view the scene from different points of view to better control transformations in three dimensions. While you can switch the 3D Viewer to different points of view, doing so frequently can become cumbersome. Happily, you can instead enable a Quad View with which to divide the Viewer into four panes. These panes can then display four different angles of the scene at one time.

To toggle the display of the Quad view, do one of the following:
- Right-click anywhere within the Viewer, and choose Views > Quad View from the contextual menu.
- Press Shift-Q.
While there are four panes in the Quad View, they all show the same scene. When assigning views within a Quad view, you can choose between displaying Front, Left, Top, Bottom and Perspective orthographic views, or you can choose the view through any camera or spotlight that’s present in the scene.

**To assign different views to panes of a Quad View, do one of the following:**

- Right-click directly on the POV label at the bottom left of the pane you want to reassign, and choose another camera, light, or Point Of View from the contextual menu.

**Quad View Layouts**

There are a variety of Quad view layouts, ranging from four equally sized panels to having three small panels across the bottom of a larger single panel.

**To switch to a different Quad view layout, do the following:**

1. Enable the Quad view.
2. Right-click anywhere within the Viewer, and choose an option from the Views > Quad Layouts submenu of the contextual menu.

**Using Quad Views for 2D Scenes**

Quad views aren't only useful for 3D scenes. They can also be used with 2D scenes, with each pane showing a different image channel or subview type. For example, one pane can show the image while the other panes show the alpha channel, a vectorscope, and a histogram.

**To assign different channels or subviews to panes of a quad view for a 2D scene:**

1. Enable the Quad view.
2. Click once in the pane you want to reassign.
3. Do one of the following:
   a. Choose a channel from the Channel Viewer menu.
   b. Turn the Subview button on, then choose a subview, and press Shift- to force it into the pane you clicked.

**Guides**

Guides are onscreen overlays that are used to help you compose elements within a boundary or along the center vertical and horizontal axis. While guides are displayed in the Viewer, they're not rendered into the scene. There are four commonly used guides that can be displayed, including Monitor Safety, Safe Title, Center, and Film.

**Methods of using guides:**

- **To display guides in a viewer:** Right-click in the Viewer, then choose Guides > Show Guides from the contextual menu, or press Command-G.
- **To change the aspect ratio of the displayed guides:** Right-click in the Viewer, then choose an option from the Guides > Frame Aspect submenu. The frame aspect is usually set to Default, which forces the frame aspect to the same resolution as the image that's displayed in the view. However, when the frame aspect is set to a specific value, the guides will conform to the exact boundaries of the specified format and any image area outside of that will be dark gray.
To show or hide specific guides: Right-click in the Viewer, then choose an option from the Guides submenu. A variety of specific guides are provided, each of which can be individually enabled and disabled.

- **Monitor Safety**: Monitor Safety indicates the safe action area viewable on most monitors and TV screens.
- **Safe Title**: Safe Title indicates the safe area for titles viewable on all TV and monitor screens.
- **Center**: Center shows a cross hair for the Center point and X- and Y-axis of the view.
- **Film**: Some frame formats include film guides preset for you, whereas some will require customization. The film guides can be customized in the Preferences > Frame Format window.

The Guides submenu in the Viewer’s contextual menu

**Frame Format Settings**

In the Frame Format panel of the Fusion Settings window (available in the Fusion menu), there are two film guide settings that you can use to customize these guides.

- Guide 1 contains four fields that specify the offset from the edges of the image for the left, top, right and bottom guides, in that order. As with all offsets in Fusion, this is a resolution independent number where 1 is the width of the full image and 0.5 is half the width of the image.
- Guide 2’s text box is used to set the aspect ratio of the projection area.
Domain of Definition and Region of Interest

As a compositing environment, the Fusion page uses the standard compositing conventions of Region of Interest (RoI) and Domain of Definition (DoD) to dramatically improve rendering.

**Domain of Definition (DoD)**

In compositing, the Domain of Definition, frequently abbreviated to DoD, refers to a rectangular region that defines what part of an image actually contains data. DoD makes the concept of an image’s actual frame somewhat flexible, since rendering is no longer limited to the actual width and height of the image. This has two effects on the way the Fusion page renders images.

Firstly, nodes will no longer be required to render portions of the image that do not get affected by the node. This helps the renderer to optimize its performance. Secondly, the Fusion page can now keep track of, and apply a node’s effect to, pixels that lie outside the visible portion of the image.

For example, consider the output of a Text+ node rendered against a transparent background. The text only occupies a portion of the pixels in the image. Without Domain of Definition, you would be required to process every pixel in the image needlessly. With a DoD you are able to optimize effects applied to the image, producing faster results and consuming less memory in the process.

The following image shows an image with the DoD outlined.

![ShowDoDResult](image)

The DoD is shown as two XY coordinates indicating the corners of an axis aligned bounding box (in pixels).

For the most part, the DoD is calculated automatically and without the need for manual intervention. For example, all of the nodes in the Generator category automatically generate the correct DoD. For nodes like Fast Noise, Mandelbrot and Background, this is usually the full dimensions of the image. In the case of Text+ and virtually all of the Mask nodes, the DoD will often be much smaller or larger.

Clips from the Edit page timeline or Media Pool will typically also have the DoD default to the full image width of the source media. The exception is media stored in the .raw or OpenEXR format. These formats are capable of storing the data window of the image, and the Fusion page will apply this as the DoD when loading such an image and will write out the DoD if output directly.

The DoD is established as soon as the image is created or loaded into the composition. From there it passes downstream, where Viewers combine it with their “Region of Interest” in order to determine exactly what pixels should be affected by the node. As you work, different nodes will automatically shrink, expand or move the DoD as they apply their effect to an image, causing the DoD to change from node to node.
Showing the DoD

If the current DoD for a node is different from the frame size of that image, it’s shown in the tooltip that appears when the pointer hovers over a node in the Node Editor. The DoD is also visible in the Viewer when you right-click in a viewer and choose Region > Show DoD from the contextual menu.

Setting the DoD Manually in the Node Editor

It is also possible to set the DoD for an image manually using the Tools > Miscellaneous > Auto Domain node in the Effects Library. This node can be useful when dealing with pre-created media that does not occupy the full image dimensions. For example, a rendering of a 3D character that walks toward the camera will frequently only occupy a portion of the image. The Auto Domain node can be used to animate a DoD that covers the character and ignores the rest of the image, making image processing more efficient.

Region of Interest (RoI)

The Region of Interest, frequently abbreviated to RoI, is a rectangular region similar to the Domain of Definition. However, unlike the DoD, which tells the node what pixels are actually present in the image, the RoI tells the node which pixels actually need to be rendered. When a node renders, it intersects the current RoI with the current DoD to determine what pixels should be affected.

Enabling RoI Controls

You can turn on the RoI controls to restrict rendering to a small region of the image to significantly improve performance when you’re only working on a small part of a high-resolution or complex composition. For example, if you’re using paint to clean up some holes in a matte on the floor of a composition with many, many high resolution layers, 3D, and Lighting operations, you can use the RoI controls to isolate the part of the floor you’re working on, which makes caching that part of the composition much faster.

To enable the RoI controls, do one of the following:
- Click the RoI button in the 2D Viewer toolbar.
- Right-click in a viewer and choose Region > Show DoD from the contextual menu.

When RoI is enabled and Show is selected from the menu, a rectangular RoI control appears in the Viewer. If this is the first time RoI has been enabled, it will be set to the full width and height of the image. Otherwise, the last known position of the RoI for that view is used. However, if you want to set the RoI to a custom area within the frame, you can do one of the following.

To adjust the RoI controls, do one of the following:
- Drag any edge of the RoI rectangle to adjust one side of the RoI.
- Drag a corner to adjust the size of the RoI rectangle from that corner.
- Drag the small circle found at the top left corner of the RoI rectangle to move the RoI without adjusting its dimensions.

Sometimes, it’s faster to simply draw a rectangle where you want the RoI to be.

To quickly draw the RoI at the desired size:

1. Choose Set from the Viewer menu next to the RoI button, or right-click anywhere within the Viewer and choose Region > Set Region.
2. When the pointer turns into an RoI drawing cursor, drag within the Viewer to set a RoI rectangle.
Alternately, an Auto command sets the RoI to fit whichever pixels are visible at the current zoom/pan level in the Viewer. This lets you quickly limit the RoI to whatever part of the composition you’ve zoomed into.

**To automatically draw the RoI:**
- Choose Auto from the Viewer menu next to the RoI button.
- Right-click anywhere within the Viewer and choose Region > Auto Region.

When you’re finished needing to use the RoI, you can reset it.

**To reset the RoI to the full width and height of the current image, do one of the following:**
- Choose Reset from the Viewer menu next to the RoI button.
- Right-click anywhere within the Viewer and choose Region > Reset Region from the contextual menu or the Toolbar button menu.
- Disable the ROI control, which will also reset it.

**While the RoI is Active**
The RoI is only used for previewing your composition while you work, not for output from the Fusion page to the rest of DaVinci Resolve. While the RoI is active, the Fusion page will only request rendering of the pixels inside the region when it displays an image in that Viewer. Flipbook previews that you create in that Viewer will also respect the current RoI. MediaOut nodes will always use the full image dimensions when writing the image to disk, ignoring any RoI you’ve set in the Viewers.

The RoI improves not only rendering speed and memory use, it can also reduce file I/O, since MediaIn nodes only load pixels from within the RoI, if one is specified. This does require that the file format used supports direct pixel access. Cineon, DPX and many uncompressed file formats support this feature, as well as OpenEXR and TIFF in limited cases.

Please note that changes to the viewed image size or color depth will cause the pixels outside the RoI to be reset to the image’s canvas color. This also happens when switching in and out of Proxy mode, as well as during Proxy mode switching with Auto Proxy enabled. When the image size is maintained, so are the last rendered pixel values outside the RoI. This can be useful for comparing changes made within the RoI with a previous node state.

**TIP:** Image Overlay will defeat RoI, forcing renders of pixels for the entire image.

**Managing Viewer Lookup Tables (LUTs)**

Lookup Tables, or LUTs, can be used to help match the appearance of a viewer to its eventual output destination. They’re essentially image processing operations that affect only the image being previewed in the Viewer, not the image data itself. There are two basic ways that LUTs can calculate color transformations: the first is a simple 1D LUT, while the second is a more sophisticated 3D LUT.

- **The simplest form of a LUT is a 1D LUT.** It accounts for one color channel at a time, so it can make overall tonality changes but not very specific color changes.
- **A 3D LUT looks at each possible color value (red, green and blue) independently.** A 3D LUT allows for large global changes as well as very specific color changes to be applied to images very quickly.
How Lookup Tables Work in Fusion

A Lookup Table (LUT) is a table of values used to transform the color and luminance of an image. A 1D LUT uses a two column table for input color and output color, while a 3D LUT uses more of a matrix. A LUT is primarily used to correct for variances in the monitor or the source color space of the image. You can choose to apply a LUT to all the Viewers or apply different LUTs to each 2D viewer.

Image LUTs

Image LUTs can be applied to each viewer. In fact, you can even apply separate LUTs for the A and B buffers of a single viewer. These LUTs can only be applied to 2D images and not 3D scenes. Image LUTs are routinely used to get from one scene referred colorspace to another. For example, if you’re working with log-encoded media but you want to see how the image will look in the final color space, you can choose a LUT to make this image transform as a preview.

Buffer LUTs

The Buffer LUT is applied to all of the Viewers, regardless of contents, including 3D scenes, 3D materials, and subview types. Only one buffer LUT can be applied. If a 2D image is being displayed with an image LUT applied, then the buffer LUT is applied to the result of the image LUT. Buffer LUTs are typically used to simulate another output color space that’s particular to the display you’re using. For instance, making a DCI-P3 projector show the image as it would look on an sRGB monitor.

When dealing with nonlinear files from many of today’s digital cinema cameras, a modern workflow would be to convert everything to linear at the beginning of the node tree, then create your composite, and then apply an image LUT or buffer LUT that matches the color space you want it to be in for grading in the Color page at the end of the node tree.

However, in more elaborate production pipelines, you may have the need to apply multiple LUTs consecutively.

Resolve Color Management

At the time of this writing, the Fusion page does not automatically interact in any way with Resolve Color Management (RCM). Images coming into the Fusion page via MediaIn nodes are in the Timeline gamma and color space. For some simple operations, this may be fine, but it’s not always ideal.

Types of Viewer LUTs

Aside from the industry standard 1D and 3D LUTs, other types of LUTs are supported, including script-based fuse node LUTs, and macros assembled from standard nodes. Generally, LUT processing is performed on the graphics card’s GPU in real time, although the performance of macro based LUTs is based on the nodes they contain.

Fusion View LUT

The Fusion View LUT is the default and most frequently used LUT type. It provides an RGBA curve that can be used to assign IN/OUT value pairs. This control is identical to that provided by the Color Curve node.

Since the purpose of the View LUT is to provide an unchanging correction for the monitor or the file’s color space, however, these splines cannot be animated.

Log-Lin View LUT

The Log-Lin LUT converts logarithmic data to linear, and vice versa. This can be particularly useful when used in conjunction with supplied LUT files that expect logarithmic data. It is similar to the Cineon Log node.
Gamut View
Converts a source color space to an output color space, with options to deal with gamma settings, alpha channels, and premultiplication.

Macro LUTs
Any macro node can also be used as a Viewer LUT, simply by saving the macro’s .setting file to the correct DaVinci Resolve application support directory. On macOS, the /Users/UserName/Library/Application Support/Blackmagic Design/DaVinci Resolve/Fusion/LUTs/ directory lets that macro appear in the Viewer LUT menu.

For this to work, the macro must have one image input and one image output. Any controls exposed on the macro will be available when the Edit option is selected for the LUT.

For more information about creating Macros, see Chapter 59, "Node Groups, Macros, and Fusion Templates."

Preset LUTs
All LUTs that are available to DaVinci Resolve in the Color page are also available to the Fusion page, which includes custom LUTs you’ve installed, as well as preset LUTs that come installed with DaVinci Resolve, such as the highly useful VFX IO category that includes a wide variety of miscellaneous to Linear and Linear to miscellaneous transforms. All of these LUTs appear, by category, in the Viewer LUT menu.

Fuse LUTs
Fuses are scriptable plug-ins that are installed with the application or that you create in Fusion. A fuse named CT_ViewLUTPlugin can be applied as a LUT to a viewer. You can also script fuses that use graphics hardware shaders embedded into the LUT for real time processing. Since fuse LUTs require shader-capable graphics hardware, they cannot be applied in software. For more information about fuses, see Chapter 51, “Node Groups, Macros, and Fusion Templates."

Using Viewer LUTs
Viewer LUTs can be enabled, edited, and turned off using the Viewer LUT button and menu, as well as by using the Viewer contextual menu. This menu shows all LUTs that are available to DaVinci Resolve, including custom LUTs you’ve installed yourself.
To turn the current Viewer LUT on and off:

- Click the LUT button in the Viewer toolbar to toggle the Viewer LUT on and off.
- The LUT menu can also be found as a submenu in the Viewers’s contextual menu.

To choose another Viewer LUT:

Open the menu to the right of the Viewer LUT button and choose an option from the Viewer LUT menu.

To apply a Buffer LUT:

- Right-click anywhere within the Viewer, and choose Global Options > Buffer LUT > Enable.
- To choose a specific Buffer LUT, right-click again and choose a LUT from the Global Options > Buffer LUT submenu.
- Buffer LUTs are often useful for applying monitor corrections, which do not usually change between projects.

To remove a Buffer LUT:

Right-click anywhere within a viewer and choose Global Options > Buffer LUT > Enable to uncheck it.

Editing Viewer LUTs

The Viewers are the primary area where color correction is assessed, so it’s crucial that they provide an accurate representation of what the content will look like when it’s played for an audience. The LUT Editor allows you to customize your viewer’s output to match the gamma and color characteristics of your eventual playback device, or to test how the current image looks in a completely different color space, or how it holds up over a range of different color spaces.

To open any editable Viewer LUT option’s Editor:

1. Click the LUT button in the Viewer toolbar to enable it.
2. Do one of the following:
   - Choose Edit from the bottom of the Viewer LUT menu.
   - Right-click in the Viewer, then choose LUT > Edit from the contextual menu.

Editing the Fusion View Lookup Table

Similarly to the Color Curves node, the Fusion View LUT Editor uses spline-based color correction. In addition to the ability to modify the separate color channels, the LUT has Gain and Gamma sliders. The Gain slider is helpful for temporarily brightening or darkening the viewed image, allowing easier examination of shadow or highlight detail. The Color Gamma and Alpha Gamma sliders are used to duplicate the gamma values of the eventual output device. Video monitors, for example, commonly have a gamma of 1.7, while computer monitors can range anywhere from 1.6 to 2.2. Alpha Gamma is only applied when viewing the alpha channel of an image, or when viewing masks.
Editing the Gamut View LUT

The Gamut View LUT Editor lets you choose a Source and Output color space to guide the Viewer transform. The Remove and Add Gamma checkboxes let you choose to do the gamut conversion with linear or non-linear gamma, or they let you simply remove or add the appropriate gamma values without changing the color space. Selecting the Pre-Divide/Post-Multiply checkbox will cause the image’s pixel values to be divided by the alpha values prior to this conversion, and then re-multiplied by the alpha value after this conversion. This helps to avoid the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.

Editing the Log-Lin LUT

The Log-Lin LUT lets you apply a Log to Lin or Lin to Log operation using the Mode pop-up menu. You can choose the type of log-encoding to process from the Log Type pop-up, and whether or not to lock the R, G, and B channels together. A level adjustment lets you redefine the digital range of values used for the output, while Soft Clip (Knee), Film Stock Gamma, and
Conversion Gamma sliders let you further customize the color transform being made. Lastly, a Conversion Table field and Browse button let you add an additional LUT as part of this operation.

The Log-Lin LUT Editor

**LUT Processing Order**

In elaborate workflows, facilities may apply multiple LUTs in a row before the image is seen. The order of these is important since each LUT delivers different outputs. For instance, for a Cineon file in Log color space you may often apply 3 LUTs. First a Log->Lin conversion, followed by a Fusion View LUT to apply a color calibration, and a third one to correct it for display on an sRGB monitor, or replace the last with a 3D DCP LUT if you are viewing on a projector.

When you select a node to be displayed, the image produced is processed before it is shown in the Viewers. The processing order is slightly different for 2D images and 3D scenes.

2D images first have the image LUT applied, and the result is composited over the checker underlay. 3D scenes are instead rendered with OpenGL.

---

<table>

<th>Post Processing</th>
<th>Buffer LUT</th>
<th>Viewer Output</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Macro LUTs</td>
<td>Fusion View LUT</td>
<td>(single)</td>
<td></td>
</tr>
</tbody>
</table>

The order of processing for 2D images and 3D scenes

For either 2D or 3D, the result may be drawn to an offscreen buffer where a buffer LUT can be applied, along with dithering, a full view checker underlay, and any stereo processing. The final result is then drawn to the Viewer, and any onscreen controls are drawn on top.

**Applying Multiple LUTs**

The Viewer contextual menu can be used to apply multiple image LUTs into a processing chain.
To apply an additional LUT, do the following:

1. Right-click anywhere within the Viewer.
2. From the Viewer’s contextual menu, choose LUT -> Add New.
3. From the Add New submenu choose a LUT to add.

To remove a LUT other than the first LUT, do the following:

1. Right-click anywhere within the Viewer.
2. From the Viewer’s contextual menu, choose LUT -> Delete.
3. From the Delete submenu choose a LUT to remove.

A complete stacked LUT configuration can be saved to and loaded from a .viewlut file, as described below.

**Saving Custom LUTs**

There are a variety of ways to create and use different Viewer LUTs in Fusion. You can save LUTs when you save Viewer settings, you can import LUTs that have been exported from Fusion or other applications and you can open any one of the various supported LUT file types. In addition, you can use the standard nodes in Fusion to create macros, which can then be saved and used as a LUT.

**LUT Settings**

The most straightforward way to save a LUT you have created using the Fusion View LUT Editor, is to use the LUT > Save menu found in the Viewer contextual menu. The settings are saved as an ASCII file with the extension .viewlut in the LUTs folder. Any files with this extension found in that folder will appear in the Image LUT menus, for ease of loading. You can also load the settings that are not found in the menu by choosing LUT > Load from the Viewer’s contextual menu.

**Using Viewer Settings**

If you’ve modified a LUT, choosing Settings > Save New from the Viewer’s contextual menu will save all the Viewer’s settings, including all LUT curves and gain/gamma values. You can save these under different names, and each settings file can be reloaded at any time by choosing Settings > File name from the Viewer’s contextual menu. Choosing Save Default from the same menu will make these settings the standard for all new comps.

**Using LUT Curves**

The Viewer LUT edit window can be used to import and export LUT curves. You can export the LUT curves as either ASCII or Saved format. The ASCII (.alut) file format is useful for sharing LUT curves with other software, whereas the Saved (.lut) file format is preferred for Fusion, as it is more compact, accurate and allows further editing. For details on the ASCII LUT file format, see the ASCII Import Appendix.

**To export a LUT, do the following:**

1. Click the Viewer LUT button to enable it.
2. Click the Viewer LUT menu, then choose Edit.
3. Right-click on the LUT Curve Editor, then choose Export LUT.
4. Select a LUT format at the bottom of the file browser window.
5. Enter a name for the LUT and click Save.
The Import LUT option will load LUT files back into the Curve Editor, or alternatively, if the file has been saved in Fusion’s LUTs folder, it will appear in the LUT popup menu list.

**TIP:** This is one way to move LUTs between viewers or to and from the Color Curves node or any other LUT Editor in Fusion.

### LUT Files

Any supported LUT files in the LUTs folder can be used by choosing them either from the LUT popup menu, or the Viewer’s contextual menu. This includes 1D and 3D LUTs such as Fusion’s .lut, .alut and .alut3 formats, as well as .shlut, .look, .3dl and .itx formats. This is a convenient way to access standard format LUT files for different projects.

### Settings and Macros

Since LUTs are a form of color correction, you can also use any node, macro, or group of nodes as a Viewer LUT.

**To use a node, group or macro as a Viewer LUT, do the following:**

1. Select the node, group, or macros.
2. Right-click over the selected node, then choose Settings > Save As from the menu.
3. In the file browser go to the LUTs folder as set in Preferences > Global > Path Map > LUTS.
4. Click Save to save the settings file.

This allows almost any combination of nodes to be used as a Viewer LUT. This is the most flexible approach but is also potentially the slowest. The LUT nodes must be rendered solely on the CPU, whereas other methods are GPU-accelerated.

### Setting a Default LUT

The default LUT applied when a new composition is created can be assigned in the View panel of the Fusion Settings window. Clicking the Enable Display LUT checkbox allows you to select a LUT from the Display LUT plug-ins list.

The LUT Default settings found in the View panel of the Fusion Settings window.
Viewer Preferences and Settings

The default settings for each viewer can be changed using the Viewer panel in the Preferences. The position and size of each floating viewer can also be saved using the Layout menu in the Preferences.

Viewer Settings

It is often preferable to switch between entirely different viewer configurations while working. For example, while keying, the image maybe in the main Viewer and the alpha channel may be in a subview. Viewer settings toward the end of a project may consist of the histogram, vectorscope and waveform, as well as the image in a view set to Quad view.

Fusion provides the ability to quickly load and save Viewer settings to help reduce the amount of effort required to change from one configuration to another.

To Save a Viewer setting, do the following:
1. Right-click over the Viewer you want to save.
2. From the contextual menu, choose Setting > Save New.
3. Enter a name for the settings and click Save.

To Load a Viewer setting, do the following:
1. Right-click over the Viewer you want to load a setting into.
2. From the contextual menu, choose Settings > Settings name.

Loading and Saving Defaults for a Viewer

The Viewer can save new defaults and be returned to its defaults using the Load Defaults and the Save Defaults options in the Settings portion of the View contextual menu.

The Viewer Options Menu

The Options menu of the Viewer contains several ways you can customize the look and behavior of the Viewer. Many of these options are also in the Viewer contextual menu.

Show Controls

When onscreen controls are not necessary or are getting in the way of evaluating the image, you can temporarily hide them using the Show Controls option. This option is toggled using Command-K.

Checker Underlay

The Checker Underlay shows a checkerboard beneath transparent pixels to make it easier to identify transparent areas. This is the default option for 2D viewers. Disabling this option replaces the checkerboard with black.

Pixel Grid

Enabling this option will show a light black grid that outlines the exact boundaries of pixels in the image when the image is scaled past a certain threshold. The default is Off.
Smooth Resize
The Smooth Resize option uses a smoother bilinear interpolated resizing method when zooming into an image in the Viewer. When smooth resize is disabled, scaling uses the nearest neighbor method and shows noticeable aliasing artifacts but is more useful for seeing the actual pixels of the viewed image when you zoom all the way down to a pixel level since there is no interpolation. This option is enabled by default and can be toggled by clicking on the SmR button in the Viewer toolbar.

Show Square Pixels
Depending on the frame format preferences and the type of footage loaded, many images may have pixels that are rectangular instead of square. Both the NTSC and PAL video standards, as well as some anamorphic film formats, use rectangular pixels. A computer monitor uses perfectly square pixels. To compensate for this, aspect correction is automatically performed when viewing non square pixels. This prevents non square pixel images from appearing squashed or stretched in the Viewer.

You can enable the Show Square Pixels option to override the aspect correction. Show Square Pixels can also be toggled on and off using the 1:1 button in the Viewer toolbar.

Gain/Gamma
Exposes or hides a simple pair of Gain and Gamma sliders that let you adjust the viewed image. Especially useful for “gamma slamming” a composite to see how well it holds up with a variety of gamma settings. Defaults to no change.

360º View
Sets the Fusion page Viewer to properly display spherical imagery in a variety of formats, selectable from this submenu. Disable toggles 360 viewing on or off, while Auto, LatLong, Vert Cross, Horiz Cross, Vert Strip, and Horiz Strip let you properly display different formats of 360º video.

Locking the Viewer (Command-L)
You can lock a viewer to prevent it from updating. The node that's loaded into that viewer still processes and the new image is queued for display in the Viewer, but until you unlock it, the Viewer does not update. By default the Viewer is unlocked.

Additional Viewer Options
There are additional commands when you right-click anywhere within a viewer and choose from the generically named Options submenu.

Alpha Overlay
When you enable the alpha overlay, the Viewer will show the alpha channel overlaid on top of the color channels. This can be helpful when trying to see where one image stops and another begins in a composite. This option is disabled by default.

Overlay Color
When you turn the alpha overlay on, the default color is to show white for the area the alpha covers. There are times when white does not show clearly enough, depending on the colors in the image. You can change the color by choosing a color from the list of Overlay Color options.
Follow Active
Enabling the Follow Active option will cause the Viewer to always display the currently active node in the Node Editor. This option is disabled by default, so you can view a different node than what you control in the Control Panel.

Show Controls
When onscreen controls are not necessary or are getting in the way of evaluating the image, you can temporarily hide them using the Show Controls option. This option is toggled using Command-K.

Show Full Color Range
When working with floating point images, you will occasionally need to visualize the values that fall outside the normal luminance range. Enabling the Show Full Color Range option using the Toolbar button automatically normalize any image displayed in the Viewer. Normalization causes the brightest pixel in a color channel to be mapped to a value of 1.0 (white) and the darkest pixel to be mapped to a value of 0.0 (black). Midrange values are scaled appropriately to fit within that range. It is also useful when viewing Z-buffer or other auxiliary channels, which often use value ranges far different from those in the color channels.

Show Labels
Lets you toggle the display of the text that sometimes accompanies onscreen controls in the Viewer, without disabling the functions that are showing those overlays, and without hiding the onscreen controls themselves.

Status Bar Information
The status bar at the bottom of the Fusion window provide the exact RGBA and Z values for the pixel beneath the pointer when it’s hovering within one of the Viewers. Additional information about the X and Y coordinates of the cursor and the exact pixel position are also displayed.
Chapter 61

Editing Parameters in the Inspector

The Inspector is where you adjust the parameters of each node to do what needs to be done. This chapter covers the various node parameters and methods for working with the controls that are available.
Overview of the Inspector

While the creation and connection of nodes in the Node Editor determine the tools and order of operations that make up a composition, the Inspector (previously called the Control Panel) is where you adjust the various parameters inside each node to do what needs to be done.

Inspector displays the Brightness Contrast controls

This chapter covers the different methods for opening node parameters in the Inspector, to edit them in different ways according to the type of controls that are available.

**To display the Inspector:**

Click the Inspector button on the UI toolbar.

The Tools and Modifiers Panels

The Inspector is divided into two overall panels.

- The Tools panel is where the parameters of selected nodes appear so you can edit them.
- The Modifiers panel is where Modifiers, which are automated expressions that you can attach to individual parameters to create animated effects, are placed and where Modifier parameters can be edited. Additionally, certain nodes such as the Paint node generate data such as Strokes, which are saved in the Modifiers panel.

Modifiers displayed in the Modifiers panel
Customizing the Inspector

There are a variety of ways you can customize how the Inspector is presented.

Inspector Height

A small arrow button at the far right of the UI toolbar lets you toggle the Inspector between full height and half height views, depending on how much room you need for the editing of parameters.

In maximized height mode, the Inspector takes up all the right side of the UI, letting you see every control that a node has available, or creating enough room to see the parameters of two or three pinned nodes all at once. In half height mode, the top of the Inspector is aligned with the tops of the Viewers, expanding the horizontal space that’s available for the Node Editor.

Inspector Display Preferences

By default, you only see selected nodes in the Inspector, and only the Active node is expanded to show its controls. You can change this behavior by choosing Fusion > Fusion Settings and opening the User Interface panel. In the User Interface preferences are checkboxes that manage the display of controls.

- **Auto Control Open**: When enabled (the default), whichever node is Active automatically open its controls in the Inspector. When disabled, selecting an active node opens that node’s control header in the Inspector, but the parameters remain hidden unless you click the control header.
- **Auto Control Hide**: When enabled (the default), only selected nodes are visible in the Inspector, and all deselected nodes are automatically removed from the Inspector to reduce clutter. When disabled, parameters from selected nodes remain in the Inspector, even when those nodes are deselected, so that the Inspector accumulates the parameters of every node you select over time.
• **Auto Control Close Tools**: When enabled (the default), only the parameters for the Active node can be exposed. When disabled, you can open the parameters of multiple nodes in the Inspector if you want.

• **Auto Controls for Selected**: When enabled (the default), selecting multiple nodes opens multiple control headers for those nodes in the Inspector. When disabled, only the Active node appears in the Inspector, multi-selected nodes that are highlighted white do not.

**Opening Nodes in the Inspector**

Before you can edit a node’s parameters, you need to open it in the Inspector

---

**To display a node’s controls in the Inspector:**

Select one or more nodes from the Node Editor, Keyframe Editor, or Spline Editor.

When you select a single node so that it’s highlighted orange in the Node Editor, all of its parameters appear in the Inspector. If you select multiple nodes at once, control headers appear for each selected node (highlighted in white in the Node Editor), but the parameters for the Active Node (highlighted in orange) are exposed for editing.

Opening multiple nodes in the Inspector

Only one node’s parameters can be edited at a time, so clicking another node’s control header opens that node’s parameters while closing the parameters of the previous node you were working on. This also makes the newly opened node the Active node, highlighting it orange in the Inspector.
Pinning Multiple Nodes in the Inspector

For instances where you need to work quickly by editing the parameters of multiple nodes at the same time, you can use the Pin button in the control header of nodes in the Inspector to keep those parameters exposed in the Inspector, regardless of whether that node is selected, active, or not.

While the Pin button is on, that node’s parameters remain open in the Inspector. If you select another node in the Node Editor, that node’s parameters appear beneath any pinned nodes.

You can have as many pinned nodes in the Inspector as you like, but the more you have, the more likely you’ll need to scroll up or down in the Inspector to get to all the parameters you want to edit. To remove a pinned node from the Inspector, just turn off its Pin button in the Control Header.

Hiding Inspector Controls

If you like, Inspector parameters for specific nodes can be hidden so they never appear, even when that node is selected. This can be useful for preventing accidental changes by you or other compositors who may be working on a composition in situations where you don’t want to lock the node.
To Toggle the Inspector controls for a node or or off:

Right-click on the node in the Node Editor, or on the Control Header, and choose Modes > Show Controls from the contextual menu.

Using the Control Header

When you select a node, it populates the Inspector with a title bar, or control header, that displays that node’s name as well as other controls that govern that node. A node’s control header itself has a variety of controls, but clicking (or double-clicking) on a control header also exposes that node’s parameters.

A node’s control header

When you select multiple nodes at once, you’ll see multiple control headers in the Inspector. By default, only the parameters for the Active node (highlighted orange in the Node Editor) can be opened at any given time, although you can change this behavior in the Fusion Settings.

Selecting and Viewing Nodes in the Inspector

Control headers are click targets for selecting nodes, opening and closing node parameters, and other things.

Methods of using control headers:

- **To select a node using the Control Header:** When multiple nodes are selected, you can make a node the Active node by clicking its control header in the Inspector. As the actively selected node, the Control Header and the corresponding node in the Node Editor are highlighted orange, and its parameters are exposed.

- **To load a node into the Viewer using the Control Header:** You can view a node by dragging its control header into one of the Viewers.

- **To view a node’s splines with the Control Header:** If you want to view the animated curves of a node in the Spline Editor, you can add them by dragging the Control Header into the Spline Editor. All animated splines for the parameters of that node will automatically be displayed.

Using Header Controls

The controls found in each node’s control header makes it fast to do simple things.

- **To turn nodes off and on:** Each control header has a toggle switch to the left of its name, which can be used to enable or disable that node. Disabled nodes pass image data from the previous upstream node to the next downstream node without alteration.

- **To change the Control Header name:** The name of the node corresponding to that control header is displayed next. You can change the name by right-clicking the Control Header to expose contextual menu commands similar to those found when you right-click a node in the Node Editor, and choosing Rename. Alternately, you can click a control header and press F2 to edit its name. A Rename dialog appears, where you can enter a new name and click OK (or press Return).
• To color-code nodes: A color pop-up menu lets you color codes with one of 16 colors. Choose Clear Color if you want to return that node to the default color.

• To version nodes: Turning on the Versions button displays a Version bar with six buttons. Versioning is described in the following section.

• To pin Inspector controls: Clicking the Pin button "pins" that node’s parameters in the Inspector so they remain in place, even if you deselect that node. You can have as many pinned nodes as you like in the Inspector, but the more you have, the more likely you’ll be scrolling up and down the Inspector to navigate all the available parameters.

• To lock nodes: Clicking the Lock button locks that node so no changes can be made to it.

• To reset Inspector controls: The right-most button in the control header is a reset button that resets the entire node to the default settings for that node.

Versioning Nodes

Each button is capable of containing separate parameter settings for that node, making it easy to save and compare up to six different versions of settings for each node. All versions are saved along with your project for future use.

![The Version bar, underneath a control header with versions enabled](image)

An orange underline indicates the currently selected version, which is the version that’s currently being used by your composition. To clear a version you don’t want to use any more, right-click that version number and choose Clear from the contextual menu.

Parameter Tabs

Underneath the control header is a series of panel tabs, displayed as thematic icons. Clicking one of these icons opens a separate tab of parameters, which are usually grouped by function. Simple nodes, such as the Blur node, consist of two tabs where the first contains all of the parameters relating to blurring the image, and the second is the Settings tab.

![The parameter tabs of the Blur node](image)

More complicated nodes have more tabs containing more groups of parameters. For example, the Delta Keyer has seven tabs, separating Key, Pre-Matte, Matte, Fringe, Tuning, and Mask parameters, along with the obligatory Settings tab. These tabs keep the Delta Keyer from being a giant scrolling list of settings and make it easy to keep track of which part of the keying process you’re finessing as you work.
The Settings Tab

Every node that comes with DaVinci Resolve has a Settings tab. This tab includes a set of standard controls that appear for nearly every node, although some nodes have special Settings tab controls that others lack.

The following controls are common to most nodes, although some are node-specific. For example, Motion Blur settings have no purpose in a Color Space node.

Blend

The Blend control is found in all nodes, except MediaIn and Generator nodes. It is used to blend between the node’s unaltered image input and the node’s final processed output. When the blend value is 0.0, the outgoing image is identical to the incoming. Ordinarily, this will cause the node to skip processing entirely, copying the input straight to the output. The default for this node is 1.0, meaning the node will output the modified image 100%.

Process When Blend is 0.0

This checkbox forces the node to process even when the input value is zero and the image output is identical to the image input. This can be useful on certain nodes or third-party plug-ins that store values from one frame to the next. If this checkbox is disabled on nodes that operate in this manner, the node will skip being processed when the Blend is set to 0, producing incorrect results on subsequent frames.
Red/Green/Blue/Alpha Channel Checkboxes

Most nodes have a set of RGBA checkboxes in the Settings tab. These checkboxes let you exclude any combination of these channels from being affected by that node.

For example, if you wanted to use the Transform node to affect only the green channel of an image, you can turn off the Red, Blue, and Alpha checkboxes. As a result, the green channel is processed by this operation, and the red, blue, and alpha channels are copied straight from the node’s input to the node’s output, skipping that node’s processing to remain unaffected.

Skipping Channel Processing

Under the hood, most nodes actually process all channels first, but afterwards copy the input image to the output for channels that have been unchecked. Modern workstations are so fast that this isn’t usually noticeable, but there are some nodes where deseleting a channel actually causes that node to skip processing that channel entirely. Nodes that operate this way have a linked set of Red, Green, Blue and Alpha checkboxes on another tab in the node.

In these cases, the Common Control channel checkboxes are instanced to the channel boxes found elsewhere in the node. Blur, Brightness/Contrast, Erode/Dilate, and Filter are examples of nodes that all have RGBA checkboxes in the main Controls tab of the Inspector, in addition to the Settings tab.
Apply Mask Inverted
When the Apply Mask Inverted checkbox is enabled, masks attached to the Effect Mask input of that node are inverted.

TIP: The Apply Mask Inverted check box only operates on effects masks, not on garbage masks.

Multiply By Mask
Selecting this option will cause the RGB values of the masked image to be multiplied by the Mask channel’s values. This will cause all pixels of the image not included in the mask (i.e., those set to 0) to become black. This creates a premultiplied image.

Use Object/Use Material (For Masking)
Some 3D animation and rendering software can output to file formats that support auxiliary channels. Notably, the Open EXR file format supports “object” and “material ID” channels, either of which can be used as a mask for an effect. This checkbox determines whether the channels will be used if they are available. The specific Material ID or Object ID affected is chosen using the next set of controls.

Pick Controls
The Pick Controls are only displayed once the Use Object or Use Material checkbox is enabled. These controls select which ID is used to create a mask from the Object or Material channels saved in the image. You use the Pick button to grab IDs from the image in the Viewer, the same way you use the color picker to select a color. The image or sequence must have been rendered from a 3D software package with those channels included.

Correct Edges
The Correct Edges check box is only displayed once the Use Object or Use Material checkbox is enabled. When the Correct Edges checkbox is enabled, the Coverage and Background Color channels are used to separate and improve the effect around the edge of the object. When disabled (or no Coverage or Background Color channels are available), aliasing may occur on the edge of the mask.

Motion Blur
For nodes that are capable of introducing motion such as Transform nodes, Warp nodes, and so on, the Motion Blur checkbox toggles the rendering of motion blur on or off for that node. When this checkbox is enabled, the node’s predicted motion is used to produce the blur caused by a virtual camera shutter. When the control is disabled, no motion blur is created.

When Motion Blur is disabled, no additional controls are displayed. However, turning Motion Blur on reveals four additional sliders with which you can customize the look of the motion blur you’re adding to that node.

Quality
Quality determines the number of samples used to create the blur. The default quality setting of 2 will create two samples on either side of an object’s actual motion. Larger values produce smoother results but will increase the render time.
Shutter Angle
Shutter Angle controls the angle of the virtual shutter used to produce the Motion Blur effect. Larger angles create more blur but increase the render times. A value of 360 is the equivalent of having the shutter open for one whole frame exposure. Higher values are possible and can be used to create interesting effects. The default value for this slider is 100.

Center Bias
Center Bias modifies the position of the center of the motion blur. Adjusting the value allows for the creation of trail type effects.

Sample Spread
Adjusting Sample Spread modifies the weight given to each sample. This affects the brightness of the samples set with the Quality slider.

Scripting
Scripting fields are present on every node and contain one or more editable text fields that can be used to add scripts that process when that node is rendering. For more details on the contents of this tab, please consult the Scripting documentation.

Comments
A Comments field is found on every node, and contains a single text field that is used to add comments and notes to that node. To enter text, simply click within the field to place a cursor, and begin typing.

When a note is added to a node, the comments icon appears in the Control Header and can be seen in a node’s tooltip when the cursor is placed over the node in the Node Editor. The contents of the Comments tab can be animated over time, if required.

Additional controls appear under this tab if the node is a Loader. For more information, see Chapter 81, “Generator Nodes”

Inspector Controls Explained
Although a few nodes use fully customized interface elements that are unique to only that node, the vast majority of nodes use a mix of sliders, angle wheels, and checkboxes. This section explains how to use these controls.

Fusion Slider Controls
Slider Controls are used to select a single value from a range of values. You change the value by dragging the slider or entering a value into the edit box. This is fairly standard behavior for sliders. However, there is additional functionality that can increase your productivity when making changes with sliders.

Clicking on the gutter to the left or right of the handle will increase or decrease the value. Holding Command (macOS) or Ctrl (Windows) while clicking on the gutter will adjust the values in smaller increments. Holding Shift while clicking will adjust the value in larger increments.

<table>
<thead>
<tr>
<th>Size</th>
<th>0.1378</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tracking</td>
<td>1.0</td>
</tr>
</tbody>
</table>

Hold Command or Ctrl while clicking in the gutter to move in smaller increments.
Once you click directly on a slider handle you can make changes to its value using the Left and Right Arrow keys. The Command/Ctrl and Shift keys can again be used to modify the value in larger or smaller increments.

While slider controls use a minimum and maximum value range, entering a value in the edit box outside that range will often expand the range of the slider to accommodate the new value. For example, it is possible to enter 500 in a Blur Size control, even though the Blur Size sliders default maximum value is 100. The slider will automatically adjust its maximum displayed value to allow entry of these larger values.

If the slider has been altered from its default value, a small circular indicator will appear below the gutter. Clicking on this circle will reset the slider to its default.

**Thumbwheel**

A Thumbwheel control is identical to a slider except it does not have a maximum or minimum value. To make an adjustment you drag the center portion left or right or by entering a value directly into the edit box. Thumbwheel controls are typically used on angle parameters, although they do have other uses as well.

You can use the arrowheads at either end of the control to fine tune your adjustments. Once the thumbwheel has been selected either by dragging or using the arrow keys, you can use the Left and Right Arrows on your keyboard to further adjust the values. As with the slider control, the Command/Ctrl and Shift keys can be used to increase or decrease the change in value in smaller or larger increments.

If the thumbwheel has been altered from its default value, a small circular indicator will appear below above the thumbwheel. Clicking on this circle will reset the thumbwheel to its default.

**Range Controls**

The Range controls are actually two separate controls, one for setting the Low Range value and one for the High Range value. To adjust the values, drag the handles on either end of the Range bar. To slide the high and low values of the range simultaneously, drag from the center of the Range bar. You can also expand or contract the range symmetrically by holding Command (macOS) or Ctrl (Windows) and dragging either end of the Range bar. You find Range controls on parameters that require a high and low threshold, like the Matte Control, Chroma Keyer and Ultra Keyer nodes.

**TIP:** You can enter floating point values in the Range controls by typing the values in using the Low and High numeric entry boxes.
Checkboxes

Checkboxes are controls that have either an On or Off value. Clicking on the Checkbox control will toggle the state between selected and not selected. Checkboxes can be animated, with a value of 0 for Off and a value of 0.0 or greater for On.

![Checkboxes used to select options for tracking](image)

Pop-up Menus

Pop-up menus are used to select one option from a menu. Once the menu is open, choosing one of the items will select that entry. When the menu is closed the selection is displayed in the Inspector.

![Pop-up menu in the TimeSpeed node](image)

Pop-up menu selections can be animated, with a value of 0 representing the first item in the list, 1 representing the second, and so forth.

Button Arrays

Button arrays are groups of buttons that allow you to select from a range of options. They are almost identical in function to drop down menu controls, except that in the case of a button array it is possible to see all of the available options at a glance. Often button arrays use icons to make the options more immediately comprehensible.

![The Lens Type button array in the Defocus node](image)

Color Wheel and Picker

The color picker is displayed wherever a parameter requires a color as its value, such as the Fill or Outline color in the Text+ node. The selected color is shown in a swatch below the Pick button. The swatch has two halves; the left half shows the color and the right half shows the color overlaid on a checkerboard background to preview transparency.

![The color swatch with transparency preview](image)
The color picker is extremely flexible and has four different techniques for selecting and displaying colors.

**TIP:** Color can be represented by 0–1, 0.255, or 0–65000 by setting the range you want in the Preferences > General panel.

**MacOS and Windows Color Nodes**
Clicking on the Pick button will display the operating system’s standard Color Selection node.

Each operating system has a slightly different layout, but the general idea is the same. You can choose a color from the swatches provided, the color wheel on macOS, or the color palette on Windows. However you choose your color, you must click OK for the selection to be applied.

**The Color Chooser**
You also have access to the built in color chooser, which includes sections for choosing grayscale values, as well as the currently chosen hue with different ranges of saturation and value. A hue bar and alpha bar (depending on the node) let you choose different values.
Picking Colors from an Image

If you are trying to match the color from an image in the Viewer, you can press the cursor down over the Pick button, then drag the cursor into the Viewer. The cursor will change to an eye dropper and a pop-up swatch will appear above the cursor with the color you are hovering over and its values. When you are over the color you want, release the mouse button to set the color.

The eye dropper with color swatch

The color picker normally selects from a single pixel in the image, but you can adjust the size of the selection by dragging into the Viewer with the eye dropper, then holding Command (macOS) or Ctrl (Windows) and dragging out a rectangle for the sample side you want. The size change applies to all color pickers until the size is changed again.

Gradients

The Gradient Control bar is used to create a gradual blend between colors. The gradient bar displays a preview of the colors used from start to end. By default there are two triangular color stops, one on the left that determines the start color and one on the right that determines the end color.

The default Gradient controls

Gradient Type

The Gradient Type button array is used to select the form used to draw the gradient. Linear draws the gradient along a straight line from the starting color stop to the ending color stop.
Reflect draws the gradient by mirroring the linear gradient on either side of the starting point.

Square draws the gradient by using a square pattern when the starting point is at the center of the image.

Cross draws the gradient using a cross pattern when the starting point is at the center of the image.

Radial draws the gradient in a circular pattern when the starting point is at the center of the image.

Angle draws the gradient in a counter-clockwise sweep when the starting point is at the center of the image.
Start and End Position

The Start and End Position controls have a set of X and Y edit boxes which are useful for fine tuning the start and end position of the gradient. The position settings are also represented by two crosshair on screen controls in the Viewer, which may be more practical for initial positioning.

Gradient Colors Bar

The Gradient Colors bar is used to select the blending colors for the gradient. The default two color stops set the start and end colors. You can change the colors used in the gradient by selecting the color stop, then using the eye dropper or color wheel to set the new color.

You can add, move, copy and delete colors from the gradient using the Colors bar.

To add a color stop to the Gradient Colors bar:

1. Click anywhere along the bottom of the Gradient Colors bar.
2. Use the eye dropper or color wheel to set the color for the color stop.

To move a color stop on the Colors bar:

Drag a color stop left or right along the Gradient Color bar.

To copy a color stop on the Colors bar:

Hold Command (macOS) or Ctrl (Windows) while you drag a color stop.

To delete a color stop from the Colors bar, do one of the following:

- Drag the color stop up past the Gradient Colors bar.
- Select the color stop, then click the red X button to delete it.

Interpolation Space

The Gradient Interpolation Method pop-up menu lets you select what color space is used to calculate the colors between color stops.

Offset

When you adjust the Offset control, the position of the gradient is moved relative to the start and end markers. This control is most useful when used in conjunction with the repeat and ping-pong modes described below.

Once/Repeat/Ping-Pong

These three buttons are used to set the behavior of the gradient when the Offset control scrolls the gradient past its start and end positions. The Once button is the default behavior, which keeps the color continuous for offset. Repeat loops around to the start color when the offset goes beyond the end color. Ping-pong repeats the color pattern in reverse.

1x1, 2x2, 3x3, 4x4, 5x5

These buttons control the amount of sub-pixel precision used when the edges of the gradient become visible in Repeat mode, or when the gradient is animated. Higher settings will take significantly longer to render but be more precise.

Gradient Contextual Menu

Gradients have their own contextual menu that you can bring up by right-clicking on the Gradient bar. In the Gradient contextual menu are options for animating, publishing and connecting one gradient to another. There is also a gradient-specific modifier that builds a custom gradient by sampling colors from the output of a node in the Node Editor.
Modifiers

Modifiers are expressions, calculations, trackers, paths and other mathematical components that you attach to a parameter to extend its functionality. When a modifier is attached to a parameter, its controls will appear separately in the Inspector Modifiers tab.

To attach a modifier:
1. Right-click over the parameter to which you want to attach a modifier.
2. Make a selection from the Modifier submenu in the contextual menu.

Animating Parameters in the Inspector

The Fusion page has keyframing controls that are similar to those found in other pages of DaVinci Resolve. Most parameters in most effects nodes can be keyframed, in order to create animated effects such as animated transforms, rotoscoping with splines, dynamically altering warping behaviors; the list is endless. For convenience, a set of keyframing controls are available within the Inspector next to each keyframable parameter. These controls are:

- A gray Keyframe button to the right each keyframable parameter. Clicking this gray button creates a keyframe at the current position of the playhead, and turns the button orange.
- Whenever the playhead is sitting right on top a keyframe, this button turns orange. Clicking an orange Keyframe button deletes the keyframe at that frame and turns the button gray again.
- Small navigation arrows appear to the right and left if there are more keyframes in those directions. Clicking on navigation arrows to the right and left of keyframes jump the playhead to those keyframes.

Orange Keyframe buttons in the Inspector show there’s a keyframe at that frame

Once you’ve keyframed one or more parameters, the node containing the parameters you keyframed displays a Keyframe badge, to show that node has been animated.

A keyframed node displays a Keyframe badge in the Node Editor

Once you’ve started keyframing node parameters, you can edit their timing in the Keyframe Editor and/or Spline Editor. For more information about keyframing in the Fusion page, see Chapter 62, “Keyframing in the Fusion Page.”
Removing Animation From a Parameter

To remove a keyframed spline from a parameter:
1. Right-click the keyframe control of the parameter you want to remove animation from.
2. Choose Remove Path1 from the contextual menu (Path1 may be numbered differently depending on how many parameters are animated).

**TIP:** If you change the default spline type from Bezier, the contextual menu will display the name of the current spline type.

Attaching a Parameter to an Existing Animation Curve

Multiple parameters can be connected to the same animation curve. This can be an invaluable time saver if you are identically animating different parameters in a node.

To connect a second parameter to the same animation curve:
1. Right-click on the second parameter you want to attach.
2. In the contextual menu, hover over the Connect To submenu.
3. In the Connect To submenu, choose the name of the animated parameter.

Connecting Parameters

It is often useful to connect two parameters together even without an animation curve. There are two methods you can use.

Connecting Parameters by Publishing

If you want to tie two parameters together so adjusting one adjusts the other, you must connect them together using the Publish menu command on the first parameter and the Connect menu command on the second parameter.

To Publish and Connect parameters:
1. Right-click the name of the parameter you want to publish, and choose Publish from the contextual menu.
2. Right-click on the second parameter you want to attach, and choose the name of the parameter you just published from the Connect To submenu.

The Publish contextual menu
Connecting Parameters by Pickwhipping

You can also use simple expressions to link two parameters together. By using simple expressions and pickwhipping, values can be connected and combined visually without the need to publish a value first.

To link two parameters using a pickwhip:
1. Double-click the field of a parameter you want to pickwhip to another parameter, type =, and then press the Return key.
2. When Pickwhip controls appear underneath the parameter, drag a “whip” from the Add button to the target parameter.

Now, adjusting the target parameter automatically adjusts the original parameter.

TIP: Disabling the Auto Control Close node’s General preference, then selecting two nodes in the Node Editor will allow you to pickwhip two parameters from different nodes.

The Expression field can further be used to add mathematical formulas to the value received from the target parameter.

For more information on Pickwhipping and Expressions, see Chapter 64 “Animating With Modifiers and Expressions.”

Contextual Menus

There are two types of contextual menus you can invoke within the Inspector.

Node Contextual Menus

To display the Node Context menu from the Inspector, right-click on the control header. The node’s contextual menu includes the same menu options that are accessed by right-clicking on a node in the Node Editor. See Chapter 58, “Working in the Node Editor,” for more information on these options.

Parameter Contextual Menus

The contextual menu for individual parameters is accessed by right-clicking over a slider, thumbwheel, range control, button array or other control type. For example, right-clicking on a slider will provide the slider’s contextual menu, with options to animate the control or add additional modifiers. Many of these options were described in this chapter.
Customizing Node Parameters with UserControls

The user interface for each node in Fusion is designed to provide access to the parameters in a logical manner. Sometimes, though, you may want to add, hide, or change the controls. This is commonly done for simple expressions and macros, but it can be done for usability and aesthetic reasons for favorites and presets.

User custom controls can be added or edited via the Add Controls dialog. Right-click the name of a node in the Inspector (in the header bar) and choose Edit Controls from the contextual menu. A new window will appear, titled Edit Control.

The Edit Control window

In the Input attributes you can select an existing control or create a new one, name it, define the type, and assign it to a tab. In the Type attributes you define the input controls, the defaults and ranges, and whether it has an onscreen preview control. The Input Ctrl attributes box contains settings specific to the selected node control, and the View Ctrl attributes box contains settings for the preview control, if any.

All changes made using UserControls are stored in the node instance itself, so they can be copy/pasted, saved to a setting, added to the Bins, or added to your favorites.

An Example of Customizing DirectionalBlur

In the following example, let’s suppose we wanted to create a more intuitive way of controlling a linear blur than using the Length and Angle sliders independently.

Default DirectionalBlur controls in the Inspector
We could use the Center input control, along with its preview control, to set an angle and distance from directly within the Viewer using expressions.

1. Right-click the label for the Length parameter, choose Expression from the contextual menu, and then paste the following expression into the Expression field that appears:

\[-\sqrt{((\text{Center.X-.5})*(\text{Input.XScale}))^2+((\text{Center.Y-.5})*(\text{Input.YScale})*(\text{Input.Height}/\text{Input.Width}))^2}\]

2. Next, right-click the label for the Angle parameter, choose Expression from the contextual menu, and then paste the following expression into the Expression field that appears:

\[\text{atan2}(\text{Center.Y-.5})/(\text{Input.OriginalWidth}/\text{Input.X} , .5-\text{Center.X}) * 180 / \pi\]

DirectionalBlur controlled by the Center’s position

This functions fine, but the controls are confusing. The Center control doesn’t work as the center anymore, it should be named “Blur Vector” instead. The controls for the Length and Angle aren’t meant to be edited, so they should be hidden away, and we’re only doing a linear blur, so we don’t need the buttons for Radial or Zoom. We just need to choose between Linear and Centered.

Adding Another Control

For the first task, let’s rename the Center. From the Add Control window, select Center from the ID list. A dialog will appear asking if you would like to Replace, Hide, or Change ID. We’ll chose Replace. Now we are editing the Center input. We’ll change the Name to Blur Vector, set the Type to Point, and the Page to Controls, which is the first tab where the controls are normally.

Press OK, and our new input will appear on our node in the Node Editor. The ID of the control is still Center, so our SimpleExpressions did not change.

To hide the Length and Angle, we’ll run the UserControls script again. This time when we select the Length and Angle IDs, we’ll choose Hide in the dialog. Press OK for each.
Finally, to change the options available in the Type, we have two options. We can hide the buttons and use a checkbox instead, or we can change the MultiButton from 4 entries to 2. Let’s try both.

To add the checkbox, run UserControls again, but this time instead of selecting an existing ID, we’ll type Centered into the Name. This will set the name and the ID of our input to Centered. The Type is set to Number and the Page is set to Controls. Now in the Type Attributes, set the Input Ctrl to be CheckboxControl. Press OK, and now we have our checkbox. To make the new control affect the Type, add a SimpleExpression to the Type:

\[ \text{iif(Centered==1, 2, 0)}. \]

Once that’s done, we can use the UserControls to hide the Type control.

To make a new MultiButton, run the UserControl script, and add a new control ID, TypeNew. You can set the Name to be Type, as the Names do not need to be unique, just the IDs. Set the Type to Number, the Page to Controls, and the Input Ctrl to MultiButtonControl. In the Input Ctrl attributes, we can enter the names of our buttons. Let’s do Linear and Centered. Type them in and hit Add for each. Press OK, and we have our new buttons with the unneeded options removed. To make this new control affect the original Type, add a SimpleExpression to the Type:

\[ \text{iif(TypeNew==0, 0, 2)}. \]

Once that’s done, we can use the UserControls to hide the original Type control.
Chapter 62

Keyframing in the Fusion Page

This chapter covers how you can keyframe effects in the Inspector, and how you can edit clips, effects, and keyframes in the Keyframe Editor.

Keyframing in the Inspector

The Fusion page has keyframing controls that are similar to those found in other pages of DaVinci Resolve. Most parameters in most effects nodes can be keyframed, in order to create animated effects such as animated transforms, rotoscoping with splines, dynamically altering warping behaviors; the list is endless.

For convenience, a set of keyframing controls are available within the Inspector next to each keyframable parameter. These controls are:

- A gray Keyframe button to the right each keyframable parameter. Clicking this gray button creates a keyframe at the current position of the playhead, and turns the button orange.
- Whenever the playhead is sitting right on top a keyframe, this button turns orange. Clicking an orange Keyframe button deletes the keyframe at that frame and turns the button gray again.
- Small navigation arrows appear to the right and left if there are more keyframes in those directions. Clicking on navigation arrows to the right and left of keyframes jump the playhead to those keyframes.

Once you've keyframed one or more parameters, the node containing the parameters you keyframed displays a Keyframe badge, to show that node has been animated.

Removing Animation In the Inspector

To remove a keyframed spline from a parameter:

1. Right-click the keyframe control of the parameter you want to remove animation from.
2. Choose Remove Path1 from the contextual menu (Path1 may be numbered differently depending on how many parameters are animated).
Attaching a Parameter to an Existing Animation Curve

Multiple parameters can be connected to the same animation curve. This can be an invaluable time saver if you are identically animating different parameters in a node.

To connect a second parameter to the same animation curve:
1. Right-click on the second parameter you want to attach.
2. In the contextual menu, hover over the Connect To submenu.
3. In the Connect To submenu, choose the name of the animated parameter.

Keyframe Editor Overview

The Keyframe Editor is essentially another timeline view of your composition, within which each clip and effect node in your composition is represented by a track. These tracks have the same color coding as the nodes they represent and are labeled where appropriate. A Time Ruler at the top indicates the timing of your composition, while numerous controls let you control the contents of the Keyframe Editor.

The Keyframes Editor can be used for one of two things:

- To adjust the timing of elements in a project, whether they’re clips or effects. You can trim and extend clips, adjust the timing of an animation spline, or trim the duration of an effects node. You can freely rearrange the order of nodes in the Timeline without affecting the layering order of your composition. All compositing operations are handled in the Node Editor, while the Keyframes Editor manages the timing of your composition.

- To create and/or edit keyframes that you’ve applied to effects in a track-based manner. You can retime keyframes, add and delete keyframes, and even edit keyframe values

To show the Keyframe Editor, do one of the following:
- Click the Keyframe Editor button in the UI toolbar to toggle visibility of the Keyframe Editor on and off.
- Press F7 on the keyboard.
Keyframe Editor Tracks

While each clip and effect node in your composition is represented by a track, keyframed parameters are exposed either as keyframes superimposed upon the track to which they’re applied (as seen on the “MOVEMENT” track), or they can be opened up onto their own tracks for more precise editing, one keyframe track per keyframed parameter, by clicking a disclosure control to the left of that track’s name in the Timeline header (as seen under the “Drip1” track).

The Timeline Header

The Timeline header area on the left side of the Timeline is a hierarchical list of all tracks in a composition. Each track displays the name of its corresponding node, a lock button, and a disclosure control for revealing keyframe tracks for each keyframe animation, modifier, and mask that’s attached to it.

Collapse/Open All

A quick way to open or close all available keyframe tracks at once is to use the Expand/Collapse Tool Controls commands in the Keyframe Timeline option menu.

The Playhead

As elsewhere in DaVinci Resolve, the playhead is a vertical bar that runs through the Timeline view to indicate the position of the current frame or time. The Timeline Editor playhead is locked to the Viewer playhead, so the image you’re viewing is in sync.

You must click on the playhead directly to drag it, even within the Timeline ruler (clicking and dragging anywhere else in the Timeline ruler scales the Timeline). Additionally, you can jump the playhead to a new location by holding the Command-Option keys down and clicking in the track area (not the Timeline ruler).
Spreadsheet

If you turn on the Spreadsheet and then click on the name of a layer in the keyframe track, the numeric time position and value (or values if it’s a multi-dimensional parameter) of each keyframe appear as entries in the cells of the Spreadsheet. Each column represents one keyframe, while each row represents a single aspect of each keyframe.

For example, if you’re animating a blur, then the “Key Frame” row shows the frame each keyframe is positioned at, and the “Blur1BlurSize” row shows the blur size at each keyframe. If you change the Key Frame value of any keyframe, you’ll move that keyframe to a new frame of the Timeline.

Scaling and Panning the Timeline

At the top, a series of zoom and framing controls let you adjust the work area containing the layers.

- A Horizontal zoom controls let you scale the size of the editor.
- A Zoom to Fit button fits the width of all tracks to the current width of the Keyframe Editor.
- A Zoom to Rect tool lets you draw a rectangle to define an area of the Keyframe Editor to zoom into.
- A Sort pop-up menu lets you sort or filter the tracks in various ways.
- An Option menu provides access to many other ways of filtering tracks and controlling visible options.
Working with Segments in the Timeline

Most of the work in the Timeline involves trimming and aligning clip segments that may have been added to a composition directly from the Media Pool.

To select a single segment in the Timeline, do one of the following:

• Click the node’s name in the header.
• Click the node’s segment in the Timeline.

To add another segment to the selection, do one of the following:

• Hold Command and click additional segments to select discontiguous selections.
• Select a segment, then hold Shift and click another segment to make a contiguous selection of all segments in-between.

To remove a segment from the selection, do the following:

• Hold Command and click a selected segment to de-select it.

TIP: Selecting a node’s name from the Timeline header also selects the node’s tile in the Node Editor, with its controls displayed in the Inspector.

Moving Segments in the Timeline

To move the position of a segment, drag on the node’s segment in the Keyframe Editor. The cursor will resemble a bar with two arrows pointing in either direction. Moving a segment changes where that clip begins and ends.

Resizing Segments

Resizing segments has different effects on MediaIn and Effect nodes:

• Resizing a MediaIn node is similar to resized clips in the Edit page, in that you’re changing the in and out points of the range of media that clip makes available to your composition.
• Resizing the segments of effect nodes instead modifies the range of that node’s effect in the composition. Outside of the trimmed region, that effect node will behave as if it were disabled.

TIP: Shortening the duration of effects nodes can optimize processing. Imagine a MediaIn node that represents a clip that’s 100 frames long and is connected to a Defocus node that’s animated from frames 80–100. There is little to no point in processing the defocus node between frames 0–79, so trimming the defocus segment to start at frame 80 in the Timeline will effectively prevent it from rendering and consuming either memory or processor time until needed.
To trim a segment in the Timeline, do the following:

Drag on either end of the node’s segment in the Timeline.

The cursor changes to a vertical bar with a single arrow when the cursor is in the right location to trim.

Holding the First or Last Frame

If you want to hold a Loader’s First or Last frame of a clip for a certain number of frames, also called a freeze frame, you can hold Command while you drag beyond the first or last of the segment in the Timeline.

Working with Keyframes in the Timeline

Keyframes can be drawn in one of two ways. When keyframe tracks are closed, they’re drawn over the node’s segment. Clicking on the disclosure icon to the left of the node’s name in the track header expands the display so each keyframed parameter has its own track in the Timeline, enabling precise editing.

Furthermore, each keyframe track, whether open or closed, exposes a miniature curve overlay that provides a visual representation of the rise and fall of keyframed values. This little overlay isn’t directly editable.

Drag and Drop Keyframe Editing

Here are pointer-based keyframe editing methods that will get you started.

Methods of selecting keyframes:

- Click a single keyframe to select it.
- Drag a bounding box over a series of keyframes to select them all.
- Command-click to select discontiguous keyframes.
- Shift-click the first and last of a range of keyframes to select a contiguous range.
Methods of adjusting keyframes:

- You can drag keyframes left and right to reposition them in time.
- You can right-click one or more selected keyframes and use contextual menu commands to change keyframe interpolation, copy/paste keyframes, or even create new keyframes.

**Keyframe Editing Using the Time Editor**

A pop-up and editing field at the bottom right of the Keyframe Editor lets you numerically edit the timing, in frames, of any selected keyframe, making it easy to make precise adjustments.

**To change the position of a keyframe using the toolbar, do one of the following:**

- Select a keyframe, then enter a new frame number in the Time Edit box.
- Choose T Offset from the Time Editor pop-up, select one or more keyframes, and enter a frame offset.
- Choose T Scale from the Time Editor pop-up, select one or more keyframes, and enter a frame offset.

The Time button can switch to Time Offset or Time Scale for moving keyframes.

**The Keyframe Spreadsheet**

If you turn on the Spreadsheet and then click on the name of a layer in the keyframe track, the numeric time position and value (or values if it’s a multi-dimensional parameter) of each keyframe appear as entries in the cells of the Spreadsheet. Each column represents one keyframe, while each row represents a single aspect of each keyframe.

For example, if you’re animating a blur, then the “Key Frame” row shows the frame each keyframe is positioned at, and the “Blur1BlurSize” row shows the blur size at each keyframe. If you change the Key Frame value of any keyframe, you’ll move that keyframe to a new frame of the Timeline.
Duplicating Spline Keyframes

Keyframes can be duplicated, either onto the same keyframe track or onto different tracks. This can save you time if you need to repeat a keyframe sequence at another time on the same segment, or even just create identically-timed keyframes on two different segments.

To duplicate keyframes, do the following:

1. Select one or more keyframes you want to duplicate.
2. Hold Command and drag one of the selected keyframes to a new position.

Time Stretching Keyframes

If you select a range of keyframes in a keyframe track, you can turn on the Time Stretch tool to show a box you can use to squeeze and stretch the entire range of keyframes relative to one another, to change the overall timing of a sequence of keyframes without losing the relative timing from one keyframe to the next. Alternately, you can turn on Time Stretch and draw a bounding box around the keyframes you want to adjust to create a time stretching boundary that way. Click the Time Stretch tool again to turn it off.

Showing Keyframe Values

When a node and its accompanying segment have animated parameters, keyframes appear as colored tick marks in keyframe tracks to indicate when animated changes occur. If the tracks and splines are open on a parameter, choosing Show Values from the Keyframe Editor option menu shows editable fields beneath each keyframe. These fields show each keyframe’s current value, and allow you to edit them simply by entering a new number.

Timeline Filters

When a composition grows to include hundreds of nodes, locating specific node layers can quickly become difficult. Timeline filters can be created and applied to sift out nodes that are not necessary to the current operation. The Global Timeline preferences include a number of pre-made filters that you can enable, or create new ones as needed.

To use a Timeline filter:

Open the Keyframe Editor option menu and choose an item from the top of the menu.

Default Timeline filters include:
- Show All, which shows all node layers in the current composition.
- Show None, which hides all layers.
– Show Tools at Current Time, which only display node layers that are under the playhead.
– If you’ve created custom filters, they appear here as well, in alphabetical order.

To go back to showing everything:
To disable the currently applied filter, choose Show All from the Keyframe Editor option menu. All layers should reappear.

Choosing a Timeline filter

To create a Timeline filter:
1. Choose Create/Edit Filters from the Keyframe Editor option menu to open the Timeline panel of the Fusion Settings window. This is where you can create new Timeline filters.

![Timeline filter options](image)

The Global Timeline preferences for enabling filters

2. Click the “New” button, enter a name for your new filter setting, and click OK. The filter you created is now selected in the Filter pop-up at the top.

3. Use the “Settings for filters” list to turn on the checkboxes of nodes you want to be seen and turn off the checkboxes of nodes you want to filter out. Each category of node can be turned on and off, or you can open up a category’s disclosure control to turn individual nodes on and off. Clicking Invert All right away turns all node categories off.

4. When you’re finished creating filters, click the Save button to hide the Fusion Settings window.

Filters that you’ve created in the Timeline panel of the Fusion Settings window appear in the Keyframe Editor option menu.
To delete a filter:

1. Choose Create/Edit Filters from the Keyframe Editor option menu to open the Timeline panel of the Fusion Settings window. This is where you can delete Timeline filters.
2. Choose the filter you want to delete from the Filter pop-up menu.
3. Click the Delete button, and when a dialog asks if you really want to do that, click OK.

**Selected Filtering**

Choosing “Show only selected tools” from the Keyframe Editor option menu filters out all segments except for layers corresponding to selected nodes. This option can be turned on or off.

**TIP:** When the “Show only selected tools” is enabled, you can continue to select nodes in the Node Editor to update what’s displayed in the Keyframe Editor.

**Sorting in the Timeline**

There are three ways you can change the order in which the nodes are displayed from top to bottom in the Timeline.

- You can freely drag them into any order you like.
- You can use the Sort pop-up menu.

**The Sort Menu**

The Sort menu reorders how the layers of each node appear in the Keyframe Editor. Setting the menu back to All Tools will display them in a linear order, scanning the Node Editor from left to right and top to bottom. This is the default setting.

- **All Tools:** An option that forces all tools to be displayed in the Keyframe Editor.
- **Hierarchy:** Sorts with the most background layers at the top of the header, through to the most foreground layers at the bottom, following the connections of the nodes in the Node Editor.
• **Reverse:** The opposite of Hierarchy, working backward from the last node in the Node Editor toward the most background source node.

• **Names:** Sorts by the alphabetical order of the nodes, starting at the top with the beginning of the alphabet.

• **Start:** Orders layers based on their starting point in the composition. Nodes that start earlier in the Global project time are listed at the top of the header, while nodes that start later are at the bottom.

• **Animated:** A filter that restricts the Timeline to showing animated layers only. This is an excellent mode to use when adjusting the timing of animations on several nodes at once.

### Guides

Guides are similar to the markers found everywhere else in DaVinci Resolve, and they’re designed to help identify important frames in a project that might affect how you keyframe animation. They may indicate the frame where a dragon breathes fire at a protagonist, the moment that someone passes through a portal, or any other important frame in a composition that you need to keep track of. Guides are created in the Time Ruler, where they appear as a small marker with a line extending vertically through the graph view.

![A guide being moved in the Timeline](image)

**To create a guide, do the following:**

Right-click at a frame in the Timeline Ruler of the Keyframe Editor and choose Add Guide from the contextual menu.

### Working With Guides

The most important attribute of a guide is its position. For it to add value it needs to be placed on the frame you intended it to be on. Hovering the cursor over a guide displays a tooltip with its current frame position. If it is on the wrong frame, you can drag it along the Timeline to reposition it.
Jumping to Guides
Double-clicking a guide jumps the playhead to that guide's position.

Renaming Guides
By default, a guide uses the frame number it's on as its only name, but you can give it a more descriptive name to go along with the frame number, making it easier to identify. To rename a guide, right-click at the top of the guide and choose Rename Guide from the contextual menu. Enter a name in the dialog and click OK.

Show Guide List
Guides can be used to jump to specific locations in a composition using the Guide List. If you right-click the top of a guide to bring up the contextual menu, you can choose Show Guide List or press Shift-G to display the Guide List dialog. The Guide List is a floating dialog and will remain on top of the main window until closed.

The Guide List shows all the current guides in the composition, listed according to their position in time along with any custom name you've given them. If you double click a guide's name from the list, the playhead jumps to the guide's location.

Deleting Guides
You can delete a guide by dragging it up beyond the axis labels and releasing the mouse. You can also use the Guide's contextual menu to choose Delete Guide.
**Autosnap**

To help with precisely positioning spline keyframes and the start and end of segments as you drag in the Timeline, you can have them snap to a field, frame or to guides. Autosnap is an option that is accessed through the Timeline’s contextual menu. There are two submenu options for autosnapping. One option controls the snapping behavior when you drag keyframes, control points or the starting and ending edges of segments. The other option controls the snapping behavior of guides.

**Autosnap Points**

When you drag keyframes or the edges of segments, often you want them to fall on a specific frame. Autosnap restricts the placement of keyframes and segment edges to frame boundaries by default, but you have other options found in the contextual menu. To configure autosnapping on keyframes and segment edges, right-click anywhere within the Keyframe Editor and choose Options > Autosnap Points from the contextual menu. This will display the Autosnap Points submenu with options for the snapping behavior. The options are:

- **None**: None allows free positioning of keyframes and segment edges with subframe accuracy.
- **Frame**: Frame forces keyframes and segment edges to snap to the nearest frame.
- **Field**: Field forces keyframes and segment edges to snap to the nearest field, which is 0.5 of a frame.
- **Guides**: When enabled, the keyframes and segment edges snap to guides in the Timeline.

**Autosnap Guides**

When you click to create a new guide, the default behavior is that it will snap to the closest frame. If you reposition the guide, it also snaps to the nearest frame as you drag. This behavior can be changed in the Keyframe Editor’s contextual menu by choosing from the Options > Autosnap Guides submenu. The options are:

- **None**: Guides can be placed anywhere with subframe accuracy.
- **Frame**: Frame forces all guides to snap to the nearest frame.
- **Field**: Field forces all guides to snap to the nearest field.

**The Spreadsheet Editor**

The Spreadsheet Editor is a separate panel that can be displayed beneath the Keyframe Editor. It is used to compactly show the numeric values of the keyframes for selected parameters in the Timeline header, via a table with rows and columns, showing time and value.
The Spreadsheet Editor showing editable data for six keyframes

To reveal the Spreadsheet Editor, click on the Spreadsheet button in the toolbar. The Spreadsheet will split the Work Area panel and appear below the Timeline interface.

**Selecting a Node to Edit**

To display a node’s timing in the Spreadsheet, select the node’s name in the Timeline header. The Start and End points of the selected node will appear in the keyframe’s line of the Spreadsheet.

To edit an animation parameter in the Spreadsheet Editor, select the parameter in the Timeline header. The keyframe row includes a box for each frame number that contains a keyframe. The value of the keyframe is displayed in the cell below the frame number. Clicking on a cell allows you to change the frame number the keyframe is on or the parameter’s value for that keyframe.

![Spreadsheet Editor](image)

Clicking on the parameter’s keyframe value allows you to change it

**TIP:** Entering a frame number using a decimal point (e.g., 10.25 or 15.75) allows you to set keyframes on a subframe level to create more natural animations.

**Inserting Keyframes**

You can also add new keyframes to an animation by clicking in an empty keyframe cell and entering the desired time for the new keyframe. Using the cell under the new keyframe, you can enter a value for the parameter.

**Selecting Multiple Nodes to Edit**

Multiple splines and nodes can be edited together in the Spreadsheet. By default, selecting a new parameter in the Timeline header will replace the parameter and keyframes currently listed in the Spreadsheet Editor. Holding Command, you can click on additional parameters on different nodes to add to the Spreadsheet.

**TIP:** You can use the Tab and Shift Tab key shortcuts to move the selection right or left in the Spreadsheet Editor.
Customizing the Keyframe Editor

There are a few ways you can change the appearance of the Keyframe Editor to better fit your needs. All of these options are found by right-clicking anywhere within the Keyframe Editor and choosing an option from the contextual menu that appears.

Line Size

The Line Size option controls the height of each Timeline segment individually. It is often useful to increase the height of a Timeline bar, especially when editing or manipulating complex splines.

Methods of increasing or decreasing the height of segments:

- To change the height of just one segment: Right-Click anywhere within the Keyframe Editor and choose a size from the Line Size submenu. The options are Minimum, Small, Medium, Large, and Huge.
- To change the height of all segments: Right-click anywhere within the Keyframe Editor and choose a size from the All Line Size submenu. The options are Minimum, Small, Medium, Large, and Huge.

Display Point Values

A more traditional view of keyframes is to view them as control points instead of vertical bars, making them easier to select for some people. From the Timeline contextual menu, you can right-click anywhere within the Keyframe Editor and choose Options > Display Point Values to change how keyframes look.

Here are the two options, compared.
Chapter 63

Animating with Motion Paths in the Fusion Page

Moving layers and 3D objects can have their animation edited and controlled using motion paths. This chapter discusses how motion paths can be used in the Fusion page.

Animating Using Motion Paths

Motion Paths are polylines that define the movement for two- and three-dimensional controls, such as the Center X/Y and Pivot X/Y parameters of Transform, mask, and effect nodes. Keyframing these kinds of parameters creates visible motion paths in viewers with which you can visually adjust how different effects move. For all motion paths, the coordinate control represents the position of an object or effect, such as a Merge node’s center or published polyline points on a mask. Coordinate controls are represented onscreen with a crosshair or an X.

It’s not possible to add a motion path to a one-dimensional value, like a blur strength or merge angle. However, you can use the Spline Editor to edit these kinds of values in a visual way.

Types of Motion Paths

There are three types of Motion paths: Poly paths, XY paths and 3D motion paths for 3D scenes. A Poly path uses two splines to record the path, one for shape of the path and a displacement spline for the timing along the path.

- The XY path type employs a spline for the X position of the point and another for the Y position. The XY paths are explained in detail toward the end of this chapter.
- The Poly path is the default type for motion paths and most documentation in this chapter assumes that this type is used.
- 3D motion paths only pertain to positional controls within 3D scenes.

Poly Paths

Poly paths are reasonably easy to work with. They’re similar to X/Y paths when you’re working in the Viewer, but they provide a simpler curve editing experience in the Spline Editor.
To create a Poly path, do the following:

1. Position the playhead on the frame where the motion will begin.
2. Position the control for the layer, effect or mask at its starting position.
3. Right-click on the onscreen control in the Viewer, and choose Path from the contextual menu for that control.

![Initiating path keyframing for the center position of a text title](image1)

The Center X/Y parameter for that node will display keyframes at those frames to indicate that the parameter is now animated. Any changes made to the control will cause a new keyframe to be created.

4. Move the playhead to a new frame.
5. Drag the onscreen control or adjust the Offset or Center values in the Control panel. A keyframe is automatically created on the motion path and a polyline is drawn from the original keyframe to the new one.

![Two keyframes spaced several frames apart display a motion path showing the direction of animation](image2)

6. The position of the control is interpolated between the two keyframes. You can continue adding points by moving the playhead and adjusting the control until the entire motion path you need is created. For motion paths, there's no need to close the spline path; you can leave it open.
Upon completion, set the polyline to Insert and Modify mode by pressing Command-I or clicking the Modify button on the toolbar. Don’t worry too much about the overall shape of the motion path at this point. The shape can be refined further by adding additional points to the polyline.

To remove a poly path:
Right-click the coordinate control of the object you’re animating, and choose “Remove Path1” from the submenu of the “NameOfObject: Center” submenu.

Path Modifier
There’s also an XY Path modifier that lets you add a motion path to any compatible control. Simply right-click on the name of a compatible parameter in the Inspector (such as Center X/Y) and choose Modify With > X/Y Path to add that modifier.
When you create a path this way, controls for that path appear in the Modifiers tab of the Inspector.

Now, you can use the modifier controls to create a motion path, while using the object’s original controls as an offset to this motion path, if you need to. Using the XYZ, Center X/Y, Size, Angle, and Heading Offset controls automatically set keyframes, and an editable motion path appears in the Viewer once you’ve set two or more keyframes to create animation.

Displacement Splines and Path Timing

Every Poly path has an associated Displacement Spline in the Spline Editor. The displacement spline represents the position of the animated control along its path, represented as a value between 0.0 and 1.0.
Displacement splines are used to control the speed of the movement along a path. To slow down, speed up, stop or even reverse the motion of the control along the path, adjust the points for the path’s displacement in the Spline Editor.

A displacement value of 0.0 in the Spline Editor indicates that the control is at the very beginning of a path. A value of 1.0 indicates that the control is positioned at the end of the path.

**Types of Control Points**

Displacement paths are composed of Locked and Unlocked points. Whether a point is locked or not is determined by how it was added to the polyline. Locked points on the motion path will have an associated point on the displacement spline. Unlocked points will not have a corresponding point on the displacement spline. Each has a distinct behavior, as described below.

**Locked Points**

Locked points are the motion path equivalents of keyframes. They are created by changing the playhead position and moving the animated control. These points indicate that the animated control must be in the specified position at the specified frame.

The locked points are displayed as larger sized hollow squares in the Viewer. Each locked key has an associated point on the path’s displacement in the Spline Editor.

Deleting a locked point from the motion path will change the overall timing of the motion.

**Unlocked Points**

Unlocked points are created when additional points are added to the motion path while in Insert and Modify mode. These points are used to adjust the overall shape of the motion path, without directly affecting the timing of the motion.

Unlocked points do not have corresponding points on the path’s displacement spline. They are represented in the Viewer as smaller, solid square points.
To experience the difference between locked and unlocked points, do the following:

1. Add a Text node to the Node Editor and type a word in the Text node.
2. Position the text’s center in the upper left corner of the frame.

   ![Text placed in the upper left corner of the frame](image)

3. Set the Playhead at frame 0.
4. In the Viewer, right-click on the text center and choose Animate from the contextual menu.
   This creates the first locked point of the path.

5. Position the playhead on frame 45.
6. Move the text center to the center of the screen.

   ![Moving the playhead and repositioning the text adds a locked point](image)

   This sets the second locked point.

7. View the Spline Editor and display Path 1’s: Displacement Spline.
At a value of 0.0, the control will be located at the beginning of the path. When the value of the displacement spline is 1.0, the control is located at the end of the path.

8. Select the keyframe at frame 45 in the displacement spline and drag it to frame 50. The motion path is now 50 frames long, without making any changes to the motion path’s shape.

If you try to change this point’s value from 1.0 to 0.75 it cannot be done because the point is the last in the animation, so the value must be 1.0 in the displacement spline.

9. Position the playhead on frame 100 and move the text center to the bottom right corner of the screen.

This will create an additional locked point and set a new ending for the path.

10. Select the motion path spline by using the Tab key to cycle controls until the path is selected.

Currently, the path is in Click Append mode.

11. To insert some points, click the Insert and Modify button in the toolbar.
12 Click on the path and create two new points: one part-way between the first and the second points and the other part-way between the second and the third.

Add two new points to the path

13 Smooth these new points to create a curve in the path.

Adjust the path using the newly added points

The two points just added are not present in the motion path’s displacement spline. These are unlocked points, used to shape the motion but unrelated to the timing of the path. This behavior can be used to make the layer’s motion pause briefly.

14 Select the point at frame 50 in the displacement spline and hold down Command (macOS) or Ctrl (Windows) while dragging it to frame 65. The point is copied at frame 65.

Create a pause in the motion by copying locked points

15 Select the point at frame 0 and at frame 50 and press Shift-S while in the Spline Editor to smooth the displacement curve.

This will cause the motion to accelerate slightly at the beginning and slow to a stop at the center.
Render a preview of frames 0 to 100 to see the results so far.

Remove the preview when done.

In the Viewer, delete the unlocked point added between the first point and the middle point. The spline segment of the motion path will become linear.

Deleting this point did not change the amount of time it takes the spline to reach the center of the screen, only the path it takes to get there.

Step through a few of the frames in the scene to confirm this.

Now delete the locked point in the center of the screen.

Removing this point changes the timing of the animation rather profoundly because the key point in the displacement spline is also removed.

Knowing the difference between locked and unlocked points gives you independent control over the spatial and temporal aspects of motion paths.

### Locking and Unlocking Points

You can change an unlocked point into a locked point, and vice versa, by selecting the point(s) and choosing the Lock point option from the contextual menu.

### XY Paths

The XY path type uses a separate spline in the Spline Editor to calculate position along the X-axis, as it does for the position along the Y-axis.

#### To animate a coordinate control using an XY path, do the following:

Right-click on the onscreen control and choose Control name > Modify With > XY Path from the contextual menu.

At first glance, XY paths work like displacement paths. To create the path, position the playhead and drag the onscreen control where you want it. Position the playhead again and move the onscreen control to its new position. The difference is that the control points are only there for spatial positioning. There are no locked points for controlling temporal positioning.

The Spline Editor for the XY path displays the X and Y channel splines. Changes to the controls position will be keyframed on these splines. The advantage to the XY path is that you can explicitly set an XY coordinate at a specific time for more control.

**TIP:** XY path and Poly path can be converted between each other from the contextual menu. This gives you the ability to change methods to suit your current needs without having to redo animation.

### Switching Default Paths

If you want to change the Default Path type to XY path you can choose Fusion > Preferences > Globals (macOS) or File > Preferences > Globals (Windows) and select the Defaults category. In the Point With pop-up menu, choose XY path. The next time Animate is selected from a coordinate control’s contextual menu, an XY path will be used instead of a displacement path.
Tips For Manipulating Motion Paths

There are a variety of ways you can create and edit motion paths in the Viewer.

Path Centers

Every motion path has a defined center represented by a crosshair. Path centers allow paths to be connected to other controls and behave in a hierarchical manner, which is an exceptionally powerful way of creating complex motion by combining relatively simple paths.

A useful example of this technique would be animating the path of a bee in flight. A bee often flies in a constant figure eight pattern while simultaneously moving forward. The easy way of making this happen involves two paths working together.

The bee would be connected to a first path in a Transform node, which would be a figure eight of the bee moving in place. This first path's center would then be connected to another path defining the forward motion of the bee through the scene via a second Transform node.

Copying and Pasting Motion Paths

It is possible to copy an entire motion path to the clipboard and then paste it onto another node or path or composition.

Methods of copying and pasting motion paths:

- **To copy a motion path:** In the Inspector’s Modifier tab, right-click on the path’s control header and choose Copy from the contextual menu.
- **To cut a motion path out of a node:** In the Inspector, right-click on the path’s control header and choose Cut from the contextual menu.
- **To paste the copied path over another path:** In the Inspector, right-click on the path’s control header and choose Paste from the contextual menu.

In all cases, the old motion path will be overwritten with the one in the clipboard.
Removing Motion Paths

To remove a control from a motion path, right-click on the motion path’s control header and select Delete from the motion path’s context menu. Alternately, right-click on the animated control and select Remove “Name of Modifier.”

Recording Motion Paths

You can animate both of the control’s spatial and temporal information at the same time using the Record mode. This is useful when both position and speed are crucial to achieve the desired result.

Right-click on the desired path to display its context menu and select Record from the contextual menu. This displays a submenu of available data that may be recorded.

Use the Record Time option in conjunction with the Draw Append mode to create complex motion paths that will recreate the motion precisely as the path is drawn.

The time used to record the animation may not suit the needs of a project precisely. Adjust the path’s displacement spline in the Spline Editor to more correctly match the required motion.

Importing and Exporting Polylines

You can import and export polyline shapes into a common editable ASCII text file or its native format. These methods are used to save a particularly useful or generic mask or path for future use or for use in another application, such as Maya or LightWave. You can also import FXF, SSF or Nuke shape files.

Native Format

To save a polyline shape in Fusion’s native ASCII format, you right-click on the header of the Mask node in the Inspector and select Settings > Save As from the contextual menu. Provide a name and path for the saved file and select OK to write a file with the .setting extension. This file will save the shape of a mask or path, and any animation splines applied to its points or controls.

To load the saved setting back into Fusion, you first create a new polyline of the same type, then select Settings > Load from the mask’s context menu or drag the .setting file directly into the Node Editor.

If you want to move a polyline from one composition to another, you can also copy the node to the clipboard, open your second composition and paste it from the clipboard into the new composition.
Chapter 64

Animating with Modifiers and Expressions

This chapter discusses how modifiers and SimpleExpressions can be used to control parameters and automatically create animations that would be difficult to achieve manually.

Modifiers

Parameters can be controlled with modifiers to help you automatically create animation that would be difficult to achieve manually. Modifiers can be as simple as keyframe animation or linking the parameters to other nodes, or can be complex expressions, procedural functions, external data, third-party plug-ins, or fuses.

You can add modifiers to an input through the Inspector contextual menu or on the Preview control in the Viewer.

Adding the Right Modifier for the Job

Which modifiers are available depend on the type of parameter you’re trying to add one to. Numeric values, text, polylines, gradients, points, each have different sets of modifiers that will work with them.

Knowing Which Parameters are Modified

The Fusion page user interface will alert you that an input is modified by adding a keyframe highlight for that parameter in the Inspector. Some parameters, like those for numbers and points, will also color the numerical entry field.

Using the Modifier Tab

Modifiers with additional UI will be displayed in the Modifiers tab of the Inspector. When a selected node has modifiers applied, a marker will appear on the Modifier tab as an indication.
Modifiers appear with header bars and header controls just like nodes. A modifier’s title bar can also be dragged into a viewer to see its output.

**Connecting Multiple Parameters to One Modifier**

Once a modifier has been applied to a parameter, you can connect another parameter to that modifier so that the modifier can affect both parameters. This can be handled through the Connect To contextual menu. As with modifier assignment, the list is filtered by the type of the parameter. This connection is bi-directional. Editing either parameter will cause the other parameter to change.

The Publish modifier does nothing by itself, but it does let you connect parameters together without animation or having to use another modifier.

**Adding Modifiers to Modifiers**

Modifiers can be connected to each other and branched, just like any other node in the Fusion page. For example, the Calculation modifier outputs a Number, but has two Number parameters, both of which can have modifiers added to them. If you want to insert a modifier between the existing modifier and the modified parameter, use the Insert submenu of the parameter’s contextual menu. Insert submenu

For more information on all Modifiers available in the Fusion page, see Chapter 103, “Modifiers.”
SimpleExpressions

SimpleExpressions are a special type of script that can be placed alongside the parameter it is controlling. These are useful for setting simple calculations, building uni-directional parameter connections, or a combination of both.

SimpleExpressions can be added from the parameter’s contextual menu.

A text entry box will appear below the control, and a yellow indicator will appear to the left of the control. The current value of the parameter will be entered into the text box.

Inside this text box you can enter one line scripts in Lua with some Fusion page specific shorthand. Some examples of SimpleExpressions and their syntax:

**time**

This returns the current frame number.

**Merge1.Blend**

This returns the value of another input, Blend, from another node, Merge1.

**Merge1:GetValue(“Blend”, time-5)**

This returns the value from another input, but sampled at a different frame, in this case 5 frames before the current one.

**sin(time/20)/2+.5**

This returns a sine wave between 0 and 1. If you look in the Spline Editor, you can see the values plotted out over time. This is a good way to check how your SimpleExpression evaluates over time.
A sine wave in the Spline Editor, generated by the expression used for Text1: Size

\[ \text{iif(Merge1.Blend == 0, 0, 1)} \]

This returns 0 if the Blend value is 0, and returns 1 if it is not. The iif() function is a shorthand conditional statement, if-then-else.

\[ \text{iif(Input.Metadata.ColorSpaceID == \"sRGB\", 0, 1)} \]

This returns 0 if the image connected to the current node’s Input is tagged with sRGB colorspace. When no other node name is supplied, the expression assumes the Input is coming from the current node. It is equivalent to self.Input. The Input in most, but not all, Fusion page nodes is the main image input shown in the Node Editor as an orange triangle. Images have members that you can read, like Depth, Width, Metadata, and so on.

\[ \text{Point(Text1.Center.X, Text1.Center.Y-.1)} \]

Unlike the previous examples, this returns a Point, not a Number. Point inputs use two members, X and Y. In this example, the Point returned is 1/10 of the image height below the Text1’s Center. This can be useful for making unidirectional parameter links, like offsetting one Text from another. Another way to get the same result would be:

\[ \text{Text1.Center} - \text{Point(0,.1)} \]

\[ \text{Text(\"Colorspace: \trie(Merge1.Background.Metadata.ColorSpaceID)}) \]

This SimpleExpression returns Text instead of a Number or Point. The string inside the quotes is concatenated with the metadata string, perhaps returning:

\[ \text{Colorspace: sRGB} \]

\[ \text{Text(\"Rendered \trie(os.date(\"%b %d, %Y\").. \trie at \trie(os.date(\"%H:%M\").. \trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\trie\tr}
For more details about writing SimpleExpressions, see the Fuse Guide, Scripting Guide, and the official Lua documentation.

**Pickwhipping**

To the left of the SimpleExpression sits a button with a + on it. Click dragging the button onto another control, or "pickwhipping," will let you easily get the name of that control. Hovering over a tab while pickwhipping will open that tab.

SimpleExpressions can also be created and edited within the Spline Editor. Right click on the parameter in the Spline Editor and select Set Expression from the contextual menu. The SimpleExpression will be plotted in the Spline Editor, allowing you to see the result over time.

A quick way of setting a SimpleExpression in a Number or Point input is to type = into the text box to the left of the number already there.
Chapter 65

Using the Tracker Node

This chapter shows the many capabilities of the Tracker node in the Fusion page, starting with how they can be connected in your node trees, and finishing with the different tasks that can be performed.

Introduction to Tracking on the Fusion Page

Tracking is one of the most powerful automation nodes available to a compositor, and the Fusion page has a variety of different tracking nodes available to let you analyze different kinds of motion, and use the resulting data to match the motion of one image to that of another, stabilization, motion smoothing, and a host of other essential tasks.

Overview of the Tracker Node

There are four primary applications for tracking data.

Stabilizing

You can use one or more trackers to remove all of the motion from the sequence or to smooth out vibration and shakiness. When you use a single tracker pattern to stabilize, you only stabilize the X and Y position. Using multiple patterns together, you are able to stabilize position, rotation and scaling.

Match Moving

The reverse of stabilizing is match moving, which detects position, rotation and scaling in an image sequence using one or more patterns. Instead of removing that motion, it is applied to another image that matches the movement so that the two images can be composited together.

Corner Positioning

Corner positioning tracks four patterns which are then used to map the four corners of a new foreground into the background. This technique is generally used to replace signs or mobile phone screens.

Perspective Positioning

Perspective positioning again tracks four patterns to identify the four corners of a rectangle. Each corner is then mapped to a corner of the image, rescaling and warping the image to remove all apparent perspective.

An Overview of the Tracker Node Workflow

All tracking workflows on the Fusion page consist of three fundamental steps.

First, Attach a Tracker Node’s Background Input to the Image You Want to Analyze

You attach a Tracker node’s background input to the output of the node with the image you want to track, as seen in the following screenshot. The Tracker node only analyzes the state of the image that’s attached to its background input.

If you intend to use the Tracker node itself to do a transform operation using the tracking data it analyzes, you can connect it serially. However, if you’re just using a Tracker node to analyze data for use elsewhere, you could choose to branch it and leave its output disconnected to indicate that Tracker node is a data repository. Please note that this is not necessary; serially connected Tracker nodes can be set to have no effect on the image as well.
Second, Analyze the Image to be Tracked

One or more features in the image that you wish to track (referred to as patterns) are identified by creating trackers (there’s one by default). Tracker on-screen controls appear in the Viewer that you can position over the patterns you need to track. After the Tracker node analyzes the shot, the resulting tracking data is stored within that Tracker node. Keyframes, one per frame, indicate the “Tracked Center X and Y” data that has been saved, while a motion path shows the path of tracked data that is now available.

Third, Apply the Tracking Data

The resulting tracking data stored within the Tracker node is used to stabilize, match move, cornerpin, or perspective position that or other images, in one of two ways.

Use the Tracker node itself to match move and merge

You can connect the image you want to match the motion of the analyzed background image to the foreground input of the Tracker node, and then set the Operation parameter in the Operation tab in the Inspector to Match Move, Corner Position, or Perspective Position as necessary. This is an easy workflow for simple situations. In this case, the Tracker node then also does what the Merge node does as well.
Using a Tracker node to do a match move and merge, all in one

Connect the Tracker you analyzed to specific parameters:
Alternately, you can apply the tracking data from the Tracker node to the specific parameters of other nodes that will actually do the work, for instances where setting up a match move isn’t just a matter of transforming a foreground image. For example, in the following node tree, an Ellipse node is being used to limit a Blur effect to a woman’s face for a documentary. However, the ellipse needs to follow the motion of the woman’s face, so a Tracker node is used to analyze the movement of the woman’s nose so that track data can be used to animate the ellipse by connecting the track data to a specific parameter.

Blurring an actor’s face by connecting tracking data to the center position of an Ellipse node

This is made easier by renaming the Tracker you created to something descriptive of what’s being tracked.
Once the nose on the woman’s face has been tracked, this tracking data is then connected to the Center parameter of an Ellipse node that’s limiting a Blur node to the woman’s face by right-clicking the label of the Center parameter in the Inspector, and choosing Tracker1 > Face: Offset position from the Connect to submenu of the contextual menu. All of the data from every Tracker node in your node tree appears within this submenu, and since we named the Tracker we want, it’s easy to find. We choose Offset position because that’s the value that gives us the most control.

You can connect any Tracker node’s data to any other node’s parameter, however you’ll most typically connect track data to center, axis, or corner X/Y style parameters. When you use tracking data this way, it’s not necessary to connect the Tracker node itself to anything else in your node tree; the data is passed from the Tracker to the Center parameter as an expression.
Tracker Inspector Controls

The layout of the Tracker node’s tabs in the Inspector reflects this workflow. It’s divided into three main tabs:

- **The Tracker tab**: Where you create on-screen trackers with which to target patterns, and where the controls appear that let you perform the required track analysis.

- **The Operations tab**: Where you decide how the tracking data is used.

- **The Display Options tab**: Where you can customize how the onscreen controls look in the Viewer.
Motion Tracking Workflow In Depth

Analyzing motion using one or more trackers within the Tracker node is easy.

First: Connect a Tracker Node to the Image You Need to Track

Tracker nodes serve two purposes. They provide the nodes you need to analyze a subject you want to follow, and they serve as a container for the resulting track data. Regardless of whether or not you actually use the Tracker node itself to do anything with the tracking data, the background input (yellow) of a Tracker node must be connected to the output of the image you want to track for there to be a successful analysis. While the Tracker node has a foreground input, it’s ignored for purposes of tracking analysis, so you must connect the background for tracking to work successfully.

Second: Add Trackers to the Tracker List in the Inspector

Although each Tracker node starts with a single tracker to get you started, a single node is capable of analyzing multiple trackers that have been added to the Tracker list, enabling you to track multiple features of an image all at once for later use and to enable different kinds of transforms. Additional trackers can be added by clicking on the Add button immediately above the Tracker List control.

Multiple patterns are useful when stabilizing and corner or perspective positioning. They also help to keep the Node Editor from becoming cluttered by collecting into a single node what would otherwise require several nodes.
Methods of managing the Tracker list:

- **To select a tracker:** Click the name of the Tracker you want to select.
- **To rename a tracker:** You can rename trackers to make it easier to reference them later. For example, if you're tracking a car door handle, you can name the Tracker "Car Handle" so it's easy to find later. To do so, just double-click the default name of the Tracker in the Tracker list, type a new one, and press Return.
- **To delete a tracker:** Select a tracker and click the Delete button.
- **To disable, suspend, or re-enable trackers:** Click the checkbox to the left of each tracker's name in the Tracker list. It's a three-way toggle that switches between Enabled, Suspended and Disabled.
  - **Enabled:** An Enabled tracker will re-track its pattern every time the track is performed. Its path data is available for use by other nodes and the data is available for stabilization and corner positioning.
  - **Suspended:** When the checkbox appears gray, it is Suspended. In this state it does not re-track its pattern when the track is performed. The data is locked to prevent additional changes, but the data from the path is still available for other nodes. The data is also available for advanced tracking modes like stabilization and corner positioning.
  - **Disabled:** A Disabled tracker does not create a path when tracking is performed. Its data is not available to other nodes or for advanced tracking operations like stabilization and corner positioning.

Third: Position the Pattern Boxes of Each Tracker

A pattern is the region of pixels that are targeted for tracking within an image using a pattern box. The pattern box is defined in the Viewer by a rectangle when a tracker is active. A single Tracker node can have many trackers, each targeting different patterns. Each tracked pattern will produce its own motion path.

Clicking any part of a tracker's on-screen controls will select it. Selected pattern boxes are red, while de-selected pattern boxes are green.

When you add a Tracker node to the Node Editor, you start with one pattern box displayed in the Viewer as a small rectangle. When the cursor is placed over the pattern rectangle, the control expands and two rectangles appear. The outer has a dashed line and the inner has a solid line. The outer rectangle is the search area and the inner rectangle is the pattern.

If you need to select a new pattern, you can move it by dragging the small and easily missed handle at the top left of the inner pattern box.

![A pattern box positioned over an eye you want to track](image)

![To move a pattern in the Viewer, drag it from the upper left corner](image)
While moving the pattern box, an overlay pop-up appears, showing a zoomed version of the pixels contained within the rectangle to help you precisely position the pattern via the crosshairs within.

The pattern rectangle can also be resized by dragging on the edges of the rectangle. You want to size the pattern box so that it fits the detail you want to track, and excludes area that doesn’t matter. Ideally, you want to make sure that every pixel of the pattern you’re tracking is on the same plane, and that no part of the pattern is actually an occluding edge that’s in front of what you’re really tracking. When you resize the pattern box, it resizes from the center, so one drag lets you create any rectangle you need.

Fourth: Define the Search Area of Each Tracker

A second rectangle with a dotted border surrounds the pattern box. This is the search area. When progressing from one frame to another while tracking, the Tracker analyzes the region defined by the search area, which surrounds the last known tracker position, in an attempt to relocate the pattern. The larger the search area, the better a chance you have of successfully tracking fast moving objects, but the longer the track will take. However, there are some ways to optimize tracking for specific content.

For example, tracking a pattern that is moving quickly across the screen from left to right requires a wide search area but does not require a very tall one, since all movement is horizontal. If the search area is smaller than the movement of the pattern from one frame to the next, the Tracker will likely fail and start tracking the wrong pixels, so it’s important to take the speed and direction of the motion into consideration when setting the search area.
Fifth: Perform the Track Analysis

Before you begin analyzing, you’ll need to make sure you’ve set a render range in the Time Ruler that corresponds to the range of frames during which the pattern is visible. This may be an entire clip, or only a small portion of that clip. Depending on the type of motion you’re tracking, you may want to use the Adaptive Mode option to aid the analysis (see below for more details).

Once your options are set, you can use any of the tracking transport buttons at the top of the Inspector to start tracking. Once tracking has started you cannot work in the Node Editor until it has completed.

The tracking transport buttons and analysis parameters

To begin tracking, do one of the following:

- Click the Track Reverse button to track from the very end of the render range.
- Click Track Backward from Current Frame to track backward from the current playhead position.
- Click the Track Forward button to track from the very start of the render range.
- Click Track Forward from Current Frame to track forward from the current playhead position.

Pattern tracking will stop automatically when it reaches the end of the render range (or the start when tracking backward), but you can also interrupt it and stop tracking at anytime.

To stop tracking, do one of the following:

- Click the Stop Tracking button in the tracker transports.
- Click Stop Render at the bottom of the Fusion window.
- Press the Escape key.

When tracking is complete, the path will be connected to the pattern. The path from that pattern can now be connected to another node or used for more advanced operations like stabilization and corner positioning.

Sixth: Use the Track

Once the track is complete, assuming it’s good, you can use the various techniques in this chapter to use the track in your composition.

Tips for Choosing a Good Pattern

The Tracker works by searching each frame for the pixels contained in the pattern. In order for a track to be successful, a fairly high contrast and unique region of the image must be located in the footage. This process is known as pattern selection.

The first step in pattern selection is to review the footage to be tracked several times. Watch for candidate patterns that are visible through the entire range of frames, where the contrast is high and the shape of the pattern does not change over time. The more unique the pattern, the more likely the track is to be successful.
In addition to locating high contrast, defined patterns, watch for the frames where the pattern moves the most. Identifying the maximum range of a pattern’s motion will help to determine the correct size for the pattern search area.

It is not uncommon to have a scene that requires the use of several different patterns to generate a single path. This most often occurs because the pattern moves out of frame or is temporarily obscured by another scene element. Combining patterns into a single pattern is described later in the chapter.

### Selecting the Pattern’s Image Channels

When a pattern of pixels is selected, the Tracker automatically selects the color channel used for tracking the pattern based on an analysis of each channel for contrast, clarity and reliability. The channels selected are highlighted in the bars to the right of the Pattern display window in the node controls.

You can override the automatic channel selection by clicking the buttons beneath the bars for each channel to determine the channel used for tracking.

You can choose any one of the color channels, the luminance channels or the alpha channel to track a pattern.

When choosing a channel, the goal is to choose the cleanest, highest contrast channel for use in the track. Channels that contain large amounts of grain or noise should be avoided. Bright objects against dark backgrounds often track best using the luminance channel.

### Selecting Patterns for Stabilization

Selecting patterns for stabilization can be a tricky business. The location of the pattern, when it is selected, is used to determine precisely how the image will be stabilized. At least two patterns are required to correct for rotation; using three patterns will correct for scaling and more will usually improve the quality of the solution.

Try not to select just any potentially valid pattern in the sequence, as some patterns will make the solution worse rather than better. To help with your selection, use the following guidelines when selecting patterns for stabilization.

- Locate patterns at the same relative depth in the image. Objects further in the background will move in greater amounts compared to objects in the foreground due to perspective distortion. This can confuse the stabilization calculations, which do not compensate for depth.

- Locate patterns that are fixed in position relative to each other. Patterns should not be capable of moving with reference to each other. The four corners of a sign would be excellent candidates, while the faces of two different people in the scene would be extremely poor choices for patterns.
Using The Pattern Flipbooks

Each pattern has a pair of thumbnail windows shown in the Inspector. The left window shows the pattern that is selected, while the right window is updated during the track to show the actual pattern that has been acquired for each frame.

![The Tracker Pattern Selection and Flipbook thumbnails](image)

Each pattern that’s stored is added to a Flipbook. Once the render is complete, you can play this Pattern flipbook to help you evaluate the accuracy of the tracked path. If you notice any jumps in the frames, then you know something probably went wrong.

Using Adaptive Pattern Tracking

Even the most ideal pattern will usually undergo shifts in profile, lighting conditions and other variables. These can adversely affect pattern recognition to the point that a pattern becomes unusable. The Tracker offers three modes of pattern acquisition during tracking that can help to correct these conditions. The modes can be set using the Adaptive Mode buttons in the Inspector.

![The Adaptive Mode options](image)

None

When the Adaptive mode is set to None, the pattern within the rectangle is acquired when the pattern is selected, and that becomes the only pattern used during the track.

Every Frame

When Every Frame is chosen, the pattern within the rectangle is acquired when the pattern is selected, then re-acquired at each frame. The pattern found at frame 1 is used in the search on frame 2, the pattern found on frame 2 is used to search frame 3, and so on. This method helps the Tracker adapt to changing conditions in the pattern.

Every Frame tracking is slower and can be prone to drifting from sub-pixel shifts in the pattern from frame to frame. Its use is therefore not recommended unless other methods fail.

Best Match Tracking

Best Match tracking works in much the same way as Every Frame tracking, however, it will not re-acquire the pattern if the difference between the original pattern and the new one is too great. This helps to prevent cases where transient changes in the image cause the Tracker to become confused.
As a comparison between the two Adaptive modes, if a shadow passes over the tracker point, the Every Frame tracking mode may start tracking the shadow instead of the desired pattern. The Best Match mode would detect that the change from the previous frame's pattern was too extreme and would not grab a new pattern from that frame.

The Adaptive mode is applied to all active patterns while tracking. If you only want some patterns to use the Adaptive mode, disable all other patterns in the list before tracking.

**Dealing With Obscured Patterns**

Often, an otherwise ideal pattern can be temporarily obscured (occluded) or blocked from tracking; for example, when tracking a car that passes behind a telephone pole.

In these situations, you divide the render range up into two ranges, the range before the pattern is obscured and the range after the pattern becomes visible again. After tracking the two ranges individually, the Tracker will automatically interpolate between the end of the first range and the start of the second.

If you need to edit the resulting motion path to account for any non-linear motion that take place between the two tracked ranges, you can select the track path to expose a Node toolbar with controls for adjusting the control points on this path. For example, you can choose Insert and Modify mode to insert points in the non-tracked range to compensate for any non-linear motion in the tracked pattern.

![Tools for modifying tracker paths in the Node toolbar of the Viewer](image)

**Dealing With Patterns That Leave the Frame**

There are two options when a tracker leaves the frame. If the pattern re-enters the frame, you can treat it like an obscured pattern. If the pattern does not re-enter the frame, or it is undesirable to hand track portions of the movement, you can use the Track Center (Append) mode to select a new pattern.

![The Track Center (Append) mode pop-up menu](image)

The Track Center (Append) mode selects a new pattern that will continue to add keyframes to the existing path. The offset between the old pattern and the new pattern is automatically calculated to create one continuous path.
To use the Track Center (Append) mode, do the following:

1. When the pattern has become untrackable for some reason, stop analysis and move the playhead to the last frame that tracked successfully.
2. Choose Track Center (Append) from the Path Center pop-up menu in the Inspector.
3. Now, drag the Pattern selector to a new pattern that can be tracked from that point onward.
4. Restart tracking from the current frame.

When selecting a pattern to use in appending to an existing path, a pattern that is close to the old pattern and at the same apparent depth in the frame generates the best results. The further away the new pattern is, the more likely it is that the difference in perspective and axial rotation will reduce accuracy of the tracked result.

Setting Up Tracker Offsets

Often, it’s impossible to track the thing you want to apply an effect to. For example, the only pattern available for an accurate track is a button on an actor’s sleeve. However, the effect requires the person’s hand to be glowing. To cause the glow’s effect mask to be centered on the actor’s hand, it’s necessary to use the Tracker Offset control.

The Tracker Offset controls in the Inspector

The X and Y Offset controls allow for constant or animated positional offsets to be created relative to the actual Tracker’s pattern center. The position of the offset in the Viewer will be shown by a dashed line running from the pattern center to the offset position. You can also adjust the offset in the Viewer using the Tracker Offset button. Clicking the button enables you to reposition the path while keeping the Tracker pattern in place.

Once an offset for a pattern is set, you can connect other positional controls to the Tracker’s Offset menu using the Connect To > Tracker: Offset Position option in the control’s contextual menu. The path created during the track remains fixed to the center of the pattern.
The Many Tasks of Match Move

When a Tracker node is set to Match Move in the Operations tab, it is capable of a variety of functions:

- Stabilizing footage to completely remove motion from the scene or smooth existing motion.
- Applying the motion from one clip to another, basically matching the movement and stabilizing one shot with reference to another.

Here are some common scenarios for stabilization that are handled when the Tracker is set to Match Move.

- A sequence that should be steady has vibrations or undesirable movement.
- A sequence that requires a smooth camera move suffers from jarring.

Stabilizing Motion (Using the Match Move Mode)

Stabilizing motion completely removes the appearance of motion from the image. The motion from frame to frame is calculated, and the contents of the frame are transformed to return the image to a reference position. This position can be either the start or end of the sequence or a manually selected frame from the sequence.

Stabilization can correct for position with as little as one pattern. Two or more patterns are required to correct for rotation or scaling within the image.

When the Match Move button is selected in the Tracker’s Operation tab, the Tracker can use the data from its patterns for stabilization. Only the controls that are applicable for stabilization operations will appear in the Operation tab.

Several of the stabilization controls are always available, collected under the Match Move Settings disclosure button. These controls are available at all times because the Steady and Unsteady positions of a tracker are always published. This makes them available for connection by other controls, even when the Tracker’s operation is not set to match moving.
**Merge**

The Merge buttons determine to what input connection on the Tracker node the stabilization data is applied. When stabilizing an image to remove all motion, or smooth the motion, the Merge button should be set to BG Only.

**Edges**

The Edges buttons determine whether the edges of an image that leave the visible frame are cropped, duplicated, or wrapped when the stabilization is applied. Wrapping edges is often desirable for some methods of match moving, although rarely when stabilizing the image for any other purpose. These controls are described in greater detail in the Node References for the Tracker later in this manual.

**Position/Rotation/Scaling**

Use the Position, Rotation, and Scaling checkboxes to select what aspects of the motion are corrected.

**Pivot Type**

The Pivot Type for the stabilization is used to calculate the axis of rotation and scaling calculations. This is usually the average of the combined pattern centers but may be changed to the position of a single tracker or a manually selected position.

**Reference**

The Reference controls establish whether the image is stabilized to the first frame in the sequence, the last frame, or to a manually selected frame. Any deviation from this reference by the tracked patterns is transformed back to this ideal frame.

As a general rule, when tracking to remove all motion from a clip, set the Merge mode to BG Only, the Pivot type to Tracker Average or Selected Tracker and the Reference control to Start, End or Select Time.

**Smoothing Motion**

When confronted with an image sequence with erratic or jerky camera motion, instead of trying to remove all movement from the shot, you often need to preserve the original camera movement while losing the erratic motion.

The Start & End reference option is designed for this technique. Instead of stabilizing to a reference frame, the tracked path is simplified. The position of each pattern is evaluated from the start of the path and the end of the path along with intervening points. The result is smooth motion that replaces the existing unsteady move.
To preserve some of the curvature of the original camera motion, you can increase the value of the Reference Intermediate Points slider that appears when the Start & End reference mode is selected.

When tracking to create smooth camera motion, ensure that the Start & End reference mode is enabled and set the Merge mode to BG Only. It is recommended to leave the Pivot type control set to Tracker Average.

Using the Tracker Node for Match Moving

A simple match moving example is shown at the beginning of this chapter, but this section will show additional details that you may not have been aware of. Examples of match moving include:

- A static CG element must be believably added to a moving sequence.
- Two sequences with different motions must be composited together.

Some clips may need to be stabilized so that an element from another source can be added to the shot. After the element or effect has been composited, the stabilization should be removed to make the shot look natural again.

Simple Match Moving

Match moving essentially applies the movement from the tracked clip to another clip. There are two ways to perform match moving. One method involves connecting other nodes, such as transform or merge, to a tracker’s outputs. The other method is to stabilize an image by trying to remove all motion, but instead of setting the Merge buttons to BG Only, set it to FG Over BG, FG Only, or in rare occasions, BG Over FG.
When using this Merge buttons, you connect a foreground image to the Tracker node’s Input connection in the Node Editor.

![Connect a foreground image to the Tracker’s foreground input](image)

Enabling the FG Only mode will apply the motion from the background to the foreground, and the Tracker will only output the modified FG image. This result can later be merged over the original, allowing further modifications of the foreground to be applied using other nodes before merging the result over the background clip.

**Corner Positioning Operations**

The Corner Positioning operation maps the four corners of a foreground image to four patterns within the Tracker. This operation or technique is most commonly used for sign replacements.

The Corner Positioning operation of the Tracker requires the presence of a minimum of four patterns. If this operation mode is selected and there are not four patterns set up in the Tracker already, additional patterns will automatically be added to bring the total up to four.

When this mode is enabled, a set of drop down boxes will appear to select which tracker relates to each corner of the rectangle. It has no effect when the Merge control buttons are set to BG Only.

**Perspective Positioning Operations**

The Perspective Positioning operation is used to remove perspective from a foreground image or apply the perspective from one sequence to another.

The Perspective Positioning operation of the Tracker requires the presence of a minimum of four patterns. If this operation mode is selected and there are not four patterns set up in the Tracker already, additional patterns will automatically be added to bring the total up to four.

When this mode is enabled, a set of drop down boxes will appear to select which tracker relates to each corner of the rectangle. It has no effect when the Merge control buttons are set to BG Only.
Connecting Trackers to Other Operations

One of the most common applications for a tracked pattern is using the tracked position or path to drive the position of another node’s parameters. For example, tracking an eye in order to color correct the eye to blue using an effect mask. You start off by tracking the eye, then create a color corrector with the desired settings. You create a mask in the shape of the eye and connect the Tracker’s position to the Center of the mask.

In addition to the path, each pattern in a tracker outputs five values for use as connections that are available for use by other nodes.

You connect a node’s position parameters to a tracker by selecting the connection type from the controls contextual menu (for example, Transform 1: Center > Connect To > Tracker 1 > Unsteady Position).

There are five connection types available to connect to a position parameter in another node.

Steady Position

Steady Position can be used to stabilize footage in both X and/or Y to remove camera shake and other unwanted movement. The connection inverts the output of the tracked pattern’s motion. When you connect a Center parameter to the Steady Position of the Tracker, it will be placed at 0.5/0.5 (the center of the screen) by default at frame 1. You can change this using the Reference mode in the Tracker’s Operation tab.

Steady Angle

The Steady Angle mode can be used to stabilize footage in both X and/or Y to remove camera shake and other unwanted movement. When you connect a control, for example the Angle of a Transform, to the Steady Angle of the Tracker, it will be placed at 0 degrees by default at frame 1. This can be changed by means of the Reference mode in the Tracker’s Operation tab. From there on, the resulting motion of the Steady Angle mode will rotate into the opposite direction of the original motion.

So if the actual angle at frame 10 is 15 degrees, the result of the Steady Angle will be -15 degrees. To use Steady Angle you need at least two tracked patterns in your tracker. With just one point you can only apply (Un)Steady Position.

Offset Position

An Offset Position is available for each single tracker in the Tracker node and refers to that single tracker only. When you connect the Center X and Y parameters to the offset position of the Tracker, the node’s center will follow exactly the path of that tracker. Connecting to single trackers is always useful when you want to match elements with object motion in your footage. For example, you could track a hand of your actor and attach a ball to the Tracker’s offset position, so that the ball follows the exact motion of the hand. Or you could track an element that needs rotoscoping and attach the mask’s center to the Tracker’s offset position.
Unsteady Position

The Unsteady Position is used to re-introduce the original movement on an image after an effect or new layer has been added. The resulting motion from Unsteady Position is basically an offset in the same direction as the original motion.

Steady Size

The Steady Size connection outputs the inverse of the tracked pattern’s scale. When you connect a parameter, for example the Size of a Transform, to the Steady Size of the Tracker, it will be placed with a Size of 1 (i.e., the original size) by default at frame 1. This can be changed by means of the Reference mode in the Tracker’s Operation tab. The resulting size of the Steady Size mode will then counteract the size changes of the original motion. So if the actual size at frame 10 is 1.15, the result of the Steady Size will be 1-(1.15-1)=0.85.

To use Steady Size you need at least two tracked patterns in your tracker. With just one point you can only apply (Un)Steady Position.

The connections above are output by pattern in the Tracker node. Each node itself also outputs a Steady Position, Angle and Size output. The values of these outputs are calculated using all of the patterns in that tracker, as configured by the Stabilize Settings controls in the Tracker’s Operation tab.

As an example, to use the Connect To menu to perform a match move, do the following:

1. Add a Transform node to the clip you want to match move.
2. Right click over the Transform’s Center and choose Connect to > Steady Position.
3. Set the Transform node’s Edges mode to Mirror so that pixels will not get cropped from the image when it is stabilized.
4. Add another Transform node to the Node Editor after the merge.
5. Connect the new Transform’s Center to the Tracker’s Unsteady Position. The image will be restored to its original state with the additional effect included.

To better understand how this works, imagine a pattern that is selected at frame 1, at position 0.5, 0.5. The pattern does not move on frame 2, so its position is still 0.5, 0.5. On the third frame, it moves 10 percent of the image’s width to the right. Now its position is 0.6, 0.5.

If a transform center is connected to the Steady Position output of the Tracker, the Transform node’s center is 0.5, 0.5 on the first and second frames because there has been no change. On frame 3, the center moves to 0.4, 0.5. This is the inverse of the horizontal motion that was tracked in the pattern, moving the image slightly to the right by 10 percent of the image width to counteract the movement and return the pattern of pixels back to where they were found.
Using Tracker Modifiers

Another technique for adding a tracker directly to a control is to add it as a modifier.

The differences between a Tracker modifier and a Tracker node are as follows:

- The Tracker modifier can only track a single pattern.
- A source image must be set for the Tracker modifier.

The Tracker modifier can only output a single value and cannot be used for complex stabilization procedures.

As an example, to apply the Tracker as a modifier, do the following:

Imagine that you needed to track an actor’s eyes so that an unearthly, alien glow could be applied to the eyes.

1. Add a Glow node.
2. Create an ellipse mask in the shape of the eye.
3. In the Inspector, right click on the mask’s Center parameter.
4. From the contextual menu choose Modify With > Tracker Position.

Choosing the Tracker from the Modify with Contextual menu adds a modifier in the Inspector with a set of parameters almost identical to those found in the Tracker node itself.

The default source image for the modifier is the node immediately upstream of the node that contains the modifier (i.e., when adding a Tracker modifier to a Glow node with a Loader as its input, the Tracker Source input will default to the output of the Loader). You can set a different source image for the Tracker modifier by typing in the name of the node at the top of the Inspector Modifier tab. Alternately, drag and drop the source node from the Node Editor into the Text Box control or use Connect To from the contextual menu.

For detailed information on the Tracking controls please see Chapter 100, “Tracker Nodes.”
Chapter 66

Planar Tracking

This chapter provides an overview of how to use the Planar Tracker node, and how to use it to make match moves simple. For more information about the Planar Tracker node, see Chapter 100, "Tracker Nodes."

Using the Planar Tracker

The Planar Tracker node is designed to deal with match moving issues that commonly arise during post-production. Examples include moving footage containing planar surfaces such as a license plate, a road sign, or a brick wall that often needs images merged on top of them, such as replacing the numbers in the license plate, changing the city’s name in the road sign, or placing a billboard poster on the empty brick wall.

The Planar Tracker automates this process by analyzing the perspective distortions of a planar surface on a background plate over time, and then re-applying those same perspective distortions to a different foreground.

**TIP:** Part of using the Planar Tracker is also knowing when to give up and fall back to using Fusion’s Tracker node or to manual keyframing. Some shots are simply not trackable or the resulting track suffers from too much jitter or drift. The Planar Tracker is a time-saving node in the artist’s toolbox and, while it can track most shots, it’s not always a 100% solution.

Different Ways of Using the Planar Tracker Node

Like the other tracking nodes found in the Fusion page, the Planar Tracker can both analyze and contain the resulting image tracking data interior to the node, and it can also use that tracking data to transform either another image or the current image in different ways.

The Planar Tracker has four modes of operation.

- **Track:** Used to isolate a planar surface and track its movement over time. Then, you can create a Planar Transform node that uses this data to match move another clip in various ways.
- **Steady:** After analyzing a planar surface, this mode removes all motion and distortions from the planar surface, usually in preparation for some kind of paint or roto task, prior to “unsteadying” the clip to add the motion back.
- **Corner Pin:** After analyzing a planar surface, this mode computes and applies a matching perspective distortion to a foreground image you connect to the foreground input of the Planar Tracker node, and merges it on top of the tracked footage.
- **Stabilize:** After analyzing a planar surface, allows smoothing of a clip’s translation, rotation, and scale over time. Good for getting unwanted vibrations out of a clip while retaining the overall camera motion that was intended.
Setting Up to Use the Planar Tracker

To do a planar track, you need to connect the output of the image you want to track to the background input of a Planar Tracker node.

Connecting an image to the background input of a PlanarTracker node

Check for Lens Distortion

If the image has barrel distortion, or any other kinds of lens distortion, it can adversely affect your track. The more lens distortion in the footage, the more the resulting track will slide and wobble. If you can see distortion in the image or you’re having problems with the track, you’ll want to try inserting the Lens Distort node between the image and the Planar Tracker to eliminate this problem.

A Basic Planar Tracker Match Move Workflow

Using the Planar Tracker is a process, but it’s straightforward once you’ve learned how to use it. The following procedure tries to make this process as clear as possible.

To track a surface using the Planar Tracker:

1. Make sure the Operation Mode is set to Track, as you need to analyze an image to track a surface before you do anything else.

2. With the background input of the Planar Tracker connected to an image, and the Planar Tracker open in a Viewer, move the playhead to a frame of video where the planar surface you want to track is at its largest, is unoccluded, and is clearly a plane, and then click the Set button in the Track panel of the Inspector to make this the reference frame that will be used to guide the track.

3. Next, you’ll need to identify the specific pattern within the image that you want to track. In most cases, this will probably be a rectangle, but any arbitrary closed polygon can be used. The pixels enclosed by this region will serve as the pattern that will be searched for on other frames. Please note that it is important that the pattern is drawn on the reference frame. In this example, we want to track the wall behind the man, so we draw a polygon around part of the wall that the man won’t pass over as he moves during the shot.
Drawing a polygon to identify the part of the image you want to track, which should be a flat trackable plane.

**TIP:** Do not confuse the pattern you’re identifying with the region you’re planning to corner pin (which always has four corners and is separately specified in Corner Pin mode).

4 (Optional) If moving objects partially cover up or occlude the planar surface, you may wish to connect a mask that surrounds and identifies these occlusions to the white “occlusion mask” input of the Planar Tracker. This lets the Planar Tracker ignore details that will cause problems.

When using the Hybrid tracker, providing a mask to deal with occluding objects is nearly mandatory, while with the Point tracker it is recommended to try tracking without a mask.

5 If necessary, move the playhead back to the reference frame, which in this case was the first frame. Then, click the Track To End button and wait for the track to complete.

As the clip tracks, you can see Track Markers and Trails (if they’re enabled in the Options tab of the Inspector) that lets you see how much detail is contributing to the track, and the direction of motion that’s being analyzed.

During tracking, you can see Track Markers and Trails to follow how well the track is going.
Once the track is complete, play through the clip to visually inspect the track so you can evaluate how accurate it is. Does it stick to the surface? Switching to Steady mode can help here, as scrubbing through the clip in Steady mode will help you immediately see unwanted motion in the track.

Since we’re doing a match move, click the Create Planar Transform button to export a Planar Transform node that will automatically transform either images or masks to follow the analyzed motion of the plane you tracked.

In this case, the Planar Transform node will be inserted after a pair of Background and Paint nodes that are being used to put some irritatingly trendy tech jargon graffiti on the wall. The Planar Transform will automatically transform the Paint node’s output connected to its background input to match the movement of the wall.

Adding the PlanarTransform node after a Paint node to match move it to the background image, combining it via a Merge node

The end result is a seamless match move of the fake graffiti married to the wall in the original clip.

The final result; the paint layer is match moved to the background successfully

TIP: If you want to composite transparent paint strokes on the wall, you can attach a Paint node to a Background node set to 100 transparency, as seen in the node tree above. The resulting image will be whatever paint strokes you make against transparency, easy to composite.
Tips For Choosing Good Planes to Track

The region to track is specified by drawing a polygon on the reference frame. Make sure the region selected belongs to a physically planar surface in the shot. Sometimes a region that is only approximately planar can be used. In general, the less planar the surface, the poorer the quality of the resulting track.

As a rule of thumb, the more pixels in the pattern, the better the quality of the track. In particular, this means on the reference frame, the pattern to be tracked should:

- Be as large as possible.
- Be as much in frame as possible.
- Be as unoccluded as possible by any moving foreground objects.
- Be at its maximal size (e.g., when tracking an approaching road sign, it is good to pick a later frame where it is 400x200 pixels big rather than 80x40 pixels).
- Be relatively undistorted, (e.g., when the camera orbits around a flat stop sign, it is better to pick a frame where the sign is face on parallel to the camera rather than a frame where it is at a highly oblique angle).

If the pattern contains too few pixels or not enough trackable features, this can cause problems with the resulting track such as jitter, wobble, and slippage. Sometimes dropping down to a simpler motion type can help in this situation.
This chapter covers how to use masks to rotoscope, one of the most common tasks in compositing.

Introduction to Masks and Polylines

Polylines are splines that are used whenever a control is animated with a motion path or when a node’s effect is masked with a drawn shape. They are also used in the Paint and Grid Warp nodes. In a more basic form, polylines are used to control the animation in the Spline Editor. Since these splines are used for just about everything, they are extremely flexible, with a considerable amount of controls, modes and options.

This chapter offers an overview of polylines and their operation with sections on how to create paths or effect masks.

Mask Nodes

Masks are like other creator nodes in the Node Editor, with the exception that they create a single channel image rather than a full RGBA image. Most of these Mask nodes are also located under the Viewers, with the exception of Ranges Mask and Triangle Mask.

For more information on the controls for each Mask node, see Part 7, “Fusion Page Effects.”

Polygon Mask

Polygon Masks are user-created Bezier shapes. This is the most common type of polyline and the basic workhorse of rotoscoping.

B-Spline Masks

B-Spline Masks are user-created shapes made with polylines that are drawn using the B-Splines. They behave identically to polyline shapes when linear, but when smoothed, the control points influence the shape through tension and weight. This generally produces smoother shapes while requiring fewer control points.

Bitmap Masks

The Bitmap Mask allows images from the Node Editor to act as masks for nodes and effects. Bitmap Masks can be based on values from any of the color, alpha, hue, saturation, luminance and the auxiliary coverage channels of the image. The mask can also be created from the Object or Material ID channels contained in certain 3D rendered image formats.

Mask Paint

Mask Paint allows a mask to be painted using Fusion’s built-in vector paint nodes.
Wand Mask

A Wand Mask provides a crosshair that can be positioned in the image. The color of the pixel under the crosshair is used to create a mask, where every contiguous pixel of a similar color is also included in the mask. This type of mask is ideal for secondary color correction.

Ellipse, Rectangle and Triangle Masks

These are primitive shape masks. See Rectangle, Ellipse, and Triangle in the Node Reference.

Ranges Mask

Similar to Bitmap Mask, the Ranges Mask allows images from the Node Editor to act as masks for nodes and effects. Instead of creating a simple luminance-based mask from a given channel, Ranges allows spline-based selection of low, mid and high ranges, similar to the Color Corrector.

Polyline Types

You can draw polylines using B-Spline or Bezier spline types. Which you choose depends on the shape you want to make and your comfort with the spline style.

Bezier Polylines

Bezier Polylines are shapes that are composed of control points and handles. Several points together are used to form the overall shape of a polyline.

Each control point has a pair of handles that are used to define the exact shape of the polyline segments passing through each control point. Adjusting the angle or length of the direction handles will affect whether that segment of the polyline is smooth or linear.

If you’re familiar with applications such as Adobe Photoshop or Illustrator, you’ll already be familiar with many of the basic concepts of editing Bezier polylines.
B-Spline Polylines
A B-Spline polyline is similar to a Bezier spline, however, these polylines excel at creating smooth shapes. Instead of using a control point and direction handles for smoothness, the B-Spline polyline uses points without direction handles to define a bounding box for the shape. The smoothness of the polyline is determined by the tension of the point, which can be adjusted as needed.

Converting Polylines From One Type to Another
Just because a shape using a B-Spline or polyline has been created does not mean that the spline type has to be used. You can convert from B-Spline to Bezier, or Bezier to B-Spline, as needed. Once you create a polyline, you can right click in the Viewer and choose Convert Bezier Spline to B-Spline or Convert B-Spline to Bezier from the spline’s contextual menu. Only the appropriate option will be displayed.

When converting from one type to another, the shape is preserved. The new polyline generally has twice as many control points as the original shape to ensure the minimum change to the shape.

Although animation is preserved, the conversion process will not yield perfect results every time. It is a good idea to review the animation after you convert spline types.

How to Use Masks With Other Nodes
Typically, a node applies its effect to every pixel of an image. However, many nodes have mask inputs that can be used to limit the effect that node has on the image.
Masks are single channel images that can be used to define which regions of an image you want to affect. Masks can be created using primitive shapes (such as circles and rectangles), complex polyline shapes that are useful for rotoscoping, or by extracting channels from another image.

Each mask node is capable of creating a single shape. However, Mask nodes are designed to be added one after the other so you can combine multiple masks of different kinds to create complex shapes. For example, two masks can be subtracted from another to cut holes into the resulting mask channel.

The Fusion page offers several different ways you can use masks to accomplish different tasks. You can attach Mask nodes after other nodes in which you want to create transparency, or you can attach Mask nodes directly to the specialized inputs of other nodes to limit or create different kinds of effects.

**Attaching Masks to an Image for Rotoscoping**

There are two ways you’ll typically attach a Mask node, such as a Polygon node, so that it adds an alpha channel to an image for compositing later in the node tree.

**Using a MatteControl Node**

The MatteControl node is the main node used for combining masks in different ways and inserting the result into an image stream. The MatteControl node is attached downstream of the node outputting the image you want to rotoscope, and you’ll typically attach a Polygon or B-Spline node to the Garbage Matte input of the MatteControl node to use the spline as an alpha channel.

To use this setup, you’ll load the MatteControl node into the Viewer, and select the Polygon node to expose its controls so you can draw and modify a spline while viewing the image you’re rotoscoping. The MatteControl node’s Garbage Matte > Invert checkbox lets you choose which part of the image becomes transparent.
Connecting a Mask to a MediaIn Node’s Input

This method is a bit simpler, but requires you to know that you can view one node while adjusting another node, even if that other node is disconnected. If you add an unattached Mask node such as a Polygon or B-Spline node, and then load a MediaIn node directly into the Viewer while selecting the Mask node, you can draw a spline to rotoscope the image.

When you’re finished rotoscoping, you simply connect the Polygon node’s output to the MediaIn node’s input, and an alpha channel is automatically added to that node.

**TIP:** If you connect a Mask node to a MediaIn node’s effect input without any shapes drawn, that mask outputs full transparency, so the immediate result is that the image output by the MediaIn node becomes completely blank. This is why when you want to rotoscope by connecting a mask to the input of a MediaIn node, you need to work within a disconnected mask node first. Once the shape you’re drawing has been closed, connect the Mask node to the MediaIn node’s input, and you’re good to go.

Combining Multiple Masks

Masks are designed to be added one after the other, with each Mask node acting as an additional layer of masking.
When a Mask node’s input is attached to another mask, a Paint Mode pop-up appears, which allows you to choose how you want to combine the two masks.

The default option is Merge, but you can also choose subtract, minimum, maximum, multiply, or any other operation that will give you the mask boolean interaction you need. Additionally, a pair of Invert and Solid checkboxes let you further customize how to combine the current mask with the one before it.

**Mask Inputs on Other Nodes**

Masks can be used for a variety of reasons, so there are several categories of mask inputs that different nodes have to accommodate these different uses. Incidentally, in most cases you can connect either masks or mattes to a mask input to take advantage of that input’s functionality.

**TIP**: If you select a node with a mask input and add a mask, it’ll automatically be connected to that input.

**Effects Mask Inputs**

Almost every node on the Fusion page has an Effect input (colored blue), which let you choose which parts of the image will or will not be affected by that node.
While masks (or mattes) are connected via an input, they are actually applied “post effect,” which means the node first applies its effect to the entire image, and then the mask is used to limit the result by copying unaffected image data from the input over.

A Polygon node used as a mask to limit the Blur node’s effect

Although many nodes support effects masking, there are a few where this type of mask does not apply, notably Savers, Time nodes, and Resize, Scale and Crop nodes.

**TIP:** Effects masks define the domain of definition (DoD) for that effect, making it more efficient.

**Pre-Masking Inputs**

Unlike effect masks, a pre-mask input (the name of which is usually specific to each node using them) is used by the node before the effect is applied. This usually causes the node to render more quickly and to produce a more realistic result. In the case of the Highlight and the Glow nodes, a pre-mask restricts the effect to certain areas of the image but allows the result of that effect to extend beyond the limits of the mask.

The advantage to pre-masking is that the behavior of glows and highlights in the real world can be more closely mimicked. For example, if an actor is filmed in front of a bright light, the light will cause a glow in the camera lens. Because the glow happens in the lens, the luminance of the actor will be affected even though the source of the glow is only from the light.

In the case of the DVE node, a pre-mask is used to apply a transformation to a selected portion of the image, without affecting portions of the image outside of the mask. This is useful for applying transformations to only a region of the image.

**Garbage Matte Inputs**

Garbage Matte inputs (usually colored gray) are used to exclude lighting instruments, rigging, and boom microphones that intrude upon masks being pulled via blue and green screen keys. In the following example, a lighting stand to the left is removed from the image via a B-Spline node’s mask connected to the Garbage Matte input of the DeltaKeyer node.
A B-Spline node is connected to the Garbage Matte input of a DeltaKeyer node to eliminate a light stand at the left of frame.

**TIP:** You can quickly add a mask node to the Effect/Solid/Garbage Matte inputs of a keyer node by right-clicking the header bar of that node in the Inspector, and choosing whichever mask node you want to use from the Effect Mask, SolidMatte, and GarbageMatte submenus.

You choose whether a garbage matte is applied to a keying node as opaque or transparent in the Inspector for the node to which it’s connected.

**Solid Matte**

Solid Matte inputs (colored white) are intended to fill unwanted holes in a matte, often with a less carefully pulled key producing a dense matte with eroded edges, although you could also use a polygon to serve this purpose. In the example below, a gentle key designed to preserve the soft edges of the talent’s hair leaves holes in the mask of the woman’s face, but using another DeltaKeyer to create a solid matte for the interior of the key that can be eroded to be smaller than the original matte lets you fill the holes while leaving the soft edges alone. This could also be done with a MaskPaint or Polygon node, if necessary.
Filling in holes in the mask pulled by the DeltaKeyer1 node (at left) with another, harder but eroded key in DeltaKeyer2 that’s connected to the SolidMatte input of DeltaKeyer1.

**TIP:** You can quickly add a mask node to the Effect/Solid/Garbage Matte inputs of a keyer node by right-clicking the header bar of that node in the Inspector, and choosing whichever mask node you want to use from the Effect Mask, SolidMatte, and GarbageMatte submenus.

**Creating and Editing Polylines In-Depth**

This section covers the Polygon node’s capabilities in depth.

**The Polyline Toolbar**

Whenever a node that contains one or more polylines is selected, the polyline is shown on all Viewers and the Polyline toolbar is displayed along the side of each Viewer. The toolbar contains several buttons that make switching polyline modes and options easy to access.

If you hover the cursor over any of the Polyline Toolbar buttons, a tooltip that describes the button’s function appears. Clicking on a button will affect the currently active polyline or the selected polyline points, depending on the button.
You can change the size of the toolbar icons, add labels to the buttons, or make other adjustments to the toolbar’s appearance in order to make polylines easier to use. All the options can be found by right clicking on the toolbar and selecting from the options displayed in the contextual menu.

**Selecting a Specific Polyline**

It is possible to have several polylines in the Viewer at once if you select multiple Mask nodes in the Node Editor, so it’s important to be able to switch between polylines easily.

**To make a polyline active, do one of the following:**

- Click one of the polyline’s control points or segments.
- Press Tab and Shift-Tab to cycle between available polylines.
- Right click in the Viewer and choose the desired polyline by name from the Controls > Select menu.

**Polyline Creation Modes**

There are several different modes available from the toolbar for creating and modifying polylines. The specific mode used when a polyline is first added will depend on whether it is used as a path or a mask.

Each of the modes is described in more detail below.

**Click Append**

This mode is the default mode for mask creation. It’s used to quickly define the rough shape of the mask, after which you switch to Insert and Modify mode to refine the mask further.

The Click Append toolbar button (Shift-C)

**To create a mask using the Click Append mode, do the following:**

1. Select Click Append from the toolbar or press Shift-C.
2. Click the cursor where you want to start the shape.
3. Move and click the cursor to append a point to the last one.
4. To close the shape, place the mouse pointer over the first point created and click when the cursor changes shape.

When a shape is closed, the polyline is automatically switched to Insert and Modify mode.

Although the Click Append mode is rarely used with paths, it can be helpful when you know the overall shape of a motion path, but you don’t know the timing yet.

**Tip:** Holding Shift while you draw a mask constrains subsequent points to 45 degree angles relative to the previous point. This can be very helpful when drawing regular geometry.
Insert and Modify
Masks, which are created in Click Append mode, automatically switch to Insert and Modify mode when the mask shape is closed. You can also manually switch to this mode by clicking the Insert and Modify button in the toolbar or using the Shift-I keyboard short cut. This mode makes it easier to add additional points and refine the shape of the mask. Dragging the control points or direction handles modifies existing points on the polyline.

Insert and Modify mode is also the default mode for creating motion paths. A new control point is automatically added to the end of the polyline, extending or refining the path, any time a parameter that is animated with a motion path is moved.

Draw Append
The Draw Append mode creates a freehand polyline shape directly on the Viewer, like drawing with a pencil or a paintbrush. This mode is ideal to use in conjunction with a tablet and for the creation of garbage mattes and effect masks around complex shapes.

Protection Modes
In addition to the modes used to create a polyline, two other modes are used to protect the points from further changes after they have been created.

Modify Only
Modify Only mode allows existing points on the polyline to be modified, but new points may not be added to the shape.

TIP: Even with Modify Only selected, it is still possible to delete points from a polyline.

Done
The Done mode prohibits the creation of any new points, as well as further modification of any existing points on the polyline.
Closing Polylines

There are several ways to close a polyline, which will connect the last point to the first.

To close a polyline, do one of the following:

- Hover the cursor over the first point created, then click on the point.
- Press Shift-O on the keyboard.
- Click the Close button on the polyline toolbar.
- Choose Closed from the polyline’s contextual menu.

All of these options are toggles that can also be used to open a closed polygon.

Selecting and Adjusting Polylines

To create the shape you need for a mask or a motion path, you need to know how to manipulate the splines. In Fusion there are a number of simple techniques for selecting, moving and smoothing a spline, but also more complex adjustment techniques for scale, skewing and twisting a spline.

Polyline Points Selection

To select one or more control points on a polyline, do one of the following:

- Click directly on the control points.
- Lasso around the points.

To add or remove points from the current selection, do one of the following:

- Hold the Shift to select a continuous range of points.
- Hold Command (macOS) or Ctrl (Windows) and click each control point you want to add or remove.
- Press Command-A or Ctrl-A to select all of the points on the active polyline.

**TIP:** Once a control point is selected, you can press Page Down or Page Up on the keyboard to select the next control point in a clockwise or counter clockwise rotation. This can be very helpful when control points are very close to each other.

Moving Polyline Points

The selected polyline points can be moved using either the keyboard or the mouse.
To move selected control points using the cursor, do one of the following:

- Drag on the selected points anywhere in the Viewer.
- Hold Shift while dragging to restrict movement to a single axis.
- Hold Option (Mac OS X) or Alt (Windows) and drag anywhere in the Viewer to move the selected control point.

To move selected control points using the keyboard, do one of the following:

- Press the Left, Right, Up or Down Arrow keys on the keyboard.
- Hold Command-Arrow keys (MacOS) or Ctrl-Arrow Keys (Windows) to move in smaller increments.
- Hold Shift-Arrow keys to move in larger increments.

**Smoothing a Polyline Segment**

If you want to shape the polyline and control its slope, you can choose to smooth a spline segment by adjusting the Bezier direction handles.

To smooth the selected points on an active polyline, do one of the following:

- Press Shift-S.
- Click the Smooth button on the Polyline toolbar.
- Choose Smooth from the polyline’s contextual menu.

![The Smooth button in the toolbar (Shift-S)](image)

**Linearizing a Polyline Segment**

To make certain that a polyline segment is perfectly straight, that segment needs to be linearized. A linear segment aligns the Bezier direction handles with the segment and therefore has no curvatures. The segment is always drawn in a straight line between two points on the polyline.

To linearize the selected points on an active polyline, do one of the following:

- Press Shift-L.
- Click the Linear button on the polyline’s toolbar.
- Choose Linear from the polyline’s contextual menu.

![The Linear button in the toolbar (Shift-L)](image)
Transforming Individual or Multiple Points

Select the points to be transformed, then do one of the following:

- Hold T and drag to twist.
- Hold S and drag to scale.
- Hold X and drag to scale horizontally only.
- Hold Y and drag to scale vertically only.
- Hold O and drag to offset the points perpendicular to the tangent.

The position of the cursor when the transformation begins becomes the center used for the transformation.

Deleting Selected Points

You can delete a selected point or group of points by pressing the Delete (macOS) or Backspace (Windows), choosing Delete from the contextual menu, or by clicking the Del button in the toolbar. The shape of the polyline changes to reflect the removal of these points.

**TIP:** Deleting all of the points in a polyline does not delete the polyline itself. To delete a polyline, you must delete the node or modifier that created the polyline.

Editing Bezier Handles

For Bezier polylines, each control point has two direction handles that adjust the slope of a curve through the control point. These direction handles only appear when the point is selected.

Dragging a direction handle makes adjustments to the curve of the segment that emerges from the control point. The direction handle on the opposing side of the control point will also move to maintain the relationship between these two handles.

To break the relationship between direction handles and adjust one independently, hold Command (macOS X) or Ctrl (Windows) while dragging a handle. Subsequent changes will maintain the relationship, unless the Command or Ctrl is held during each adjustment.

If you want to adjust the length of a handle without changing the angle, hold Shift while moving a direction handle.
Point Editor

The Point Editor dialog can be used to reposition control points using precise X and Y coordinates. Pressing the E key on the keyboard will bring up the dialog and allow you to reposition one or more selected control points.

The dialog box contains the X- and Y-axis values for that point. Entering new values in those boxes repositions the control point.

When multiple control points are selected, all the points move to the same position. This is useful for aligning control points along the X or Y axis.

If more than one point is selected, a pair of radio buttons at the top of the dialog box determines whether adjustments are made to all selected points or to just one. If the Individual option is selected, the affected point is displayed in the Viewer with a larger box. If the selected point is incorrect you can use the next and previous buttons that appear at the bottom of the dialog to change the selection.

In addition to absolute values for the X- and Y-axis, you can adjust points using relative values from their current position. Clicking once on the label for the axis will change the value to an offset value. The label will change from X to X-offset or from Y to Y-offset.

If you are not sure of the exact value, you can also perform mathematical equations in the dialog box. For example, typing 1.0-5 will move the point to 0.5 along the given axis.
**Reduce Points**

When freehand drawing a polyline or an editable paint stroke, the spline is often created using more control points than you need to efficiently make the shape. If you choose Reduce Points from the polyline’s contextual menu or toolbar, a dialog box will open allowing you to decrease the number of points used to create the polyline.

![The Reduce Points button in the toolbar](image)

The overall shape will be maintained while eliminating redundant control points from the path. When the value is 100, no points are removed from the spline. As you drag the slider to the left you reduce the number of points in the path.

**Shape Box**

If you have a polyline shape or a group of control points you want to scale, stretch, squish, skew or move, you can use the shape box to easily perform these operations.

**To enable the shape box, do one of the following:**

- Click the Shape Box toolbar button.
- Choose Shape Box from the contextual menu.
- Press Shift-B.

![The Shape Box button in the Polyline toolbar](image)

If there are selected points on the polyline when the Shape Box mode is enabled, the shape box is drawn around those points. Otherwise, you can drag the shape box around the area of control points you want to include.

If you want to freely resize the shape box horizontally and vertically, you can drag a corner handle. Dragging a handle on the side of the shape box resizes the polyline along a specific axis.

![Dragging a side handle resizes along a specific axis](image)
Holding Command or Ctrl while dragging a shape box handle will apply adjustments from the center of the shape box, constraining the transformation to the existing proportions of the shape box. Holding Shift while dragging a corner handle affects only that handle, allowing skewed and non-uniform transformations.

Hold shift while dragging a corner to perform non-uniform transformations

**Showing and Hiding On-Screen Polyline Controls**

It is often difficult to identify individual points when they are placed closely together. You can choose to display both points and their direction handles, just points, or just handles. These display mode options are selected using the Show Key Points and Show Handles toolbar buttons, or from the polyline’s context menu.

You use these options to simplify the screen display when adjusting control points placed closely together and to avoid accidentally modifying controls and handles that are adjacent to the intended target.

**Stop Rendering**

While points along the polyline are being moved, the results are rendered to the Viewer to provide constant interactive feedback. Although extremely useful, there are situations where this can be distracting and can slow down performance on a complex effect. To disable this behavior so renders only happen when the points stop moving, you can toggle the Stop Rendering button in the toolbar or select this option from the polyline contextual menu.

**Roto Assist**

You can enable the Roto Assist button in the toolbar when you begin drawing your shape to have points snap to the closest edge as you draw the shape. The points that have snapped to an edge are indicated by a cyan outline.

There are three main Roto Assist options.

- **Multiple Points**: Allows adding multiple points along an entire edge with a single click instead of having to add each point individually.
- **Distance 8**: Defines the range within which searching for an edge will take place.
- **Reset**: Used for resetting the snap attribute of the snapped points. After resetting, the points will become unavailable for tracking.
Creating Softness Using Double Polylines

The standard soft edge control available in all Mask nodes softens the entire mask equally. However, there are times, particularly with a lot of motion blur, when softening part of the curve while keeping other portions of the curve sharp is often required.

This form of softness is called non-uniform softness, which is accomplished by converting the shape from a single polyline to a double polyline. The double polyline is composed of two shapes, an inner and an outer shape. The inner shape is the original shape from the single polyline, whereas the outer shape is used to determine the spread of the softness. The further the outer shape gets from the inner shape, the softer that segment of the shape becomes.
Converting a Single Polyline to a Double Polyline

To convert a mask into a double polyline, click the Double Polyline button in the Polyline toolbar or right click in the Viewer and select Make Outer Polyline from the mask’s contextual menu.

The shape will be converted into an inner and an outer polyline spline. Both polylines start with exactly the same shape as the original single polyline. This keeps the mask sharp to start with and allows any animation that may have already been applied to the shape to remain.

The control points on the outer shape are automatically parented to their matching points on the inner shape. This means that any changes made to the inner shape will also be made to the outer shape. The relationship is one way. Adjustments to the outer shape can be made without affecting the inner shape.

A dashed line drawn between the points indicates the relationship between the points on the inner and outer shapes.

Adding Softness to a Segment

The outer shape is drawn using a green dashed line instead of a solid line to help distinguish it from the inner shape. If you want to select the outer shape, use the Tab key to cycle between the onscreen controls until the dashed outline is visible, or you can select the outer polyline using the contextual menu’s Controls > Select menu.

Once the outer polyline is selected, you can drag any of the points away from the inner polyline to add some softness to the mask.

TIP: Press Shift-A to select all the points on a shape then hold 0 and drag to offset the points from the inner shape. This gives you a starting point to edit the falloff.

The farther the outer shape segment is from the inner shape, the larger the falloff will be in that area.

Adding Additional Points to the Shape

It is not necessary for every point on the inner shape to have a match on the outer shape, or vice versa. You can add additional control points to refine the shape of either shape.

Each polyline stores its animation separately; however, if a point is adjusted on the inner shape that is parented to a point on the outer shape, a keyframe will be set for both splines. Adjusting a parented point on the outer shape only sets a keyframe for the outer shape’s spline. If a point that is not parented is adjusted, it will only set a keyframe on the relevant spline. You can disable this behavior entirely for this polyline by disabling “Follow Inner Polyline” from the contextual menu.
**Locking/Unlocking Point Pairs**

If you want to parent additional control points you can select the points, right click in the Viewer and choose Lock Point Pairs from the contextual menu for either spline. This will cause the selected point on the outer shape to become parented to the selected point on the inner shape.

Any animation already applied to either point is preserved when the points become parented.

To unlock a point so it is no longer parented, select the point, right click in the Viewer and deselect Lock Point Pairs from the contextual menu.

**Animating Polyline Masks**

Animating masks is surprisingly easy. When Polygon or B-Spline masks are added to the Node Editor, they’re automatically ready to be animated. All you have to do to animate a mask is move the playhead to a new frame change the shape of the mask, and a new keyframe is added in the Spline Editor and Timeline Editor. This one keyframe controls the position of all control points for that mask at that frame. Once two or more keyframes have been created, the shape of the polygon or B-Spline is automatically interpolated from one keyframe to the next.

To adjust the overall timing of the mask animation, you edit the Keyframe horizontal position spline using the Spline Editor or Timeline Editor. Additional points can be added to the mask at any point to refine the shape as areas of the image become more detailed.

**Removing Animation from a Polyline Mask**

If you want a Polyline mask to remain static, you can remove the automatic animation setting. In the Inspector for the mask, right click in the bottom of the panel where it says Right Click Here For Shape Animation. From the contextual menu choose Remove Bezier Spline. If you decide you need to animate the mask at a later time, right click in the same area again and choose Animate.

Adding and Removing Points from an Animated Mask

When adding points to an animated mask, the new point is fit into the shape at all keyframes. Deleting a point removes that point from all keyframes in the animated mask.

**Publishing Specific Control Points**

Although you can rapidly animate the entire shape of a polyline using a single keyframe, by default the Spline Editor and Timeline only display one keyframe for the entire shape at any given frame.

This default keyframing behavior is convenient when quickly animating shapes from one form to another, but it doesn’t allow for specific individual control points that need to be keyframed independently of all other control points for a particular shape. If you’re working on a complex mask that would benefit from more precise timing or interpolation of individual control points, you can expose one or more specific control points on a polyline by publishing them.

Be aware that publishing a control point on a polyline removes that point from the standard animation spline. From that point forward, that control point can only be animated via its own keyframes on its own animation spline. Once removed, this point will not be connected to paths, modifiers, expressions, or trackers that are connected to the main polyline spline.
To publish a selected point or points, do one of the following:

- Click on the Publish Points button in the Polyline toolbar.
- Select Publish Points from the Polyline’s contextual menu.

A new coordinate control is added to the Polyline mask controls for each published point, named Point 0, Point 1, and so on.

The Publish Points controls in the Inspector

The onscreen control indicates published points on the polyline by drawing that control point much larger. Once a published point is created, it can be connected to a tracker, path, expression or modifier by right-clicking on this control and selecting the desired option from the point’s contextual menu.

The published point in the Viewer

Using “Publish Point to Path” to Preserve Animation

When a point is published, any animation already applied to that point is removed. However, if you need to keep the animation, you can use the “Publish Point to Path” option. This Polyline contextual menu option publishes the selected points and converts their existing animation to a path. You can also use the Publish Point to Path button in the Polyline toolbar.

Using “Follow Published Points” to Add Points

There are times when you will need to have control points that lie between two other published points follow the motion of the published points, while still maintaining their relative offset and shape. For this reason, points in a Polyline mask can be set to “Follow Published Points” using the Polyline’s contextual menu.

When a point of an effect mask is set to follow points, the point will be drawn as a diamond shape rather than a small box.

A control point set to Follow Points

When this mode is enabled, the new “following” control points will maintain their position relative to the motion of any published points in the mask, while attempting to maintain the shape of that segment of the mask. Unlike published points, the position of the following points can still be animated to allow for morphing of that segment’s shape over time.
3D Compositing Basics

This chapter covers many of the nodes used for creating 3D composites, the tasks they perform, and how they can be combined to produce effective 3D scenes.

An Overview of 3D Compositing

Traditional image based compositing is a two dimensional process. Image layers have only the amount of depth needed to define one as foreground and another as background. This is at odds with the realities of production, since all images are either captured using a live action camera with freedom in all three dimensions, in a shot that has real depth, or have been created in a true 3D modeling and rendering application.

Within the Node Editor of the Fusion page, you have a complete GPU-accelerated 3D compositing environment that includes support for imported geometry, point clouds, and particle systems for taking care of such things as:

- Converting 2D images into image planes in 3D space
- Importing matched cameras and point clouds from applications such as SynthEyes or PF Track
- Importing cameras, lights, and materials from 3D applications such as Maya, 3ds Max, or LightWave
- Creating rough primitive geometry
- Importing mesh geometry from FBX or Alembic scenes
- Creating realistic surfaces using illumination models and shader compositing
- Rendering with realistic depth of field, motion blur, and supersampling
- Creating and using 3D particle systems
- Creating, extruding, and beveling 3D text
- Lighting and casting shadows across geometry
3D Compositing Fundamentals

The 3D category or nodes (which includes the Light, Material, and Texture subcategories) work together to create 3D scenes. Examples are nodes that generate geometry, import geometry, modify geometry, create lights and cameras, and combine all of these elements into a scene. Nearly all of these nodes are collected within the 3D category of nodes found in the Effects Library.

Conveniently, at no point are you required to specify whether your overall composition is 2D or 3D, because you can seamlessly combine any number of 2D and 3D “scenes” together to create a single output. However, the nodes that create these scenes must be combined in specific ways for this to work properly.

Creating a Minimal 3D Scene

Creating a 3D scene couldn’t be easier, but you need to connect the required nodes in the right way. At minimum, you need only connect a geometry node (such as a Text3D node) to a Renderer3D node to output a 2D image that can be combined with other 2D images in your composition, as seen below. However, you’re only going to get a simply shaded piece of geometry for your trouble, although you can color and transform it in the Inspector using controls internal to whichever geometry node you’re using.
More realistically, each 3D scene that you want to create will probably have three to five nodes to give you a better lit and framed result. These include:

- One of the available geometry nodes (such as Text3D or Object3D)
- A light node (such as SpotLight)
- A camera node
- A Merge3D node
- A Renderer3D node

All of these should be connected together as seen below, with the resultantly more complex 3D scene shown below.

To briefly explain how this node tree works, the geometry node (in this case Text3D) creates an object for the scene, and then the Merge3D node provides a virtual stage that combines the attached geometry with the light and camera nodes to produce a lit and framed result with highlights and shadows, while the aptly named Renderer3D node renders the resulting 3D scene to produce 2D image output that can then be merged with other 2D images in your composition.

In fact, these nodes are so important that they appear at the right of the Fusion page toolbar, enabling you to quickly produce 3D scenes whenever you require. You might notice that the order of the 3D buttons on the toolbar, from right to left, correspond to the order in which these nodes are ordinarily used. So, if you simply click on each one of these buttons from left to right, you cannot fail to create a properly assembled 3D scene, ready to work on, as seen in the previous screenshot.
The Elements of a 3D Scene

All 3D nodes can be divided into a number of categories.

Geometry Nodes

You can add 3D geometry to a composition using the ImagePlane3D node, the Shape3D node, the Cube3D node, the Text3D node, or optionally by importing a model via the FBX Mesh 3D node. Furthermore, you can add particle geometry to scenes from pEmitter nodes. You can connect these to a Merge 3D node either singly or in multiples, to create sophisticated results combining multiple elements.

A more complex 3D scene combining several geometry nodes including the Text3D, Shape3D, and ImagePlane3D nodes

Texturing Geometry

By itself, geometry nodes can only consist of a simple flat color. However, you can alter the look of 3D geometry by texturing it using clips (either still images or movies), using material nodes such as the Blinn and Phong nodes to create more sophisticated textures with combinations of 2D images and environment maps, or you can use a preset shader from the Templates > Shader bin of the Effects Library, which contains materials and texture presets that are ready to use.

If you’re working with simple geometric primitives, you can texture them by connecting either an image (a still image or movie) or a shader from the Templates bin of the Effects Library directly to the material input of a Shape3D, Cube3D, or other compatible node, as shown below.
An image connected to the material input of a Shape3D node set to Taurus; (Left) the image, (Right) the shaded taurus

If you’re shading or texturing Text3D nodes, you need to add a texture in a specific way since each node is actually a scene with individual 3D objects (the characters) working together. In the following example, the RustyMetal shader preset is applied to a Text3D node using the ReplaceMaterial3D node. The interesting thing about the ReplaceMaterial3D node is that it textures every geometric object within a scene at once, meaning that if you put a ReplaceMaterial3D node after a Text3D node, you texture every character within that node. However, if you place a ReplaceMaterial3D node after a Merge3D node, then you’ll end up changing the texture of every single geometric object being combined within that Merge3D node, which is pretty powerful.

The geometry created by a Text3D node is textured using a shader connected to a ReplaceMaterial3D node that’s connected downstream of the object you want to shade
The Merge 3D Node

The Merge 3D node combines the output of one or more 3D nodes into a single scene. Unlike the 2D Merge node, the ordering of elements in the scene is not restricted to only background and foreground inputs. Instead, the Merge 3D node lets you connect an unlimited number of inputs, with the resulting output combined according to each object’s absolute position in 3D space.

Combining Objects Directly

While the Merge3D node provides a structured way of combining objects, you can also combine 3D objects such as Text3D and Shape3D nodes by connecting the output of one 3D object node to the input of another, as seen in the following screenshot. When you do this, you must use each node’s internal transform parameters to transform their position, size, and rotation directly, but the transform control of downstream 3D object nodes also transforms all upstream 3D object nodes. This even works for lights and the Camera3D node, giving you a fast way of combining a set of objects that always go together, which you can later connect to a Merge3D node for additional lighting and eventual connection to a Renderer3D node.
Connecting one Shape3D node to another directly to combine them, transforming the last downstream 3D object also transforms all upstream objects; the last Shape3D node is viewed, showing both.

Combining Multiple Merge3D Nodes

Furthermore, Merge 3D nodes can be combined with other Merge 3D nodes, allowing you to create composite 3D scenes that are made up of multiple “sub-scenes,” each put together within individual Merge 3D nodes.

Lighting Multiple Merge3D Nodes

Once you’ve combined multiple Merge3D nodes, there’s an easy way to control how lights that are connected to upstream Merge3D nodes affect the results of other Merge3D nodes connected downstream. Each Merge3D node’s Controls tab contains a single checkbox, “Pass Through Lights,” which enables lighting to pass through the output of an upstream Merge3D node in order to shine onto objects connected to downstream Merge3D nodes.
You can light downstream Merge3D scenes with lights connected to upstream Merge3D scenes by turning on “Pass Through Lights”.

This checkbox is disabled by default, which lets you light elements in one Merge3D scene without worrying about how the lighting will affect geometry attached to other Merge3D nodes further downstream. For example, you may want to apply a spotlight to brighten the wall of a building in one Merge3D node without having that spotlight spill over onto the grass or pavement at the foot of the wall modeled in another Merge3D node. In the example shown below, the left image shows how the cone and taurus connected to a downstream node remain unlit by the light in an upstream node with “Pass Through Lights” disabled, while the right image shows how everything becomes lit when turning “Pass Through Lights” on.

(Left) The result of lights on the text in one Merge3D node not affecting the cone and taurus added in a downstream Merge3D node. (Right) Turning on “Pass Through Lights” in the upstream Merge3D node results in those lights also illuminating the downstream shapes.

Transforming Merge3D Scenes
Each Merge3D node includes a Transform tab. These transform parameters adjust the position, scale and rotation of all objects being combined within that Merge 3D node together, including lighting and particles. All transformations take place around a common pivot point. This forms the basis of parenting in the 3D environment.

The Transform tab of a Merge3D node.
If you transform a Merge3D node that’s connected to other Merge3D nodes, what happens depends on which node you’re transforming, an upstream node or the downstream node:

- If you transform a downstream Merge3D node, you also transform all upstream nodes connected to it as if they were all a single scene.
- If you transform an upstream Merge3D node, this has no effect on downstream Merge3D nodes, allowing you to make transforms that are specific to that particular node’s scene.

**Transforming Upstream, Lighting Downstream**

It’s common, when building complex scenes using multiple Merge3D nodes being combined together, to use one last downstream node to combine light and camera nodes to illuminate the final scene, while leaving the upstream Merge3D nodes free for controlling object transforms and animation. This way, you can transform and animate subsets of your overall scene without worrying about accidentally altering the overall lighting scheme or cameras for that scene, unless you’ve specifically connected lights or cameras upstream that are meant to be attached to the geometry you’re transforming.

**The Renderer3D Node**

Every 3D node you add outputs a complete 3D scene. This is unlike most traditional 3D modeling and animation programs, where all objects reside within a global scene environment. This means that the scenes created by a Camera 3D node and an image plane are separate until they’re combined into the same scene via a Merge3D node, which itself outputs a complete 3D scene. However, this 3D scene data can neither be composited with other 2D images in your composition nor connected to a MediaOut node to output to the Color page without first being rendered within the node tree using a Renderer3D node.

To be more specific, 3D Nodes that output 3D scenes cannot be connected directly to inputs that require 2D images. For example, the output of an ImagePlane3D node cannot be connected directly to the input of a Blur node, nor can the output of a Merge3D node be directly connected to a regular Merge node. First, a Renderer3D node must be placed at the end of your 3D scene to render it into 2D images, which may then be composited and adjusted like any other 2D image in your composition.
The Renderer 3D uses one of the cameras in the scene (typically connected to a Merge3D node) to produce an image. If no camera is found, a default perspective view is used. Since this default view rarely provides a useful angle, most people build 3D scenes that include at least one camera.

The image produced by the Renderer 3D can be any resolution with options for fields processing, color depth, and pixel aspect.

**Software vs GPU Rendering**

The Renderer3D node lets you choose between using a software renderer or an OpenGL renderer, trading off certain aspects of rendered image quality for speed, and trading off depth of field rendering for soft shadow rendering, depending on the needs of a particular element of your composition. To choose which method of rendering to use, there’s a Renderer Type pop-up menu in the Controls tab of each Renderer3D node’s parameters in the Inspector. The default is Software Renderer.

**Software Renderer**

The software renderer is generally used to produce the final output. While the software renderer is not the fastest method of rendering, it has twin advantages. First, the software renderer can easily handle textures much larger than one half of your GPU’s maximum texture size, so if you’re working with texture images larger than 8K you should choose the software renderer to obtain maximum quality.

Second, the software renderer is required to enable the rendering of “constant” and “variable” soft shadows with adjustable Spread, which is not supported by the OpenGL renderer. Soft shadows are more naturalistic, and they’re enabled in the Shadows parameters of the Controls tab of light nodes; you can choose Sampling Quality and Softness type, and adjust Spread, Min Softness, and Filter Size sliders. Additionally, the software renderer supports alpha channels in shadow maps, allowing transparency to alter shadow density.
When the Renderer3D node “Renderer Type” pop-up is set to OpenGL Renderer, you cannot render soft shadows or excessively large textures. When the Renderer3D node “Renderer Type” pop-up is set to Software Renderer, you can render higher quality textures and soft shadows.

**OpenGL Renderer**

The OpenGL renderer takes advantage of the GPU in your computer to render the image; the textures and geometry are uploaded to the graphics hardware, and OpenGL shaders are used to produce the result. This can produce high quality images that can be perfect for final rendering, and can also be potentially orders of magnitude faster than the software renderer, but it does pose some limitations on some rendering effects, as soft shadows cannot be rendered, and the OpenGL renderer also ignores alpha channels during shadow rendering, resulting in a shadow always being cast from the entire object.

On the other hand, because of its speed, the OpenGL renderer exposes additional controls for Accumulation Effects, that let you enable depth of field rendering for creating shallow focus effects. Unfortunately, you can’t have both soft shadow rendering and depth of field rendering, so you’ll need to choose which is more important for any given 3D scene you render.

**Don’t Forget You Can Combine Rendered Scenes in 2D**

While it may seem like an insurmountable limitation that you can’t output both soft shadows and depth of field using the same renderer, don’t forget that you can create multiple 3D scenes each using different renderers and composite them in 2D later on. Furthermore, you can also render out auxiliary channels that can be used by 2D image processing nodes such as AmbientOcclusion, DepthBlur, and Fog to create pseudo-3D effects using the rendered images.

**OpenGL UV Renderer**

When you choose the OpenGL UV Renderer option, a Renderer3D node outputs an “unwrapped” version of the textures that are applied to upstream objects, at the resolution that’s specified within the Image tab of that Renderer3D node.

(Left) When the Renderer3D node “Renderer Type” pop-up is set to OpenGL Renderer, you cannot render soft shadows or excessively large textures. (Right) When the Renderer3D node “Renderer Type” pop-up is set to Software Renderer, you can render higher quality textures and soft shadows.

(Left) A normally rendered 3D scene, (Right) The same scene rendered using the OpenGL UV Renderer mode of the Renderer3D node.
This specially output image is used for baking out texture projections or materials to a texture map for one of two reasons:

- Baking out projections can speed up a render.
- Baking out projections lets you modify the texture using other 2D nodes within your composition, or even using third-party paint applications (if you output this image in isolation as a graphics file) prior to applying it back onto the geometry.

For instance, you have a scene on a street corner and there’s a shop sign with a phone number on it, but you want to change the numbers. If you track the scene and have standing geometry for the sign, you can project the footage onto it, do a UV render, switch the numbers around with a Paint node, and then apply that back to the mesh with a Texture2D.

The UV renderer can also be used for retouching textures. You can combine multiple DSLR still shots of a location, project all of those onto the mesh, UV render it out, then retouch the seams and apply it back to the mesh.

You could project tracked footage of a road with cars on it, UV render out the projection from the geometry, do a temporal median filter on the frames, then map a “clean” roadway back down.

### Loading 3D Nodes into the Viewer

When you load a 3D node into the Viewer, it switches to a 3D Viewer, which lets you pan, zoom, and rotate the scene in 3D, making it easy to make adjustments in three dimensions.

The interactive 3D Viewer is highly dependent on the computer’s graphics hardware, relying on support from OpenGL. The amount of onboard memory as well as the speed and features of your workstation’s GPU make a huge difference in the speed and capabilities of the 3D Viewer.
Displaying a node with a 3D output in any viewer will switch the display type to a 3D Viewer. Initially, the contents of the scene will be displayed through a default perspective view.

A 3D Viewer's default perspective view

To change the viewpoint, right-click in the Viewer and choose the desired viewpoint from the ones listed in the Camera submenu. A shortcut to the Camera submenu is to right-click on the axis label displayed in the bottom corner of the Viewer.

Right-click the Axis label of the Viewer to change the viewpoint

In addition to the usual Perspective, Front, Top, Left and Right viewpoints, if there are cameras and lights present in the scene as potential viewpoints, those are shown as well. It’s even possible to display the scene from the viewpoint of a Merge3D or Transform3D by selecting it from the contextual menu’s Camera > Other submenu. Being able to move around the scene and see it from different viewpoints can help with the positioning, alignment and lighting, as well as other aspects of your composite.
Navigating the 3D View

For the most part, panning and scaling of the 3D Viewer uses the same controls as the 2D Viewer. For more information about the options available in the 3D Viewer, see Chapter 60, “Using Viewers.”

To pan in a 3D Viewer, do the following:
Hold the middle mouse button and drag in the Viewer.

To dolly (zoom) in the 3D Viewer, do one of the following:
- Hold down the middle and left mouse buttons and drag left or right in the Viewer.
- Hold down the Command key and use your pointing device’s scroll control.

To rotate around the 3D Viewer, do the following:
Hold down the Option key and middle-button-drag left and right in the Viewer.

If you want to frame certain objects in the Viewer:
1. Select the Viewer you want to work in.
2. Do one of the following:
   - Press A to Fit all objects in the Viewer.
   - Press F to Fit to selection (or Fit All if nothing is selected).
   - Press C to Rotate the Viewer to look at the center of the currently selected object without moving the Viewer’s position.

Furthermore, selecting a 3D node in the Node Editor also selects the associated object in the 3D Viewer.

Transforming Cameras and Lights Using the Viewers

When the Viewer is set to look through a 3D object in the scene, such as a camera or spotlight, the usual controls for panning and rotating the Viewer will now directly affect the position of the camera or spotlight you’re viewing through. Here’s an example.
To adjust a camera’s position when looking through it in a viewer:

1. Right-click the viewpoint label, and choose a camera from the contextual menu. (Optional) If you’re in two-viewer mode, you can load the camera you’ve selected in one viewer into the other viewer to see its position as you work.

2. Move the pointer into the Viewer that’s displaying the camera’s viewpoint.

3. Hold the middle and left mouse buttons down and drag to zoom the Viewer, or middle-click-drag to pan the Viewer, or option-middle-click-drag to rotate the Viewer, all while also moving the camera.

When a viewer is set to display the view of a camera or light, panning, zooming, or rotating the Viewer (seen at right) actually transforms the camera or light you’re viewing through (seen at left)

It is even possible to view the scene from the perspective of a Merge3D or Transform3D node by selecting the object from the Camera > Others menu. The same transform techniques will then move the position of the object. This can be helpful when you are trying to orient an object in a certain direction.

**Transparency Sorting**

While generally the order of geometry in a 3D scene is determined by the Z-position of each object, sorting every face of every object in a large scene can take an enormous amount of time. To provide the best possible performance, a Fast Sorting mode is used in the OpenGL renderer and viewers. This is set by right clicking in the Viewer and choosing Transparency > Z-buffer or enabling the Fast button in the Viewer toolbar. While this approach is much faster than a full sort, when objects in the scene are partially transparent it can also produce incorrect results.

The Sorted (Accurate) mode can be used to perform a more accurate sort at the expense of performance. This mode is selected from the Transparency menu of the Viewer’s contextual menu. The Renderer 3D also presents a Transparency menu when the Renderer Type is set to OpenGL. Sorted mode does not support shadows in OpenGL. The software renderer always uses the Sorted (Accurate) method.
The basic rule is when a scene contains overlapping transparency, use the Full/Quick Sort modes, and otherwise use the Z-buffer (Fast). If the Full Sort method is too slow, try switching back to Z-buffer (Fast).

**Material Viewer**

When you view a node that comes from the 3D > Material category of nodes in the Effects Library, the Viewer automatically switches to display a Material Viewer. This Material Viewer allows you to preview the material applied to a lit 3D sphere rendered with OpenGL by default.

The type of geometry, the renderer, and the state of the lighting can all be set by right-clicking the Viewer and choosing options from the contextual menu. Each viewer supports A and B buffers to assist with comparing multiple materials.

**Methods of working with the Material Viewer:**

- You can change the shape of the previewed geometry by right-clicking the Viewer and choosing an option from the Shape submenu of the contextual menu. The geometry that the material is applied to is locked to the center of the Viewer and scaled to fit. It is not possible to pan or scale the Material Viewer,

- The Material Viewer can be rotated to provide a different angle on the material by holding Option while pressing the middle mouse button and dragging to the left and right.

- You can adjust the position of the light used to preview the material by dragging with the middle mouse button. Or, you can right-click the Viewer and choose an option from the Lighting > Light Position submenu of the contextual menu.

- You can also toggle lighting off and on by right-clicking the Viewer and choosing Lighting > Enable Lighting from the contextual menu.

- You can choose the renderer used to preview the material by right-clicking the Viewer and choosing an option from the Renderer submenu of the contextual menu.

**Transformations**

Merge3D, 3D Objects, and Transform3D all have Transform parameters that are collected together into a Transform tab in the Inspector. The parameters found in this tab affect how the object is positioned, rotated, and scaled within the scene.
The Transform parameters are used to position the object in local space, the Rotation parameters affect the object’s rotation around its own center, and the Scale slider(s) affect its size (depending on if they’re locked together or not). The same adjustments can be made in the Viewer using on-screen controls.

**Onscreen Transform Controls**

When an object is selected, it displays onscreen Transform controls in the Viewers that allow you to adjust the object’s position, rotation and scale. There are buttons in the Transform toolbar so you can switch modes, or you can use the keyboard short cuts.

**To switch Transform modes, use the following keyboard short cuts:**

- Press Q for Position
- Press W for Rotation
- Press E for Scaling

Using On-Screen Transform Controls

In all three modes, red indicates the object’s local X-axis, green the Y-axis, and blue the Z-axis respectively (just remember RGB = XYZ). You can drag directly on the red, green, or blue portion of any onscreen control to constrain the transform to that axis, or if you drag the center of the onscreen control you can apply a transform without constraints. Holding Option and dragging in the Viewer allows you to freely translate in all three axes without clicking on a specific control.
If the Scale’s Lock XYZ checkbox is enabled in the Inspector, only the overall scale of the object is adjusted by dragging the red or center onscreen control while the green and blue portions of the onscreen control have no affect. If you unlock the parameters, you are able to scale an object along individual axes separately to squish or stretch the object.

Selecting Objects

With the onscreen controls visible in the Viewer, you can select any object by clicking on its center control. Alternately, you can also select any 3D object by clicking its node in the Node Editor.

Pivot

In 3D scenes, objects rotate and scale around an axis called a pivot. By default, this pivot goes through the object’s center. If you want to move the pivot so it is offset from the center of the object, you can use the X, Y and Z Pivot parameters in the Inspector.

Target

Targets are used to help orient a 3D object to a specific point in the scene. No matter where the object moves, it will rotate in the local coordinate system so that it always faces its target, which you can position and animate.

To enable a target for a 3D object:

1. Select that object’s node.
2. Open the object’s Transform panel in the Inspector.
3. Turn on the Use Target checkbox.
4. Use the X/Y/Z Target Position controls in the Inspector or the Target onscreen control in the Viewer to position the target and in turn position the object it’s attached to.
In the Viewer, a line is drawn between the target and the center of the 3D object it’s attached to, to show the relationship between these two sets of controls. Whenever you move the target, the object is automatically transformed to face its new position.

A taurus facing its onscreen Target controls

For example, if a spotlight is required in the scene to point at an image plane, enable the spotlight’s target in the Transform tab and connect the target’s XYZ position to the image plane’s XYZ position. Now, no matter where the spotlight is moved, it will rotate to face the image plane.

A light made to face the wall using its enabled target control
Parenting

One of the many advantages of the node based approach to 3D compositing is that parenting between objects becomes implicit in the structure of a 3D node tree. The basis for all parenting is the Merge3D node. If you're careful about how you connect the different 3D objects you create for your scene, you can use multiple Merge3D nodes to control which combinations of objects are transformed and animated together, and which are transformed and animated separately.

For example, picture a scene with two spheres that are both connected to a Merge 3D. The Merge 3D can be used to rotate one sphere around the other, like the moon around the earth. Then the Merge 3D can be connected to another Merge 3D to create the earth and the moon orbiting around the sun.

Here are the two simple rules of transforming parented Merge3D nodes:

- Transforms and animation applied to a Merge 3D are also applied to all 3D objects connected to that Merge3D node, including cameras, lights, geometry, and other merge nodes connected upstream.
- Transforms and animation applied to upstream merge nodes don’t affect downstream merge nodes.

Cameras

When setting up and animating a 3D scene, the metaphor of a camera is one of the most comprehensible ways of framing how you want that scene to be rendered out, as well as animating your way through the scene. Additionally, compositing artists are frequently tasked with matching cameras from live action clips, or matching cameras from 3D applications.

To accommodate all of these tasks, the Fusion page provides a flexible Camera3D node with common camera controls such as Angle of View, Focal Length, Aperture, and Clipping planes, to either set up your own camera or to import camera data from other applications. The Camera3D node is a virtual camera through which the 3D environment can be viewed.
Cameras are typically connected and viewed via a Merge3D node, however you can also connect cameras upstream of other 3D objects if you want that camera to transform along with that object when it moves.

**Quickly Viewing a Scene Through a Camera**

When you've added a camera to a scene, you can quickly view the scene “through the camera” by setting up the following.

**To view the scene through the camera:**

1. Select the Merge3D node that the camera is connected to, or any node downstream of that Merge 3D.
2. Load the selected Merge3D or downstream node into a viewer.
3. Right-click on the axis label in the bottom corner of the Viewer and choose the camera name.

The Viewer’s frame may be different from the camera frame, so it may not match the true boundaries of the image that will be rendered by the Renderer3D node. If there is no Renderer3D node added to your scene yet, you can use Guides that represent the camera’s framing. To learn more about Guides, see Chapter 60, “Using Viewers.”

**Plane of Focus and Depth of Field**

Cameras have a plane of focus, for when depth of field rendering is available. Here’s the procedure for enabling depth of field rendering in your scenes.

**To render depth of field in a 3D scene:**

1. You must add a Renderer3D node at the end of your 3D scene.
2. Select the Renderer3D node, and set the Renderer Type to OpenGL Renderer.
3. Open the Accumulation Effects disclosure control that appears, and turn on the Enable Accumulation Effects checkbox in the OpenGL render.
Turning on "Enable Accumulation Effects" exposes a Depth of Field checkbox along with Quality and Amount of DoF Blur sliders that let you adjust the depth of field effect. These controls only affect the perceived quality of the depth of field that is rendered. The actual depth of field that’s generated depends solely on the setup of the camera and its position relative to the other 3D objects in your scene.

When you select your scene’s Camera3D node to view its controls in the Inspector, a new checkbox appears in the Control Visibility group, "Focal Plane." Turning this on lets you see the green focal plane indicator in the 3D Viewer that lets you visualize the effect of the "Focal Plane" slider, which is located in the top group of parameters in the Camera3D node’s Controls tab.

For more information about these specific camera controls, see the Camera3D section Chapter 66, “3D Nodes.”

**Importing Cameras**

If you want to match cameras between applications, you can import camera paths and positions from a variety of popular 3D applications. The Fusion page is able to import animation splines from Maya and XSI directly with their own native spline formats. Animation applied to cameras from 3ds Max and LightWave are sampled and keyframed on each frame.

**To import a camera from another application, do the following:**

1. Select the camera in the Node Editor.
2. At the bottom of the Inspector, click the Import Camera button.
3. In the file browser, navigate to and select the scene that contains the camera you want to import.
A dialog box with several options will appear. When the Force Sampling checkbox is enabled, the Fusion page will sample each frame of the motion, regardless of the format.

![Select Camera dialog](image.png)

**TIP:** When importing parented or rigged cameras, baking the camera animation in the 3D application before importing it into the Fusion page often produces the more reliable results.

---

**Lighting and Shadows**

You can add light sources to a scene to create very detailed lighting environments and atmosphere. There are four different types of lights you can use in 3D scenes: ambient, directional, point, and spotlights.

**Enabling Lighting in the Viewer**

A scene without lights uses a default directional light, but this automatically disappears once you add a 3D light object. However, even when you add light objects to your scene, lighting and shadows won’t be visible in the Viewer unless you first enable lighting in the Viewer contextual menu by right-clicking anywhere within a viewer and choosing 3D Options > Lighting or Shadows to turn one or both on.

**Enabling Lighting to be Rendered**

Lighting effects won’t be rendered in the Renderer3D node until the Enable Lighting and/or Shadows checkboxes are checked in the Inspector.

![Lighting button](image.png)

**NOTE:** When lighting is disabled in either the Viewer or final renders, the image will appear to be lit by a 100% ambient light.
Controlling Lighting Within Each 3D Object

All nodes that create or merge geometry also include lighting options which are used to choose how each object is affected by light:

- Merge3D nodes have a “Pass Through Lights” checkbox that determines whether or not lights attached to an upstream Merge3D node also illuminate objects attached to downstream Merge3D nodes.
- ImagePlane3D, Cube3D, Shape3D, Text3D, and FBXMesh3D nodes have a set of Lighting controls that let you turn three controls on and off, “Affected by Lights,” “Shadow Caster,” and “Shadow Receiver.”

3D objects have individual lighting controls that let you control how each object interacts with light and shadows

Lighting Types Explained

Here’s a more detailed explanation of each type of light in the Fusion page.

**Ambient Light**
You use Ambient light to set a base light level for the scene, since it produces a general uniform illumination of the scene. Ambient light exists everywhere without appearing to come from any particular source; it cannot cast shadows and will tend to fill in shadowed areas of a scene.

**Directional Light**
A Directional light is composed of parallel rays that light up the entire scene from one direction, creating a wall of light. The sun is an excellent example of a directional light source.

**Point Light**
A Point light is a well defined light that has a small clear source, like a light bulb, and shines from that point in all directions.

**Spot Light**
A Spot light is an advanced point light that produces a well defined cone of light with falloff. This is the only light that produces shadows.

(Left to Right) Directional Light, Point Light, and Spot Light

All of the Light nodes display on-screen controls in the Viewer, although not all controls affect every light type. In the case of the ambient light, the position has no effect on the results. The directional light can be rotated, but position and scale will be ignored. The point light ignores rotation. Both position and rotation apply to the spotlight.
**Lighting Hierarchies**

Lights normally do not pass through a Merge, since the “Pass Through Lights” checkbox is off by default. This provides a mechanism for controlling which objects are lit by which lights. For example, in the following two node trees, two shapes and an ambient light are combined with a Merge3D node, which is then connected to another Merge3D node that’s also connected to a plane and a spotlight. At the left, the first Merge3D node of this tree has “Pass Through Lights” disabled, so you can only see the two shapes lit. At the right, “Pass Through Lights” has been enabled, so both the foreground shapes and the background image plane receive lighting.

![Lighting Hierarchies example](image)

**Lighting Options**

Most nodes that generate geometry have additional options for lighting. These options are used to determine how each individual object reacts to lights and shadows in the scene.

3D objects have individual lighting controls that let you control how each object interacts with light and shadows.

- **Affected By Lights**: If the Affected By Lights checkbox is enabled, lights in the scene will affect the geometry.
- **Shadow Caster**: When enabled, the object will cast shadows on other objects in the scene.
- **Shadow Receiver**: If this checkbox is enabled, the object will receive shadows.

**Shadows**

The only light that can cast shadows is the spotlight. Spotlight nodes cast shadows by default, although these shadows will not be visible in the Viewer until shadows are enabled using the Viewer toolbar button. Shadows will not appear in the output of the Renderer 3D unless the Shadows option is enabled for that renderer. If you want to prevent a spotlight from casting shadows, you can disable the Enable Shadows checkbox in the node’s inspector.
See the spotlight section of Chapter 67, “Light Nodes,” for a more detailed description of the shadow controls.

**Shadow Maps**

A Shadow Map is an internal depth map that specifies each pixel’s depth in the scene. This information is used to assemble the shadow layer created from a spotlight. All the controls for the shadow map are found in the Spotlight Inspector.

The quality of the shadow produced depends greatly on the size of the shadow map. Larger maps generate better looking shadows but will take longer to render. The wider the cone of the spotlight, or the more falloff in the cone, the larger the shadow map will need to be to produce useful quality results. Setting the value of the Shadow Map Size control sets the size of the depth map in pixels.

Generally, through trial and error, you’ll find a point of diminishing returns where increasing the size of the shadow map no longer improves the quality of the shadow. It is not recommended to set the size of the shadow maps any larger than they need to be.

The Shadow Map Proxy control is used to set a percentage by which the shadow map is scaled for fast interactive previews, such as Autoproxy and LoQ renders. A value of .4, for example, represents a 40% proxy.

**Shadow Softness**

By default, the spotlight generates shadows without soft edges but there are options for constant and variable soft shadows. Hard edged shadows will render significantly faster than either of the Soft Shadow options. Shadows without softness will generally appear aliased, unless the shadow map size is large enough. In many cases, softness is used to hide the aliasing rather than increasing the shadow map to preserve memory and avoid exceeding the graphics hardware capabilities.

Setting the spotlight’s shadow softness to None will render crisp and well defined shadows. The Constant option will generate shadows where the softness is uniform across the shadow, regardless of the shadow’s distance from the casting geometry. The Variable option generates shadows that become softer as they get farther from the geometry that is casting the shadow.
This is a more realistic effect, but the shadows are somewhat harder to control. When this option is selected, additional controls for adjusting the falloff of the shadow will appear, as well as sliders for the minimum and maximum softness.

Selecting the Variable option reveals the Spread, Min Softness and Filter Size sliders. A side effect of the method used to produce variable softness shadows is that the size of the blur applied to the shadow map can become effectively infinite as the shadow’s distance from the geometry increases. These controls are used to limit the shadow map by clipping the softness calculation to a reasonable limit.

The filter size determines where this limit is applied. Increasing the filter size increases the maximum possible softness of the shadow. Making this smaller can reduce render times but may also limit the softness of the shadow or potentially even clip it. The value is a percentage of the shadow map size.

For more information, see Spotlight in Chapter 67, “3D Light Nodes.”

**Multiplicative and Additive Bias**

Shadows are essentially textures applied to objects in the scene that occasionally result in “fighting.” Z-fighting results when portions of an object that should be receiving shadows instead renders over the top of the shadow because they effectively exist in the same exact location in 3D space.
Two Biasing sliders in the Shadows group of Spotlight parameters work by adding a small depth offset to move the shadow away from the surface it is shadowing, eliminating the Z-fighting. When too little bias is added, the objects can self shadow themselves. When too much is added, the shadow can become separated from the surface.

![The Multiplicative and Additive Bias sliders, and the Non-Transmissive Materials checkbox, all in the Spotlight Inspector controls](image)

The goal is to adjust the Multiplicative Bias slider until the majority of the Z-fighting is resolved, then adjust the Additive Bias slider to eliminate the rest. The softer the shadow, the higher the bias will probably have to be. You may even need to animate the bias to get a proper result for some particularly troublesome frames.

**Force All Materials Non-Transmissive**

How light passes through a semi-transparent material plays an important role in determining the appearance of the shadow an object casts. Normally, this transmittance behavior is defined in each object’s Materials tab. However, selecting Force All Materials Non-Transmissive in the Spotlight Inspector overrides this, causing the shadow map produced by the node to ignore transmittance entirely.

---

**Materials and Textures**

In order to render a 3D scene, the renderer must take into account the shape of the object as well as its appearance. The geometry of an object defines the shape of the object, while the material applied to the object defines its appearance. The Fusion page has a range of options for applying materials and textures to geometry, so you can give your 3D objects the surface qualities you want.

Nodes that describe the geometry’s response to light are called illumination models. Blinn, Cook-Torrance, Ward, and Phong are the included illumination models. These nodes are found in the 3D > Material category of nodes in the Effects Library.

Most materials also accept textures, which are typically 2D images. Textures are used to refine the look of an object further, by adding photorealistic details, transparency or special effect. More complex textures like bump maps, 3D textures and reflection maps are also available and located in the 3D > Texture category.

Materials can also be combined to produce elaborate and highly detailed composite materials. Each node that creates or loads geometry into a 3D scene also assigns a default material. The default material is the Blinn illumination model, but you can override this material using one of several nodes that output a 3D material. Some of these materials provide a greater degree of control over how the geometry reacts to light, providing inputs for diffuse and specular texture maps, bump mapping and environmental maps, which mimic reflection and refraction.
Material Components

All of the standard illumination models share certain characteristics that must be understood.

**Diffuse**
The Diffuse parameters of a material control the appearance of an object where light is absorbed or scattered. This diffuse color and texture are the base appearance of an object, before taking into account reflections. The opacity of an object is generally set in the diffuse component of the material.

**Alpha**
This parameter defines how much the object is transparent to diffuse light. It does not affect specular levels or color. However, if the value of alpha, either from the slider or a Material input from the diffuse color, is very close to or at zero, those pixels, including the specular highlights, will be skipped and disappear.

**Opacity**
This parameter fades out the entire material, including the specular highlights. This value cannot be mapped; it is applied to the entire material.
**Specular**

The Specular parameters of a material control the highlight of an object where the light is reflected to the current viewpoint. This causes a highlight that is added to the diffuse component. The more specular a material is, the glossier it appears. Surfaces like plastics and glass tend to have white specular highlights, whereas metallic surfaces like gold have specular highlights that tend to inherit their color from the material color.

Specularity is made up of color, intensity and exponent. The specular color determines the color of light that reflects from a shiny surface. Specular intensity is how bright the highlight will be.

The specular exponent controls the falloff of the specular highlight. The larger the value, the sharper the falloff and the smaller the specular component will be.

L to R: white, complimentary, and matching specular colors
Transmittance
When using the software renderer, the Transmittance parameters control how light passes through a semi-transparent material. For example, a solid blue pitcher will cast a black shadow, but one made of translucent blue plastic would cast a much lower density blue shadow. The transmittance parameters are essential to creating the appearance of stained glass.

**TIP:** You can adjust the opacity and transmittance of a material separately. It is possible to have a surface that is fully opaque yet transmits 100% of the light arriving upon it, so in a sense it is actually a luminous/emissive surface.

Transmissive surfaces can be further limited using the Alpha and Color Detail control.

Attenuation
The transmittance color determines how much color is passed through the object. For an object to have fully transmissive shadows, the transmittance color to must be set to RGB = (1, 1, 1), which means 100% of green, blue and red light pass through the object. Setting this color to RGB = (1, 0, 0) means that the material will transmit 100% of the red arriving at the surface but none of the green or blue light.

Alpha Detail
When this slider is set to 0, the non-zero portions of the alpha channel of the diffuse color are ignored and the opaque portions of the object casts a shadow. If it is set to 1, the alpha channel determines how dense the object casts a shadow.

**NOTE:** The OpenGL renderer ignores alpha channels for shadow rendering, resulting in a shadow always being cast from the entire object. Only the software renderer supports alpha in the shadow maps.

The following examples for Alpha Detail and Color Detail cast a shadow using this image. It is a green-red gradient from left to right. The outside edges are transparent and inside is a small semi-transparent circle.
Color Detail

Color Detail is used to color the shadow with the object’s diffuse color. Increasing the Color Detail slider from 0 to 1 brings in more of diffuse color and texture into the shadow.

**TIP:** The OpenGL renderer will always cast a black shadow from the entire object, ignoring the color. Only the software renderer supports color in the shadow maps.

Saturation

Saturation will allow the diffuse color texture to be used to define the density of the shadow without affecting the color. This slider lets you blend between the full color and luminance only.

Transmittance and Shadows

The transmittance of an object’s material plays an important role in determining the appearance of the shadow it casts. Normally, the transmittance behavior is defined in each object’s Materials tab as explained above. However, selecting Force All Materials Non-Transmissive in the Spotlight Inspector overrides this, causing the shadow map produced by the spotlight to ignore transmittance entirely.
Illumination Models

Now that you understand the different components that make up a material or shader, we’ll look at them more specifically. Illumination models are advanced materials for creating realistic surfaces like plastic, wood or metal. Each illumination model has advantages and disadvantages, which make it appropriate for particular looks. An illumination model determines how a surface reacts to light, so these nodes require at least one light source to affect the appearance of the object. There are four different illumination models that can be found in the Nodes > 3D > Material menu.

Standard
The Standard material provides a default Blinn material with basic control over the diffuse, specular, and transmittance components. It only accepts a single texture map for the diffuse component with the alpha used for opacity. The Standard Material controls are found in the Material tab of all nodes that load or create geometry. Connecting any node that outputs a material to that node’s Material Input will override the Standard material and the controls in the Material tab will be hidden.

Blinn
The Blinn material is a general purpose material that is flexible enough to represent both metallic and dielectric surfaces. It uses the same illumination model as the Standard material, but the Blinn material allows for a greater degree of control by providing additional texture inputs for the specular color, intensity, and exponent (falloff), as well as bump map textures.

Phong
The Phong material produces the same diffuse result as Blinn, but with wider specular highlights at grazing incidence. Phong is also able to make sharper specular highlights at high exponent levels.

Cook-Torrance
The Cook-Torrance material combines the diffuse illumination model of the Blinn material with a combined microfacet and Fresnel specular model. The microfacets need not be present in the mesh or bump map; they are represented by a statistical function, Roughness, which can be mapped. The Fresnel factor attenuates the specular highlight according to the Refractive Index, which can be mapped.

Ward
The Ward material shares the same diffuse model as the others but adds anisotropic highlights, ideal for simulating brushed metal or woven surfaces, as the highlight can be elongated in the U or V directions of the mapping coordinates. Both the U and V spread functions are mappable. This material does require properly structured UV coordinates on the meshes it is applied to.
Textures

Texture maps modify the appearance of a material on a per pixel basis. This is done by connecting an image or other material to the inputs on the Material nodes in the Node Editor. When a 2D image is used, the UV mapping coordinates of the geometry are used to fit the image to the geometry, and when each pixel of the 3D scene is rendered, the material will modify the material input according to the value of the corresponding pixel in the map.

**TIP:** UV Mapping is the method used to wrap a 2D image texture onto 3D geometry. Similar to X and Y coordinates in a frame, U and V are the coordinates for textures on 3D objects.

Texture maps are used to modify various material inputs, such as diffuse color, specular color, specular exponent, specular intensity, bump map, and others. The most common uses of texture maps is the diffuse color/opacity component.

The Fast Noise texture used to control the roughness of a Cook-Torrance material.

A node that outputs a material is frequently used, instead of an image, to provide other shading options. Materials passed between nodes are RGBA samples; they contain no other information about the shading or textures that produced them.

The Texture2D node is used to translate a texture in the UV space of the object, as well as set the filtering and wrap mode.
Composite Materials

Building complex materials is as easy as connecting the output of a Material node to one of the Material inputs of another Material or Texture node. When a Material input is supplied just as with a 2D image, its RGBA values are used per pixel as a texture. This allows for very direct compositing of shaders.

For instance, if you want to combine an anisotropic highlight with a Blinn material you can take the output of the Blinn, including its specular, and use it as the diffuse color of the Ward material. Or, if you do not want the output of the Blinn to be relit by the Ward material, you can use the Channel Boolean material to add the Ward material’s anisotropic specular component to the Blinn material with a greater degree of control.

![Combining an anisotropic highlight with a Blinn material using the Channel Boolean material](image1)

Reflections and Refractions

Environment maps can be applied with the Reflect material in the 3D > Material category. This node can be used to simulate reflections and refractions on an object. Reflections are direct bounce light that hits an object, while refractions simulate the distortion of light seen through semi-translucent surfaces.

The reflections and refractions use an environment mapping technique to produce an approximation that balances realistic results with greater rendering performance. Environment maps assume an object’s environment is infinitely distant from the object and rendered into a cubic or spherical texture surrounding the object.

The Nodes > 3D > Texture > Cube Map and Sphere Map nodes can be used to help create environment maps, applying special processing and transforms to create the cubic or spherical coordinates needed.

![Sphere map example](image2)

To produce reflections with real time interactive feedback at a quality level appropriate for production environment maps you make some trade offs on functionality when compared with slower but physically accurate raytraced rendering. Environment mapped reflections and
refractions do not provide self-reflection or any other kind of interaction between different objects. In particular, this infinite distance assumption means that objects cannot interact with themselves (e.g., the reflections on the handle of a teapot will not show the body of the teapot). It also means that objects using the same cube map will not inter-reflect with each other. For example, two neighboring objects would not reflect each other. A separate cube map must be rendered for each object.

The Reflect node outputs a material that can be applied to an object directly, but the material does not contain an illumination model. As a result, objects textured directly by the Reflect node will not respond to lights in the scene. For this reason, the Reflect node is usually combined with the Blinn, Cook-Torrance, Phong or Ward nodes.

**Reflection**

Reflected outputs a material making it possible to apply the reflection or refraction to other materials either before or after the lighting model with different effects.

A Blinn material connected to a Background Material input of the Reflect. This causes the reflection to be added to the Blinn output.

A Reflect is connected to the Diffuse Color component of the Blinn, causing the reflection to be multiplied by the diffuse color and modulated by the lighting.

**Refraction**

Refraction only occurs where there is transparency in the background material, which is generally controlled through the Opacity slider and/or the alpha channel of any material or texture used for the Background Material Texture input. The Reflect node provides the following material inputs:

- **Background Material**: Defines both the opacity for refraction and the base color for reflection.
- **Reflection Color Material**: The environment reflection.
- **Reflection Intensity Material**: A multiplier for the reflection.
- **Refraction Tint Material**: The environment refraction.
- **Bump map Texture**: Normal perturbing map for environment reflection/refraction vectors.

Working with reflection and refraction can be tricky. Here are some techniques to make it easier:

- Typically, use a small amount of reflection, between 0.1 and 0.3 strength. Higher values are used for surfaces like chrome.
- Bump maps can add detail to the reflections/refractions. Use the same bump map in the Illumination model shader that you combine with Reflect.
- When detailed reflections are not required, use a relatively small cube map, such as 128 x 128 pixels, and blur out the image.
The alpha of refracted pixels is set to 1 even though the pixels are technically transparent. Refracted pixels increase their alpha by the reflection intensity.

If the refraction is not visible even when a texture is connected to the Refraction Tint Material input, double check the alpha/opacity values of the background material.

**Bump Maps**

Bump mapping helps add details and small irregularities to the surface appearance of an object. Bump mapping modifies the geometry of the object or changes its silhouette.

To apply a bump map you typically connect an image containing the bump information to the BumpMap node. The bump map is then connected to the Bump input of a Material node. There are two ways to create a bump map for a 3D material: a height map and a bump map.

**Using a Height Map**

A height map is an image where the value of a pixel represents the height. It is possible to select which color channel is used for bump creation. White means high and black means low, however it is not the value of a pixel in the height map that determines the bumpiness, but rather how the value changes in the neighborhood of a pixel.

**Using a Bump Map**

A bump map is an image containing normals stored in the RGB channels.

**TIP:** Normals are generated by 3D modeling and animation software as a way to trick the eye into seeing smooth surfaces, even though the geometry used to create the models only uses triangles to build the objects.

Normals are 3 float values \((nx, ny, nz)\) whose components are in the range \([-1, +1]\). Because you can store only positive values in the Fusion page’s integer images, the normals are packed from the range \([-1, +1]\) to the range \([0, 1]\) by multiplying by 0.5 and adding 0.5. You can use Brightness Contrast or a Custom node to do the unpacking.
If you were to connect a bump map directly to the bump map input of a material it will result in incorrect lighting. The Fusion page prevents you from doing this, however, because the Fusion page uses a different coordinate system for doing the lighting calculation. You first must use a BumpMap which expects a packed bump map or height map and will do the conversion of the bump map to work correctly.

If your bump mapping doesn’t appear correct, here are a few things to look for:

- Make sure you have the nodes connected correctly. The height/bump map should connect into a BumpMap and then, in turn, should connect into the bump map input on a material.
- Change the precision of the height map to get less banding in the normals. For low frequency images, float32 may be needed.
- Adjust the Height scale on the BumpMap. This scales the overall effect of the bump map.
- Make sure you set the type to HeightMap or BumpMap to match the image input. The Fusion page cannot detect which type image you have.
- Check to ensure High Quality is on (right-click in the transport controls bar and choose High Quality from the contextual menu). Some nodes like Text+ produce an anti-aliased version in High Quality mode that will substantially improve bump map quality.
- If you are using an imported normal map image, make sure it is packed [0–1] in RGB and that it is in tangent space. The packing can be done in the Fusion page, but the conversion to tangent space cannot.

Projection Mapping

Projection is a technique for texturing objects using a camera or projector node. This can be useful for texturing objects with multiple layers, applying a texture across multiple separate objects, projecting background shots from the camera’s viewpoint, image based rendering techniques, and much more.

There are three ways to do projection mapping in the Fusion page.

Using the Projector/Camera Tool to Project Light

When lighting is enabled, a Camera 3D or Projector 3D can act as a light with all the lighting features. When Camera Projection is enabled or you use a projector, you can choose if the projection behaves like a spotlight or an ambient light, however, alpha channels cannot be projected. Overlapping projections add together like any other light node. An internal clipping plane (at around 0.01 distance from camera) limits how close the projector or camera can get to the receivers of the projection.
Project a Texture onto a Catcher Material

If you do not want to work with light sources you can use the projector or camera as a texture projector. To work without lighting, a catcher is required in order to receive the texture and apply it to a material. Only objects using this material will receive the projection. This offers some advantages, like the projection of alpha channels, and texturing other channels like specular color or roughness. If the software renderer is used, overlapping projections can be combined in various ways (mean, median, blend, and so on) via the Catcher node. When using the OpenGL renderer, one catcher per projector is used, and the results can be combined using another material. Similar to the Light Projection technique, an internal clipping plane (at around 0.01 distance from camera) limits how close the projector/camera can get to the projection receivers.
Project using the UVMap Node

This mode requires a camera and a UVMap3D node downstream of the objects to which the texture is being projected. In the Inspector, when the UVMap Map mode is set to Camera, it gathers the information from the camera and creates new UVs for the input objects; these are used for texturing. Because the UVs are stored in the vertices of the mesh, the object must be tessellated sufficiently.

Textures are assigned to the object like any other texturing technique. The UVs can be locked to the vertices at a chosen frame using the Ref Time slider. This locking only works as long as vertices are not created or destroyed or reordered (e.g., projection locking will not work on particles because they get created/destroyed, a Cube3D with its subdivision level slider animated, a Duplicate3D node with its time offset set to non zero so additional meshes get created over time).

**TIP:** Projected textures can be allowed to slide across an object. If the object moves relative to the Projector 3D, or alternatively, by grouping the two together with a Merge 3D, they can be moved as one and the texture will remain locked to the object.

In the following section of a much larger composition, an image (the MediaIn1 node) is projected into 3D space by mapping it onto five planes (Shape3D nodes renamed ground, LeftWall, RightWall, and so on), which are positioned as necessary within a Merge3D node to apply reflections onto a 3D car to be composited into that scene.

The output of the Merge3D node used to assemble those planes into a scene is then fed to a UV Map node, which in conjunction with a Camera3D node correctly projects all of these planes into 3D space so they appear as they would through that camera in the scene. Prior to this UVMap projection, you can see the planes arranged in space at left, each plane has the scene texture mapped to it. At right is the image after the UVMap projection, where you can see that the scene once again looks “normal,” with the exception of a car-shaped hole introduced to the scene.
However, this is now a 3D scene, ready for a digital car to be placed within it, receiving reflections and lighting and casting shadows into the scene as if it were there.

The new 3D scene casting reflections and lighting onto a 3D car, and receiving shadows caused by the car

**Geometry**

There are five nodes used for creating geometry in the Fusion page. These nodes can be used for a variety of purposes. For instance, the Image Plane 3D is primarily used to place image clips into a 3D scene, while the Shapes node can add additional building elements to a 3D set and Text 3D can add three dimensional motion graphics for title sequences and commercials. Although each node is covered in more detail in Part 7, “Fusion Page Effects,” a summary of the 3D creation nodes is provided below.

**Cube 3D**
The Cube 3D creates a cube with six inputs that allow mapping of different textures to each of the cube’s faces.

**Image Plane 3D**
The Image Plane 3D is the basic node used to place a 2D image into a 3D scene with an automatically scaled plane.

**Shape 3D**
This node includes several basic primitive shapes for assembling a 3D scene. It can create planes, cubes, spheres, cylinders, cones and toruses.

**Text 3D**
The Text 3D is a 3D version of the Text+ node. This version supports beveling and extrusion but does not have support for the multi-layered shading model available from Text+.

**Particles**
When a pRender node is connected to a 3D view, it will export its particles into the 3D environment. The particles are then rendered using the Renderer 3D instead of the Particle renderer. See Chapter 97, “Particle Nodes,” for more detail.

**Common Visibility Parameters**
Visibility parameters are found in the Controls tab of most 3D geometry-producing nodes, exposed via a disclosure control. These parameters let you control object visibility in the Viewers and in the final render.
A 3D geometry node’s visibility parameters

**Visible**
If the Visibility checkbox is not selected, the object will not be visible in a viewer, nor will it be rendered into the output image by a Renderer 3D. A non-visible object does not cast shadows. This is usually enabled by default, so objects that you create are visible in both the Viewers and final renders.

**Unseen by Cameras**
If the Unseen by Cameras checkbox is selected, the object will be visible in the Viewers but invisible when viewing the scene through a camera, so the object will not be rendered into the output image by a Renderer 3D. Shadows cast by an Unseen object will still be visible.

**Cull Front Face/Back Face**
Use these options to cull (exclude) rendering of certain polygons in the geometry. If Cull Back Face is selected, all polygons with normals pointing away from the view will not be rendered and will not cast shadows. If Cull Front Face is selected, all polygons with normals pointing away from the view will likewise be excluded. Selecting both checkboxes has the same effect as deselecting the Visible checkbox.

**Ignore Transparent Pixels in Aux Channels**
For any piece of geometry, the Renderer 3D rejects transparent pixels in the auxiliary image channels. The reason this is the default is to prevent aux channels (e.g., normals, Z-channel, UVs) from filling in where there should be blank space or full transparency. For example, suppose in post you want to add some fog to the rendered image. If you had fully transparent geometry in the foreground affecting the Z-channel, you would get incorrect fog rendering. By deselecting this checkbox, the transparency will not be considered and all of the aux channels will be filled for all of the pixels. This could be useful if you wanted to replace texture on a 3D element that is fully transparent in certain areas with a texture that is transparent in different areas; it would be useful to have the whole object set aux channels (in particular UVs).

**Adding FBX Models**
The Filmbox FBX format is a scene interchange format that facilitates moving 3D scene information from one application to another. The Fusion page’s FBX format extends model import support to other 3D files such as Collada and OBJ.

**Importing An FBX Scene**
To import an entire FBX scene, you add an FBXMesh3D node to your node tree. After being prompted to choose a scene or object file, DaVinci Resolve imports it to create a composition with the same lights, cameras, materials and geometry found in an FBX file.
An imported model, via the FBXMesh3D node

**FBX Scene Import dialog**

The FBX Mesh node is used to import mesh geometry from an FBX file. The first texture applied to a mesh will also be imported, if available.

Since different 3D applications use different units to measure their 3D scenes, the imported geometry may be enormous compared to the rest of the scene, because the Fusion page treats its scale of measurement as equal to its own system. For example, if your 3D application defaults to using millimeters as its scale, an object that was 100 millimeters in size will import as a massive 100 units.

You can use the Size slider in the FBX Mesh Inspector parameters to reduce the scale of such files to something that matches the Fusion page's 3D scene.

**FBX Exporter**

You can export a 3D scene from the Fusion page to other 3D packages using the FBX Exporter node. On render it saves geometry, cameras lights, and animation into different file formats such as .dae or .fbx. The animation data can be included in one file, or it can be baked into sequential frames. Textures and materials cannot be exported.

**Using Text3D**

The Text3D node is probably the most ubiquitous node employed by motion graphics artists looking to create titles and graphics from the Fusion page. It's a powerful node filled with enough controls to create nearly any text effect you might need, all in three dimensions. This section seeks to get you started quickly with what the Text3D node is capable of. For more information, see Chapter 74, “3D Nodes” in Part 7, Fusion Page Effects.

**Assembling Text Objects**

Each Text3D node is a self-contained scene within which each character of text is an individual object. Because of this, the ideal way to combine numerous text objects that you might want to animate or style independently from one another is to connect as many Text3D objects as you want to be able to independently animate or style to one or more Merge3D nodes.
TIP: If you click the Text icon in the toolbar to create a Text3D node, and then you click it again while the Text3D node you just created is selected, a Merge3D node is automatically created and selected to connect the two. If you keep clicking the Text icon, more Text3D nodes will be added to the same selected Merge3D node.

**Entering Text**

When you select a Text3D node and open the Inspector, the Text tab shows a “Styled Text” text entry field at the very top into which you can type the text you want to appear onscreen. Below, a set of overall styling parameters are available to set the Font, Color, Size, Tracking, and so on. All styling you do in this tab affects the entire set of text at once, which is why you need multiple text objects if you’re going to want differently styled words in the same scene.

Near the bottom of the Text tab are the Extrusion parameters, available within a disclosure control.
The Extrusion parameters near the bottom of the Text tab

By default all text created with the Text3D node is flat, but you can use the Extrusion Style, Extrusion Depth, and various Bevel parameters to give your text objects thickness.

(Left) Unextruded text (Right) Extruded text

Positioning and Transforming Text

By default, every new Text3D node is positioned at 0, 0, 0, so when you add multiple Text3D nodes, they’re all in the same place. Fortunately, every Text3D node has built-in transform controls in the Transform tab.

Additionally, selecting a Text3D node exposes all of the on-screen transform controls discussed elsewhere in this chapter. Using these controls, you can position and animate each text object independently.
Repositioned text objects to create a title sequence

Combining Text3D nodes using Merge3D nodes doesn’t just create a scene, it also enables you to transform your text objects either singly or in groups:

- Selecting an individual Text3D node or piece of text in the Viewer lets you move that one text object around by itself, independently of other objects in the scene.
- Selecting a Merge3D node exposes a transform control that affects all objects connected to that Merge3D node at once, letting you transform the entire scene.

Layout Parameters

The Layout tab presents parameters you can use to choose how text is drawn: on a straight line, a frame, a circle, or a custom spline path, along with contextual parameters that change depending on which layout you’ve selected (all of which can be animated).

“Sub” Transforms

Another Transform tab (which the documentation has dubbed the “Sub” Transform tab) lets you apply a separate level of transform to either characters, words, or lines of text, which lets you create even more layout variations. For example, choosing to Transform by Words lets you change the spacing between words, rotate each word, and so on. You can apply simultaneous transforms to characters, words, and lines, so you can use all of these capabilities at once if you really need to go for it. And of course all of these parameters are animatable.
Shading

The Shading tab lets you shade or texture a text object using standard Material controls.

Fog 3D and Softclipping

The Fog3D node helps to create atmospheric depth cues.

The Fog3D node works well with depth of field and antialiasing supported by the OpenGL renderer. Since it is not a post processing node (like the VolumeFog node found in the Nodes > Position menu or Fog node in Nodes > Deep Pixel), it does not need additional channels like Position or Z-channel color. Furthermore, it supports transparent objects.

The SoftClip node uses the distance of a pixel from the viewpoint to affect opacity, allowing objects to gradually fade away when too close to the camera. This prevents objects from “popping off” should the camera pass through them. This is especially useful with particles that the camera may be passing through.
Geometry nodes such as the Shape3D node use a Matte Objects checkbox to enable masking out parts of the 3D scene. Effectively, everything that falls behind a matte object doesn’t get rendered. However, matte objects can contribute information into the Z-channel and the Object ID channel, leaving all other channels at their default values. They do not remove or change any geometry; they can be thought of as a 3D garbage matte for the renderer.

Matte Object Parameters
Opening the Matte disclosure control reveals the IsMatte option, which when turned on enables two more options.

IsMatte
Located in the Controls tab for the geometry, this is the main checkbox for matte objects. When enabled, objects whose pixels fall behind the matte object’s pixels in Z do not get rendered.

Opaque Alpha
When the IsMatte checkbox is enabled, the Opaque Alpha checkbox is displayed. Enabling this checkbox sets the alpha value of the matte object to 1. Otherwise the alpha, like the RGB, will be 0.

Infinite Z
When the IsMatte check box is enabled, the Infinite Z checkbox is displayed. Enabling this checkbox sets the value in the Z-channel to infinite. Otherwise, the mesh will contribute normally to the Z-channel.
Matte objects cannot be selected in the Viewer unless you right-click in the Viewer and choose 3D Options > Show Matte Objects in the contextual menu. However, it’s always possible to select the matte object by selecting its node in the node tree.

Material and Object IDs

Most nodes in the Fusion page that support effect masking can use Object ID and Material ID auxiliary channels to generate a mask. The parameters used to accomplish this are found in the Common Controls tab of each node.

The Material ID is a value assigned to identify what material is used on an object. The Object ID is roughly comparable to the Material ID, except it identifies objects and not materials.

Both the Object ID and Material ID are assigned automatically in numerical order beginning with 1. It is possible to set the IDs to the same value for multiple objects or materials even if they are different. Override 3D offers an easy way to change the IDs for several objects. The Renderer will write the assigned values into the frame buffers during rendering, when the output channel options for these buffers are enabled. It is possible to use a value range from 0 to 65534. Empty pixels have an ID of 0, so although it is possible to assign a value of 0 manually to an object or material, it is not advisable because a value of 0 tells the Fusion page to set an unused ID when it renders.

World Position Pass

The World Position Pass or WPP is a render pass generated from 3D applications. Each pixel is assigned the XYZ position where the pixel was generated in the world coordinates. So if the face from which the pixel was derived in the scene sits at (0,0,0), the resulting pixel will have a Position value of (0,0,0). If we visualize this as RGB, the pixel will be black. If a face sits at (1,0,0) in the original scene, the resulting RGB pixel will be red. Due to the huge range of possible positions in a typical 3D scene, and 7/8 of those possible positions containing negative coordinates, the Position channel is always rendered in 32-bit float.
3D Scene Input

Nodes that utilize the World Position channel are located under the Position category. VolumeFog and Z to WorldPos require a camera input matching the camera that rendered the Position channels, which can either be a Camera3D or a 3D scene containing a camera. Just as in the Renderer3D, you can choose which camera to use if more than one are in the scene. The VolumeFog can render without a camera input from the Node Editor if the world space Camera Position inputs are set to the correct value. VolumeMask does not use a camera input. Nodes that support the World Position Pass, located under the Position category, offer a Scene input, which can either be a 3D Camera or a 3D scene containing a camera.

There are three Position nodes that can take advantage of World Position Pass data.

- Nodes > Position > Volume Fog
- Nodes > Position > Volume Mask
- Nodes > Position > Z to World
- The “Dark Box”

Empty regions of the render will have the Position channel incorrectly initialized to (0,0,0). To get the correct Position data, add a bounding sphere or box to your scene to create distant values and allow the Position nodes to render correctly.
Point Clouds

The Point Cloud node is designed to work with locator clouds generated from 3D tracking software. 3D camera tracking software, such as SynthEyes and PF Track, will often generate hundreds or even thousands of tracking points. Seeing these points in the scene and referencing their position in 3D and screen space is important to assist with lining up live action and CG, but bringing each point in as an individual Locator3D would impact performance dramatically and clutter the node tree.

The Point Cloud node can import point clouds written into scene files from match moving or 3D scanning software.

**To import a point cloud, do the following:**

1. Add the PointCloud3D node to your composition.
2. Click the Import Point Cloud button in the Control panel.
3. Browse to the scene file and select a cloud to import from the scene.

The entire point cloud is imported as one object, which is a significantly faster approach.

**Finding, Naming and Publishing Points**

Many 3D trackers allow for the naming of individual tracking points, as well as setting tracking points on points of interest. The Point Cloud 3D will quickly find these points and publish them. A published point in the cloud can be used to drive the animation of other parameters.
To find a point in the point cloud, do the following:

1. Right-click anywhere within a viewer.
2. Choose Find from the Point Cloud’s submenu in the contextual menu.
3. Type the name of the point and click OK.

Finding a point cloud using the Viewer contextual menu.

If a point that matches the name you entered is found, it will be selected in the point cloud and highlighted yellow.

**TIP:** The Point Cloud Find function is a case-sensitive search. A point named tracker15 will not be found if the search is Tracker15.

Renaming a Point in the Cloud

You can use the Point Cloud contextual menu to rename a selected point. This only works for a single point. A group of points cannot be renamed.
Publishing a Point

If you want to use a point's XYZ positions for connections to other controls in the scene, you can publish the point. This is useful for connecting objects to the motion of an individual tracker. To publish a point, right-click over it and choose Publish from the contextual menu.
This chapter presents an overview of using the Camera Tracker node and the workflow it involves.
Introduction to 3D Camera Tracking

Camera tracking is match moving and a vital link between 2D and 3D, allowing compositors to integrate 3D renders into live action scenes. The Camera Tracker node is used to calculate the path of a live action camera and generate a virtual camera in 3D space. This virtual camera’s motion is intended to be identical to the motion of the actual camera that shot the scene. Using the calculated position and movement of the virtual camera provides the flexibility to add 3D elements to a live action scene. The Camera Tracker will also create a point cloud in 3D space which can be used to align objects and other 3D models to the live action scene.

An example of 3D elements integrated in a live action scene

The 3D Camera Tracking Workflow

The Camera Tracker is a complete workflow in one tool. By tracking the frames from a camera that is moving in a scene, the 3D environment of the location and the camera’s motion can be reconstructed. To do this, the track needs to be of a scene that has tracking features that are in a fixed frame of reference. Moving objects or people need to be masked out from the tracker to get a good solve, as these false tracks will cause inaccuracies when solving for the virtual camera. When solving for the virtual camera, it is helpful to provide certain additional pieces of information, such as the camera sensor size, the focal length of the lens, and measured distances of known tracking marks. This will help guide the solver toward generating a more accurate 3D camera and point cloud.
The Camera Tracker’s task is to create a 3D animated camera and point cloud of the scene. To generate a camera, the basic approach to camera tracking has two steps. Tracking, which is the analysis of a scene, and Solving, which calculates the virtual camera and point cloud. Once these steps are taken, an animated camera can be exported from the tool.

There are five tabs in the Camera Tracker node: Track, Camera, Solve, Export, and Options. To define the workflow where an image sequence is tracked, set basic Camera parameters, Solve, then Export the 3D virtual camera and point cloud. The top buttons of each tab section are the operational process that will trigger the actions for each process.

**Tracking**

Tracking is the term used to describe the task of observing or analyzing the shot. The Camera Tracker node needs to take into account the movement of the source footage before it can determine the location and movement of the virtual camera. To do this, the tool searches for features, which are high contrast patterns within the shot, and assigns trackers automatically to those features. A wide spread of tracking points across the scene will result in the best possible track, and adjusting controls such as the Minimum Feature Separation will help populate the scene with more points. It is recommended when tracking a scene to avoid features on moving objects or features that are caused by parallax differences at different depths.

One way of avoiding these problem areas is masking. Applying a mask to the Camera Tracker will isolate areas of a scene the Camera Tracker can analyze. For example, suppose some footage shot with a moving camera of a subject standing in front of a green screen needs camera tracking. Apply a mask to the subject, invert that mask (so the subject is black and the environment is white) and attach it to the Camera Tracker Track Mask input. By doing this, the tool will look for features within the mask area and not on the subject. Alternatively, tracks can be selected and deleted from the Viewer.
Camera Tracker tab

Camera

This section is where the basic settings of the camera are set, like film gate size, focal length, and lens distortion parameters. If the actual values are not known, try a best guess. The solver will attempt to find a camera near these parameters, and it helps the solver by giving parameters as close to the live action as possible.

Solving

Solving is the process in which the tool takes the currently existing tracks and calculates from them the movement of the live action camera. From a user’s point of view, solving should be thought of as an iterative process:

1. Run the solver.
2. Delete poor tracks and/or adjust the initial guess provided in the Camera tab.
Tips For Solving Camera Motion

When solving camera movement, it’s important to provide accurate live action camera information, such as focal length and film gate size, which can greatly improve the accuracy of the camera solve. For example, if the provided focal length is too far away from the correct physical value, the solver can fail to converge, resulting in a useless solution.

For the solver to accurately triangulate and reconstruct the camera and point cloud, it is important to have:

- A good balance of tracks across objects at different depths with not too many tracks in the distant background or sky (these do not provide any additional perspective information to the solver).
- Tracks distributed evenly over the image and not highly clustered on a few objects or on one side of the image.
- Track starts and ends staggered in time with not too many tracks ending on the same frame.

Sometimes There’s Nothing You Can Do

Some shots, if they do not have enough camera motion to triangulate feature locations, cannot be reconstructed with any useful accuracy. Ensuring that a shot is camera-trackable begins on the set with proper usage of track markers and ensuring camera moves have enough perspective for the solver to “latch” onto.
Cleaning Up Camera Solves

Sometimes the first solve will be good enough. Other times it may take many hours of cleaning up tracks to get a good solve, and other times it is impossible. With experience, one gets a feel for which tracks should be deleted and which should be kept, and which shots will be easy, difficult, or impossible to solve. Be aware that deleting too many tracks can cause solve quality to decrease as the solver has too little information to work with. In particular, if there are less than eight tracks on any frame, mathematically there is not enough information to solve the shot, however, it is strongly recommended to use a lot more than eight tracks to get a robust and accurate solve.

**IMPORTANT** It may be tempting for users unfamiliar with working with camera trackers to try to directly edit the 3D splines of the resulting camera in order to improve a solved camera's motion path. This option should be used as an absolute last resort, preferring instead to modify the 2D tracks being fed into the solver.

How to Judge Track Accuracy

Cleaning up false tracks is facilitated by showing the tracks overlaid on top of the live action footage you’re analyzing. Under the Options tab, the length of these tracks can be lengthened to show longer motion paths. Tracks can be selected either individually or in multiples via a bounding box, and the Delete button will remove tracks you decide are erroneous.

Tips For What to Keep and What to Delete

Understanding what false tracks look like, and then manually cleaning the track data to reduce it to a precise set of clear tracks will result in a more accurate solve. When cleaning up tracks, keep the following in mind:

- Keep all tracks with motion that’s completely determined by the motion of the live action camera.
- Delete tracks on moving objects or people and tracks that have parallax issues.
- Delete tracks that are reflected in windows or water.
- Delete tracks of highlights that move over a surface.
- Delete tracks that do not do a good job of following a feature.
- Delete tracks that follow false corners created by the superposition of foreground and background layers.
- Consider deleting tracks that correspond to locators which the solver has reconstructed at an incorrect Z-depth.
Tips for Deleting Tracks

When deleting tracks, it’s good practice to note the current “Average Solve Error,” then rerun the solver, and note whether the changes increased or decreased the average solve error. In addition to looking at the average solve error to judge the quality of a camera solve, it is useful to also:

- Look at the camera path in 3D views to see if it contains any unexpected jumps, breaks, or jitter.
- Look through the camera in a 3D view at the locators in the 3D point cloud to see how well they stick to features in the live action footage.

Using Filters to Delete Problem Tracks

The Solve tab has filters that can be used to delete tracks based on track length, track error, and solve error. These can be used to quickly remove poorly performing tracks that may be misleading to the resulting camera, leaving a concise list of accurate tracks.

Export

Before exporting, it is a good idea to line up the virtual ground plane in Fusion’s 3D environment with the physical ground plane in the live action footage. Camera Tracker provides various translation, rotation, and scale controls to accomplish this. By selecting tracking points on screen, the ground plane can be aligned to these points, as well as rotation. By using two points of known distance, the scale of the scene can be set.

The Export will maintain a link to the exported tools, so adjustments and new solves will auto update these tools.

NOTE: Camera Tracker saves all its 2D tracks into the composition, sometimes resulting in a rather large file on disk. If there are too many 2D tracks over a long shot, the saved composition can reach over a gigabyte in size. In some cases, this can make compositions containing Camera Tracker nodes cumbersome to load and work with. While it is possible to work directly with the Camera Tracker tool via the camera coming out of the 3D output, once the quality of the solve is satisfactory, consider instead using the Export functionality to take a “low memory” snapshot which can be cut and paste into another composition.
Outputting from the Camera Tracker

The Camera Tracker node has two outputs: the primary output is 2D and there is also a 3D output for viewing the camera path and point cloud in 3D space. When refining tracks to increase the accuracy of the solve, it can be helpful to simultaneously view the 2D and 3D outputs in side-by-side views. Note that selection of tracks in the 2D view and their corresponding locators (in the point cloud) in the 3D view are synchronized. There are also on Viewer menus available in both the 2D and 3D views to give quick control of functionality of this tool.

2D View

The 2D view is the primary display for the node. By dragging and dropping the node to the view, it will display the image being tracked as well as overlay tracker markers and plotted paths of the tracker motion.

A dedicated tool bar gives you access to the common features used to track and solve a shot.

A 2D view of the camera track data
3D View

The second output of the Camera Tracker node displays a 3D scene. To view this, connect this 3D output to a 3D transform node and view that tool. The 3D output will display the point cloud and the camera along with the image connected to it.

Selecting points will invoke the onscreen menu that will give control of various functions such as, displaying Frame Ranges, Solve Error, and Name, as well as Renaming, Deleting, and changing the colors.

A 3D view of the camera track data
Chapter 70

Particle Systems

This chapter is designed to give you a brief introduction to the creation of fully 3D particle systems, one of the Fusion page’s most powerful features. Once you understand these basics, for more information on each Particle System node that’s available, see Chapter 97, “Particle Nodes.”

Introduction to Particle Systems

Particle systems are computer simulations using customizable rules to automatically generate and animate 3D geometry that’s designed to act like smoke, dust, fire, leaves, sparks, or any other animated system of shapes. As the Fusion page is a fully featured 3D compositing environment, particle systems are fully 3D systems, which makes them incredibly flexible and capable of producing all kinds of visual effects or abstract animated content for use in motion graphics.

A 3D particle system, also created entirely within the Fusion page

The three most fundamental nodes required for creating particle systems are found on the Fusion page toolbar. As with the 3D nodes to the right, these are arranged, from left to right, in the order in which they must be connected to work, so even if you can’t remember how to hook up a simple particle system, all you need to do is to click the three particle system nodes from left to right to create a functional particle system.

The three Particle System nodes available from the Fusion page toolbar

However, these three nodes are only the tip of the iceberg. Opening the Particle bin of the Effects Library reveals many, many Particle nodes designed to work together to create increasingly complex particle interactions.
All particle nodes begin with the letter “p,” and they’re designed to work together to produce sophisticated effects from relatively simple operations and settings. The next section shows different ways Particle nodes can be connected to produce different effects.

**Anatomy of a Simple Particle System**

The simplest particle system you can create is a pEmitter node connected to a pRender node. The pEmitter node has all the controls for creating various kinds of particles in different ways, while the pRender node is required to render a 2D or 3D result that can be composited with other scenes of within your composition.

If your needs are more complicated, you can combine two or more pEmitter nodes using a pMerge node (the particle system version of a Merge node), to create compound particle systems where multiple types of particles combine with one another to create a result.
If you’re trying to create particle systems with more naturalistic effects, you can add “forces” to each emitter. These forces are essentially physics or behavioral simulations that automatically cause the particles affected by them to be animated with different kinds of motion, or to be otherwise affected by different objects within scenes.

You can also attach the following types of nodes to a pEmitter node to deeply customize a particle system:

- Attach a 2D image to a pEmitter node to create highly customized particle shapes. Make sure your image has an appropriate alpha channel.
- Attach a Shape3D or other 3D geometry node to a pEmitter node to create a more specific region of emission (by setting Region to Mesh in the Region tab).

The above examples assume you’ll be outputting 2D renders to combine into the rest of a 2D composition. However, because particle systems in the Fusion page are fully 3D, you also have the option of outputting your particle system in such a way as to be used from within other 3D scenes in your composition.
Connecting a particle system to a Merge3D node so the particles are subject to lighting and shadows within a 3D scene.

The Output Mode of the pRender node, at the very top of the controls exposed in the Inspector, can be set to either 2D or 3D, depending on whether you want to combine the result of the particle system with 2D layers, or with objects in a 3D scene.

Choosing whether a particle system’s output is 2D or 3D in the pRender node’s Inspector controls.

If you connect a pRender node to a Merge3D node, the Output Mode is locked to 3D, meaning that 3D geometry is output by the pRender node for use within the Merge3D node’s scene. This means that the particles can be lit, they can cast shadows, and they can interact with 3D objects within that scene.

The result of using a particle system within a 3D scene.
Particle System Distribution

To adjust the distribution of particles being emitted, select the pEmitter node to expose its controls into the Inspector, then open the Velocity controls in the Controls tab, and use the Angle, Angle Variance, Angle Z, and Angle Z Variance controls to adjust the direction and width over which particles are emitted. All of these controls can be animated.

A pEmitter node’s Velocity Angle and Angle Variance controls let you adjust the direction and width of particle distribution.

Particle systems can be positioned and rotated by loading the pEmitter nodes that generate particles into a viewer and using the onscreen 3D position and Rotation controls provided to move the particle system around.

Alternately, you can use the controls of the pEmitter’s Region tab in the Inspector to adjust translation, rotation, and pivot. All of these controls can be animated.
Particle Nodes Explained by Type

This section introduces the four types of particle system nodes that are available in the Effects Library.

Emitters

pEmitter nodes are the source of all particles. Each pEmitter node can be set up to generate a single type of particle with enough customization so that you’ll never be creating the same type of particle twice. Along with the pRender node, this is the only other node that’s absolutely required to create a particle system.

pEmitter nodes have four tabs worth of parameters:

- **Controls:** The primary controls governing how many particles are generated (Number), how long they live (Lifespan), how fast they move (Velocity) and how widely distributed they are (Angle and Angle Variance), their rotation (Rotation Mode with X, Y, and Z controls), and whether there’s spin (Spin X, Y, and Z controls). For each parameter of particle generation, there’s an accompanying “Variance” control that lets you make that parameter less uniform and more naturalistic by introducing random variation.

- **Sets:** This tab contains settings that affect the physics of the particles emitted by the node. These settings do not directly affect the appearance of the particles. They modify behavior such as velocity, spin, quantity and lifespan instead.

- **Style:** While the Controls tab has a simple control for choosing a color for particles, the Style tab has more comprehensive controls including color variance and “Color Over Life” controls. Additionally, size controls including “Size Over Life,” fade controls, and blur controls let you create sophisticated particle animations with a minimum of adjustments, while Merge controls give you an additional level of control over how overlapping particles combine visually. A set of controls at the bottom let you choose how animated effects are timed.
• **Region:** The Region tab lets you choose what kind of geometric region is used to disperse particles into space, and whether you’re emitting particles from the region’s volume or surface. The Winding Rule and Winding Ray Direction controls determine how the mesh region will handle particle creation with geometric meshes that are not completely closed, as is common in many meshes imported from external applications. Tweaking these last parameters is common when using imported mesh geometry as a region for emitting particle, since even geometry which appears closed will frequently appear to “leak” particles thanks to improperly welded vertices.

**Forces**

Many of the particle nodes found in the Particles bin of the Effects Library are “forces,” that enhance a particle simulation by simulating the effect of various forces acting upon the particles generated by an emitter.

Some forces, including pDirectionalForce, pFlock, pFriction, pTurbulence, and pVortex, are rules that act upon particles without the need for any other input. These are simply “acts of nature” that cause particles to behave in different ways.

Other forces, such as pAvoid, pBounce, pFollow, and pKill, work in conjunction with 3D geometry in a scene such as shapes or planes to cause things to happen when a particle interacts or comes near that geometry. Note that some of the particles described previously can also use geometry to direct their actions, so these two categories of forces are not always that clear-cut.

**Compositing**

The pMerge node is a simple way to combine multiple emitters so that different types of particles work together to create a sophisticated result. The pMerge node has no parameters; you simply connect emitters to it and they’re automatically combined.

**Rendering**

The pRender node is required whether you’re connecting a particle system’s output to a 2D Merge node, or to a Merge3D node for integration into a 3D scene. Along with the pEmitter node, this is the only other node that’s absolutely required to create a particle system.

• **Controls:** The main controls that let you choose whether to output 2D or 3D image data, and whether to add blur or glow effects to the particle systems, along with a host of other details controlling how particles will be rendered.

• **Scene:** These controls let you transform the overall particle scene all at once.

• **Grid:** The Grid is a helpful, non-rendering guide used to orient 2D particles in 3D space. The grid is never output in renders. The width, depth, number of lines and grid color can be set using the controls found in this tab.

• **Image:** Controls the output of the pRender node, with controls over the process mode, resolution, and color space settings of the output.
Example Particle Systems

The Particles bin of the Templates category of the Effects Library has ten different examples of particle systems creating a variety of effects. One of the best ways of learning how to create and customize particle systems is to open these and investigate how they're made.

Simply drag and drop any of the particle systems you see here into the Node Editor, load the last node into the Viewer, and you'll see how things are put together.

Overview

Resolve Studio includes 3D stereoscopic and optical flow-based nodes, which partially overlap in functionality.

Stereoscopic Overview

All stereoscopic features are fully integrated into Fusion’s 3D-environment. Stereoscopic images can be created using a single camera, which supports eye separation and convergence distance, and a Renderer 3D for the virtual left and right eye. It is also possible to combine two different cameras for a stereo camera rig.

Stereoscopic nodes can be used to solve 3D stereoscopic shooting issues, like 3D rig misalignment, image mirror polarization differences, camera timing sync issues, color alignment, convergence, and eye separation issues. The stereo nodes can also be used for creating depth maps.

Optical Flow Overview

Optical Flow analyzes the motion in a clip and generates motion vectors between neighboring frames. It generates X and Y vectors from the previous frame to the current frame (Back Vectors) and to the next frame in sequence (Forward Vectors). Once calculated, Optical Flow data can be used to create smooth slow motion and variable retiming of clips, repair missing frames and even correct disparity in stereo 3D clips.

The OpticalFlow node is used to analyze a clip and generate motion vector fields. These motion vectors are then used by additional nodes to apply functions to images.

Toolset Overview

Here is an overview of the available nodes.

Optical Flow Nodes

- **Optical Flow > OpticalFlow**: analyzes motion between neighboring frames in a sequence to generate motion vectors
- **Miscellaneous > TimeSpeed**: retimes a clip at a constant speed using Flow Interpolation mode
- **Miscellaneous > TimeStretcher**: retimes a clip at variable speeds using Flow Interpolation mode
- **Optical Flow > RepairFrame**: generates a new frame using the motion vectors between two neighboring frames
- **Optical Flow > SmoothMotion**: smoothes the color or aux channels using motion vectors
- **Optical Flow > Tween**: interpolates between two non-sequential images to generate a new frame
- **Color > CopyAux**: copies aux channels, including motion vectors, into RGBA more efficiently than Channel Booleans

**Stereoscopic Nodes**

- **Stereo > Anaglyph**: for combing stereo images to create a single anaglyph image for viewing
- **Stereo > Combiner**: stacks a separate stereo images into a single stacked pair, so they can be processed together
- **Stereo > Disparity**: generates disparity between Left/Right images
- **Stereo > DisparityToZ**: converts disparity to Z-depth
- **Stereo > Global Align**: shifts each stereo eye manually to do basic alignment of stereo images
- **Stereo > NewEye**: replaces left and/or right eye with interpolated eyes
- **Stereo > Splitter**: separates a stacked stereo image into to left and right images
- **Stereo > StereoAlign**: for adjusting vertical alignment, convergence, eye separation
- **Stereo > ZToDisparity**: converts Z-depth to disparity

---

**Working with Aux Deep Channels**

Fusion images can contain channels other than RGBA color, called aux deep channels. Stereo Disparity and OpticalFlow deal directly with auxiliary deep channels.

**Aux channels supported in Resolve Studio:**

- **RGBA**: These are the standard colors
- **Z**: The eyespace Z coordinate is almost always negative since in eyespace Fusion’s camera sits at (0, 0, 0) looking down the Z-axis, Z values start at Z = 0 at the camera focal point and progressively become more negative for objects deeper in the scene
- **Coverage**: The percentage of the pixel that is covered by the frontmost pixel, used for antialiased Z-compositing
- **Object ID**: These are user-assigned integers to meshes
- **Material ID**: These are user-assigned integers to materials
- **Texture Coords**: Normalized texture coordinates stored as (u, v) pairs
- **Normal Vector**: Normal vector (nx, ny, nz) where the components are typically in the range [-1, +1]
- **Background Color**: The color of the pixel if the frontmost layer were removed, used for antialiased Z-compositing
- **Vector**: The forward motion vector is an offset (vx, vy) that compares every pixel’s position in one frame to the same pixel’s position in the next frame
- **Back Vector**: The backward motion vector is an offset (vx, vy) that compares every pixel’s position in one frame to the same pixel’s position in the previous frame
- **World Position**: The position (wx, wy, wz) of the pixel in world coordinates
- **Disparity**: An offset (dx, dy) that maps a pixel in the Left > Right or Right > Left frames
These extra channels are used by some Fusion nodes. For example:

- Merge can use the Z channel to perform a depth merge. If the Coverage and BackgroundColor channels are present, it can do a better job on antialiased edges during the Z merge.
- Most image processing nodes (e.g., BrightnessContrast) have options on their common controls tab to limit their processing by MaterialID and ObjectID.
- The Fog and DepthBlur nodes make use of the Z channel.
- The Texture node makes use of the TexCoord channel.
- The Shader node makes use of the Normal channel.

There are a couple of ways to retrieve or generate those extra channels. For example:

- The Renderer3D node is capable of generating most of these channels.
- The OpticalFlow node generates the Vector and BackVector channels, then TimeStretcher and TimeSpeed can make use of these channels.
- The Disparity node generates the Disparity channels and then DisparityToZ, NewEye, and StereoAlign nodes can make use of the Disparity channels.
- The OpenEXR format can be used to import or export aux channels into Fusion by specifying a mapping from EXR attributes to Fusion Aux channels using CopyAux.

**Optical Flow Workflows**

The Optical Flow analysis is a non real time process, and depending on your computer, the clip's resolution, and the duration of the clip, it can take some time. Because of this, the general idea is that you pre-generate the motion vectors, either by performing the analysis overnight or using a render farm, and save results into an OpenEXR sequence. The Optical Flow toolset is designed around four types of nodes that either generate, destroy, pass through, or construct the motion vectors.

**OpticalFlow**

The Optical Flow node generates the Vector and BackVector data. Typically, for optimal performance, you connect the Optical Flow output to a Saver to save the image as OpenEXR files with the motion vectors stored in an aux channel.

**TimeSpeed, TimeStretcher**

You can create smooth constant or variable slow motion effects using the TimeSpeed or TimeStretcher node. When Optical Flow motion vectors are available in the aux channel of an image, enabling Flow mode in the TimeSpeed or TimeStretcher Interpolation settings will take advantage of the Vector and BackVector channels. For the Flow mode to work there must be either an upstream OpticalFlow node generating the hidden channels or an OpenEXR Loader bringing these channels in. These nodes use the Vector/BackVector data to do interpolation on the motion channel and then destroy the data on output since the input Vector/BackVector channels are invalid. For more information on TimeSpeed or TimeStretcher see the Nodes Reference guide.
**SmoothMotion**

SmoothMotion can be used to smooth the Vector and BackVector channels or smooth the disparity in a stereo 3D clip. This node passes through, modifies, or generates new aux channels, but does not destroy them.

**RepairFrame, Tween**

The Tween and Repair Frame nodes are different from standard optical flow nodes because they have the OpticalFlow analysis and motion vector generation built in. Tween will compare two frames and create an in-between frame, which is good for recreating a missing or flawed frame. Repair Frame will look at frames on either side of the current frame and repair scratches, dust marks, and so on. Because these nodes work with flow values between non-sequential frames, they cannot use the optical flow stored in the input image’s Vector/BackVector channels, but rather must regenerate the flow of each frame, do their processing, and then destroy the flow channels. This being the case, these nodes are computationally expensive. For more information on Tween or Repair Frame see the Nodes Reference guide.

**Stereoscopic Workflows**

Disparity is the difference between the left and right image. The Disparity map is used by nodes to align and massage the stereo pair of images.

The Disparity node analyzes a stereo pair of images and generates an X&Y disparity map.

The workflow is to load a left and right stereo image pair and process those in the Disparity node. Once the Disparity map is generated, other nodes can process the images.

**TIP:** When connecting Stereo pairs in the node tree, make sure that the left and right images are connected to the left and right inputs of the Disparity node.
Disparity generation, like Optical Flow, is computationally expensive, so the general idea is that you can pre-generate these channels, either overnight or on a render farm, and save them into an EXR sequence.

The toolset is designed around this philosophy.

**Stereo Camera**

There are two ways to set up a stereoscopic camera. The common way is to simply add a Camera 3D and adjust the eye separation and convergence distance parameters.

Stereoscopic cameras can be done with a single camera or two connected cameras.

The other way is to connect another camera to the RightStereoCamera input port of the Camera 3D. When viewing the scene through the original camera or rendering, the connected camera is used for creating the right-eye content.
**Stereo Materials**

Using the Stereo Mix material node, it is possible to assign different textures per eye.

![Material Viewer showing stereoscopic material](image)

**Disparity**

The Disparity node does the heavy lifting of generating disparity maps. This generates the Disparity channel and stores it in the hidden aux channels of their output image.

**NewEye, StereoAlign**

These use and destroy the Disparity channel to do interpolation on the color channel. The hidden channels are destroyed in the process because, after the nodes have been applied, the original Disparity channels would be invalid.

For these nodes to work there must be either an upstream Disparity node generating the hidden channels or an OpenEXR Loader bringing these channels in.

**DisparityToZ, ZToDisparity**

These nodes pass through, modify, or generate new aux channels, but do not destroy any.

**TIP:** If the colors between shots are different, use Color Corrector or Color Curves to do a global alignment first before calculating the Disparity map. Feed the image you will change into the orange input and the reference into the green input. In the Histogram section of the Color Corrector, select Match, and also select Snapshot Match Time. In the Color Curves’ Reference section, select Match Reference.

**Separate vs Stack**

Stereo nodes can work in “Separate” or “Stack” modes. When in Stack mode, the left/right eyes are stacked horizontally or vertically, forming one image with double width or height respectively.

The advantage to using Stack mode is that you do not have to have duplicate branches of the Node Editor for the left and right eyes. As a consequence, you will see Stereo nodes with two inputs and two outputs labeled as “Left” and “Right.”

When in Stack mode, the stack should be connected to the left eye input and the Left output should be used for connecting further nodes. In Stack mode the respective Right eye inputs and outputs are hidden.
Setting up Stereo in the Node Editor

The disparity generation is the first operation to happen. This can be configured in the Node Editor in two different ways.

Two stereoscopic workflows (shown in a previous version of Fusion)

In the above example the workflow on the right takes the left and right eye, generates the disparity, then NewEye is used to generate a new eye for the image right away.

The example on the left renders the frames with disparity to intermediate EXR images. These images are then loaded back into Stereo nodes and used to create the NewEye images.

By using Render nodes to compute the disparity first, the later processing of the creative operations can be a much faster and interactive experience.

Although not shown in the above diagram, it is usually a good idea to color correct the right eye to be similar to the left eye before disparity generation as this helps with the disparity-tracking algorithm. The color matching does not need to be perfect, for example, it can be accomplished using the “Match” option in a Color Corrector’s histogram options.

About the Disparity Channel

The Disparity channel stores the displacement vectors that match pixels in one eye to the other eye. The left image’s Disparity channel will contain vectors that map left->right and the right image’s Disparity channel will contain vectors that map right->left. For example:

\[(x_{\text{left}}, y_{\text{left}}) + (D_{\text{left}. x}, D_{\text{left}. y}) \rightarrow (x_{\text{right}}, y_{\text{right}}) \quad (x_{\text{right}}, y_{\text{right}}) + (D_{\text{right}. x}, D_{\text{right}. y}) \rightarrow (x_{\text{left}}, y_{\text{left}})\]

You would expect for non-occluded pixels that \(D_{\text{left}} = -D_{\text{right}}\), although, due to the disparity generation algorithm, this is only an approximate equality.

**NOTE:** Disparity stores both X and Y values because rarely are left/right images perfectly registered in Y, even when taken through a carefully setup camera rig.

Both Disparity and Optical Flow values are stored as un-normalized pixel shifts. In particular, note that this breaks from Fusion’s resolution independent convention. After much consideration, this convention was chosen so the user wouldn’t have to worry about rescaling the Disparity/Flow values when cropping an image or working out scale factors when importing/exporting these channels to other applications. Because the Flow and Disparity channels store...
things in pixel shifts, this can cause problems with Proxy and AutoProxy. The convention that Fusion follows is that, for proxied images, these channels store unscaled pixel shifts valid for the full sized image. So if you wish to access the Disparity values in a script or via a probe, you need to remember to always scale them by (image. Width/image. OriginalWidth, image. Height/image. OriginalHeight).

**Viewing of Disparity and Vector Channels**

Aux channels can be displayed directly in the Viewers through the Channel viewer button's menu.

The CopyAux node is used to copy those channels directly into the RGB channels for viewing or further processing. The advantage of using the CopyAux node is that it does static normalization, which reduces a lot of flicker that the Viewer’s time-variant normalization causes. When viewing long sequences of aux channels, the CopyAux node has the option to kill off aux channels and keep only the current RGB channels, freeing up valuable memory so you can cache more frames.

**TIP:** Although you can use the Channel Booleans to copy any aux channel into RGBA, it involves a few additional clicks when compared to CopyAux.

One thing to be aware of is that aux channels tend to consume a lot of memory. A float32 1080p image containing just RGBA uses about 32MB of memory but, with all the aux channels enabled, it consumes around 200MB of memory.

**Stereo and Optical Flow Best Practices**

How you create your composition, the images you are using, and the type of shot you are working on can all have an impact on the success of the Disparity generation and Optical Flow analysis. Below we’ll take a look at some of the situations to be aware of and how you can avoid some pitfalls when dealing with optical flow.

**Semi-Transparent Objects**

The Optical Flow and Disparity generation algorithms Fusion uses assume there is only one layer per pixel when tracking pixels from frame to frame. In particular, transparent objects and motion blur will cause problems. For example, a shot flying through the clouds with the semi-transparent clouds in the foreground and a distant landscape background will confuse the Optical Flow/Stereo algorithms as they do not recognize overlapping objects with different motions. Usually the optical flow will end up tracking regions of one object or the other. If the transparent object and the background are near the same depth and consequently have the same disparity, then it is not a problem.
Motion Blur

Motion blur is also a serious problem for the reason explained in the previous point. The Disparity and Optical Flow algorithms are unsure whether or not to assign a pixel in the motion blur to the moving object or the background pixel. Because the algorithms used are global in nature, not only the vectors on the motion blur will be wrong, but it will confuse the algorithm on regions close to the motion blur.

Depth of Field

Depth of field is also another problem related to the above two problems. The problem occurs when you have a defocused foreground object over a background object that is moving (Optical Flow case) or shifts between L/R (Stereo Disparity case). The blurred edges will confuse the tracking since they can’t figure out the edges are actually two separate objects.

Where to Calculate Disparity and Optical Flow?

Where you chose to generate optical flow or disparity in your composition can drastically affect the results.

For example, if you have compositied a lens flare in, it is better to compute OpticalFlow/Disparity before that, since the semi-transparent lens flare will confuse the tracking algorithms.

If you are color correcting the left/right eyes to match or for deflickering, it is better to apply the OpticalFlow/Disparity after since it will be easier for the tracking algorithm to find matches if the color matches between frames.

If you are removing lens distortion, think carefully about whether you want to do it before or after Disparity computation. If you do it after, your Disparity map will also act as a lens distortion map, combining the two effects as one.

As a general rule of thumb, it is best to use OpticalFlow/Disparity before any compositing operations except an initial color matching correction and a lens distortion removal.

Cropping the Source

As a general tip, if you are cropping your input images down for any reason, it is probably better to compute the optical flow or disparity before the crop and then afterward crop the flow/disparity along with the color.

The reason is that flow/disparity matching works well when there is common pixel data to match in both frames, but when there are pixels that show up in just one frame (or one eye), then the Disparity/OpticalFlow nodes have to make a guess and fill in the data. The biggest occlusions going from L <-- R are usually pixels along the L/R edges of the images that get moved outside. This is similar for optical flow when you have a moving camera.

Another thing to be aware of are black borders around the edges of your frames, which you should crop away.

Nodes with Multiple Outputs

Many of the stereo nodes in the Fusion toolset have multiple outputs. This can cause some confusion to new users. One particularly confusing thing is that when you drag a Stereo node to the view, it will always display the left output. There is no way to view the right output without connecting another node like BC (BrightnessContrast) to the right output and viewing that.
Picking from Aux Channels

Some nodes, like StereoAlign, allow one to drag pick from the Z or Disparity auxiliary channels. You must pick from a node upstream of the StereoAlign, not from the output of the StereoAlign. If you try to pick a disparity from the output of a StereoAlign node, you will get nothing because StereoAlign consumes/destroys the Disparity aux channel (and even if it did not destroy the Disparity channel you would still be picking the wrong value since you would be picking from the aligned result).

The typical workflow for picking is:

1. View StereoAlign in the left view
2. View the node upstream of StereoAlign in the right view
3. Pick the Disparity value from the left eye in the right view

Although this picking functionality does not operate any differently from normal picking of color channels, this issue may cause some confusion. If it helps, the analogous workflow mistake with color nodes would be a user trying to pick a gradient color for a Background node from a view showing the Background node itself (you are trying to pick a color for a node from its own output).

Another issue that you need to be aware of is which eye you are picking. To avoid problems, it’s a good idea to always pick from the left eye. The reason is that the Disparity channels for the left and right eyes are different, and when you pick from a horizontal/vertical stereo stack, Fusion has no way of knowing whether you picked the Disparity value from the left or right eye.

The above are not hard and fast rules; rather, they are guidelines to prevent foot shootings. If you understood the above reasoning fully, you’ll realize there are exceptions, like picking disparity from the left output of DisparityToZ and Z from the left/right output of ZToDisparity, where everything is okay.

Vector and Disparity Channels

The Vector and BackVector channels store the forward and reverse optical flow.

The Vector channel might be better named “forward vector” or “forward flow,” since the name “Vector” to describe a channel is “not technically correct,” as the more mathematically-inclined user might recognize that all of the channels except the scalar channels Z/ID are technically “vector” channels. A frames Vector aux channel will store the flow forward from the current frame to the next frame in the sequence and the BackVector aux channel will store the flow backward from the current frame to the previous frame. If either the previous or next frames do not exist (either not on disk or the global range of a loader does not allow OpticalFlow to access them), Fusion will fill the corresponding channels with zeros (transparent black).

The Disparity channel stores the displacement vectors that match pixels in one eye to the other eye. The left image’s Disparity channel will contain vectors that map left > right and the right image’s Disparity channel will contain vectors that map right > left.

For example:

\[(x_{\text{left}}, y_{\text{left}}) + (D_{\text{left. x}}, D_{\text{left. y}}) \rightarrow (x_{\text{right}}, y_{\text{right}}) \quad (x_{\text{right}}, y_{\text{right}}) + (D_{\text{right. x}}, D_{\text{right. y}}) \rightarrow (x_{\text{left}}, y_{\text{left}})\]

You would expect for non-occluded pixels that \(D_{\text{left}} = -D_{\text{right}}\), although due to the disparity generation algorithm, this is only an approximate equality. Note that Disparity stores both X and Y values because rarely are left/right images perfectly registered in Y, even when taken through a carefully setup camera rig.
Disparity and Optical Flow values are stored as un-normalized pixel shifts. In particular, note that this breaks from Fusion’s resolution independent convention. After much consideration, this convention was chosen so the user wouldn’t have to worry about rescaling the Disparity/Flow values when cropping an image or working out scale factors when importing/exporting these channels to other applications. Because the Flow and Disparity channels store things in pixel shifts, this can cause problems with Proxy and AutoProxy. The convention that Fusion follows is that, for proxied images, these channels store unscaled pixel shifts valid for the full sized image. So if you wish to access the disparity values in a script or via a probe, you need to remember to always scale them by (image. Width/image. OriginalWidth, image. Height/image. OriginalHeight).

When using Vector and BackVector aux channels remember that all nodes expect these aux channels to be filled with the flow between sequential frames.

More precisely, if you have sequence of 3 frames A, B, C then:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>Vector will contain the flow B&gt;C</td>
</tr>
<tr>
<td>B</td>
<td>BackVector will contain the flow B&gt;A</td>
</tr>
<tr>
<td>A</td>
<td>Vector will contain the flow A&gt;B</td>
</tr>
<tr>
<td>A</td>
<td>BackVector is written with zeros as there is no frame before A</td>
</tr>
<tr>
<td>C</td>
<td>Vector is written with zeros as there is no frame D to flow C&gt;D</td>
</tr>
<tr>
<td>C</td>
<td>BackVector will contain the flow C&gt;B</td>
</tr>
</tbody>
</table>

When working with these channels, it is the user’s responsibility to follow these rules (or for clever users to abandon them). Nodes like TimeStretcher will not function correctly since they still expect them to contain flow forward/back by 1 frame.

**NOTE:** Currently DoD/RoI is not supported for all Fusion nodes.
Chapter 72

Using OFX and ResolveFX

The Fusion page supports third-party OFX that are compatible with DaVinci Resolve.
Chapter – 72 Using OFX and ResolveFX
Using OFX

The Fusion page is able to use compatible OFX that are installed on your workstation. All OFX appear in the OpenFX category of the Effects Library, alongside all other effects that are available in the Fusion page.
This section presents the different Fusion page options that are available in the Fusion Settings window.

Fusion Settings Overview

The Fusion Settings window provides a wide variety of optional settings available for you to configure Fusion’s behavior to better suit your working environment. These settings are accessed via the Preferences dialog. The Preferences dialog can be opened from the File menu at the top of the interface.

**To open the Fusion Settings window:**

Choose Fusion > Fusion Settings.

The Fusion Settings window is divided into a sidebar that appears on the left, which is used to select which of the settings panels appear on the right.

**NOTE:** In the standalone Fusion application, there are two levels of settings: Global and Composition. These don’t exist in the Fusion page of DaVinci Resolve, but the explanation remains here. The Global preferences are used to set options that are specific to Fusion’s overall behavior as well as defaults for each new composition. The Composition preferences can further modify the currently open composition without affecting the Global preferences, or any other node tree that is open but not displayed.

**Categories of Settings**

The first entry in the Preferences sidebar is assigned to the Global preferences. Clicking the disclosure arrows for the Global preferences reveals the following sections.

**3D View**

The 3D View preference offers control over various parameters of the 3D Viewers including grids, default ambient light set up, and Stereoscopic views.

**Defaults**

The Default preference is used to select default behavior for a variety of options, such as animation, global range, timecode display, and automatic node merging.

**Flow**

Use the Flow preference to set many of the same options found in the Flow contextual menu, like settings for Tile picture, the Navigator and pipe style.

**Frame Format**

The Frame Format preference is used to create new frame formats as well as select the default image height and width when adding new creator nodes like Background and Text+. It is also where the frame rate for playback is set.

**General**

General preference contains options for the general operation, such as auto save and gamma settings for color controls.

**Path Map**

Path Map preference is used to configure virtual file path names used by Loaders and Savers, as well as the folders used by Fusion to locate comps, macros, scripts, node settings, disk caches, and more.
Script
The preference for Scripting includes a field for passwords used to execute scripts externally, programs to use for editing scripts, and the default Python version to use.

Spline Editor
The Spline Editor preference is used to set various spline options for Autosnap behavior, handles, markers and more.

Splines
Options for the handling and smoothing of animation splines, Tracker path defaults, onion-skinning, roto assist, and more are found in the Splines preference.

Timeline
The Timeline preference is used to create and edit Timeline/Spline filters and set default options for the Timeline Editor.

Tweaks
Tweaks preference handles miscellaneous settings for modifying the behavior when loading frames over the network and queue/network rendering.

User Interface
These Preferences set the appearance of the User Interface window and the Control Panel display.

View
The View preference is used to manage settings for Viewers, including default control colors Z-depth channel viewing ranges, default LUTs, padding for fit zoom, and more.

VR Headsets
The VR Headsets preference allows configuration of any connected Virtual Reality headsets, including how stereo and 3D scenes are viewed.

Import
The Import settings contains options for EDL Import that affect how flows are built using the data from an EDL.
Preferences In Depth

The following sections describe all preferences found in this window.

3D View Preferences

The 3D View preferences contain settings over various defaults in the 3D Viewers, including grids, default ambient light set up, and Stereoscopic views.

Grid

The Grid section of the 3D View preference configures how the grid in 3D Viewers are drawn.

- Grid Antialiasing: Depending on the graphics drivers installed in your computer, the antialiased lines of the grid may sort incorrectly in the 3D Viewer. Disabling this checkbox will disable antialiasing of the grid lines, correcting the issue. To turn the grid off completely, use the 3D View > Right click > Grid option, rather than preferences.
- Size: Increasing the Size value will increase the number of grid lines drawn. The units used for the spacing between grid lines are not defined in Fusion. A 'unit' is whatever you want it to be.
- Scale: Adjusting the overall scaling factor for the grid is useful, for example, if the area of the grid appears too small compared to the size of your geometry.

Perspective Views

The Perspective Views section handles the appearance of the perspective view in both a normal and stereoscopic project.

- Near Plane/Far Plane: These values set the nearest and farthest point any object can get to or from the camera before it is clipped. The minimum setting is 0.05. Setting Near Plane too low and Far Plane too far results in loss of depth precision in the Viewer.
- Eye Separation/Convergence/Stereo Mode: This group of settings define the defaults when stereo is turned on in the 3D Viewer.

Fit to View

The Fit to View section has two value fields that manage how much empty space is left around objects in the Viewer when the F key is pressed.

- Fit Selection: Fit Selection determines the empty space when one or more objects are selected and the F key is pressed.
- Fit All: Fit All determines the empty space when you press F with no objects selected.

Default Lights

These three settings control the default light set up in the 3D Viewer.

The default ambient light is used when lighting is turned on and you have not added light to the scene. The default light moves with the camera, so if the default light is set to “upper left,” the default light appears to come from the upper left side of the image/camera.
Defaults

The choices made here are used to determine Fusion’s behavior when new nodes are added to the node tree and when controls are animated.

Default Animate

The Default Animate section is used to change the type of modifier attached to a parameter when the Animate option is selected from its contextual menu. The default option is Nothing, which uses a Bezier spline to animate numeric controls and a path modifier for positional controls.

- **Number with and Point with**: Drop-down lists are used to select a different modifier for the new default. For example, change the default type used to animate positions by setting the Point with drop-down menu to XY Path.

  Choices shown in this menu come from installed modifiers that are valid for that type of parameter. These include third-party plug-in modifiers, as well as native modifiers installed with Fusion.

Auto Tools

The Auto Tools section determines which nodes are added automatically for the most common operations of the Background nodes and Merge operations.

- **Background**: When set to None a standard Background node is used, however, the drop-down menu allows you to choose from a wide variety of available nodes, including 2D and 3D nodes to customize the operation to your workflow.

- **Merge**: When set to None, nothing happens. When set to Merge, connecting the outputs of two nodes or dragging multiple clips on the Node Editor area uses a standard Merge. Other valid options for this are Anaglyph, Channel Booleans, and Dissolve.

  - **Use Merge Only When Connecting Outputs Directly**: When this option is active, Merges are not automatically added when you drag multiple clips from the Finder or Windows Explorer onto the Node Editor area.

Global Range

Using the Start and End fields, you can define the Global Start and End frame used when creating new compositions.

Time Code

Use this option to determine if new compositions will default to showing SMPTE Time Code or frames (Feet + Frames) to represent time.

Flow

Many of the same options found in the Flow contextual menu, like settings for Tile picture, the Navigator and pipe style, are found in this category.

Force

The Force section can set the default to display pictures in certain node tiles on the node tree, rather than showing plane tiles. The Active checkbox sets pictures for the actively selected node, the All checkbox enables pictures for all nodes, and the Source and Mask checkbox enables tile pictures for just Source and Mask nodes.
When All is enabled, the picture shown will either be a thumbnail of the image rendered by the node if the node has rendered, or if the Show Thumbnails option is disabled, the node’s default icon is used. Concatenated transforms will also show a default icon.

- **Show Modes/Options**: Enabling this option will display icons in the node tile depicting various states, like Disk Caching or Locked.
- **Show Thumbnails**: When this checkbox is selected, node tiles set to show tile pictures will display the rendered output of the node. When the checkbox is cleared, the default icon for the node is used instead.

**Options**
The Options section has a number of settings that control or aid in the layout and alignment of nodes in the node tree.

- **Arrange to Grid**: This enables a new node tree’s Snap to Grid option to force the node layout to align with the grid marks in the node tree.
- **Arrange to Connected**: Nodes snap to the vertical or horizontal positions of other nodes they are connected to.
- **Auto Arrange**: This option enables the Node Editor to shift the position of nodes as needed to make space when inserting new nodes or auto-merging layers.
- **Show Grid**: This enables or disables the display of the Node Editor’s background grid.
- **Auto Remove Routers**: Pipe Routers or “elbow nodes” in the node tree are considered to be ‘orphaned’ if the nodes connected to either the input or output are deleted. When this option is enabled, orphaned routers are automatically deleted.
- **Pipes Always Visible**: When enabled, the connecting pipes between nodes will be drawn over top of the node tiles.
- **Keep Tile Picture Aspect**: Enabling this option forces node tile thumbnail pictures to preserve the aspect of the original image in the thumbnail.
- **Full Tile Render Indicators**: Enabling this checkbox will cause the entire node to change color when it is rendering. This can make it easier to identify which nodes are rendering in a large composition. The coloring itself will form a progress bar to alert you to how close slower nodes are to finishing their renders.
- **Show Instance Links**: This option can be used to select whether Instance nodes will show links, displayed as green lines, between Instance nodes.
- **Navigator**: The Navigator is a small square overview of your entire composition, which you can use to quickly navigate to different parts of the node tree while you are zoomed in. The checkboxes in this section determine when the Navigator is displayed, if at all.
  - **On**: The Node Navigator will always be visible.
  - **Off**: The Node Navigator will always be hidden.
  - **Auto**: The Node Navigator will only be visible when the Node Editor’s contents exceed the currently visible Node area.
- **Pipe Style**: This drop-down menu selects which method is used to draw connections between nodes. The Direct method uses a straight line between nodes and Orthogonal uses horizontal and vertical lines.
- **Build Direction**: When auto-building or laying out a node tree, Build Direction controls whether nodes are organized horizontally or vertically.
- **Scale**: The Scale menu allows you to select the default zoom level of the Node Editor when a new node tree is created.
Pipe Grab Distance
This Pipe Grab Distance slider allows you to choose how close the cursor must be (in pixels) to the pipes in the node tree when selecting them.

Group Opacity
This slider controls the opacity of an expanded group’s background in the node tree.

Frame Format
Frame Format preferences select the format settings for the interface. The settings in this preferences dialog are described in greater detail in the Frame Formats chapter of the manual.

Default Format
This drop-down menu is used to select the default resolution for nodes and media from a list of presets. This is only a default setting; Loaders and Creators may be adjusted to different resolutions.

Use the edit boxes to change any of the default settings. When creating a new setting, press the New button and enter a name for the setting in the dialog box that appears and enter the parameters.

Settings
The Settings section defines the format that is selected in the Default Format menu. You can modify an existing format or create a new one.

- **Width/Height:** When creating a new format for the menu or modifying an existing menu item, you specify the Width or Height in pixels of the format using these fields.
- **Frame Rate:** Enter or view the frames per second played by the format. This sets the default Frame Rate for previews and final renders from the Saver node. It also sets the playback for the comp itself, as well as the frame to timecode conversion for nodes with temporal inputs.
- **Has Fields:** When this checkbox is enabled, any Creator or Loader node added to the node tree will be in Fields process mode.
- **Film Size:** This field is used to define how many frames are found in one foot of film. The value is used to calculate the display of time code in Feet + Frames mode.
- **Aspect Ratio:** These two fields set the pixel Aspect Ratio of the chosen frame format.
- **Guide 1:** The four fields for Guide 1 define the left, top, right and bottom guide positions for the custom guides in the Viewer. To change the position of a guide, enter a value from 0 to 1. The bottom left corner is always 0/0, the top right corner is always 1/1. If the entered value’s aspect does not conform to the frame format as defined by the Width and Height parameters, an additional guide is displayed on screen. The dotted line represents the image aspect centered about Guide 1’s Center values.
- **Guide 2:** This setting determines the image aspect ratio in respect to the entire frame format width and height. Values higher than 1 cause the height to decrease relative to the width. Values smaller than 1 cause height to increase relative to width.
- **New Button:** You use the New button to create a new default setting in the drop-down menu. Once you click the button you type a name for the setting in the dialog box that appears.
- **Copy Button:** The Copy button copies the current setting to create a new one for customization.
- **Delete Button:** The Delete button will remove the current setting from the default drop-down list.
**Color Depth**

The three menus in the Color Depth section are used to select the color mode for processing preview renders, interactive renders and full (final) renders. Processing images at 8-bit is the lowest color depth and is sufficient for almost all video and multimedia tasks. 16-bit color has much higher color fidelity but uses more system resources. 16-bit and 32-bit float per channel uses even more system resources and is best for digital film and HDR rendered images.

Generally, these options are ignored by the composition unless a Loader or Creator node’s Color Depth control is set to Default.

**General**

The sections contained in the General preferences affect the behavior of the Control Panel as well as some other user interface elements.

**Usability**

Usability has a number of Project, Node and User Interface settings that can make the application easier to work with, depending on your workflow.

- **Auto Clip Browse**: When this checkbox is enabled, the File Browser is automatically displayed when a new Loader or Saver is added to the node tree.
- **New Comp on Startup**: When checked, a new, empty node tree is created each time the application is launched.
- **Summarize Load Errors**: When loading comps that contain unknown nodes (e.g., comps that have been created on other computers with plug-ins not installed on the current machine), the missing nodes are summarized in the console rather than a dialogue being presented for every missing node.
- **Save Compressed Comps**: This option enables the saving of compressed node trees, rather than ASCII based text files. Compressed node trees take up less space on disk, although they may take a moment longer to load. Node trees containing complex spline animation and many paint strokes can grow into tens of megabytes when this option is disabled. However, compressed comps cannot be edited with a text editor unless saved again as uncompressed.
- **Show Video I/O Splash**: This toggles whether the Splash image will be displayed over the video display hardware.
- **Use Simplified Copy Names**: This option reduces the occurrence of underscores in node names when copying.
- **Show Render Settings**: When this checkbox is selected, the Render Settings dialog will be displayed every time a render is started. Holding Shift while starting a render will prevent the display of the dialog for that session, using whatever settings were applied during the last render. Disabling this option reverses this behavior.
- **Mouse Wheel Affects the Window Under the Pointer**: Normally the Mouse wheel or Apple Mouse swiping works in the currently active window. With this option enabled it will work in the window underneath the cursor, so you don’t have to click into a window first to make it active.
- **Frames Start From**: This designates the starting frame number for clip times in the Loader and its Clip list.
- **Show Color As**: This setting determines the numeric scale used to represent colors. The available options are Normalized (0 to 1), 8-bit (0 to 255) and 16-bit (0 to 65,535). This does not affect the actual processing or quality of the image, but it can make the mental math sometimes used to figure out adjustments a bit easier.
Controls

The Controls section includes settings for how the Control Panel is displayed.

- **Auto Control Close**: When enabled, multiple node headers will be visible, but only one node header will be opened to display parameters. When disabled, any number of nodes may be opened to display parameters at the same time. This setting has no effect unless the Auto Control Hide checkbox is disabled.

- **Auto Control Hide**: When enabled, only the parameters for the currently active node will be made visible. Otherwise, all node headers will be visible and displayed based on the Auto Control Close setting.

- **Auto Control Advance**: If the Auto Control Advanced checkbox is enabled, the Tab key and Return/Enter key will cause the keyboard focus to advance to the next edit box within a node’s control. When disabled, Return/Enter will cause the value entered to be accepted, but the keyboard focus will remain in the same edit box of the control. The Tab key can still be used to advance the keyboard focus.

- **Show Controls for Selected**: When this option is disabled, only the active node’s parameters are shown in the Control Panel. By default, it is enabled showing controls for the active node as well as all selected nodes.

- **Combined Color Wheel**: When the Color Corrector node is displayed in the Control Panel, enabling this checkbox will show one color wheel with buttons to switch between the master, shadow, midtones and highlight channels. Otherwise, four color wheels are displayed in the Control Panel.

- **Grab Distance**: This slider ranges from 1 to 10 and defaults to 5. It designates the active area around the cursor and can be modified if you have difficulties in selecting points for modification in paths and spline curves. Smaller values represent more accurate selection.

Auto Save

When enabled, comps are automatically saved to a backup file at regular intervals defined by the Delay setting. If a backup file is found when attempting to open the comp, you are presented with the choice of loading either the backup or the original.

If the backup comp is opened from the location set in the Path Map preference, saving the backup will overwrite the original file. If the backup file is closed without saving, it is deleted without affecting the original file.

- **Save Before Render**: When enabled, the comp is automatically saved before a preview or final render is started.

- **Delay**: This preference is used to set the interval between Auto Saves. The interval is set using mm:ss notation, so entering 10 causes an Auto Save to occur every 10 seconds where as entering 10:00 causes and Auto Save every 10 minutes.

Proxy

- **Update All, Selective, No Update**: The Update mode button is located in the Time Ruler. You can use this preference to determine the default mode for all new comps. Selective is the usual default. It renders only the nodes needed to display the images in the Display view. All will render all nodes in the composition, whereas None prevents all rendering.

- **Standard and Auto**: These sliders designate the default ratio used to create proxies when the Proxy and Auto Proxy modes are turned on. These settings do not affect the final render quality.
Even though the images are being processed smaller than their original size, the image viewing scales in the Viewers still refer to original resolutions. Additionally, image processing performed in Proxy Scale mode may differ slightly from full resolution rendering.

The Proxy and Auto Proxy size ratios may be changed from within the interface itself by right-clicking on the Prx and APrx buttons beside the Render button and selecting the desired value from the contextual menu.

Path Map

Path Maps are virtual paths used to replace segments of filepaths with variables. For example, define the path ‘movie_x’ as actually being X\Shows\Movie_X. Using this example, Fusion would understand the path ‘movie_x\scene_5\scan.000.cin’ as actually being X:\Shows\Movie_X\scene_5\scan.000.cin.

There are two main advantages to virtual Path Maps instead of actual filenames. One is that you can easily change the path to footage (for example, copying from one share to another), without needing to make any changes at all to their compositions.

Also, path maps are used in render farms to bypass the different filename conventions.

- **Built in Path Maps:** There are several built in path maps. Comp refers to the folder where the current composition is saved. Temp refers to the system’s temporary folder. Fusion refers to the folder where Fusion is installed.

  If the Reverse Pathmap option is enabled, Fusion will automatically attempt to replace portions of filenames that match known path maps. For example, a composition saved as C:\Comps\example1.comp would automatically replace the path to c:\comps\example.jpg with Comp\example.jpg.

- **Global and Composition Path Maps:** Both Global and Composition preferences show a Path Maps preferences panel. The Global preferences are applied to all compositions, while Composition path maps are saved with the composition and only apply to it.

  Composition path maps will override Global path maps with the same name. The built-in Comp.Path Map refers to the default Composition folder when used in a Global path map.

- **Nesting Path Maps:** You can use a path map in a path map’s definition, provided it has been defined first. For example, define a path map called ‘Episode’ that maps to x\shows\Episode1. Then create path maps called Renders and Stills that mapped to Episode\Renders_v1 and Episode\Still_v1.

- **Creating a Path Map:** To create a path map, click on the New button and enter the name of the path map in the From field below. Enter the value of the path map in the To: field.

- **Deleting a Path Map:** To delete a path map, select it from the list and click on the delete button.

- **Enable Reverse Mapping of Paths Preferences:** When this checkbox is selected, the built-in path maps for entries in the Paths preferences will be taken into account when applying mapping to existing filenames.
Script
The preferences for Scripting include a field for passwords used to execute scripts from the command line and programs for use when editing scripts.

Login
- No Login Required to Execute Script: If a username and password is assigned, Fusion will refuse to process incoming external script commands (from FusionScript, for example), unless the Script first logs onto the workstation. This only affects scripts that are executed from the command line, or scripts that attempt to control remote copies of Fusion. Scripts executed from within the interface do not need to log in regardless of this setting. See the Scripting documentation for details.

Options
- Script Editor: Use this preference to select an external editor for scripts (used when selecting Scripts > Edit from the menu).

Spline Editor
The Spline Editor preference allows you to set various spline options for Autosnap behavior, handles, markers, and more.

Spline Editor Options
Independent Handles: Enabling this option allows the In or Out direction handle on newly created keyframes to be moved independently without affecting the other.
- Follow Active: The Spline Editor focuses on the currently active node.
- Show Key Markers: Small colored triangles will be displayed at the top of the Spline Editor Time Ruler to indicate keyframes on active splines. The colors of the triangles match the colors of the splines.
- Show Tips: Toggles if tooltips are displayed or not.
- Autosnap points: When moving points in the Spline Editor, these will snap to the Fields or Frames or can be moved freely.
- Guides: When moving points in the Spline Editor, these will snap to Guides as well.
- Autosnap Guides: When moving or creating Guides, these will snap to the Fields or Frames or can be moved freely.
- Autoscale: Keeps the Spline View scales intact on changing the editable spline content of the view.
- Scroll: Scrolls horizontally and vertically to show all or most of the spline points on changing the editable spline content of the view.
- Fit: Zooms to fit all points within a Spline view, if necessary, on changing the editable spline content of the view.

LUT View Options
- Independent Handles: Enabling this option allows the In or Out direction handle on newly created keyframes to be moved independently without affecting the other.
- Show Key Markers: Small colored triangles will be displayed at the top of the Spline Editor Time Ruler to indicate keyframes on active splines. The colors of the triangles match the colors of the splines.
• **Show Tips:** Toggles if tooltips are displayed or not.

**Splines**
Options for the handling and smoothing of animation splines, tracker path defaults and more are found in the Splines preferences.

**Autosmooth**
Automatically smooths out any newly created points or keyframes on the splines selected in this section. This is valid for both animation splines as well as masks, LUTs, paths and meshes.

**B-Spline Modifier Degree**
This setting determines the degree used for interpolating B-Splines when used as modifiers. Cubic B-Splines determine a segment through 2 control points between the anchor points, and Quadratic B-Splines determine a segment through 1 control point between the anchor points.

**B-Spline Polyline Degree**
This setting is like the one above, but applies to polylines, like those used for masks.

  • **Tracker Path Points Visibility:** This setting controls the control points on tracker paths. You have three options. You can show them, hide them, or show them when your cursor hovers over the path, which is the default behavior.

  • **Tracker Path:** The default tracker creates a Bezier-style spline paths. Two other options in this setting allow you to choose B-Spline or XY Spline paths.

  • **Polyline Edit Mode on Done:** This setting determines the Polyline node that is selected in the toolbar once you complete the drawing of a Polyline.

**Onion Skinning**
The Onion Skinning settings determine the number of frames displayed while rotoscoping, allowing you to preview and compare a range of frames. You can also adjust if the preview frames are only from frame prior to the current frame, after the current frames, or split between the two.

**Timeline**
The Timeline preference is where you create and edit Timeline/Spline filters and set default options for the Timeline Editor.

**Filter/Filter to Use**
The Filter menu populates the hierarchy area below the menu with that setting. It lets you edit the filters. The Filter to Use menu actually sets the filter in the Timeline.

**Settings for Filters**
To create a new filter and define its settings, you first click the New button. Creating a new filter will allow you to select any of the nodes that the filter will contain. The Settings for Filters area includes a list of all the nodes. Only nodes that are checked will appear in the Timeline or Spline Editor when the filter is selected. You can also create a copy of the filter using the Copy button or remove a filter from the list by clicking the Delete button.
Timeline Options

The Timeline Options configure which options in the Timeline are enabled by default. A series of checkboxes correspond to buttons located in the Timeline, allowing you to determine the states of those button at the time a new comp is created. For more information on the Timeline functions see Chapter 26, “Creating and Working with Timelines.”

- **Autosnap points**: When moving points in the Timeline Editor, the points will snap to the fields, frames, or can be moved freely.
- **Guides**: When moving points in the Timeline Editor, the point will snap to the guides that are placed in the Timeline.
- **Autosnap Guides**: When moving or creating guides, the guides will snap to the fields, frames, or can be moved freely.
- **Autoscale**: Keeps the Timeline scales intact while changing the editable spline content of the view. When set to scroll, the Timeline scrolls horizontally and vertically to show all or most of the spline points when changing the editable spline content of the view. When set to Fit, the Timeline zooms to fit all points within the Viewer, if necessary.
- **Tools Display Mode**: This menu controls the default sort order or the tools displayed in the Timeline. The default can be changed using the Sort order menu in the Timeline.

Tweaks

The Tweaks preferences handle a collection of settings for fine tuning I/O, memory, and graphics hardware behavior.

File I/O

- **I/O Canceling**: This option enables a feature of the operating system that allows queued operations to be canceled when the function that requested them is stopped. This can improve the responsiveness, particularly when loading large images over a network.

  Enabling this option will specifically affect performance while loading and accessing TIFF, VideoPump and other formats that perform a large amount of seeking.

  This option has not been tested with every hardware and OS configuration, so it is recommended to enable it only after you have thoroughly tested your hardware and OS configuration using drive loads from both local disks and network shares.

- **Enable Direct Reads**: Enabling this checkbox uses a more efficient method when loading a large chunk of contiguous data into memory by reducing I/O operations. Not every operating system employs this ability, so it may produce unknown behavior.

- **Read Ahead Buffers**: This slider determines the number of 64K buffers that are use to read ahead in a file I/O operation. The more buffers, the more efficient loading frames from disk will be, but the less responsive it will be to changes that require disk access interactively.

Area Sampling

- **Automatic Memory Usage**: This checkbox determines how Area Sampling uses available memory. Area Sampling is used for Merges and Transforms. When the checkbox is enabled (default), Fusion will detect available RAM when processing the node and determine the appropriate trade off between speed and memory.

  If less RAM is available, Fusion will use a higher proxy level internally and take longer to render. The quality of the image is not compromised in any way, just the amount of time
it takes to render. In node trees that deal with images larger than 4K, it may be desirable to override the automatic scaling and fix the proxy scale manually. This can preserve RAM for future operations.

- **Pre-Calc Proxy Level**: De-selecting the Automatic Memory will enable the Pre-Calc Proxy Scale slider. Higher values will use less RAM, but take much longer to render.

### OpenGL

This section controls how Fusion makes use of your graphics card. Most settings may be left as they are, but since OpenGL hardware varies widely in capabilities and different driver revisions can sometimes introduce bugs, these tweaks can be useful if you are experiencing unwanted behavior.

- **Disable view LUT Shaders**: OpenGL shaders can often dramatically accelerate View LUTs, but this can occasionally involve small tradeoffs in accuracy. This setting will force Fusion to process LUTs at full accuracy using the CPU instead. Try activating this if View LUTs do not seem to be giving the desired result.

- **Use Float16 Textures**: If your graphics hardware supports 16-bit floating-point textures, activating this option will force int16 and float32 images to be uploaded to the Viewer as float16 instead, which may improve playback performance.

- **Texture Depth**: Defines in what depth images are uploaded to the Viewer.
  - **Auto**: The Auto option (recommended) lets Fusion choose the best balance of performance and capability.
  - **int8**: Similar to the Use Float16 Textures switch, this option can be used to force images to be uploaded to the Display View as int8, which can be faster but gives less range for View LUT correction.
  - **Native**: The Native option uploads images at their native depth, so no conversion is done.

- **Image Overlay**: The Image Overlay is a Viewer control used with Merge and Transform nodes to display a translucent overlay of the transformed image. This can be helpful in visualizing the transformation when it is outside the image bounds but may reduce performance when selecting the node if cache memory is low. There are three settings to choose from: None, Outside and All.
  - **None**: This setting never displays the translucent overlay or controls, which can reduce the need for background renders, in some cases, resulting in a speed up of the display.
  - **Outside**: This will display only those areas of the control that are outside the bounds of the image, which can reduce visual confusion.
  - **All**: Displays all overlays of all selected nodes.

- **Smooth Resize**: This setting can disable the Viewer’s Smooth Resize behavior when displaying floating-point images. Some older graphics cards are not capable of filtering floating-point textures or may be very slow. If Smooth Resize does not work well with float images, try setting this to flt16 or int.

- **Auto Detect Graphics Memory (MB)**: Having Fusion open alongside other OpenGL programs like 3D animation software can lead to a shortage of graphics memory. In those cases you can manually reduce the amount of memory Fusion is allowed to use on the card. Setting this too low or too high may cause performance or data loss.

- **Use 10-10-10-2 framebuffer**: If your graphics hardware and monitor support 30-bit color, this setting will render Viewers with 10-bits per primary accuracy, instead of 8-bits. Banding is greatly reduced when displaying 3D renders or images deeper than 8-bit. This is only available in Resolve Studio.
User Interface
These Preferences set the appearance of the User Interface window and how the Control Panel is displayed.

View
The View preference is used to manage settings and default controls for Viewers.

View Settings
The area at the top of the View preference lists the currently saved settings that you create from the Viewer’s contextual menu. For more details on the Viewer and its contextual menu, see Chapter 60, “Using Viewers.” You can use the Rename and Delete buttons to manage the selected entries in the list.

Settings for View
Each Viewer has its own preferences. The Settings for View drop down menu is used to select the Viewer for which you want to configure the settings.

Control Colors
The Control Colors setting allows you to determine the color of the Active/Inactive onscreen control.

Color Picking Area Size
Use these width/height controls to set the number of pixels sampled when using the color picker in the Viewers.

Fit Margin
The Fit Margin determines how much padding is left around the frame when the Fit button is pressed or Fit is selected from the Viewer’s contextual menu.

Displayed Depth Range
The Displayed Depth Range setting controls the view normalization of the Z-Channel.

Display LUT Plug-ins
This list shows the available Display LUTs and activates the selected one as default.
VR Headsets
The VR Headsets preference allows configuration of any connected Virtual Reality headsets, including how stereo and 3D scenes are viewed.

Headset Options

<table>
<thead>
<tr>
<th>API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>Turns off and hides all usage of headsets.</td>
</tr>
<tr>
<td>Auto</td>
<td>Will detect which headset is plugged in.</td>
</tr>
<tr>
<td>Oculus</td>
<td>Will set the VR output to the Oculus headset.</td>
</tr>
<tr>
<td>OpenVR</td>
<td>Will support a number of VR headsets like the HTC Vive.</td>
</tr>
</tbody>
</table>

360° Video Format

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto</td>
<td>Will detect the incoming image layout from the metadata and image frame aspect.</td>
</tr>
<tr>
<td>VCross and HCross</td>
<td>Are the six square faces of a cube laid out in a cross, vertical or horizontal, with the forward view in the center of the cross, in a 3:4 or 4:3 image.</td>
</tr>
<tr>
<td>VStrip and HStrip</td>
<td>Are the six square faces of a cube laid vertically or horizontally in a line, ordered as Left, Right, Up, Down, Back, Front (+X, -X, +Y, -Y, +Z, -Z), in a 1:6 or 6:1 image.</td>
</tr>
<tr>
<td>LatLong</td>
<td>Is a single 2:1 image in equirectangular mapping.</td>
</tr>
</tbody>
</table>

Enable Mirror Window: will show a window displaying the headset user’s live view.

Stereo

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mono</td>
<td>Will output a single non stereo eye.</td>
</tr>
<tr>
<td>Auto</td>
<td>Will detect which method the stereo images are stacked.</td>
</tr>
<tr>
<td>Vstack</td>
<td>The stereo images are stacked vertically as left on top and right at the bottom.</td>
</tr>
<tr>
<td>Hstack</td>
<td>The stereo images are stacked horizontally as left and right. Swap eyes: if stereo is reversed this option will swap the eyes</td>
</tr>
</tbody>

<td></td>
</tr>
</tbody>
</table>

Import EDL

The EDL Import options are used to determine how compositions are created from imported EDL files.

Flow Format

This drop-down menu provides three options that determine how the node tree is constructed for the imported EDL file.

- **Loader Per Clip**: A Loader will be created for each clip in the EDL file.
- **A-B Roll**: A Dissolve node will be created with the settings imported from the EDL file.
- **Loader Per Transition**: A Loader will be created with the settings representing the settings imported from the EDL file (Loader with a Clip list created).

Use Shot Names

When checked, shot names stored in the EDL file are used to locate the footage.
PART 8
Fusion Page Effects
Chapter 74

3D Nodes

This chapter covers, in great detail, the nodes used for creating 3D composites.
Alembic Mesh 3D [ABC]

There are two ways to import Alembic files:
- Using the File > Import > Alembic menu option
- Manually adding an AlembicMesh3D node to the node tree

The first method is strongly recommended.

The Alembic format allows for arbitrary user data to be stored within the file. Fusion ignores most of this metadata for various reasons. No conventions have been defined yet for how this metadata is named and metadata might change between different ABC exporters. When the Alembic file is imported through the menu option, the transforms are read into splines and into the inputs on the nodes, which get saved with the comp.

This means that when re-loading the comp, the transforms are loaded from the comp and not the Alembic file. The meshes are handled differently; they are always reloaded from the Alembic file.

Controls
**Filename**
The name of the imported Alembic file.

**Object Name**
This input shows the name of the mesh from the Alembic file that is being imported.
If this field is blank, the entire contents of the FBX geometry will be imported as a single mesh.
This input is not editable by the user; it is set by Fusion when importing Alembic files via the
File > Import > Alembic utility.

**Sampling Rate**
The framerate is set when importing the file. It can be altered using this slider
to create effects like slow motion.

**Dump File**
Opens the resulting ASCII in the preferred text editor.

**Alembic Import Dialog**
- **Writer:** The name of the plug-in/application that created/wrote out the Alembic file
- **Writer Version:** The version of the Alembic sdk that was used to write out the
  Alembic file
- **RenderRange:** This gives you an idea of the duration of the animation in the
  Alembic file in seconds
- **DetectedSamplingRates:** Fusion examines the framerates in the file and reports
  them here. This is useful to determine the value at which to set the resampling rate.

**Hierarchy**
If disabled, the transforms in the Alembic file are flattened down into the cameras and meshes.
This results in a number of meshes/cameras connected to a single merge node in Fusion. When
enabled, you get the full parenting hierarchy.

**Orphaned Transforms**
Transforms that do not parent a mesh or camera will not be imported if this option is unchecked.
For example, if you have a skeleton and associated mesh model, the model will be imported as
an Alembic mesh and the skeleton will be imported as a tree of Merge3Ds. Disabling this option
causes the Merge3Ds not to be imported.
Cameras
Near/Far/Apertures/Angles of View/Plane of Focus are imported. The resolution Gate Fit may be imported, it depends if the Writer correctly tagged the resolution Gate Fit metadata. If your camera does not import correctly, you should check to see if Camera3D.ResolutionGateFit is set correctly. Stereo information is not imported.

InverseTransform
Imports the Inverse Transform (World to Model) for cameras.

Points
Alembic supports a Points type. This is a collection of 3D points without orientation. Some 3D apps export particles as points, but keep in mind the direction and orientation of the particles are lost; you just get positions. It very well may be possible that the exocortex Alembic plug-ins write out extra user data that contains orientation.

Meshes
Optionally import UVs and normals.

ResamplingRate
When an Alembic animation is exported, it is stored on disk in seconds, not in frames. When the Alembic data is brought into Fusion, you need to supply a framerate with which to resample the animation. Ideally, you should choose the same framerate that it was exported with so your samples match up with the original samples. Detected Sampling Rates can give an idea of what to pick if unsure.

Lights
Import currently not supported. There is no universal convention on Alembic light schemas.

Materials
Import currently not supported. There is no universal convention on Alembic material schemas.

Curves
Import currently not supported.

Multiple UVs
Import currently not supported. There is no universal convention yet.

Velocities
Import currently not supported.

Cyclic/Acyclic Sampling
Currently not implemented. Uniform sampling, which is the most common mode, works fine. We recommend the use of FBX for lights/cameras/materials and Alembic for meshes only. If cameras and Alembic work for you, then go for it. The reason is that our Alembic plug-in doesn’t support lights/materials, but FBX has good support. Alembic import of cameras has problems with Resolution Gate Fit and doesn’t import stereo options.
Bender 3D [3BN]

The Bender 3D node is used to bend, taper, twist, or shear the geometry in a 3D scene based upon its bounding box. It takes a 3D scene as input and outputs a modified 3D scene. Only the geometry in the scene is modified. Any lights, cameras or materials are passed through unaffected.

The Bender node does not produce new vertices in the geometry; only existing vertices in the geometry are altered. As a result, when applying the Bender 3D node to primitives created in Fusion, it is a good idea to increase the value of the Subdivision controls in the original primitives to give a higher quality result.

External Inputs

The following inputs appear on the node in the Node Editor.

**Bender3D.SceneInput**

[gold, required] This input expects a 3D scene.

Controls

**Bender Type**

Use the Bender Type to select the type of deformation to apply to the geometry. There are four modes available: Bend, Taper, Twist, and Shear.

**Amount**

Adjust the Amount slider to change the strength of the deformation.
**Axis**
The Axis control determines the axis along which the deformation is applied and has a different meaning depending on the type of deformation. When bending, this determines the axis that is bent, in conjunction with the Angle control. In other cases, the deform is applied around the specified axis.

**Angle**
The Angle thumbwheel control determines what direction about the axis that a bend or shear is applied. It is not visible for taper or twist deformations.

**Range**
The Range control can be used to limit the effect of a deformation to a small portion of the geometry. The Range control is not visible when the Bender Type is set to Shear.

**Group Objects**
When this is checked, all the objects in the input scene are grouped together into a single object and that object is deformed around the common center, instead of deforming each component object individually.

---

**Camera 3D [3CM]**

The Camera 3D node generates a virtual camera through which the 3D environment can be viewed. It closely emulates the settings used in both real and virtual cameras in an effort to make matching the cameras used in other scene elements as seamless as possible.

The camera should be added to the scene using a Merge 3D node. Displaying a camera node directly in the Viewer shows only an empty scene; there is nothing for the camera to see.

To view the scene through the camera, view the scene from the Merge 3D node that introduces the camera, or any node downstream of that Merge 3D. Then right click in the view and select Camera > Cameraname from the contextual menu. Right clicking on the axis label found in the bottom corner will display the Camera sub-menu directly.

The aspect of the Viewer may be different from the aspect of the camera, so that the view through the camera interactively may not match the true boundaries of the image which will actually be rendered by the Renderer 3D node. To assist you in framing the shot, guides can be enabled that represent the portion of the view the camera actually sees. Right click in the Viewer and select an option from the Guides > Frame Format sub-menu. The default option will use the format enabled in the Composition > Frame Format preferences. To toggle the guides on or off, select Guides > Show Guides from the Viewers contextual menu, or use the Command-G (macOS) or Ctrl-G (Windows) keyboard shortcut when the view is active.

The Camera 3D node can also be used to perform Camera Projection, where a 2D image is projected through the camera into 3D space. This can be done as a simple Image Plane aligned with the camera, or as an actual projection, similar to the behavior of the Projector 3D node, with the added advantage of being aligned exactly with the camera. The Image Plane, Projection and Materials tabs will not appear until a 2D image is connected to the Camera 3D node in the Node Editor.
The Camera node has built-in stereoscopic features. They offer control over eye separation and convergence distance. The camera for the right eye can be replaced using a separate camera node connected to the green input. Additionally, the plane of focus control for depth of field rendering is also available here.

If you add a camera by means of dragging the 3Cm icon from the toolbar onto the 3D view, it will automatically merge it with the scene you are viewing. In addition, it will be automatically set to the current viewpoint, and the view will be set to look through the new camera.

Alternatively, it is possible to copy the current viewpoint to a camera (or spotlight or any other object) by means of the Copy PoV To option in the Viewer’s contextual menu, under the Camera submenu.

**External Inputs**

The following inputs appear on the node in the Node Editor.

- **Camera3D.SceneInput**
  [gold, required] This input expects a 3D scene.

- **Camera3D.RightStereoCamera**
  [green, optional] This input should be connected to another Camera 3D node. It is used to override the internal camera used for the right eye in stereoscopic renders and viewers.

- **Camera3D.ImageInput**
  [magenta, optional] This input expects a 2D image. The image is used as a texture when camera projection is enabled, as well as when the camera’s image plane controls are used to produce parented planar geometry linked to the camera’s field of view.

**Controls**

The options in this tab are used to set the camera’s clipping, field of view, focal length and stereoscopic properties.
**Projection Type**
Use the Projection Type button to choose between Perspective and Orthographic cameras. Generally, real world cameras are perspective cameras. An orthographic camera uses parallel orthographic projection, a technique where the view plane is perpendicular to the viewing direction. This produces a parallel camera output that is undistorted by perspective.

Orthographic cameras only present controls for the near and far clipping planes, and a control to set the viewing volume.

**Near/Far Clip**
The clipping plane is used to limit what geometry in a scene is rendered based on the object's distance from the camera's focal point. This is useful for ensuring that objects which are extremely close to the camera are not rendered and for optimizing a render to exclude objects that are too far away to be useful in the final rendering.

The default perspective camera ignores this setting unless the Adaptively Adjust Near/Far Clip checkbox control below is disabled.

The values are expressed in units, so a far clipping plane of 20 means that any object more than 20 units distant from the camera will be invisible to the camera. A near clipping plane of 0.1 means that any object closer than 0.1 units will also be invisible.

**NOTE:** A smaller range between the near and far clipping planes allows greater accuracy in all depth calculations. If a scene begins to render strange artifacts on distant objects, try increasing the distance for the Near Clip plane.

**Adaptively Adjust Near/Far Clip**
When selected, the renderer will automatically adjust the camera's near/far clipping plane to match the extents of the scene. This setting overrides the values of the Near and Far clip range control described above. This option is not available for orthographic cameras.

**Viewing Volume Size**
The Viewing Volume Size control only appears when the Projection Type is set to Orthographic. It determines the size of the box that makes up the camera's field of view.

The Z-distance of an orthographic camera from the objects it sees does not affect the scale of those objects, only the viewing size does.

**Angle of View Type**
Use the Angle of View Type button array to choose how the camera's angle of view is measured. Some applications use vertical measurements, some use horizontal, and others use diagonal measurements. Changing the Angle of View type will cause the Angle of View control below to recalculate.

**Angle of View**
Angle of View defines the area of the scene that can be viewed through the camera. Generally, the human eye can see much more of a scene than a camera, and various lenses record different degrees of the total image. A large value produces a wider angle of view and a smaller value produces a narrower, or more tightly focused, angle of view.

The angle of view and focal length controls are directly related. Smaller focal lengths produce a wider angle of view, so changing one control automatically changes the other to match.
**Focal Length**

In the real world, a lens’ Focal Length is the distance from the center of the lens to the film plane. The shorter the focal length, the closer the focal plane is to the back of the lens. The focal length is measured in millimeters. The angle of view and focal length controls are directly related. Smaller focal lengths produce a wider angle of view, so changing one control automatically changes the other to match.

The relationship between focal length and angle of view is \( \text{angle} = 2 \times \arctan\frac{\text{aperture}}{2 \text{ focal length}} \).

Use the vertical aperture size to get the vertical angle of view and the horizontal aperture size to get the horizontal angle of view.

**Plane of Focus (for Depth of Field)**

This value is used by the OpenGL renderer to calculate depth of field. It defines the distance to a virtual target in front of the camera.

**Stereo Method**

Allows you to adjust your stereoscopic method to your preferred working model.

**Toe in**

Both cameras point at a single focal point. Though the result is stereoscopic, the vertical parallax introduced by this method can cause discomfort by the audience.

**Off Axis**

Often regarded as the correct way to create stereo pairs, this is the default method in Fusion. Off Axis introduces no vertical parallax, thus creating less stressful stereo images.
Parallel
The cameras are shifted parallel to each other. Since this is a purely parallel shift, there is no Convergence Distance control. Parallel introduces no vertical parallax, thus creating less stressful stereo images.

Eye Separation
Defines the distance between both stereo cameras. If the Eye Separation is set to a value larger than 0, controls for each camera will be shown in the Viewer when this node is selected. There is no Convergence Distance control in Parallel mode.

Convergence Distance
This control sets the stereoscopic convergence distance, defined as a point located along the Z-axis of the camera that determines where both left- and right-eye cameras converge.

Film Back

Film Gate
The Film Gate menu shows a list of preset camera types. Selecting one of the options will automatically set the aperture width and aperture height to match the selected camera type.

Aperture Width/Height
The Aperture Width and Height sliders control the dimensions of the camera’s aperture, or the portion of the camera that lets light in on a real world camera. In video and film cameras, the aperture is the mask opening that defines the area of each frame exposed. Aperture is generally measured in inches, which are the units used for this control.

Resolution Gate Fit
Determines how the film gate is fit within the resolution gate. This only has an effect when the aspect of the film gate is not the same aspect as the output image. This setting corresponds to the Maya Fit Resolution Gate. The modes Overscan, Horizontal, Vertical and Fill correspond to Inside, Width, Height, and Outside.

- **Inside**: The image source will be scaled uniformly until one of its dimensions (X or Y) fits the inside dimensions of the mask. Depending on the relative dimensions of image source and mask background, either the image source’s width or height may be cropped to fit the respective dimension of the mask.
• **Width:** The image source will be scaled uniformly until its width (X) fits the width of the mask. Depending on the relative dimensions of image source and mask, the image source’s Y-dimension might not fit the mask’s Y-dimension, resulting in either cropping of the image source in Y or the image source not covering the mask’s height entirely.

• **Height:** The image source will be scaled uniformly until its height (Y) fits the height of the mask. Depending on the relative dimensions of image source and mask, the image source’s X-dimension might not fit the mask’s X-dimension, resulting in either cropping of the image source in X or the image source not covering the mask’s width entirely.

• **Outside:** The image source will be scaled uniformly until one of its dimensions (X or Y) fits the outside dimensions of the mask. Depending on the relative dimensions of image source and mask, either the image source’s width or height may be cropped or not fit the respective dimension of the mask.

• **Stretch:** The image source will be stretched in X and Y to accommodate the full dimensions of the generated mask. This might lead to visible distortions of the image source.

**Control Visibility**

Allows you to selectively activate the onscreen controls that are displayed along with the camera.

• **Frustrum:** Displays the actual viewing cone of the camera.

• **View Vector:** Displays a white line inside the viewing cone, which can be used to determine the shift when in Parallel mode.

• **Near Clip:** The Near clipping plane. This plane can be subdivided for better visibility.

• **Far Clip:** The Far clipping plane. This plane can be subdivided for better visibility.

• **Plane of Focus:** The plane of focus according to the respective slider explained above. This plane can be subdivided for better visibility.

• **Convergence Distance:** The point of convergence when using Stereo mode. This plane can be subdivided for better visibility.

**Import Camera**

The Import Camera button displays a dialog to import a camera from another application.

It supports the following file types:

<table>
<thead>
<tr>
<th>Format Type</th>
<th>File Extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>LightWave Scene</td>
<td>.lws</td>
</tr>
<tr>
<td>Max Scene</td>
<td>.ase</td>
</tr>
<tr>
<td>Maya Ascii Scene</td>
<td>.ma</td>
</tr>
<tr>
<td>*dotXSI</td>
<td>.xsi</td>
</tr>
</tbody>
</table>

**Image**

When a 2D image is connected to the camera, an Image Plane is created that is always oriented so that the image fills the camera’s field of view. The Image Plane tab is hidden until a 2D image is connected to the Camera 3D’s input on the node tree.

With the exception of the controls listed below, the options presented in this tab are identical to those presented in the Image Plane node’s control tab. Consult that node documentation for a detailed description.
Enable Image Plane
Use this checkbox to enable or disable the creation of the Image Plane.

Fill Method
Describes how to deal with the input image if the camera has a different aspect ratio.

- **Inside:** The image source will be scaled uniformly until one of its dimensions (X or Y) fits the inside dimensions of the mask. Depending on the relative dimensions of image source and mask background, either the image source’s width or height may be cropped to fit the respective dimension of the mask.

- **Width:** The image source will be scaled uniformly until its width (X) fits the width of the mask. Depending on the relative dimensions of image source and mask, the image source’s Y-dimension might not fit the mask’s Y-dimension, resulting in either cropping of the image source in Y or the image source not covering the mask’s height entirely.

- **Height:** The image source will be scaled uniformly until its height (Y) fits the height of the mask. Depending on the relative dimensions of image source and mask, the image source’s X-dimension might not fit the mask’s X-dimension, resulting in either cropping of the image source in X or the image source not covering the mask’s width entirely.

- **Outside:** The image source will be scaled uniformly until one of its dimensions (X or Y) fits the outside dimensions of the Mask. Depending on the relative dimensions of image source and mask, either the image source’s width or height may be cropped or not fit the respective dimension of the mask.

- **Depth:** The Depth slider controls the image plane’s distance from the camera.
**Projection**

If a 2D image is connected to the camera it becomes possible to project the image into the scene. A projection is different from an image plane in that the projection will fall onto the geometry in the scene exactly as if there was a physical projector present in the scene. The image is projected as light, which means the renderer must be set to enable lighting for the projection to be visible. See the Projector 3D node for additional information.

**Enable Camera Projection**

Select this checkbox to enable projection of the 2D image connected to the Camera node.

**Projection Fit Method**

This button array can be used to select the method used to match the aspect of projected image to the camera’s field of view.

**Projection Mode**

- **Light**: Defines the projection as a spotlight.
- **Ambient Light**: Defines the projection as an ambient light.
- **Texture**: Allows a projection which can be relighted using other lights. Needs a Catcher node connected to the appropriate input ports of the specific material.
**Tips for Camera 3D**

When importing a camera from a 3D application that will also be used as a projector, make sure that the Fit Resolution Gate options on the main Controls tab as well as the Projection tab are in sync. Only the first one will automatically be set to what the 3D app was using. The latter might have to be adjusted manually.

The camera’s image plane isn’t just a virtual guide for you in the Viewers. It’s actual geometry that you can also project onto. You need to use a Replace Material node after your Camera node.

**To achieve real Parallel Stereo mode you can:**

- Connect an additional external (right) camera to “Right Stereo Camera” input of your camera.
- Create separate left and right cameras
- Set the ConvergenceDistance slider to a very large value of 999999999.

**Rendering with Overscan from Fusion’s 3D Space**

If you want to render an image with overscan you also have to modify your scene’s Camera3D. Since overscan settings aren’t exported along with camera data from 3D applications, this is also necessary for cameras you’ve imported via .fbx or .ma files. The solution is to increase the film back’s width and height by the factor necessary to account for extra pixels on each side.

**Cube 3D [3CB]**

The Cube 3D node is a basic primitive geometry type capable of generating a simple cube. The node also provides six additional image inputs that can be used to map a texture onto the six faces of the cube. Cubes are often used as shadow casting objects and for environment maps. For other basic primitives, see the Shape 3D node.

**External Inputs**

- **Cube3D.SceneInput**
  [orange, optional] This input expects a scene from a 3D node output.

- **Cube3D.NameMaterialInput**
  These 6 inputs are used to define the materials applied to the six faces of the cube. They will accept either a 2D image or a 3D material as valid.
**Controls**

**Lock Width/Height/Depth**
This checkbox locks the Width, Height, and Depth dimensions of the cube together, so that they are always the same size. When selected, only a Size control is displayed, otherwise separate Width, Height, and Depth sliders are shown.

**Size or Width/Height/Depth**
If the Lock checkbox is selected then only the Size slider is shown, otherwise separate sliders are displayed for Width, Height, and Depth. The Size and Width sliders are the same control renamed, so any animation applied to Size will also be applied to Width when the controls are unlocked.

**Subdivision Level**
Use the Subdivision Level slider to set the number of subdivisions used when creating the image plane.

If the Open GL viewer and renderer are set to Vertex lighting, the more subdivisions in the mesh, the more vertices will be available to represent the lighting. For this reason, high subdivisions can be useful when working interactively with lights.

**Cube Mapping**
Enabling the Cube Mapping checkbox causes the cube to wrap its first texture across all six faces using a standard cubic mapping technique. This approach expects a texture laid out in the shape of a cross.

**Wireframe**
Enabling this checkbox will cause the Mesh to render only the Wireframe for the object when rendering with the OpenGL renderer.
Visibility

- **Visible**: If the Visibility checkbox is not selected, the object will not be visible in the Viewers, nor will it be rendered into the output image by the Renderer 3D node. A non-visible object does not cast shadows.

- **Unseen by Cameras**: If the unseen by cameras checkbox is selected, the object will be visible in the Viewers (unless the Visible checkbox is turned off), except when viewed through a camera. The object will not be rendered into the output image by the Renderer 3D node. Shadows cast by an unseen object will still be visible when rendered by the Software renderer, though not by the OpenGL renderer.

- **Cull Front Face/Back Face**: Use these options to cull (eliminate) rendering and display of certain polygons in the geometry. If Cull Back Face is selected, all polygons facing away from the camera will not be rendered, and will not cast shadows. If Cull Front Face is selected, all polygons facing toward the camera will likewise be dropped. Selecting both checkboxes has the same effect as deselecting the Visible checkbox.

- **Ignore Transparent Pixels in Aux Channels**: In previous versions of Fusion, transparent pixels were rejected by the software/GL renderers. To be more specific, the software renderer rejected pixels with R=G=B=A=0 and the GL renderer rejected pixels with A=0. This is now optional. The reason you might want to do this is to get aux channels (e.g., Normals, Z, UVs) for the transparent areas. For example, suppose in post you want to replace the texture on a 3D element that is transparent in certain areas with a texture that is transparent in different areas, then it would be useful to have transparent areas set aux channels (in particular UVs). As another example, suppose you are doing post DoF. You will probably not want the Z-channel to be set on transparent areas, as this will give you a false depth. Also, keep in mind that this rejection is based on the final pixel color including lighting, if it is on. So if you have a specular highlight on a clear glass material, this checkbox will not affect it.

Lighting

- **Affected by Lights**: If this checkbox is not selected, lights in the scene will not affect the object, it will not receive nor cast shadows, and it will be shown at the full brightness of its color, texture or material.

- **Shadow Caster**: If this checkbox is not enabled, the object will not cast shadows on other objects in the scene.

- **Shadow Receiver**: If this checkbox is not enabled, the object will not receive shadows cast by other objects in the scene.

Matte

Enabling the Is Matte option will apply a special texture to this object, causing this object to not only become invisible to the camera, but also making everything that appears directly behind the camera invisible as well. This option will override all textures. See the Matte Objects section of Chapter 60, “3D Compositing Basics,” for more information.

- **Is Matte**: When activated, objects whose pixels fall behind the matte object’s pixels in Z do not get rendered.

- **Opaque Alpha**: Sets the alpha value of the matte object to 1. This checkbox is only visible when the Is Matte option is enabled.

- **Infinite Z**: Sets the value in the Z-channel to infinite. This checkbox is only visible when the Is Matte option is enabled.
Blend Mode
A Blend mode specifies which method will be used by the renderer when combining this object with the rest of the scene. The blend modes are essentially identical to those listed in the section for the 2D Merge node. For a detailed explanation of each mode, see the section for that node.

The blending modes were originally designed for use with 2D images. Using them in a lit 3D environment can produce undesirable results. For best results, use the Apply modes in unlit 3D scenes rendered in software.

- **OpenGL Blend Mode:** Use this menu to select the blending mode that will be used when the geometry is processed by the OpenGL renderer. This is also the mode used when viewing the object in the Viewers. Currently the OpenGL renderer supports three blending modes.
- **Software Blend Mode:** Use this menu to select the blending mode that will be used when the geometry is processed by the software renderer. Currently, the software renderer supports all of the modes described in the Merge node documentation, except for the Dissolve mode.

Material Tab
The options which appear in this tab determine the appearance of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

If an external 3D material is connected to the node’s material input, then the controls in this tab will be replaced with the “Using External Material” label.
Transform Tab

The options which appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

Custom Vertex 3D [3CV]

This is a custom node for 3D geometry that can be used to do per vertex manipulations, for example on an image plane like: \((px, py, \sin(10*(px^2 + py^2) + n1))\). Other vertex attributes like normals, vertex color, texture coordinates, tangents, and velocity can be modified as well.

**NOTE:** Modifying the X, Y and Z positions of a 3D object does not modify the normals/tangents. You can use a ReplaceNormals node afterwards to recompute the normals/tangents.

**TIP:** Not all geometry has all vertex attributes. For example, most Fusion geometry does not have vertex colors, with the exception of particles and some imported FBX/Alembic meshes.
No geometry has envcoord currently. Only particles have velocities. If a stream is not present on the input geometry it is assumed to have a default value.

**NOTE:** Missing streams on the input geometry are created if the expression for a stream is non-trivial. The values for the streams will be as given in the above point. For example, if the input geometry does not have normals, then the values of \((nx, ny, nz)\) will always be \((0,0,1)\). To change this, you could use a ReplaceNormals node beforehand to generate them.

### Controls

The Displace 3D node is used to displace the vertices of an object along their normals based upon a reference image. The texture coordinates on the geometry are used to determine where to sample the image.

**Displace 3D [3DI]**

The Displace 3D node is used to displace the vertices of an object along their normals based upon a reference image. The texture coordinates on the geometry are used to determine where to sample the image.
When using Displace 3D, keep in mind that it will only displace existing vertices and will not tessellate objects. To obtain a more detailed displacement, increase the subdivision amount for the geometry that is being displaced. Note that the pixels in the displacement image may contain negative values.

Passing a particle system through a Displace 3D node will disable the Always Face Camera option set in the pEmitter. Particles are not treated as point-like objects; each of the four particle vertices are individually displaced, which may or may not be the preferred outcome.

**External Inputs**

- **Displace3D.SceneInput**
  [orange, required] This input expects to receive a 3D scene.

- **Displace3D.Input**
  [green, optional] This input expects a 2D image to be used as the displacement map. If no image is provided, this node will effectively pass the scene straight through to its output.

**Controls**

**Channel**
Determines which channel of the image is connected to Displace3D. Input is used to displace the geometry.

**Scale and Bias**
Use these sliders to scale (magnify) and bias (offset) the displacement. The bias is applied first and the scale afterwards.

**Camera Displacement**
- **Point to Camera**: When the Point to Camera checkbox is enabled, each vertex is displaced towards the camera rather than along its normal. One possible use of this option is for displacing a camera’s image plane. The displaced camera image plane would appear unchanged when viewed through the camera, but is deformed in 3D space, allowing one to comp in other 3D layers that correctly interact in Z.
- **Camera**: This drop-down box is used to select which camera viewer in the scene is used to determine the camera displacement when the Point to Camera option is selected.
Duplicate 3D [3DP]

The Duplicate 3D node can be used to quickly duplicate any geometry in a scene, applying a successive transformation to each, and creating repeating patterns and complex arrays of objects. The options in the Jitter tab allow for non-uniform transformations, such as random positioning or sizes.

External Inputs

Duplicate3D.SceneInput
[orange, required] This input expects a 3D scene.

Controls
**First/Last Copy**
Use this range control to set how many copies of the geometry to make. Each copy is a copy of the last copy so, if this control is set to [0,3], the parent is copied, then the copy is copied, then the copy of the copy is copied, and so on. This allows for some interesting effects when transformations are applied to each copy using the controls below.

Using a value for both the First Copy and the Last Copy will show only the original input. Setting the First Copy to a value greater than 0 will exclude the original input and show only the copies.

**Time Offset**
Use the Time Offset slider to offset any animations that are applied to the source geometry by a set amount per copy. For example, set the value to -1.0 and use a cube set to rotate on the Y-axis as the source. The first copy will show the animation from a frame earlier. The second copy will show animation from a frame before that, and so forth. This can be used with great effect on textured planes, for example, where successive frames of a clip can be shown.

**Transform Method**

**Accumulated**
When set to Accumulated, each object copy starts at the position of the previous object and is transformed from there. The result is transformed again for the next copy.

**Linear**
When set to Linear, transforms are multiplied by the number of the copy, and the total scale, rotation, and translation are applied in turn, independent of the other copies.

**Transform Order**
With these buttons, the order in which the transforms are calculated can be set. It defaults to Scale-Rotation-Transform (SRT).

Using different orders will result in different positions of your final objects.
**Jitter**

**XYZ Offset**
These three sliders tell the node how much offset to apply to each copy. An X offset of 1 would offset each copy 1 unit along the X-axis from the last copy.

**Rotation Order**
These buttons can be used to set the order in which rotations are applied to the geometry. Setting the rotation order to XYZ would apply the rotation on the X-axis first, followed by the Y-axis rotation, then the Z-axis rotation.

**XYZ Rotation**
These three Rotation sliders tell the node how much rotation to apply to each copy.

**XYZ Pivot**
The pivot controls determine the position of the pivot point used when rotating each copy.

**Lock XYZ**
When the Lock XYZ checkbox is selected, any adjustment to the duplicate scale will be applied to all three axes simultaneously. If this checkbox is disabled, the scale slider will be replaced with individual sliders for the X, Y, and Z scale.

**Scale**
The scale controls tell Duplicate how much scaling to apply to each copy.

**Random Seed/Randomize**
The Random Seed is used to ‘seed’ the amount of jitter applied to the duplicated objects. Two Duplicate nodes with identical settings but different random seeds will produce two completely different results. Click on the Randomize button to assign a random seed value.
Time Offset
Use the Time Offset slider to offset any animations that are applied to the source geometry by a set amount per copy. For example, set the value to –1.0 and use a cube set to rotate on the Y-axis as the source. The first copy will show the animation from a frame earlier. The second copy will show animation from a frame before that, and so forth. This can be used with great effect on textured planes, for example, where successive frames of a clip can be shown.

Translation XYZ Jitter
Use these three controls to adjust the amount of variation in the translation of the duplicated objects.

Rotation XYZ Jitter
Use these three controls to adjust the amount of variation in the rotation of the duplicated objects.

Pivot XYZ Jitter
Use these three controls to adjust the amount of variation in the rotational pivot center of the duplicated objects. This affects only the additional jitter rotation, not the rotation produced by the Rotation settings in the Controls tab.

Scale XYZ Jitter
Use this control to adjust the amount of variation in the scale of the duplicated objects. Uncheck the Lock XYZ checkbox to adjust the scale variation independently on all three axes.

FBX Exporter 3D [FBX]

The FBX Exporter provides a method of exporting a Fusion 3D scene to the FBX scene interchange format. Each node in Fusion is a single object in the exported file. Objects, lights, and cameras will use the name of the node that created them. The node can be set to export a single file for the entire scene, or to output one frame per file.

In addition to the FBX format, this node can also export to the 3D Studio’s .3ds, Collada’s .dae, Autocad’s .dxf and the Alias .obj formats.

External Inputs

**FBXExporter.Input**
[orange, required] This input expects a 3D scene.
Controls

Filename
This file browser control can be used to set the file which will be output by the node. Click on the yellow folder icon to open a file browser dialog.

Format
This control is used to set the format of the output file.
Not all of the formats support all of the features of this node. For example, the obj format does not handle animation.

Version
The Version drop-down menu shows the available versions for the format selected by the control above. The menu’s contents will change dynamically to reflect the available versions for that format. If the selected format only provides a single option, this menu will be hidden.
Choosing Default for the FBX formats uses FBX200611.

Geometry/Lights/Cameras
These three checkbox controls determine whether the node will attempt to export the named scene element. For example, deseleceting Geometry and Lights but leaving Cameras selected would output only the cameras currently in the scene.

Reduce Constant Keys
Enabling this option will automatically remove keyframes if the adjacent keyframes have the same value.

File Per Frame (No Animation)
Enabling this option will force the node to export one file per frame, resulting in a sequence of numbered files. This will disable the export of animation.
Set Sequence Start

Normally, Fusion will use the render range of a composition to determine the numeric sequence used when rendering a file sequence to disk. Enable this checkbox to reveal the Sequence Start Frame control to set the number of the first frame in the sequence to a custom value.

Sequence Start Frame

This thumbwheel control can be used to set an explicit start frame for the number sequence applied to the rendered filenames. For example, if Global Start is set to 1 and frames 1–30 are rendered, files will normally be numbered 0001–0030. If the Sequence Start frame is set to 100, the rendered output would be numbered from 100–131.

FBX Mesh 3D [FBX]

The FBXMesh3D node is used to import polygonal geometry from scene files that are saved using the FilmBox (FBX) format. It is also able to import geometry from OBJ, 3DS, DAE, and DXF scene files. This provides a method for working with more complex geometry than is available using Fusion’s built-in primitives.

When importing geometry with this node, all of the geometry contained in the FBX file will be combined into one mesh with a single pivot and transformation. The FBXMesh node will ignore any animation applied to the geometry.

The File > Import > FBX utility can be used to import an FBX and create individual nodes for each camera, light and mesh contained in the file. This utility can also be used to preserve the animation of the objects.

If the Global > General > Auto Clip Browse option is enabled (default) then adding this node to a composition from the toolbars or menus will automatically display a file browser.

External Inputs

**FBXMesh3D.SceneInput**
[orange, required] This input expects a 3D scene as its input.

**FBXMesh.MaterialInput**
[green, optional] This input will accept either a 2D image or a 3D material. If a 2D image is provided, it will be used as a diffuse texture map for the basic material built into the node. If a 3D material is connected, then the basic material will be disabled.
**Controls**

**Size**
The Size slider controls the size of the FBX geometry that is imported. FBX meshes have a tendency to be much larger than Fusion’s default unit scale, so this control is useful for scaling the imported geometry to match the Fusion environment.

**FBX File**
This control shows the filename of the currently loaded FBX. Click on the icon of the yellow folder to open a file browser that can be used to locate an FBX file. Despite the node’s name, this node is also able to load a variety of other formats.

</table>
Object Name
This input shows the name of the mesh from the FBX file that is being imported. If this field is blank, then the entire contents of the FBX geometry will be imported as a single mesh. This input is not editable by the user; it is set by Fusion when importing FBX files via the File > Import > FBX utility.

Take Name
This input shows the name of the animation take to use from the FBX file. If this field is blank, then no animations will be imported. This input is not editable by the user; it is set by Fusion when importing FBX files via the File > Import > FBX utility.

Wireframe
Enabling this checkbox will cause the mesh to render only the Wireframe for the object. Currently, only the OpenGL renderer supports wireframe rendering.

Visibility
- **Visible:** If the visibility checkbox is not selected, the object will not be visible in the Viewers, nor will it be rendered into the output image by the Renderer 3D node. A non-visible object does not cast shadows.
- **Unseen by Cameras:** If the Unseen by Cameras checkbox is selected, the object will be visible in the Viewers (unless the Visible checkbox is turned off), except when viewed through a camera. The object will not be rendered into the output image by the Renderer 3D node. Shadows cast by an Unseen object will still be visible when rendered by the software renderer, though not by the OpenGL renderer.
- **Cull Front Face/Back Face:** Use these options to cull (eliminate) rendering and display of certain polygons in the geometry. If Cull Back Face is selected, all polygons facing away from the camera will not be rendered, and will not cast shadows. If Cull Front Face is selected, all polygons facing toward the camera will likewise be dropped. Selecting both checkboxes has the same effect as deselecting the Visible checkbox.
- **Ignore Transparent Pixels in Aux Channels:** In previous versions of Fusion, transparent pixels were rejected by the software/GL renderers. To be more specific the software renderer rejected pixels with R=G=B=A=0 and the GL renderer rejected pixels with A=0. This is now optional. The reason you might want to do this is to get aux channels (e.g., Normals, Z, UVs) for the transparent areas. For example, suppose in post you want to replace the texture on a 3D element that is transparent in certain areas with a texture that is transparent in different areas, then it would be useful to have transparent areas set aux channels (in particular UVs). As another example, suppose you are doing post DoF. You will probably not want the Z-channel to be set on transparent areas, as this will give you a false depth. Also keep in mind that this rejection is based on the final pixel color including lighting, if it is on. So if you have a specular highlight on a clear glass material, this checkbox will not affect it.

Lighting
- **Affected by Lights:** If this checkbox is not selected, lights in the scene will not affect the object, it will not receive nor cast shadows, and it will be shown at the full brightness of its color, texture or material.
- **Shadow Caster:** If this checkbox is not enabled, the object will not cast shadows on other objects in the scene.
- **Shadow Receiver:** If this checkbox is not enabled, the object will not receive shadows cast by other objects in the scene.
**Matte**

Enabling the Is Matte option will apply a special texture to this object, causing this object to not only become invisible to the camera but also making everything that appears directly behind the camera invisible as well. This option will override all textures. See the Matte Objects section of Chapter 60, “3D Compositing Basics,” for more information.

- **Is Matte:** When activated, objects whose pixels fall behind the matte object’s pixels in Z do not get rendered.
- **Opaque Alpha:** Sets the alpha value of the matte object to 1. This checkbox is only visible when the Is Matte option is enabled.
- **Infinite Z:** Sets the value in the Z-channel to infinite. This checkbox is only visible when the Is Matte option is enabled.

**Blend Mode**

A blend mode specifies which method will be used by the renderer when combining this object with the rest of the scene. The blend modes are essentially identical to those listed in the section for the 2D Merge node. For a detailed explanation of each mode see the section for that node.

The blending modes were originally designed for use with 2D images. Using them in a lit 3D environment can produce undesirable results. For best results use the Apply modes in unlit 3D scenes rendered in software.

- **OpenGL Blend Mode:** Use this menu to select the blending mode that will be used when the geometry is processed by the OpenGL renderer. This is also the mode used when viewing the object in the Viewer. Currently the OpenGL renderer supports three blending modes.
- **Software Blend Mode:** Use this menu to select the blending mode that will be used when the geometry is processed by the software renderer. Currently the software renderer supports all of the modes described in the Merge node documentation, except for the Dissolve mode.

**Material Tab**

The options that appear in this tab determine the appearance of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

If an external 3D material is connected to the node’s material input, then the controls in this tab would be replaced with the Using External Material label.
Transform Tab

The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.
Fog 3D [3FO]

The Fog 3D node applies depth cue based fog to the scene. It is the 3D version of the Fog node in the Deep Pixel category. It is designed to work completely in 3D space and takes full advantage of antialiasing and depth of field effects during rendering.

The Fog 3D node essentially re-textures the geometry in the scene by applying a color correction based on the object’s distance from the camera. An optional density texture image can be used to apply variation to the correction.

External Inputs

Fog3D.SceneInput
[orange, required] This input expects a 3D scene.

Fog3D.DensityTexture
[green, optional] This input expects a 2D image. The color of the fog created by this node is multiplied by the pixels in the image. When creating the image for the density texture, keep in mind that the texture is effectively projected onto the scene from the camera.

Controls
Enable
Use this checkbox to enable or disable the node.

Show Fog in View
By default, the fog created by this node is only visible when the scene is viewed using a camera node. When this checkbox is enabled, the fog becomes visible in the scene from all points of view.

Color
This control can be used to set the color of the fog. The color is also multiplied by the densitytexture image, if one has been provided.

Radial
By default, the fog is done based upon the perpendicular distance to a plane (parallel with the near plane) passing through the eye point. When the Radial option is checked, the radial distance to the eye point is used instead of the perpendicular distance. The problem with perpendicular distance fog is that when you move the camera about, as objects move to the left or right side of the frustum move into the center, they become less fogged even though they remain the same distance from the eye. Radial fog fixes this. Sometimes Radial fog is not desirable. For example, if you are fogging an object that is close to the camera, like an image plane, the center of the image plane could be unfogged while the edges could be fully fogged.

Fog type
This control is used to determine the type of falloff applied to the fog.

- **Linear**: Defines a linear falloff for the fog.
- **Exp**: Creates a nonlinear exponential falloff.
- **Exp2**: Creates a stronger exponential falloff.

Near/Far Fog Distance
This control expresses the range of the fog in the scene as units of distance from the camera. The Near Distance determines where the fog starts, while the Far Distance sets the point where the fog has its maximum effect. Fog is cumulative, so the farther an object is from the camera, the thicker the fog should appear.
Image Plane 3D [3IM]

The Image Plane node produces 2D planar geometry in 3D space. The most common use of the node is to represent 2D images in the 3D space. An image input on the node provides the texture for the rectangle from another source in the composition. The aspect of the image plane is determined by the aspect of the image used for its diffuse texture. If planar geometry, whose dimensions are not relative to the texture image, is required, then use a Shape 3D node instead.

External Inputs

- **Imageplane3D.SceneInput**
  [orange, optional] This input expects a 3D scene. As this node creates geometry, it is not required.

- **Imageplane3D.MaterialInput**
  [green, optional] This input will accept either a 2D image or a 3D material. If a 2D image is provided, it will be used as a diffuse texture map for the basic material built into the node. If a 3D material is connected, then the basic material will be disabled.

Controls
Lock Width/Height
When checked, the subdivision of the plane will be applied evenly in X and Y. When unchecked, there are two sliders for individual control of the subdivisions in X and Y. Defaults to on.

Subdivision Level
Use the Subdivision Level slider to set the number of subdivisions used when creating the image plane. If the Open GL viewer and renderer are set to Vertex lighting, the more subdivisions in the mesh, the more vertices will be available to represent the lighting. For this reason, high subdivisions can be useful when working interactively with lights.

Wireframe
Enabling this checkbox will cause the Mesh to render only the wireframe for the object when using the OpenGL renderer.

Visibility
- **Visible:** If the Visibility checkbox is not selected, the object will not be visible in the Viewer, nor will it be rendered into the output image by the Renderer 3D node. A non-visible object does not cast shadows.
- **Unseen by Cameras:** If the Unseen by Cameras checkbox is selected, the object will be visible in the Viewers (unless the Visible checkbox is turned off), except when viewed through a camera. The object will not be rendered into the output image by the Renderer 3D node. Shadows cast by an Unseen object will still be visible when rendered by the software renderer, though not by the OpenGL renderer.
- **Cull Front Face/Back Face:** Use these options to cull (eliminate) rendering and display of certain polygons in the geometry. If Cull Back Face is selected, all polygons facing away from the camera will not be rendered, and will not cast shadows. If Cull Front Face is selected, all polygons facing toward the camera will likewise be dropped. Selecting both checkboxes has the same effect as deselecting the Visible checkbox.
- **Ignore Transparent Pixels in Aux Channels:** In previous versions of Fusion, transparent pixels were rejected by the software/GL renderers. To be more specific, the software renderer rejected pixels with R=G=B=A=0 and the GL renderer rejected pixels with A=0. This is now optional. The reason you might want to do this is to get aux channels (e.g., Normals, Z, UVs) for the transparent areas. For example, suppose in post you want to replace the texture on a 3D element that is transparent in certain areas with a texture that is transparent in different areas, then it would be useful to have transparent areas set aux channels (in particular UVs). As another example suppose you are doing post DoF. You will probably not want the Z-channel to be set on transparent areas, as this will give you a false depth. Also keep in mind that this rejection is based on the final pixel color including lighting, if it is on. So if you have a specular highlight on a clear glass material, this checkbox will not affect it.

Lighting
- **Affected by Lights:** If this checkbox is not selected, lights in the scene will not affect the object, it will not receive nor cast shadows, and it will be shown at the full brightness of its color, texture, or material.
- **Shadow Caster:** If this checkbox is not enabled, the object will not cast shadows on other objects in the scene.
- **Shadow Receiver:** If this checkbox is not enabled, the object will not receive shadows cast by other objects in the scene.
Matte
Enabling the Is Matte option will apply a special texture to this object, causing this object to not only become invisible to the camera, but also making everything that appears directly behind the camera invisible as well. This option will override all textures. See the Matte Objects section of Chapter 60, “3D Compositing Basics,” for more information.

- **Is Matte**: When activated, objects whose pixels fall behind the matte objects pixels in Z do not get rendered.
- **Opaque Alpha**: Sets the alpha value of the matte object to 1. This checkbox is only visible when the Is Matte option is enabled.
- **Infinite Z**: Sets the value in the Z-channel to infinite. This checkbox is only visible when the Is Matte option is enabled.

Blend Mode
A blend mode specifies which method will be used by the renderer when combining this object with the rest of the scene. The Blend modes are essentially identical to those listed in the section for the 2D Merge node. For a detailed explanation of each mode, see the section for that node.

The blending modes were originally designed for use with 2D images. Using them in a lit 3D environment can produce undesirable results. For best results use the apply modes in unlit 3D scenes rendered in software.

- **OpenGL Blend Mode**: Use this menu to select the blending mode that will be used when the geometry is processed by the OpenGL renderer. This is also the mode used when displaying the object in the Viewers. Currently the OpenGL renderer supports three blending modes.
- **Software Blend Mode**: Use this menu to select the blending mode that will be used when the geometry is processed by the software renderer. Currently the software renderer supports all of the modes described in the Merge node documentation except for the Dissolve mode.

Material Tab
The options that appear in this tab determine the appearance of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

If an external 3D material is connected to the node’s material input, then the controls in this tab would be replaced with the Using External Material label.
Transform Tab
The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.
Locator 3D [3LO]

The Locator 3D node’s purpose is to transform a point in 3D space to 2D coordinates that other nodes can use as part of expressions or modifiers.

When the Locator is provided with a camera and the dimensions of the output image, it will transform the coordinates of a 3D control into 2D screen space. The 2D position is exposed as a numeric output which can be connected to/from other nodes. For example, to connect the center of an ellipse to the 2D position of the Locator, right-click on the Mask center control and select Connect To > Locator 3D > Position.

The scene provided to the Locator’s input must contain the camera through which the coordinates are projected. As a result, the best practice is to place the Locator after the merge that introduces the camera to the scene.

If an object is connected to the Locator node’s second input, the Locator will be positioned at the object’s center, and the Transformation tab’s Offset XYZ sliders will function in the object’s local coordinate space rather than global scene space. This is useful for tracking an object’s position regardless of any additional transformations applied further downstream.

External Inputs

Locator3D.SceneInput
[orange, required] This input expects a 3D scene.

Locator3D.Target
[green, optional] This input expects a 3D scene. When provided, the transform center of the scene is used to set the position of the Locator. The transformation controls for the Locator become offsets from this position.

Controls
Size
The Size slider is used to set the size of the Locator’s onscreen crosshair.

Color
A basic Color control is used to set the color of the Locator’s onscreen crosshair.

Matte
Enabling the Is Matte option will apply a special texture to this object, causing this object to not only become invisible to the camera, but also making everything that appears directly behind the camera invisible as well. This option will override all textures. See the Matte Objects section of Chapter 60, “3D Compositing Basics,” for more information.

- **Is Matte:** When activated, objects whose pixels fall behind the matte object’s pixels in Z do not get rendered.
- **Opaque Alpha:** Sets the alpha value of the matte object to 1. This checkbox is only visible when the Is Matte option is enabled.
- **Infinite Z:** Sets the value in the Z-channel to infinite. This checkbox is only visible when the Is Matte option is enabled.

Sub id
The Sub ID slider can be used to select an individual sub-element of certain geometry, such as an individual character produced by a Text 3D node, or a specific copy created by a Duplicate 3D node.

Make Renderable
Defines if the Locator is rendered as a visible object by the OpenGL renderer. The software renderer is not currently capable of rendering lines and hence will ignore this option.

Unseen by Camera
This checkbox control appears when the Make Renderable option is selected. If the Unseen by Camera checkbox is selected, the Locator will be visible in the Viewers, but not rendered into the output image by the Renderer 3D node.

Camera
This drop-down control is used to select the Camera in the scene that defines the screen space used for 3D to 2D coordinate transformation.

Use Frame Format Settings
Select this checkbox to override the width, height, and pixel aspect controls, and force them to use the values defined in the composition’s Frame Format preferences instead.

Width, Height, and Pixel Aspect
In order for the Locator to generate a correct 2D transformation, it must know the dimensions and aspect of the image. These controls should be set to the same dimensions as the image produced by a renderer associated with the camera specified above. Right-clicking on these controls will display a contextual menu containing the frame formats configured in the composition’s preferences.
Merge 3D [3MG]

The Merge 3D node is used to combine separate 3D elements into the same 3D environment. For example, with a scene that is created with an image plane, a camera and a light, the camera would not be able to see the image plane and the light would not affect the image plane until all three objects are introduced into the same environment using the Merge 3D node.

The node displays only two inputs at first, but as each input is connected a new input will appear on the node, assuring there is always one free to add a new element into the scene.

The Merge provides the standard transformation controls found on most nodes in Fusion’s 3D suite. Unlike those nodes, changes made to the translation, rotation or scale of the merge affect all of the objects connected to the merge. This behavior forms the basis for all parenting in Fusion’s 3D environment.

External Inputs

Merge3D.SceneInput[#]

[any, see description] These inputs expect a 3D scene. When the node is constructed it will display two inputs. There is no limit to the number of inputs this node can accept. The node dynamically adds more inputs as needed, ensuring that there is always at least one input available for connection.

Controls

Pass Through Lights

When the Pass Through Lights checkbox is selected, lights will be passed through the merge into its output so they can affect downstream elements. Normally, the lights are not passed downstream to affect the rest of the scene. This is frequently used to ensure projections are not applied to geometry introduced later in the scene.

Transform Tab

The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.
Override 3D [3OV]

The Override node lets you change object-specific options for every object in a 3D scene simultaneously. This is useful, for example, when you wish to set every object in the input scene to render as a wireframe. Additionally, this node is the only way to set the wireframe, visibility, lighting, matte, and ID options for 3D particle systems and the Text 3D node.

It is frequently used in conjunction with the Replace Material node to produce isolated passes. For example, a scene can be branched out to an Override node which turns off the Affected by Lights property of each node, then connected to a Replace Material node that applies a Falloff shader to produce a falloff pass of the scene.

External Inputs

Override3D.SceneInput
[orange, required] This input expects a 3D scene.

Controls

The philosophy of the controls found in the Override node is fairly straightforward. First, you select the option to override using the Do [Option] checkbox. That will reveal a control that can be used to set the value of the option itself. The individual options are not documented here; a full description of each can be found in any geometry creation node, such as the Image Plane, Cube or Shape nodes.
**Do [option]**
Enables the override for this option.

**[Option]**
If the Do [option] checkbox is enabled, then the control for the property itself becomes visible. The control values of the properties for all upstream objects are overridden by the new value.

---

**Point Cloud 3D [3PC]**

A Point Cloud is generally a large number of nulls created by 3D tracking or modeling software. When produced by 3D tracking software, the points typically represent each of the patterns tracked to create the 3D camera path. These point clouds can be used to identify a ground plane and to orient other 3D elements with the tracked image. The Point Cloud 3D node creates a point cloud by importing a 3D scene.

**External Inputs**

**Pointcloud3DSceneInput**
[orange, required] This input expects a 3D scene.
Controls

Lock x/y/Z
Deselect this checkbox to provide individual control over the size of the X, Y, and Z arms of the points in the cloud.

Size X/Y/Z
These sliders can be used to increase the size of the onscreen crosshairs used to represent each point.

Density
This slider defines the probability of displaying a specific point. If the value is 1, then all points are displayed. A value of 0.2 shows only every fifth point.

Color
Use the standard Color control to set the color of onscreen crosshair controls.

Import Point Cloud
The Import Point Cloud button displays a dialog to import a point cloud from another application. Supported filetypes are:

| * Alias’s Maya         | .ma  |
| * 3DS Max ASCII Scene Export | .ase |
| * NewTek’s LightWave   | .lws |
| * Softimage XSI's      | .xsi |
Make Renderable
Determines if the point cloud is visible in the OpenGL viewport and in final renderings made by
the OpenGL renderer. The software renderer does not currently support rendering of visible
crosshairs for this node.

Unseen by Camera
This checkbox control appears when the Make Renderable option is selected. If the Unseen by
Cameras checkbox is selected, the point cloud will be visible in the Viewers but not rendered
into the output image by the Renderer 3D node.

Onscreen Contextual Menu

Frequently, one or more of the points in an imported point cloud will have been manually
assigned in order to track the position of a specific feature. These points usually have names
that distinguish them from the rest of the points in the cloud. To see the current name for a
point, hover the mouse pointer directly over a point, and after a moment a small pop-up will
appear with the name of the point.

When the Point Cloud 3D node is selected, a submenu will be added to the display Viewer’s
contextual menu with several options that make it simple to locate, rename, and separate these
points from the rest of the point cloud. The contextual menu contains the following options:

Find
Selecting this option from the display Viewer contextual menu will open a dialog that can be
used to search for and select a point by name. Each point that matches the pattern will
be selected.

Rename
Rename one or more points by selecting Rename from the contextual menu. Type the new
name into the dialog that appears and hit enter. The point will now have that name, with a
four-digit number added to the end. For example, the name window will be window0000 and
multiple points would be window0000, window0001, and so on. Names must be valid Fusion
identifiers (i.e., no spaces allowed, and the name cannot start with a number).
Delete
Selecting this option will delete the currently selected points.

Publish
Normally, the exact position of a point in the cloud is not exposed. To expose the position, select one or more points then select the publish option from this contextual menu. This will add a coordinate control to the control panel for each published point that displays the point’s current location.

</table>
The Projector 3D node is used to project an image upon 3D geometry. This can be useful in many ways: texturing objects with multiple layers, applying a texture across multiple separate objects, projecting background shots from the camera’s viewpoint, image-based rendering techniques, and much more. The Projector node is just one of several nodes capable of projecting images and textures. Each method has advantages and disadvantages. See the Projection section of Chapter 60, “3D Compositing Basics,” for more information about each approach.

Projected textures can be allowed to “slide” across the object if the object moves relative to the Projector 3D, or alternatively, by grouping the two together with a Merge 3D they can be moved as one and the texture will remain locked to the object.

The Projector 3D node’s capabilities and restrictions are best understood if the Projector is considered to be a variant on the Spotlight node. The fact that the Projector 3D node is actually a light has several important consequences when used in Light or Ambient Light projection mode:

- Lighting must be turned on for the results of the projection to be visible.
- The light emitted from the projector is treated as diffuse/specular light. This means that it will be affected by the surface normals and can cause specular highlights. If this is undesirable, set Projector 3D to project into the Ambient Light channel.
- Enabling Shadows will cause Projector 3D to cast shadows.
- Just as with other lights, the light emitted by a Projector 3D will only affect objects that feed into the first Merge 3D that is downstream of the Projector 3D node on the node tree.
- Enabling Merge 3D’s Pass Through Lights checkbox will allow the projection to light objects further downstream.
- The light emitted by a Projector 3D is controlled by the Lighting options settings on objects and the Receives Lighting options on materials.
- Alpha values in the projected image will not clip geometry in Light or Ambient Light mode. Use Texture mode instead.
- If two projections overlap, their light contributions will be added together.

To project re-lightable textures or textures for non-diffuse color channels (like Specular Intensity or Bump), use the Texture projection mode instead:

- Projections in Texture mode will only strike objects that use the output of the Catcher node for all or part of the material applied to that object.
- Texture mode projections will clip the geometry according to the alpha channel of the projected image.

See the section for the Catcher node for additional details.
The Camera 3D node also provides a projection feature, and should be used when the projection is meant to match a camera, as this node has more control over aperture, film back, and clip planes. Projector 3D was designed to be used as a custom light in 3D scenes for layering and texturing. The projector provides better control over light intensity, color, decay and shadows.

When using projectors in an OpenGL view or in the OpenGL renderer, the lighting must be set to Per-pixel (the default) in order to see the results of the projection in the main view. The Per-pixel lighting mode requires a certain level of shader support from your graphics card. Even if the graphics card does not support pixel shading, the projection will still be visible when using the software renderer.

**External Inputs**

**Projector3D.SceneInput**
[orange, optional] This input expects a 3D scene. If a scene is connected to this input, then transformations applied to the spotlight will also affect the rest of the scene.

**Projector3D.ProjectiveImage**
[white, optional] This input expects a 2D image to be used for the projection.

**Controls**

**Enabled**
When this checkbox is selected the projector affects the scene. Clear the checkbox to turn it off.

**Color**
The input image is multiplied by this color before projected into the scene.
Intensity
Use this slider to set the Intensity of the projection when the Light and Ambient Light projection modes are used. In Texture mode this option scales the Color values of the texture after multiplication by the color.

Decay Type
A projector defaults to No Falloff, meaning that its light has equal intensity on geometry, regardless of the distance from the projector to the geometry. To cause the intensity to fall off with distance, set the Decay type to either Linear or Quadratic modes.

Angle
The Cone Angle of the node refers to the width of the cone where the projector emits its full intensity. The larger the angle, the wider the cone angle, up to a limit of 90 degrees.

Fit Method
The Fit Method determines how the projection is fit within the projection cone.

The first thing to know is that although this documentation may call it a 'cone,' the Projector3D node and the Camera3D nodes do not project actual cones; it's more of a pyramid of light with its apex at the camera/projector. The Projector3D node always projects a square pyramid of light, i.e., its X and Y angles of view are the same. The pyramid of light projected by the Camera3D node can be non-square depending on what the Film Back is set to in the camera. The aspect of the image connected into the Projector3D/Camera3D does not affect the X/Y angles of the pyramid, but rather the image is scaled to fit into the pyramid based upon the fit options.

When both the aspect of the pyramid (AovY/AovX) and the aspect of the image (height * pixelAspectY)/(width * pixelAspectX) are the same, there is no need for the fit options, and in this case, the fit options all do the same thing. However, when the aspect of the image and the pyramid (as determined by the Film Back settings in Camera3D) are different, the fit options become important.

For example, 'Fit by Width' will fit the width of the image across the width of the Camera3D pyramid. In this case, if the image has a greater aspect ratio than the aspect of the pyramid, some of the projection will extend vertically outside of the pyramid.

There are five options:

- **Inside**: The image is uniformly scaled so that its largest dimension fits inside the cone. Another way to think about this is that it scales the image as big as possible subject to the restriction that the image is fully contained within the pyramid of the light. This means, for example, that nothing outside the pyramid of light will ever receive any projected light.

- **Width**: The image is uniformly scaled so that its width fits inside the cone. Note that the image could still extend outside the cone in its height direction.

- **Height**: The image is uniformly scaled so that its height fits inside the cone. Note that the image could still extend outside the cone in its width direction.

- **Outside**: The image is uniformly scaled so that its smallest dimension fits inside the cone. Another way to think about this is that it scales the image as small as possible subject to the restriction that the image covers the entire pyramid (i.e., the pyramid is fully contained within the image). This means that any pixel of any object inside the pyramid of light will always get illuminated.

- **Stretch**: The image is non-uniformly scaled, so it exactly covers the cone of the projector.
**Projection Mode**
- **Light**: Projects the texture as a diffuse/specular light.
- **Ambient Light**: Uses an ambient light for the projection.

**Texture**
When used in conjunction with the Catcher node, this mode allows re-lightable texture projections. The projection will only strike objects that use the catcher material as part of their material shaders.

One useful trick is to connect a Catcher node to the Specular Texture input on a 3D Material node (such as a Blinn). This will cause any object using the Blinn material to receive the projection as part of the specular highlight. This technique can be used in any material input that uses texture maps, such as the Specular and Reflection maps.

**Shadows**
Since the projector is based on a spotlight, it is also capable of casting shadows using shadow maps. The controls under this reveal are used to define the size and behavior of the shadow map.

- **Enable Shadows**: The Enable Shadows checkbox should be selected if the light is to produce shadows. This defaults to selected.
- **Shadow Color**: Use this standard Color control to set the color of the shadow. This defaults to black (0, 0, 0).
- **Density**: The Shadow Density determines how opaque the shadow will be. A density of 1.0 will produce a completely transparent shadow, whereas lower values make the shadow transparent.
- **Shadow Map Size**: The Shadow Map Size control determines the size of the bitmap used to create the shadow map. Larger values will produce more detailed shadow maps at the expense of memory and performance.
- **Shadow Map Proxy**: Shadow Map Proxy determines the size of the shadow map used for proxy and auto proxy calculations. A value of 0.5 would use a 50% shadow map.
- **Multiplicative/Additive Bias**: Shadows are essentially textures applied to objects in the scene, so there will occasionally be Z-fighting, where the portions of the object that should be receiving the shadows render over top of the shadow instead.

Biasing works by adding a small depth offset to move the shadow away from the surface it is shadowing, eliminating the Z-fighting. Too little bias and the objects can self-shadow themselves. Too much bias and the shadow can become separated from the surface.

Make adjustments to the multiplicative bias first, then fine tune the result using the additive bias control.

**Force All Materials Non-Transmissive**
Normally, an RGBA/Z shadowmap is used when rendering shadows. By enabling this option you are forcing the renderer to use a Z-only shadowmap. This can result in significantly faster shadow rendering while using a fifth as much memory. The disadvantage is that you can no longer cast ‘stained-glass’ like shadows.

**Shadow Map Sampling**
Sets the quality for sampling of the shadow map.
**Softness**

Soft edges in shadows are produced by filtering the shadowmap when it is sampled. Fusion has three separate filtering methods available when rendering shadows which produce different effects.

- **None:** Shadows will have a hard edge. No filtering of the shadowmap is done at all. The advantage of this method is that you only have to sample one pixel in the shadowmap, so it is fast.
- **Constant:** Shadows edges will have a constant softness. A filter with a constant width is used when sampling the shadowmap. Adjusting the Constant Softness slider controls the size of the filter. Note that the larger you make the filter, the longer it will take to render the shadows.
- **Variable:** The softness of shadow edges will grow the farther away the shadow receiver is from the shadow caster. The variable softness is achieved by changing the size of the filter based on the distance between the receiver and caster.

When this option is selected, the Softness Falloff, Min Softness and Max Softness sliders appear.

**Constant Softness**

If the Softness is set to constant, then this slider will appear. It can be used to set the overall softness of the shadow.

**Softness Falloff**

The Softness Falloff slider appears when the Softness is set to variable. This slider controls how fast the softness of shadow edges grows with distance. To be more precise, it controls how fast the shadowmap filter size grows based upon the distance between shadow caster and receiver. Its effect is mediated by the values of the Min and Max Softness sliders.

**Min Softness**

The Min Softness slider appears when the Softness is set to variable. This slider controls the Minimum Softness of the shadow. The closer the shadow is to the object casting the shadow, the sharper it will be up to the limit set by this slider.

**Max Softness**

The Max Softness slider appears when the Softness is set to variable. This slider controls the Maximum Softness of the shadow. The farther the shadow is from the object casting the shadow, the softer it will be up to the limit set by this slider.

**Transform Tab**

The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.
The Renderer 3D node converts the 3D environment into a 2D image using either a default perspective camera or one of the cameras found in the scene. Every 3D scene in a composition should terminate with at least one Render 3D node. The Renderer node can use either of the software or OpenGL render engines to produce the resulting image. Additional render engines may also be available via third-party plug-ins.

The software render engine uses the system’s CPU only to produce the rendered images. It is usually much slower than the OpenGL render engine but produces consistent results on all machines, making it essential for renders that involve network rendering. The Software mode is required to produce soft shadows, and generally supports all available illumination, texture, and material features.

The OpenGL render engine employs the GPU processor on the graphics card to accelerate the rendering of the 2D images. The output may vary slightly from system to system, depending on the exact graphics card installed. The graphics card driver can also affect the results from the OpenGL renderer. The OpenGL render engines speed makes it possible to provide customized supersampling and realistic 3D depth of field options. The OpenGL renderer cannot generate soft shadows. For soft shadows, the software renderer is recommended.

Like most nodes, the Renderer’s motion blur settings can be found under the Common Control tab. Be aware that scenes containing one or more particle systems will require that the Motion Blur settings on the pRender nodes exactly match the settings on the Renderer 3D node.

Otherwise, the subframe renders will conflict producing unexpected (and incorrect) results.
**NOTE:** The GL renderer respects the Color Depth option in the Image tab of the Renderer3D node. This can cause slowdowns on certain graphics cards when rendering to int16 or float32.

**External Inputs**

- **Renderer3D.SceneInput**
  [orange, required] This input expects a 3D scene.

- **Renderer3D.EffectMask**
  [violet, optional] This input uses a single or four channel 2D image to mask the output of the node.

**Controls**

**Camera**

The camera drop-down list is used to select which camera from the scene is used when rendering. The default option is Default, which will use the first camera found in the scene. If no camera is located, the default perspective view will be used instead.
Eye
The Eye control tells the node how to render the image in stereoscopic projects. The Mono option will ignore the stereoscopic settings in the camera. The Left and Right options will translate the camera using the stereo Separation and Convergence options defined in the camera to produce either left or right eye outputs.

Reporting
The first two checkboxes in this reveal can be used to determine whether the node will print warnings and errors produced while rendering to the console. The second row of checkboxes tells the node whether it should abort rendering when a warning or error is encountered. The default for this node enables all four checkboxes.

Renderer Type
This drop-down menu lists the available render engines. Fusion provides two: the software and OpenGL render engines (described above), and additional renderers can be added via third-party plug-ins.

All of the controls found below this drop-down menu are added by the render engine. They may change depending on the options available to each renderer. As a result, each renderer is described in its own section below.

Software Controls

Output Channels
In addition to the usual Red, Green, Blue and Alpha channels, the software renderer can also embed the following channels into the image. Enabling additional channels will consume additional memory and processing time, so these should be used only when required.

- **RGBA**: This option tells the renderer to produce the Red, Green, Blue and Alpha color channels of the image. These channels are required and they cannot be disabled.
- **Z**: This option enables rendering of the Z-channel. The pixels in the Z-channel contain a value that represents the distance of each pixel from the camera. Note that the Z-channel values cannot include anti-aliasing. In pixels where multiple depths overlap, the frontmost depth value is used for this pixel.
- **Coverage**: This option enables rendering of the Coverage channel. The Coverage channel contains information about which pixels in the Z-buffer provide coverage (are overlapping with other objects). This helps nodes that use the Z-buffer to provide a small degree of antialiasing. The value of the pixels in this channel indicates, as a percentage, how much of the pixel is composed of the foreground object.
- **BgColor**: This option enables rendering of the BgColor channel. This channel contains the color values from objects behind the pixels described in the Coverage channel.
- **Normal**: This option enables rendering of the X, Y and Z Normals channels. These three channels contain pixel values that indicate the orientation (direction) of each pixel in the 3D space. A color channel containing values in a range from $[-1,1]$ represents each axis.
- **TexCoord**: This option enables rendering of the U and V mapping coordinate channels. The pixels in these channels contain the texture coordinates of the pixel. Although texture coordinates are processed internally within the 3D system as 3-component UVW, Fusion images only store UV components. These components are mapped into the Red and Green color channel.
• **ObjectID:** This option enables rendering of the ObjectID channel. Each object in the 3D environment can be assigned a numeric identifier when it is created. The pixels in this floating-point image channel contain the values assigned to the objects that produced the pixel. Empty pixels have an ID of 0, and the channel supports values as high as 65534. Multiple objects can share a single Object ID. This buffer is useful for extracting mattes based on the shapes of objects in the scene.

• **MaterialID:** This option enables rendering of the MaterialID channel. Each material in the 3D environment can be assigned a numeric identifier when it is created. The pixels in this floating-point image channel contain the values assigned to the materials that produced the pixel. Empty pixels have an ID of 0, and the channel supports values as high as 65534. Multiple materials can share a single Material ID. This buffer is useful for extracting mattes based on a texture; for example, a mask containing all of the pixels that comprise a brick texture.

**Lighting**

• **Enable lighting:** When the Enable Lighting checkbox is selected, objects will be lit by any lights in the scene. If no lights are present, all objects will be black.

• **Enable Shadows:** When the Enable Shadows checkbox is selected, the renderer will produce shadows, at the cost of some speed.

**OpenGL Controls**
Output channels

In addition to the usual Red, Green, Blue and Alpha channels, the OpenGL render engine can also embed the following channels into the image. Enabling additional channels will consume additional memory and processing time, so these should be used only when required.

- **RGBA**: This option tells the renderer to produce the Red, Green, Blue and Alpha color channels of the image. These channels are required and they cannot be disabled.

- **Z**: This option enables rendering of the Z-channel. The pixels in the Z-channel contain a value that represents the distance of each pixel from the camera. Note that the Z-channel values cannot include anti-aliasing. In pixels where multiple depths overlap, the frontmost depth value is used for this pixel.

- **Normal**: This option enables rendering of the X, Y and Z Normals channels. These three channels contain pixel values that indicate the orientation (direction) of each pixel in the 3D space. A color channel containing values in a range from \([-1,1]\) is represented by each axis.

- **TexCoord**: This option enables rendering of the U and V mapping coordinate channels. The pixels in these channels contain the texture coordinates of the pixel. Although texture coordinates are processed internally within the 3D system as 3-component UVW, Fusion images only store UV components. These components are mapped into the Red and Green color channel.

- **ObjectID**: This option enables rendering of the ObjectID channel. Each object in the 3D environment can be assigned a numeric identifier when it is created. The pixels in this floating-point image channel contain the values assigned to the objects that produced the pixel. Empty pixels have an ID of 0, and the channel supports values as high as 65534. Multiple objects can share a single Object ID. This buffer is useful for extracting mattes based on the shapes of objects in the scene.

- **MaterialID**: This option enables rendering of the MaterialID channel. Each material in the 3D environment can be assigned a numeric identifier when it is created. The pixels in this floating-point image channel contain the values assigned to the materials that produced the pixel. Empty pixels have an ID of 0, and the channel supports values as high as 65534. Multiple materials can share a single Material ID. This buffer is useful for extracting mattes based on a texture; for example, a mask containing all of the pixels that comprise a brick texture.

Supersampling

Supersampling can be enabled for each channel by means of the SS tickbox. It produces an output image with higher quality anti-aliasing by brute force rendering a much larger image, then rescaling it down to the target resolution. Rendering a larger image in the first place, then using a Resize node to bring the image to the desired resolution can achieve the exact same results. Using the supersampling built into the renderer offers two distinct advantages over this method.

The rendering is not restricted by memory or image size limitations. For example, consider the steps to create a float16 1920 x 1080 image with 16x supersampling. Using the traditional Resize node would require first rendering the image with a resolution of 30720 x 17280, then using a resize to scale this image back down to 1920 x 1080. Simply producing the image would require nearly 4 GB of memory. When supersampling is performed on the GPU, the OpenGL renderer can use tile rendering to significantly reduce memory usage.

The GL renderer can perform the rescaling of the image directly on the GPU much more quickly than the CPU can manage it. In general, the more GPU memory the graphics card has the faster the operation will be.
Interactively, Fusion will skip the supersampling stage unless the HiQ button is selected in the Time Ruler. Final quality renders will always include supersampling, if it is enabled.

Due to hardware limitations, point geometry (particles) and lines (locators) are always rendered at their original size, independent from supersampling. This means that these elements will be scaled down from their original sizes, and will likely appear much thinner than expected.

Supersampling of Aux Channels in the OpenGL Renderer

The reason we supply separate SS options for color and aux channels is that supersampling of color channels is a quite a bit slower than aux channels. You may find that 4 x 4 SS is sufficient for color, but for worldposition or Z, you may require 64 x 64 to get adequate results. The reasons color SS is slower are that the shaders for RGBA can be 10x to even 100x or 1000x more complex, and color is rendered with sorting enabled, while aux channels get rendered using the much faster Z-buffer method.

NOTE: RGBA supersampling is no longer enabled in the Supersampling nest but rather in the OutputChannels nest. For some things, sometimes using an SS Z-buffer will improve quality, but for other things like using the merge’s PerformDepthMerge option, it may make things worse.

Do not mistake SS with improved quality. SSing an aux channel does not mean it’s better quality. In fact, SSing an aux channel in many cases can make the results much worse. The only channels we recommend you enable SS on are WorldCoord and Z.

TIP: We strongly recommend disabling SSing on MaterialID and ObjectID channels. We recommend disabling SSing on TexCoord, Normal, BackVector, and Vector channels. The issue arises when you have multiple 3D surfaces with radically different TexCoord values in one pixel. The SSing does not restrict itself to sampling the main surface but will sample both surfaces. For example, if one surface has TexCoords that are approx \((u,v)=(0, 0)\) within that pixel and the other surface has \((0.5, 0.5)\), you will get a blending of these two. The blended area of the texture could have colors like \((0, 0)\) or \((0.5, 0.5)\), resulting in an oddly colored pixel artifact being output from the 2D Texture node. The same problem can happen for normals.

Enable (HiQ Only)

This checkbox can be used to enable supersampling of the rendered image. The remaining controls in this reveal will only appear if this is selected.

Lock X/Y Supersampling Rates

When this checkbox is disabled separate sliders are presented to control the amount of supersampling on the X- and Y-axis.

Supersampling Rate X

The Supersampling Rate tells the OpenGL render how large to scale the image. For example, if the supersampling rate is set to 4 and the OpenGL renderer is set to output a 1920 x 1080 image, internally a 7680 x 4320 image will be rendered and then scaled back to produce the target image. Set the multiplier higher to get better edge antialiasing at the expense of render time. Typically 8x8 supersampling (64 samples per pixel) is sufficient to reduce most aliasing artifacts.
The supersampling rate doesn’t exactly define the number of samples done per destination pixel; the width of the reconstruction filter used may also have an impact.

**Reconstruction Filter**

When downsampling the supersized image, the surrounding pixels around a given pixel are often used to give a more realistic result. There are various filters available for combining these pixels. More complex filters can give better results but are usually slower to calculate. The best filter for the job will often depend on the amount of scaling and on the contents of the image itself.

The functions of these filters are shown in the image above. From left to right these are:

<table>
<thead>
<tr>
<th>Filter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Box</strong></td>
<td>This is a simple interpolation scale of the image.</td>
</tr>
<tr>
<td><strong>Bi-Linear (triangle)</strong></td>
<td>This uses a simplistic filter, which produces relatively clean and fast results.</td>
</tr>
<tr>
<td><strong>Bi-Cubic (quadratic)</strong></td>
<td>This filter produces a nominal result. It offers a good compromise between speed and quality.</td>
</tr>
<tr>
<td><strong>Bi-Spline (cubic)</strong></td>
<td>This produces better results with continuous tone images but is slower than Quadratic. If the images have fine detail in them, the results may be blurrier than desired.</td>
</tr>
<tr>
<td><strong>Catmul-Rom</strong></td>
<td>This produces good results with continuous tone images which are scaled down, producing sharp results with finely detailed images.</td>
</tr>
<tr>
<td><strong>Gaussian</strong></td>
<td>This is very similar in speed and quality to Quadratic.</td>
</tr>
<tr>
<td><strong>Mitchell</strong></td>
<td>This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.</td>
</tr>
<tr>
<td><strong>Lanczos</strong></td>
<td>This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.</td>
</tr>
<tr>
<td><strong>Sinc</strong></td>
<td>This is an advanced filter that produces very sharp, detailed results, however, it may produce visible ‘ringing’ in some situations.</td>
</tr>
<tr>
<td><strong>Bessel</strong></td>
<td>This is similar to the Sinc filter but may be slightly faster.</td>
</tr>
</tbody>
</table>

**Window Method**

The Window Method menu appears only when the reconstruction filter is set to Sinc or Bessel.

<table>
<thead>
<tr>
<th>Window</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hanning</td>
<td>This is a simple tapered window.</td>
</tr>
<tr>
<td>Hamming</td>
<td>Hamming is a slightly tweaked version of Hanning.</td>
</tr>
<tr>
<td>Blackman</td>
<td>A window with a more sharply tapered falloff.</td>
</tr>
</tbody>
</table>
Lighting

- **Enable Lighting**: When the Enable Lighting checkbox is selected, any lights in the scene will light objects. If no lights are present, all objects will be black.
- **Enable Shadows**: When the Enable Shadows checkbox is selected, the renderer will produce shadows, at the cost of some speed.

Texturing

- **Texture Depth**: Lets you specify the bit depth of texture maps.
- **Warn about unsupported texture depths**: Enables a warning if texture maps are in an unsupported bit depth that Fusion can't process.

Lighting Mode

The Per-vertex lighting model calculates lighting at each vertex of the scene's geometry. This produces a fast approximation of the scene's lighting, but tends to produce blocky lighting on poorly tessellated objects. The Per-pixel method uses a different approach that does not rely on the amount of detail in the scene's geometry for lighting, so generally produces superior results.

While using per-pixel lighting in the OpenGL renderer produces results closer to that produced by the more accurate software renderer, it still has some disadvantages. Even with per-pixel lighting, the OpenGL renderer is less capable of dealing correctly with semi-transparency, soft shadows and colored shadows. The color depth of the rendering will be limited by the capabilities of the graphics card in the system.

Transparency

The OpenGL renderer reveals this control for selecting which ordering method to use when calculating transparency.

- **Z Buffer (fast)**: This mode is extremely fast, and is adequate for scenes containing only opaque objects. The speed of this mode comes at the cost of accurate sorting; only the objects closest to the camera are certain to be in the correct sort order. As a result, semi-transparent objects may not be shown correctly, depending on their ordering within the scene.
- **Sorted (accurate)**: This mode will sort all objects in the scene (at the expense of speed) before rendering, giving correct transparency.
- **Quick Mode**: This experimental mode is best suited to scenes that almost exclusively contain particles.

Shading Model

Use this menu to select a Shading model to use for materials in the scene. Smooth is the shading model employed in the views and Flat produces a simpler and faster shading model.

Wireframe

Renders the whole scene as Wireframe. This will show the edges and polygons of the objects. The edges are still shaded by the material of the objects.

Wireframe Antialiasing

Enables anti-aliasing for the Wireframe render.
OpenGL UV Unwrap Renderer

Takes a model with existing textures and renders it out via the Renderergluv3D to produce an unwound flattened 2D version of the model. Optionally lighting can be baked in. You can then paint on the texture and reapply it.

NOTE: After you have baked lighting into a models texture, you need to be careful to turn lighting off on the object in the future when you render it with the burnt-in lighting texture.

- **Issue:** Beware of cases where a single area of the texture map is used on multiple areas of the model. This is often done to save texture memory and decrease modeling time. An example of this is the texture for a person where the artist mirrored the left side mesh/uvs/texture to produce the right side. Trying to burn in lighting in this case won’t work.

Unwrapping more than one mesh at once can cause problems. The reason is that most models are authored so they make maximal usage of (u,v) in [0,1]x[0,1], so that in general models will overlap each other in UV space.

- **Seams:** When the UV gutter size is left at 0 this produces seams when the model is retextured with the unwrapped texture.

- **UV Gutter Size:** Increase this value to hide seams between faces.
Replace Material 3D [3RPL]

The Replace Material 3D node replaces the material applied to all of the geometry in the input scene with its own material input. Any lights or cameras in the input scene are passed through unaffected.

The scope of the replacement can be limited using Object and Material identifiers. The scope can also be limited to individual channels, making it possible to use a completely different material on the Red channel, for example.

External Inputs

**ReplaceMaterial3D.SceneInput**
[orange, required] This input expects a 3D scene.

**ReplaceMaterial3D.MaterialInput**
[green, optional] This input will accept either a 2D image or a 3D material. If a 2D image is provided, it will be used as a diffuse texture map for the basic material built into the node. If a 3D material is connected, then the basic material will be disabled.

Controls

**Enable**
Enables the material replacement.

**Replace Mode**

**Red, Green, Blue, and Alpha Mode**
Offers several replacing modes for each RGBA channel:
- **Keep**: Prevents the channel from being replaced by the input material.
- **Replace**: Replaces the material for the according color channel.
- **Blend**: Blends the materials together.
- **Multiply**: Multiplies the according channels of both inputs.
Limit by Object id/Material id
When enabled, a slider appears where the desired IDs can be set. All other objects will keep their materials. If both options are enabled an object must satisfy both conditions.

Material Tab
The options that appear in this tab determine the appearance the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

Replace Normals 3D [3RPN]
ReplaceNormals is used to replace the Normals/Tangents on incoming geometry. All geometry in the input scene is affected. Lights/Cameras/PointClouds/Locators/Materials and other non-mesh nodes are passed through unaffected. The normals/tangents affected by this node are Per-vertex normals/tangents, not Per-face normals/tangents. The input geometry must have texture coordinates in order for tangents to be computed. Sometimes geometry does not have texture coordinates or the texture coordinates were set to All by FBX import because they were not present on the FBX.
Controls

Pre-Weld Position Vertices
Pre-welds the position vertices. Sometimes position vertices are duplicated in a geometry, even though they have the same position, causing normals/tangents to be miscomputed. The results of pre-welding are thrown away; they do not affect the output geometry’s position vertices.

Recompute
Controls when normals/tangents are recomputed.

- **Always**: The normals on the mesh will always be recomputed.
- **If Not Present**: The normals on the mesh are recomputed only if they are not present.
- **Never**: The normals will never be computed. This option is useful when animating.

Smoothing Angle
Adjacent faces with angles in degrees smaller than this will have their adjoining edges smoothed across. A typical value one might choose for the Smoothing Angle is between 20 and 60 degrees. There is special case code for 0.0f and 360.0f. When set to 0.0f, faceted normals are produced; this is useful for artistic effect.

Ignore Smooth Groups
If set to False, two faces that have different Smooth Groups will not be smoothed across (e.g., the faces of a cube or the top surfaces of a cylinder have different Smooth Groups). If you check this On and set the smoothing angle large enough, the faces of a cube will be smoothed across. There is currently no way to visualize Smooth Groups within Fusion.

Flip Normals
Flipping of tangents can sometimes be confusing. Flip will have an effect if the mesh has tangent vectors. Most meshes in Fusion don’t have tangent vectors until they reach a Renderer3D, though. Also, when viewing tangent vectors in the Viewers, the tangent vectors will be created if they don’t exist. The confusing thing is if you view a Cube3D that has no tangent vectors and press the FlipU/FlipV button, nothing happens. This is because there were no tangent vectors to create, but later the GL renderer created some (unflipped) tangent vectors.
NOTE: The FBX importer will recompute the normals if they don’t exist, but you can get a higher quality result from this node.

Bumpmaps can sometimes depend on the model’s normals. In particular, when you simplify a complex high poly model to a low poly model + bumpmap, the normals and bumpmap can become ‘linked.’ Recomputing the normals in this case can make the model look funny. The bumpmap was intended to be used with those normals.

Most primitives in Fusion are not generated with tangents; when needed they are generated on the fly by a Renderer3D and cached.

Tangents currently are only needed for bumpmapping. If a material needs bumpmapping, then tangents are created. These tangents are created with some default settings (e.g., SmoothingAngle, and so on), and if you don’t want Fusion automatically creating tangents you should manually create them using ReplaceNormals.

All the computations are done in the local coordinates of the geometries rather than in the coordinate system of the ReplaceNormals3D node. This can cause problems when there is a non-uniform scale applied to the geometry before ReplaceNormals3D is applied.

**Replicate 3D [3REP]**

The Replicate 3D node replicates input geometry at positions of destination vertices. This includes mesh vertices as well as particle positions. For each copy of the replicated input geometry, various transformations can be applied. The options in the Jitter tab allow for non-uniform transformations, such as random positioning or sizes.

**External Inputs**

- **Replicate3d.Destination**
  [orange, required] This input expects a 3D scene with vertex positions, either from meshes or 3D particle animations.

- **Replicate3d.Input[#]**
  [any, required] This input expects a 3D scene that will be replicated. Once connected, a new input for alternating 3D scenes will be created.

At least one connected input is required.
Controls

Step
Defines how many positions are skipped. For example, a step of 3 means that only every third position of the destination mesh will be used, while a step of 1 means that all positions will be used.

The step helps to keep reasonable performance for big destination meshes. On parametric geometry like a torus, it can be used to isolate certain parts of the mesh.

Pointclouds are internally represented by six points once the Make Renderable option has been set. In order to get a single point, use a step of 6 and set a X offset of –0.5 in the Replicate3D to get to the center of the pointcloud. Use –0.125 for Locator3Ds. Once these have been scaled, the offset may differ.

Input Mode
This parameter defines in which order multiple input scenes are replicated at the destination. Both parameters won’t have a visible effect if only one input scene is supplied.

With Loop, the inputs are used successively. The first input will be at the first position, the second at the second, and so on. If there are more positions in the destination present than inputs, the sequence will be looped.

Random will use a definite but random input for each position based on the seed in the Jitter tab. This input mode can be used to simulate variety with few input scenes.
Death of Particles causes their IDs to change, therefore their copy order may change.

**Time Offset**

Use the Time Offset slider to offset any animations that are applied to the source geometry by a set amount per copy. For example, set the value to –1.0 and use a cube set to rotate on the Y-axis as the source. The first copy will show the animation from a frame earlier. The second copy will show animation from a frame before that, and so forth.

This can be used with great effect on textured planes, for example, where successive frames of a clip can be shown.

**Alignment**

Alignment specifies how to align the copies in respect of the destination mesh normal or particle rotation.

- **Not Aligned**: Does not align the copy. It stays rotated in the same direction as its input mesh.

- **Aligned**: This mode uses the point’s normal and tries to reconstruct an upvector. It works best with organic meshes that have unwelded vertices, like imported FBX meshes, since it has the same rotations for vertices at the same positions. On plane geometric meshes a gradual shift in rotation will be noticeable. For best results, it is recommended to use this method at the origin before any transformations.
• **Aligned TBN**: Results in a more accurate and stable alignment based on the tangent, binormal, and normal of the destination point. Works best for particles and geometric shapes. On unwelded meshes, two copies of multiple unwelded points at the same position may result in different alignments due to their individual normals.

![TBN Aligned](image)

**Color**
Affects the diffuse color or shader of each copy based on the input’s particle color.

- **Use Object Color**: Does not use the color of the destination particle.
- **Combine Particle Color**: Uses the shader of any input mesh and modifies the diffuse color to match the color from the destination particle.
- **Use Particle Color**: Replaces the complete shader of any input mesh with a default shader. Its diffuse color is taken from the destination particle.

![Color Options](image)

**Translation**
These three sliders tell the node how much offset to apply to each copy. An X Offset of 1 would offset each copy one unit; one unit along the X-axis from the last copy.

**Rotation Order**
These buttons can be used to set the order in which rotations are applied to the geometry. Setting the rotation order to XYZ would apply the rotation on the X-axis first, followed by the Y-axis rotation, then the Z-axis rotation.

**XYZ Rotation**
These three rotation sliders tell the node how much rotation to apply to each copy.
**XYZ Pivot**
The pivot controls determine the position of the pivot point used when rotating each copy.

**Lock XYZ**
When the Lock XYZ checkbox is selected, any adjustment to the scale will be applied to all three axes simultaneously.

If this checkbox is disabled, the scale slider will be replaced with individual sliders for the X, Y, and Z scale.

**Scale**
The Scale control sets how much scaling to apply to each copy.

---

**Jitter**

![Jitter Controls](image)

**Random Seed/Randomize**
The Random Seed is used to 'seed' the amount of jitter applied to the replicated objects. Two replicate nodes with identical settings but different random seeds will produce two completely different results. Click on the Randomize button to assign a Random Seed value.

**Time Offset**
Use the Time Offset slider to offset any animations that are applied to the source geometry by a set amount per copy. For example, set the value to –1.0 and use a cube set to rotate on the Y-axis as the source. The first copy will show the animation from a frame earlier. The second copy will show animation from a frame before that, and so forth. This can be used with great effect on textured planes, for example, where successive frames of a clip can be shown.

**Translation XYZ Jitter**
Use these three controls to adjust the amount of variation in the translation of the replicated objects.
Rotation XYZ Jitter
Use these three controls to adjust the amount of variation in the rotation of the replicated objects.

Pivot XYZ Jitter
Use these three controls to adjust the amount of variation in the rotational pivot center of the replicated objects. This affects only the additional jitter rotation, not the rotation produced by the rotation settings in the Controls tab.

Scale XYZ Jitter
Use this control to adjust the amount of variation in the scale of the replicated objects. Uncheck the Lock XYZ checkbox to adjust the scale variation independently on all three axes.

Ribbon 3D [3RI]

Ribbon 3D generates an array of subdivided line segments or a single line between two points. It is quite useful for motion graphics, especially in connection with Replicate 3D to attach other geometry to the lines, and with Displace3D for creating lightning-bolt like structures. The array of lines is, by default, assigned with texture coordinates, so they can be used with a 2D texture. As usual, UVMap3D can be used to alter the texture coordinates. This node heavily relies on certain OpenGL features and will not produce any visible result in the software renderer.

Furthermore, the way lines are drawn is completely up to the graphic card vendor, so any artifacts may vary from card to card.

Controls
**Number of Lines**
The number of parallel lines drawn between the start point and end point.

**Line Thickness**
Line thickness is allowed in the user interface to take on a floating point value, but some graphics cards will only allow integer values. Some cards may only allow lines equal to or thicker than one, or max out at a certain value.

**Subdivision Level**
The number of vertices on each line between start point and endpoint. The higher the number, the more precise any 3D displacement can be applied.

**Ribbon Width**
Determines how far the lines are apart from each other.

**Start**
XYZ control to set the start point of the ribbon.

**End**
XYZ control to set the end point of the ribbon.

**Ribbon Rotation**
Allows rotation of the ribbon around the virtual axis defined by start point and end point.

**Antialiasing**
Allows you to apply antialiasing to the rendered lines. Using antialiasing isn’t necessarily advised. When activated, there will be gaps between the line segments. This is especially noticeable with high values of line thickness. Again, the way lines are drawn is completely up to the graphic card vendor, which means that these artifacts can vary from card to card.

**Shape 3D [3SH]**

The Shape 3D node is used to produce several basic primitive 3D shapes, including planes, cubes, spheres and cylinders.

**External Inputs**

**Shape3d.SceneInput**
[orange, required] This input expects to receive a 3D scene.

**Shape3d.MaterialInput**
[green, optional] This input will accept either a 2D image or a 3D material. If a 2D image is provided it will be used as a diffuse texture map for the basic material built into the node. If a 3D material is connected, then the basic material will be disabled.
Controls

Shape
Select one of these options to determine which geometry primitive will be produced by the Shape 3D node. The controls below will change to match the selected shape.

- **Lock Width/Height/Depth:** [plane, cube] If this checkbox is selected, the width, height, and depth controls are locked together as a single size slider. Otherwise, individual control over the size of the shape along each axis is provided.
- **Size Width/Height/Depth:** [plane, cube] Used to control the size of the shape.

Cube Mapping
[Cube] Uses cube mapping to apply the Shape node’s texture (a 2D image connected to the Texture input).

Radius
[Sphere, Cylinder, Cone, Torus] Sets the radius of the selected shape.

Top Radius
[Cone] This control is used to define a radius for the top of a cone, making it possible to create truncated cones.

Start/End Angle
[Sphere, Cylinder, Cone, Torus] This range control determines how much of the sweep of the shape is drawn. A start angle of 180 and end angle of 360 would only draw half of the shape.

Start/End Latitude
[Sphere, Torus] This range control is used to slice the object by defining a latitudinal sub-section of the object.

Bottom/Top Cap
[Cylinder, Cone] Used for cylinder and cone shapes only, the Bottom Cap and Top Cap checkboxes are used to determine if the end caps of these shapes are created or if the shape is left open.

Section
[Torus] Used for torus only, section controls the thickness of the tube making up the torus.
**Subdivision Level/Base/Height**

[All shapes] Used for all shapes, the Subdivision controls are used to determine the tessellation of the mesh composing the object. The higher the subdivision, the more vertices each shape will have.

**Wireframe**

Enabling this checkbox will cause the mesh to render only the wireframe for the object.

**Visibility**

- **Visible**: If the Visibility checkbox is not selected, the object will not be visible in the Viewers, nor will it be rendered into the output image by the Renderer 3D node. A non-visible object does not cast shadows.
- **Unseen by Cameras**: If the Unseen by Cameras checkbox is selected, the object will be visible in the Viewers (unless the Visible checkbox is turned off), except when viewed through a camera. The object will not be rendered into the output image by the Renderer 3D node. Shadows cast by an unseen object will still be visible when rendered by the software renderer, though not by the OpenGL renderer.
- **Cull Front Face/Back Face**: Use these options to cull (eliminate) rendering and display of certain polygons in the geometry. If Cull Back Face is selected, all polygons facing away from the camera will not be rendered, and will not cast shadows. If Cull Front Face is selected, all polygons facing toward the camera will likewise be dropped. Selecting both checkboxes has the same effect as deselecting the Visible checkbox.
- **Ignore Transparent Pixels in Aux Channels**: In previous versions of Fusion, the software/OpenGL renderers rejected transparent pixels. To be more specific, the software renderer rejected pixels with R=G=B=A=0 and the GL renderer rejected pixels with A=0. This is now optional. The reason you might want to do this is to get aux channels (e.g., Normals, Z, UVs) for the transparent areas. For example, suppose in post you want to replace the texture on a 3D element that is transparent in certain areas with a texture that is transparent in different areas, then it would be useful to have transparent areas set aux channels (in particular UVs).

As another example, suppose you are doing post DoF. You will probably not want the Z-channel to be set on transparent areas, as this will give you a false depth. Also keep in mind that this rejection is based on the final pixel color including lighting, if it is on. So if you have a specular highlight on a clear glass material, this checkbox will not affect it.

**Lighting**

- **Affected by Lights**: If this checkbox is not selected, lights in the scene will not affect the object, it will not receive nor cast shadows, and it will be shown at the full brightness of its color, texture or material.
- **Shadow Caster**: If this checkbox is not enabled, the object will not cast shadows on other objects in the scene.
- **Shadow Receiver**: If this checkbox is not enabled, the object will not receive shadows cast by other objects in the scene.

**Matte**

Enabling the Is Matte option will apply a special texture to this object, causing this object to not only become invisible to the camera, but also making everything that appears directly behind the camera invisible as well. This option will override all textures. See the matte objects section of the 3D chapter for more information.

- **Is Matte**: When activated, objects whose pixels fall behind the matte objects pixels in Z do not get rendered.
- **Opaque Alpha**: Sets the alpha value of the matte object to 1. This checkbox is only visible when the Is Matte option is enabled.

- **Infinite Z**: Sets the value in the Z-channel to infinite. This checkbox is only visible when the Is Matte option is enabled.

**Blend Mode**

A blend mode specifies which method the renderer will use when combining this object with the rest of the scene. The blend modes are essentially identical to those listed in the documentation for the 2D Merge node. For a detailed explanation of each mode, see the documentation for that node.

The blending modes were originally designed for use with 2D images. Using them in a lit 3D environment can produce undesirable results. For best results, use the Apply modes in unlit 3D scenes rendered in software.

- **OpenGL Blend Mode**: Use this menu to select the blending mode that will be used when the geometry is processed by the OpenGL renderer. This is also the mode used when viewing the object in the Viewers. Currently the OpenGL renderer supports three blending modes.

- **Software Blend Mode**: Use this menu to select the blending mode that will be used when the geometry is processed by the software renderer. Currently, the software renderer supports all of the modes described in the Merge node documentation, except for the Dissolve mode.

**Material Tab**

The options that appear in this tab determine the appearance the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

If an external 3D material is connected to the node's material input then the controls in this tab will be replaced with the “Using External Material” label.
Transform Tab

The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

Sphere Map vs. Connecting the Texture to a Sphere Directly

You can connect a latlong (equirectangular) texture map directly to a sphere instead of piping it through the Sphere Map node first. This results in a different rendering if you set the start/end angle and latitude to less than 360°/180°. In the first case, the texture will be squashed. When using the Sphere Map node, the texture will be cropped. Compare:

**NOTE:** If you pipe the texture directly into the sphere, it will also be mirrored horizontally. You can “fix” this by using a Transform node first.
The Softclip node is used to fade out geometry and particles that get close to the camera. This helps avoid the visible ‘popping off’ that affects many particle systems and 3D flythroughs.

This node is very similar to the Fog 3D node, in that it is dependent on the geometry’s distance from the camera.

The Softclip node is usually placed just before the renderer to ensure that downstream adjustments to lighting and textures do not affect the result. It can be placed in any part of the 3D portion of the node tree if the soft clipping effect is only required for a portion of the scene.

External Inputs

**Softclip.SceneInput**

[orange, required] This input expects a 3D scene.

Controls

**Enable**

This checkbox can be used to enable or disable the node.

**Smooth Transition**

Changes the linear gradient to a curve shaped one.

**Radial**

By default, the softclipping is done based upon the perpendicular distance to a plane (parallel with the near plane) passing through the eye point. When the Radial option is checked, the Radial distance to the eye point is used instead of the Perpendicular distance. The problem with Perpendicular distance softclipping is that when you move the camera about, as objects on the left or right side of the frustum move into the center, they become less clipped, even though they remain the same distance from the eye. Radial softclip fixes this. Sometimes Radial softclipping is not desirable.
For example, if you apply softclip to an object that is close to the camera, like an image plane, the center of the image plane could be unclipped while the edges could be fully clipped because they are farther from the eye point.

**Show In Display Views**
Normally, the effect is only visible when the scene is viewed using a camera node. When enabled, the softclip becomes visible in the scene from all points of view.

**Transparent/Opaque Distance**
Defines the range of the softclip. The objects will begin to fade in from an opacity of 0 at the Transparent distance and are fully visible at the Opaque distance. All units are expressed as distance from the camera along the Z-axis.

---

### Text 3D [3TXT]

The Text3D node is a 3D version of the 2D Text node. The controls for this node are mostly identical to the controls for the 2D version in almost all respects, except that it only supports one shading element. See Text Plus for more details on the controls found in this node.

The Text 3D node was based on a tool that pre-dates the Fusion 3D environment. As a result, some of the controls found in the basic primitive shapes and geometry loaders, such as many of the material, lighting, and matte options, are not found in this node’s controls. The Text 3D node has a built in material, but unlike the other 3D nodes it does not have a material input. The Shading tab contains controls to adjust the diffuse and specular components. To replace this default material with a more advanced material, follow the Text Plus node with a Replace Material 3D node. The Override 3D node can be used to control the lighting, visibility and matte options for this node.

One thing to be aware of when network-rendering a comp that contains a Text3D node is that each machine that does not have the font installed will fail. Fusion cannot share or copy fonts to Render Slaves due to legal issues.

#### External Inputs

- **Text3d.SceneInput**
  [orange, required] This input expects a 3D scene.

- **Text3d.ColorImage**
  [orange, required] This input expects a 2D image. It is only visible when the Image mode is enabled in the Material section of the Shading tab.

- **Text3d.BevelTexture**
  [orange, required] This input expects a 2D image. It is only visible when the Image mode is enabled in the Bevel Material section of the Shading tab.
Text Extrusion

Extrusion Depth
An extrusion of 0 produces completely 2D text. Any value greater than 0 will extrude the text to generate text with depth.

Bevel Depth
Increase the value of the Bevel Depth slider to bevel the text. The text must have extrusion before this control has any effect.

Bevel Width
Use the Bevel Width control to increase the width of the bevel.

Smoothing Angle
Use this control to adjust the smoothing angle applied to the edges of the bevel.
**Front/Back Bevel**
Use these checkboxes to enable beveling for the front and back faces of the text separately.

**Custom Extrusion**
In Custom mode, the Smoothing Angle controls the smoothing of normals around the edges of a text character. The spline itself controls the smoothing along the extrusion profile. If a spline segment is smoothed, for example by using the shortcut Shift-S, the Normals will be smoothed as well. If the keypoint is linear, there will be a sharp shading edge. The first and last keypoint on the spline defines the extent of the text.

- **Custom Extrusion Subdivisions**: Controls the number of subdivisions within the smoothed portions of the extrusion profile.

**TIP:** Remember that the spline can also be edited from within the Spline Editor tab and you do not have to work with the limited abilities and size of the text3D.

Extrusion profile spline control: Do not try to go to zero size at the Front/Back face. This will result in Z-fighting due to self-intersecting faces. To avoid this problem, make sure the first and last point have their profile set to 0.

**Shading**

**Opacity**
Reducing the material’s opacity will decrease the color and alpha values of the specular and diffuse colors equally, making the material transparent and allowing hidden objects to be seen through the material.

**Use One Material**
Deselecting this option will reveal a second set of Material controls for the beveled edge of the text.

**Material Tab**
Type
To use a solid color texture, select the Solid mode. Selecting the Image mode will reveal a new external input on the node that can be connected to another 2D image.

Specular Color
Specular Color determines the color of light that reflects from a shiny surface. The more specular a material is, the glossier it appears. Surfaces like plastics and glass tend to have white specular highlights, whereas metallic surfaces like gold have specular highlights that tend to inherit their color from the material color. The basic shader material does not provide an input for textures to control the specularity of the object. Use nodes from the 3D Material category when more precise control is required over the specular appearance.

Specular Intensity
Specular Intensity controls the strength of the specular highlight. If the specular intensity texture port has a valid input, then this value is multiplied by the alpha value of the input.

Specular Exponent
Specular Exponent controls the falloff of the specular highlight. The greater the value, the sharper the falloff, and the smoother and glossier the material appears. The basic shader material does not provide an input for textures to control the specular exponent of the object. Use nodes from the 3D Material category when more precise control is required over the specular exponent.

Image Source
This control determines the source of the texture applied to the material. If the option is set to Tool, then an input will appear on the node that can be used to apply the output of a 2D node as the texture. Selecting Clip will expose a file browser that can be used to select an image or image sequence from disk. The Brush option will provide a list of clips found in the Fusion\brushes folder.

Bevel Material
This reveal only appears when the Use One Material checkbox control is selected. The controls under this reveal are an exact copy of the Material controls above, but are applied only to the beveled edge of the text.

Transform
These controls can be used to transform the material applied to the text. See the Text+ node for a complete description of these nodes.

Tips for Text3D

Character Level Styling
The Text 3D node doesn’t support Character Level Styling directly. You have to create a Text+ node first and modify its text field with a Character Level Styling modifier. Then either connect the Text 3D’s text field to the modifier that is now available or copy the Text+ node and paste its settings to the Text 3D node (right-click > Paste Settings).

Uncapped 3D Text
To hide the front face of extruded text, uncheck Use One Material on the Shading tab and reduce the first material’s color to black including its alpha value.
Transform 3D [3XF]

The Transform 3D node can be used to translate, rotate, or scale all the elements within a scene without requiring a Merge 3D node. This can be useful for hierarchical transformations, or for offsetting objects that are merged into a scene multiple times. Its controls are identical to those found in other 3D nodes’ Transformation tabs.

Transform 3D Tab

Translation
- X, Y, Z Offset: These controls can be used to position the 3D element.

Rotation
- Rotation Order: Use these buttons to select the order used to apply the Rotation along each axis of the object. For example, XYZ would apply the rotation to the X-axis first, followed by the Y-axis, and then followed by the Z-axis.
- X, Y, Z Rotation: Use these controls to rotate the object around its pivot point. If the Use Target checkbox is selected, then the rotation is relative to the position of the target, otherwise the global axis is used.
Pivot Controls

- **X, Y, Z Pivot**: A pivot point is the point around which an object rotates. Normally, an object will rotate around its own center, which is considered to be a pivot of 0,0,0. These controls can be used to offset the pivot from the center.

Scale

- **X, Y, Z Scale**: If the lock X/Y/Z checkbox is checked, a single scale slider will be shown. This adjusts the overall size of the object. If the Lock checkbox is unchecked, individual X, Y, and Z sliders will be displayed to allow scaling in any dimension.

**NOTE**: If the Lock checkbox is checked, scaling of individual dimensions is not possible, even when dragging specific axes of the Transformation widget in Scale mode.

Use Target

Selecting the Use Target checkbox enables a set of controls for positioning an XYZ target. When Target is enabled, the object will always rotate to face the target. The rotation of the object becomes relative to the target.

Import Transform

Opens a file browser where you can select a scene file saved or exported by your 3D application. It supports the following file types:

<table>
<thead>
<tr>
<th>Format</th>
<th>Extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>LightWave Scene</td>
<td>.lws</td>
</tr>
<tr>
<td>Max Scene</td>
<td>.ase</td>
</tr>
<tr>
<td>Maya Ascii Scene</td>
<td>.ma</td>
</tr>
<tr>
<td>dotXSI</td>
<td>.xsi</td>
</tr>
</tbody>
</table>

The Import Transform button will only import transformation data. For 3D geometry, lights and cameras, consider using the File > FBX Import option from the menus.
On Screen Transformation Widget

A Transformation Widget represents most of the controls in this tab in the Viewer, with modes for transformation, rotation, and scaling. To change the mode of the widget, select one of the three buttons in the toolbar along the side of the Viewer. The modes can also be toggled using the keyboard shortcut q for translation, w for rotation and e for scaling. In all three modes, an individual axis of the control may be dragged to affect just that axis, or the center of the control may be dragged to affect all three axes.

The scale sliders for most 3D nodes defaults to locked, which causes uniform scaling of all three axes. Unlock the Lock X/Y/Z Scale checkbox to scale an object on a single axis only.

Triangulate 3D [3TRI]

This node has no controls. It triangulates any quads or convex polygons.
The UV map 3D node replaces the UV texture coordinates on the geometry in the scene. These coordinates tell Fusion how to apply a texture to an object. The node provides Planar, Cylindrical, Spherical, XYZ, and Cubic Mapping modes, which can be applied to basic Fusion primitives as well as imported geometry. The position, rotation, and scale of the texture coordinates can be adjusted to allow for fine control over the texture’s appearance. An option is also provided to lock the UV produced by this node to animated geometry according to a reference frame. This can be used to ensure that textures applied to animated geometry do not slide.

While it is possible to adjust the global properties of the selected mapping mode, it is not possible to manipulate the UV coordinates of individual vertices directly from within Fusion. The onscreen controls drawn in the Viewers are for reference only and cannot be manipulated.

**External Inputs**

- **UVMap3d.SceneInput**
  - [orange, required] This input expects to receive a 3D scene.

- **UVMap3d.CameraInput**
  - [green, optional] This input expects the output of the Camera 3D node. It is only visible when the Camera Map mode is used.

**Camera Projections with UV Map 3D**

The Camera Mapping mode makes it possible to project texture coordinates onto geometry through a camera. Enable the Camera Mapping mode on the UV Map 3D node. Directly connect the camera that will be used to create the UV coordinates to the new ‘Camera’ input that appears on the UV Map 3D node in the node tree.

Note that this does not directly project an image through the camera. The image to be projected should be connected to the diffuse texture input of whatever material is assigned to the objects. When the texture is applied it will use the UV coordinates created by the camera. Because this is a texture projection and not light, the alpha channel of the texture will correctly set the opacity of the geometry.

See the Camera 3D and Projector 3D node for alternate approaches to projection.

The projection can optionally be locked to the vertices as it appears on a selected frame.

This will fail if the number of vertices in the mesh changes over time, as Fusion must be able to match up the mesh at the reference time and the current time. To be more specific, vertices may not be created or destroyed or reordered. For this reason, projection locking does not work for many particle systems, for primitives with animated subdivisions, and with duplicate nodes using non-zero time offsets.

**NOTE:** The UV Map 3D node does not put a texture or material on the mesh, it only modifies the texture coordinates that the materials will use. This may be confusing because the material usually sits upstream. For example, a composition containing the nodes: Loader > Blinn > Shape 3D (cube) > UV Map 3D > Renderer 3D.
Controls

Map Mode
Defines how the texture coordinates are created. Think of it as a virtual geometry which projects the UV space on the object.

- **Planar**: Creates the UV coordinates using a plane.
- **Cylindrical**: Creates the UV coordinates using a cylindrical shaped object.
- **Spherical**: The UVs are created using a sphere.
- **XYZ to UVW**: The position coordinates of the vertices are converted to uvw coordinates directly. This is used for working with procedural textures.
- **CubeMap**: The UVs are created using a cube.
- **Camera**: Enables the Camera Input port of the node. After connecting a camera to it, the texture coordinates are created based on camera projection.

**Orientation X/Y/Z**
Defines the reference axis for aligning the Map mode.

**Fit**
Clicking this button will fit the Map mode to the bounding box of the input scene.

**Center**
Clicking this button will move the center of the Map mode to the bounding box center of the input scene.
Lock UVs on Animated Objects
If the object is animated, the UVs can be locked to it. Enabling this option will do so and also reveal the Ref Time slider, where it is possible to choose a reference frame for the UV mapping. Using this feature, it is not required to animate the uvmap parameters. It is enough to set up the UV map at the reference time.

Size X/Y/Z
Defines the size of the projection object.

Center X/Y/Z
Defines the position of the projection object.

Rotation/Rotation Order
Use these buttons to select which order is used to apply the rotation along each axis of the object. For example, XYZ would apply the rotation to the X-axis first, followed by the Y-axis and then followed by the Z-axis.

Rotation X/Y/Z
Sets the orientation of the projection object for each axis, dependent from the rotation order.

Tile U/V/W
Defines how often a texture fits into the projected UV space on the according axis. Note that the UVW coordinates are transformed, not a texture. Works best when used in conjunction with the Create Texture node.

Flip U/V/W
Mirrors the texture coordinates around the according axis.

Flip Faces (CubeMap mode only)
Mirrors the texture coordinates on the individual faces of the cube.

NOTE: To utilize the full capabilities of the UV Map 3D node it helps to have a basic understanding of how 2D images are mapped onto 3D geometry. When a 2D image is applied to a 3D surface, it is converted into a texture map that uses UV coordinates to determine how the image translates to the object. Each vertex on a mesh has a (U, V) texture coordinate pair that describes the appearance the object will take when it is unwrapped and flattened. Different mapping modes use different methods for working out how the vertices transform into a flat 2D texture. When using the UV Map 3D node to modify the texture coordinates on a mesh, it is best to do so using the default coordinate system of the mesh or primitive. So the typical workflow would look like Shape 3D > UV Map 3D > Transform 3D. The Transformation tab on the shape node would be left to its default values, and the Transform 3D node following the UV Map 3D does any adjustments needed to place the node in the scene. Modifying/animating the transform of the Shape node will cause the texture to slide across the shape, which is generally undesirable. The UV Map 3D node modifies texture coordinates per vertex and not per pixel. If the geometry the UV map is applied to is poorly tessellated, then undesirable artifacts may appear.
Weld 3D [3WE]

Sometimes 3D geometry has vertices that should have been joined but haven’t. This can cause artifacts, especially when the two vertices have different normals.

For example, you may find:

- The different normals will produce a hard shading/lighting edge where none was intended.
- If you try to Displace3D the vertices along their normals, a crack will appear.
- Missing pixels or doubled up pixels in the rendered image.
- Particles will pass through the tiny invisible cracks.

Rather than roundtripping back to your 3D modeling application to fix the ‘duplicated’ vertices, the Weld3D node allows you to do this in Fusion. Weld3D welds together vertices with the same or nearly the same positions. This can be used to fix cracking issues when vertices are displaced by welding the geometry before the Displace. There are no user controls to pick vertices. Currently, this node welds together just Position vertices; it does not weld normals, texcoords, or any other vertex stream. So even though the positions of two vertices have been made the same, their normals will still have their old values. This can lead to hard edges in certain situations.

Controls

Fracture

Fracturing is the opposite of welding, so all vertices are unwelded. This means that all polygon adjacency information is lost. For example, an Imageplane3D normally consists of connected quads that share vertices. Fracturing the image plane causes it to become a bunch of unconnected quads.

Tolerance

In auto-mode the Tolerance value is automatically detected. This should work in most cases. It can also be adjusted manually if needed.
Usage

Use Weld3D when issues occur with the geometry. Don’t use it everywhere just because it’s there, as it will influence render time.

Weld3D is intended to be used as a mesh robustness tool and not as a mesh editing tool to merge together vertices. If you can see the gap between the vertices you want to weld in the 3D view, you are probably misusing Weld3D. Unexpected things may happen when you do this; do so at your own peril.

Current Issues

Setting the tolerance too large can cause edges/faces to collapse to points.

If your model has detail distributed over several orders of scale, picking a tolerance value can be hard or impossible.

For example, suppose you have a model of the ISS and there are lots of big polygons and lots of really tiny polygons. If you set the tolerance too large, small polygons will be merged that shouldn’t; if you set the tolerance too small, some large polygons won’t be merged.

Vertices that are far from the origin can fail to be merged correctly. This is because bignumber + epsilon can exactly equal bignumber in float math. This is one reason it may be best to merge in local coords and not in world coords.

Sometimes Weld3-ing a mesh can make things worse. Take Fusion’s cone as an example. The top vertex of the cone is currently duplicated for each adjoining face and they all have different normals. If you weld the cone, the top vertices will merge together and will only have one normal, making the lighting look weird.

Weld3D is not multithreaded.

Warning

Do not misuse Weld3D to simplify (reduce the polygon count of) meshes. It is designed to efficiently weld vertices that differ by only very small values, like a 0.001 distance.

Modifier

Coordinate Transform 3D

Because of the hierarchical nature of the Fusion 3D node tree, the original position of an object in the 3D scene often fails to indicate the current position of the object. For example, an image plane might initially have a position at 1, 2, 1, but then be scaled, offset, and rotated by other nodes further downstream in the 3D scene, ending up with an absolute location of 10, 20, 5.

This can complicate connecting an object further downstream in the composition directly to the position of an upstream object. The Coordinate Transform modifier can be added to any set of XYZ coordinate controls and will calculate the current position of a given object at any point in the scene hierarchy.

To add a Coordinate Transform modifier, simply right-click on the a numeric input on any node, and select Modify With/CoordTransform Position from the Controls contextual menu.
Controls

Target Object
This control should be connected to the 3D node that produces the original coordinates to be transformed. To connect a node, drag and drop a node from the node tree into the Text Edit control, or right-click on the control and select the node from the contextual menu. It is also possible to type the node's name directly into the control.

Sub-ID
The SubID slider can be used to target an individual sub-element of certain types of geometry, such as an individual character produced by a Text 3D node or a specific copy created by a Duplicate 3D node.

Scene Input
This control should be connected to the 3D node that outputs the scene containing the object at the new location. To connect a node, drag and drop a node from the node tree into the Text Edit control, or right-click on the control and select an object from the Connect To pop-up menu.
Chapter 75

3D Light Nodes

This chapter details the 3D Light nodes available in the Fusion page.

Ambient Light [3AL]

An Ambient Light is a directionless light that globally illuminates a scene. It has no real position or rotation, although an onscreen widget will appear in the views to indicate that a light is present in the scene. Position controls for the widget are provided to make it possible to move the widget out of the way of other geometry, if necessary.

External Inputs

*AmbientLight.SceneInput*
[orange, optional] This input expects a 3D scene. If a scene is provided, the Transform controls in this node will apply to the entire scene provided.

Controls

Enabling
When the Enabled checkbox is selected, the ambient light affects the scene. Clear the checkbox to turn off the light.

Color
Use this standard Color control to set the color of the light.

Intensity
Use this slider to set the Intensity of the ambient light. A value of .2 indicates 20% percent light. A perfectly white texture lit only with a .2 ambient light would render at 20% gray (.2, .2, .2).
Transform Tab

The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

Directional Light [3DL]

A Directional Light is a light with a clear direction but without a clear source. This light shows an onscreen widget, but the position of the widget has no meaning. The rotation of the widget is used to determine from where in the scene the light appears to be coming.

External Inputs

DirectionalLight.SceneInput
[orange, optional] This input expects a 3D scene. If a scene is provided, the Transform controls in this node will apply to the entire scene provided.

Controls

This tab contains all parameters for the node.
Enabled
When the Enabled checkbox is selected, the directional light affects the scene. Clear the checkbox to turn off the light.

Color
Use this standard Color control to set the color of the light.

Intensity
Use this slider to set the intensity of the ambient light. A value of .2 indicates 20% percent light.

Transform Tab
The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

Point Light [3PL]
A Point Light is a light source with a clear position in space that emits light in all directions. A light bulb is a point light, as is the sun, although light from the sun can appear to be ambient due to scattering from the atmosphere.

This light shows an onscreen widget, although only the position of the widget affects the light. Since the light is a 360-degree source, the rotation of the widget has no meaning. Unlike both ambient and directional lights, a point light may fall off with distance.
**External Inputs**

**PointLight.SceneInput**
[orange, optional] This input expects a 3D scene. If a scene is provided, the Transform controls in this node will apply to the entire scene provided.

**Controls**

![Image of PointLight controls]

**Enabled**
When the Enabled checkbox is selected, the point light affects the scene. Clear the checkbox to turn off the light.

**Color**
Use this standard Color control to set the color of the light.

**Intensity**
Use this slider to set the Intensity of the ambient light. A value of .2 indicates 20% percent light.

**Decay Type**
A point light defaults to No Decay, meaning that its light has equal intensity at all points in the scene. To cause the intensity to fall off with distance, set the Decay Type either to Linear or Quadratic modes.

**Transform Tab**

The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.
Spot Light [3SL]

A Spotlight is a light that comes from a specific point and that has a clearly defined cone, with falloff of the light to the edges. Experienced stage and theatre lighting technicians will recognize the spotlight as being very similar to standard luminaries that are used in live productions. This is the only type of light capable of casting shadows.

External Inputs

SpotLight.SceneInput
[orange, optional] This input expects a 3D scene. If a scene is provided, the Transform controls in this node will apply to the entire scene provided.

Controls

This tab contains all parameters for the node.

Enabled
When this checkbox is selected, the spotlight light affects the scene. Clear the checkbox to turn off the light.
**Color**
Use this standard Color control to set the color of the light.

**Intensity**
Use this slider to set the Intensity of the spotlight.

**Decay Type**
A spotlight defaults to No Falloff, meaning that its light has equal intensity on geometry regardless of the distance from the light to the geometry. To cause the intensity to fall off with distance, set the Decay type either to Linear or Quadratic modes.

**Cone Angle**
The Cone Angle of the light refers to the width of the cone where the light emits its full intensity. The larger the angle, the wider the cone angle, up to a limit of 90 degrees.

**Penumbra Angle**
The Penumbra Angle determines the area beyond the cone angle where the light’s intensity falls off toward 0. A larger penumbra angle defines a larger falloff, while a value of 0 generates a hard-edged light.

**Dropoff**
The Dropoff controls how quickly the penumbra angle falls off from full intensity to 0.

**Shadows**
This section provides several controls used to define the shadow map used when this spotlight creates shadows. See the Lighting and Shadows section of Chapter 60, “3D Compositing Basics,” for details.

**Enable Shadows**
The Enable Shadows checkbox should be selected if the light is to produce shadows. This defaults to selected.

**Shadow Color**
Use this standard Color control to set the color of the shadow. This defaults to black (0, 0, 0).

**Density**
The shadow density determines how opaque the shadow will be. A density of 1.0 will produce a completely transparent shadow, whereas lower values make the shadow transparent.

**Shadow Map Size**
The Shadow Map Size control determines the size of the bitmap used to create the shadow map. Larger values will produce more detailed shadow maps at the expense of memory and performance.

**Shadow Map Proxy**
Shadow Map Proxy determines the size of the shadow map used when the Proxy or Auto Proxy modes are enabled. A value of 0.5 would produce a shadow map at half the resolution defined in the Shadow Map Size.
**Multiplicative/Additive Bias**

Shadows are essentially textures applied to objects in the scene so there will occasionally be Z-fighting, where the portions of the object that should be receiving the shadows render over top of the shadow instead. Biasing works by adding a small depth offset to move the shadow away from the surface it is shadowing, eliminating the Z-fighting. Too little bias and the objects can self-shadow themselves. Too much bias and the shadow can become separated from the surface. Make adjustments to the Multiplicative Bias first, then fine tune the result using the Additive Bias control.

See the Multiplicative and Additive Bias section of Chapter 60, "3D Compositing Basics," for examples and more information.

**Force All Materials Non-Transmissive**

Normally, a RGBA+Z shadow map is used when rendering shadows. By enabling this option you are forcing the renderer to use a Z-only shadow map. This can result in significantly faster shadow rendering while using a fifth as much memory. The disadvantage is that you can no longer cast “stained-glass” like shadows.

**Shadow Map Sampling**

Sets the quality for sampling of the shadow map.

**Softness**

Soft edges in shadows are produced by filtering the shadow map when it is sampled. Fusion has three separate filtering methods available when rendering shadows which produce different effects.

**NOTE:** Shadows will have a hard edge. No filtering of the shadow map is done at all. The advantage of this method is that you only have to sample one pixel in the shadow map, so it is fast.

- **Constant:** Shadows edges will have a constant softness. A filter with a constant width is used when sampling the shadow map. Adjusting the Constant Softness slider controls the size of the filter. Note that the larger you make the filter, the longer it will take to render the shadows.

- **Variable:** The softness of shadow edges will grow the farther away the shadow receiver is from the shadow caster. The variable softness is achieved by changing the size of the filter based on the distance between the receiver and caster. When this option is selected, the Softness Falloff, Min Softness and Max Softness sliders appear.

**Constant Softness**

If the Softness is set to constant, then this slider will appear. It can be used to set the overall softness of the shadow.

**Softness Falloff**

The Softness Falloff slider appears when the Softness is set to variable. This slider controls how fast the softness of shadow edges grows with distance. To be more precise, it controls how fast the shadow map filter size grows based upon the distance between shadow caster and receiver. Its effect is mediated by the values of the Min and Max Softness sliders.
**Min Softness**
The Min Softness slider appears when the Softness is set to variable. This slider controls the Minimum Softness of the shadow. The closer the shadow is to the object casting the shadow, the sharper it will be up to the limit set by this slider.

**Max Softness**
The Max Softness slider appears when the Softness is set to variable. This slider controls the Maximum Softness of the shadow. The further the shadow is from the object casting the shadow, the softer it will be up to the limit set by this slider.

**Transform Tab**
The options that appear in this tab determine the position of the geometry created by this node. Since these controls are identical on all nodes that generate geometry, these controls are fully described in the Common 3D Controls section of this documentation.

Blinn [3BI]

The Blinn node is a basic illumination material that can be applied to geometry in the 3D scene. It describes how the object will respond to light, and provides a large number of texture map inputs to allow fine control over the diffuse, specular, and bumpmap components of the material.

The standard basic material provided in the Material tab of most geometry nodes is a simplified version of the Blinn node. The primary difference is that the Blinn node provides additional texture map inputs beyond just diffuse.

The Blinn node outputs a 3D Material that can be connected to the material inputs on any 3D geometry node.

The Blinn model implemented by Fusion calculates the highlight as the dot product of the surface normal and the half angle vector between lightsource and viewer (dot(N, H)). This may not always match the Blinn model illumination model used by other 3D applications.

External Inputs

**Blinn.DiffuseTex**
[orange, optional] This input will accept a 2D image or a 3D material to be used as a diffuse texture map.

**Blinn.SpecularColorTex**
[green, optional] This input will accept a 2D image or a 3D material to be used as a specular color texture map.

**Blinn.SpecularIntensityTex**
[magenta, optional] This input will accept a 2D image or a 3D material to be used as an intensity map for the materials specular highlights. When the input is a 2D image, the alpha channel is used to create the map while the color channels are discarded.

**Blinn.SpecularExponentTex**
[light blue, optional] This input will accept a 2D image or a 3D material to be used as a falloff map for the materials specular highlights. When the input is a 2D image, the alpha channel is used to create the map while the color channels are discarded.

**Blinn.BumpmapTex**
[white, optional] This input will accept a 2D image or a 3D material, then uses the RGB information as texture-space normals.

Each of these inputs multiplies the pixels in the texture map by the equivalently named parameters in the node itself. This provides an effective method for scaling parts of the material.

When nodes have as many inputs as this one does, it is often difficult to make connections with any precision. Hold the Option (macOS) or Alt (Windows) key down while dragging the output from another node over the node tile, and keep holding Option or Alt when releasing the left mouse button. A small menu listing all of the inputs provided by the node will appear. Click on the desired input to complete the connection.
Alternatively, you can drag the output from a node with the right mouse button to activate the same menu.

Controls

Diffuse

Diffuse describes the base surface characteristics without any additional effects like reflections or specular highlights. In addition to defining the base color of an object, the diffuse color also defines the transparency of the object. The alpha in a diffuse texture map can be used to make portions of the surface of any object the material is applied to transparent.

Diffuse Color

A material’s Diffuse Color describes the base color presented by the material when it is lit indirectly or by ambient light. If a diffuse texture map is provided, then the color value provided here is multiplied by the color values in the texture.

Alpha

This slider sets the material’s Alpha channel value. This affects diffuse and specular colors equally and affects the alpha value of the material in the rendered output. If a diffuse texture map is provided, then the alpha value set here is multiplied by the alpha values in the texture map.

Opacity

Reducing the material’s opacity will decrease the color and alpha values of the specular and diffuse colors equally, making the material transparent.
Specular
The parameters in the Specular section describe the look of the specular highlight of the surface. These values are evaluated in a different way for each illumination model.

Specular Color
Specular Color determines the color of light that reflects from a shiny surface. The more specular a material is, the glossier it appears. Surfaces like plastics and glass tend to have white specular highlights, whereas metallic surfaces like gold have specular highlights that inherit their color from the material color. If a specular texture map is provided, then the value provided here is multiplied by the color values from the texture.

Specular Intensity
Specular Intensity controls how strong the specular highlight is. If the specular intensity texture is provided, then this value is multiplied by the alpha value of the texture.

Specular Exponent
Specular Exponent controls the falloff of the specular highlight. The greater the value, the sharper the falloff, and the smoother and glossier the material appears. If the specular exponent texture is provided, then this value is multiplied by the alpha value of the texture map.

Transmittance
Transmittance controls the way light passes through a material. For example, a solid blue sphere will cast a black shadow, but one made of translucent blue plastic would cast a much lower density blue shadow.

There is a separate opacity option. Opacity determines how transparent the actual surface is when it is rendered. Fusion allows for adjusting both opacity and transmittance separately. This might be a bit counter-intuitive to those who are unfamiliar with 3D software at first. It is possible to have a surface that is fully opaque but transmits 100% of the light arriving upon it, effectively making it a luminous/emissive surface.

Attenuation
Attenuation determines how much color is passed through the object. For an object to have transmissive shadows, set the attenuation to (1, 1, 1), which means 100% of green, blue, red light pass through the object. Setting this color to RGB (1, 0, 0) means that the material will transmit 100% of the red arriving at the surface but none of the green or blue light. This allows for “stained glass” shadows.

Alpha Detail
When the Alpha Detail slider is set to 0, the alpha channel of the object is ignored and the entire object casts a shadow. If it is set to 1, the alpha channel determines what portions of the object cast a shadow.

Color Detail
The Color Detail slider modulates light passing through the surface by the diffuse color + texture colors. Use this to throw a shadow that contains color details of the texture applied to the object. Increasing the slider from 0 to 1 brings in more of diffuse color + texture color into the shadow. Note that the alpha and opacity of the object is ignored when transmitting color, allowing an object with a solid alpha to still transmit its color to the shadow.

Saturation
The Saturation slider controls the saturation of the color component transmitted to the shadow. Setting this to 0.0 will result in monochrome shadows.
**Receives Lighting/Shadows**

These checkboxes control whether the material is affected by lighting and shadows in the scene. If turned off, the object will always be fully lit and/or unshadowed.

**Two Sided Lighting**

This makes the surface effectively two sided by adding a second set of normals facing the opposite direction on the backside of the surface. This is normally off to increase rendering speed, but it can be turned on for 2D surfaces or for objects that are not fully enclosed, to allow the reverse or interior surfaces to be visible as well.

Normally, in a 3D application only the front face of a surface is visible and the back face is culled, so that if a camera were to revolve around a plane in a 3D application, when it reached the backside, the plane would become invisible. Making a plane two sided in a 3D application is equivalent to adding another plane on top of the first but rotated by 180 degrees so the normals are facing the opposite direction on the backside. Thus, when you revolve around the back, you see the second image plane, which has its normals facing the opposite way.

Fusion does exactly the same thing as 3D applications when you make a surface two sided. The confusion about what two sided does arises because Fusion does not cull back-facing polygons by default. If you revolve around a one-sided plane in Fusion, you will still see it from the backside (but you are seeing the frontside duplicated through to the backside as if it were transparent). Making the plane two sided effectively adds a second set of normals to the backside of the plane.

**NOTE:** This can become rather confusing once you make the surface transparent, as the same rules still apply and produce a result, which is counter-intuitive. If you view from the frontside a transparent two-sided surface illuminated from the backside, it will look unlit.

**Material ID**

This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

**Channel Boolean Material [3BOL]**

The Channel Boolean Material can be used to remap and modify channels of 3D materials using mathematical operations. For example, if you want to use the red channel of a material to control a scalar input of an illumination model that uses the alpha channel (e.g., Blinn. SpecularExponent), you can remap the channels here. Furthermore, it allows the use of geometry-specific information like texture space coordinates and normals.
External Inputs

**ChannelBooleanMaterial.BackgroundMaterial**
[orange, optional] This input will accept a 2D image or a 3D material.

**ChannelBooleanMaterial.ForegroundMaterial**
[green, optional] This input will accept a 2D image or a 3D material.

Controls

![ChannelBoolean1](image)

**Operand A/B**
The Operand menus, one for each output RGBA channel, allow the user to set the desired input information for the according channel.

- **Red/Green/Blue/Alpha FG**
  Reads the color information of the foreground material.

- **Red/Green/Blue/Alpha BG**
  Reads the color information of the background material.

- **Black/White/Mid Gray**
  Sets the value of the channel to 0, 1 or 0.5.

- **Hue/Lightness/Saturation FG**
  Reads the color information of the foreground material, converts it into the HLS color space, and puts the selected information into the according channel.

- **Hue/Lightness/Saturation BG**
  Reads the color information of the background material, converts it into the HLS color space, and puts the selected information into the according channel.
• **Luminance FG**
  Reads the color information of the foreground material and calculates the luminance value for the channel.

• **Luminance BG**
  Reads the color information of the background material and calculates the luminance value for the channel.

• **X/Y/Z Position FG**
  Sets the value of the channel to the position of the pixel in 3D space. The vector information is returned in eye space.

• **U/V/W Texture FG**
  Applies the texture space coordinates of the foreground material to the channels.

• **U/V/W EnvCoords FG**
  Applies the environment texture space coordinates to the channels. Use it upstream of nodes modifying the environment texture coordinates like the Reflect 3D node.

• **X/Y/Z Normal**
  Set the value of the channel to the selected axis of the normal vector. The vector is returned in eye space.

**Operation**
Determines the Operation of how the operands are combined.

- **A:** Uses Operand A only for the output channel.
- **B:** Uses Operand B only for the output channel.
- **1-A:** Subtracts the value of Operand A from 1.
- **1-B:** Subtracts the value of Operand B from 1.
- **A+B:** Adds the value of Operand A and B.
- **A-B:** Subtracts the value of Operand B from A.
- **A*B:** Multiplies the value of both Operands.
- **A/B:** Divides the value of Operand B from A.
- **min(A,B):** Compares the values of Operands A and B and returns the smaller one.
- **max(A,B):** Compares the values of Operands A and B and returns the bigger one.
- **avg(A,B):** Returns the average value of both Operands.

**Material ID**
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.
The Cook Torrance node is a basic illumination material that can be applied to geometry in the 3D scene. The diffuse calculation for this node is similar to that used in the basic material and the Blinn node, but the specular highlights are evaluated using an optimized Fresnel/Beckmann equation. This illumination model is primarily used for shading metal or other shiny and highly reflective surfaces.

The Cook Torrance node outputs a 3D Material that can be connected to the material inputs on any 3D geometry node.

### External Inputs

- **CookTorrance.DiffuseTex**  
  [orange, optional] This input will accept a 2D image or a 3D material to be used as a diffuse texture map.

- **CookTorrance.SpecularColorTex**  
  [green, optional] This input will accept a 2D image or a 3D material to be used as a specular color texture map.

- **CookTorrance.SpecularIntensityTex**  
  [magenta, optional] This input will accept a 2D image or a 3D material to be used as an intensity map for the materials specular highlights. When the input is a 2D image, the alpha channel is used to create the map while the color channels are discarded.

- **CookTorrance.SpecularRoughnessTex**  
  [light blue, optional] This input will accept a 2D image or a 3D material to be used as a map for modifying the roughness of the specular highlight. The alpha of the texture map is multiplied by the value of the roughness control.

- **CookTorrance.SpecularRefractiveIndexTex**  
  [white, optional] This input will accept a 2D image or a 3D material to be used as a map for modifying the roughness of the specular refractive index. The alpha of the texture map is multiplied by the value of the refractive index.

- **CookTorrance.BumpmapTex**  
  [white, optional] This input will accept a 2D image or a 3D material, then uses the RGB information as texture-space normals.

Each of these inputs multiplies the pixels in the texture map by the equivalently named parameters in the node itself. This provides an effective method for scaling parts of the material.

When nodes have as many inputs as this one does, it is often difficult to make connections with any precision. Hold the Option (macOS) or Alt (Windows) key down while dragging the output from another node over the node tile, and keep holding Option or Alt when releasing the left mouse button. A small menu listing all of the inputs provided by the node will appear. Click on the desired input to complete the connection.
Controls

Diffuse
Diffuse describes the base surface characteristics without any additional effects like reflections or specular highlights. In addition to defining the base color of an object, the diffuse color also defines the transparency of the object. The alpha in a diffuse texture map can be used to make portions of the surface of any object the material is applied to transparent.

Diffuse Color
A material’s Diffuse Color describes the base color presented by the material when it is lit indirectly or by ambient light. If a diffuse texture map is provided, then the color value provided here is multiplied by the color values in the texture.

Alpha
This slider sets the material’s Alpha channel value. This affects diffuse and specular colors equally, and affects the alpha value of the material in the rendered output. If a diffuse texture map is provided, then the alpha value set here is multiplied by the alpha values in the texture map.

Opacity
Reducing the material’s Opacity will decrease the color and alpha values of the specular and diffuse colors equally, making the material transparent.

Specular
The parameters in the Specular section describe the look of the specular highlight of the surface. These values are evaluated in a different way for each illumination model.
Specular Color
Specular Color determines the color of light that reflects from a shiny surface. The more specular a material is, the glossier it appears. Surfaces like plastics and glass tend to have white specular highlights, whereas metallic surfaces like gold have specular highlights that inherit their color from the material color. If a specular texture map is provided, then the value provided here is multiplied by the color values from the texture.

Specular Intensity
Specular Intensity controls how strong the specular highlight is. If the specular intensity texture is provided, then this value is multiplied by the alpha value of the texture.

Roughness
The Roughness of the specular highlight describes diffusion of the specular highlight over the surface. The greater the value, the wider the falloff, and the more brushed and metallic the surface appears. If the roughness texture map is provided, then this value is multiplied by the alpha value from the texture.

Do Fresnel
Selecting this checkbox will add Fresnel calculations to the materials illumination model. This will provide more realistic looking metal surfaces by taking into account the refractiveness of the material.

Refractive Index
This slider appears when the Do Fresnel checkbox is selected. The Refractive Index applies only to the calculations for the highlight; it does not perform actual refraction of light through transparent surfaces. If the refractive index texture map is provided, then this value is multiplied by the alpha value of the input.

Transmittance
Transmittance controls the way light passes through a material. For example, a solid blue sphere will cast a black shadow, but one made of translucent blue plastic would cast a much lower density blue shadow.

There is a separate Opacity option. Opacity determines how transparent the actual surface is when it is rendered. Fusion allows for adjusting both opacity and transmittance separately. This might be a bit counter-intuitive to those who are unfamiliar with 3D software at first. It is possible to have a surface that is fully opaque but transmits 100% of the light arriving upon it, effectively making it a luminous/emissive surface.

Attenuation
Attenuation determines how much color is passed through the object. For an object to have transmissive shadows, set the attenuation to (1, 1, 1), which means 100% of green, blue, red light pass through the object. Setting this color to RGB (1, 0, 0) means that the material will transmit 100% of the red arriving at the surface but none of the green or blue light. This allows for ‘stained glass’ shadows.

Alpha Detail
When the Alpha Detail slider is set to 0, the alpha channel of the object is ignored and the entire object casts a shadow. If it is set to 1, the alpha channel determines what portions of the object cast a shadow.

Color Detail
The Color Detail slider modulates light passing through the surface by the diffuse color + texture colors. Use this to throw a shadow that contains color details of the texture applied to
the object. Increasing the slider from 0 to 1 brings in more of diffuse color + texture color into
the shadow. Note that the alpha and opacity of the object is ignored when transmitting color,
allowing an object with a solid alpha to still transmit its color to the shadow.

**Saturation**
The Saturation slider controls the saturation of the color component transmitted to the shadow.
Setting this to 0.0 will result in monochrome shadows.

**Receives Lighting/Shadows**
These checkboxes control whether the material is affected by lighting and shadows in the
scene. If turned off, the object will always be fully lit and/or unshadowed.

**Two Sided Lighting**
This makes the surface effectively two sided by adding a second set of normals facing the
opposite direction on the backside of the surface. This is normally off to increase rendering
speed, but it can be turned on for 2D surfaces or for objects that are not fully enclosed, to allow
the reverse or interior surfaces to be visible as well.

Normally, in a 3D application only the front face of a surface is visible and the back face is
culled, so that if a camera were to revolve around a plane in a 3D application, when it reached
the backside, the plane would become invisible. Making a plane two sided in a 3D application is
equivalent to adding another plane on top of the first but rotated by 180 degrees so the normals
are facing the opposite direction on the backside. Thus, when you revolve around the back, you
see the second image plane, which has its normals facing the opposite way.

**NOTE:** This can become rather confusing once you make the surface transparent, as
the same rules still apply and produce a result that is counter-intuitive. If you view from
the frontside a transparent two-sided surface illuminated from the backside, it will
look unlit.

**Material ID**
This slider sets the numeric identifier assigned to this material. This value will be rendered into
the MatID auxiliary channel if the according option is enabled in the renderer.

**Material Merge 3D [3MM]**

The Material Merge node can be used to combine two separate materials together. This node
can be used to composite Material nodes, combining multiple Illumination materials (Blinn,
Cook Torrance) with Texture nodes (Bumpmap, Reflection) to create complex shader networks.
The node also provides a mechanism for assigning a new material identifier to the
combined material.
**External Inputs**

**MtlMerge3D.BackgroundMaterial**
[orange, required] This input will accept a 2D image or a 3D material to be used as the background material. A 2D image will be treated as a diffuse texture map in the basic shading model.

**MtlMerge3D.ForegroundMaterial**
[green, optional] This input will accept a 2D image or a 3D material to be used as the foreground material.

A 2D image will be treated as a diffuse texture map in the basic shading model.

**Controls**

**Blend**
The Blend behavior of the Material Merge is similar to the Dissolve (DX) node for images. The two materials/textures are mixed together using the value of the slider to determine the percentage each input contributes. While the background and foreground inputs can be a 2D image rather than a material, the output of this node will always be a material.

Unlike the 2D Dissolve node, both foreground and background inputs are required.

**MaterialID**
This slider sets the numeric identifier assigned to the resulting material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

**Phong [3PH]**

The Phong node is a basic illumination material that can be applied to geometry in the 3D scene. It describes how the object will respond to light and provides a large number of texture map inputs to allow fine control over the diffuse, specular, and bumpmap components of the material.

While producing a highlight similar to that produced by the Blinn model, it is more commonly used for shiny/polished plastic surfaces.
External Inputs

**Phong.DiffuseTex**
[orange, optional] This input will accept a 2D image or a 3D material to be used as a diffuse texture map.

**Phong.SpecularColorTex**
[green, optional] This input will accept a 2D image or a 3D material to be used as a specular color texture map.

**Phong.SpecularIntensityTex**
[magenta, optional] This input will accept a 2D image or a 3D material to be used as an intensity map for the material’s specular highlights. When the input is a 2D image, the alpha channel is used to create the map while the color channels are discarded.

**Phong.SpecularExponentTex**
[light blue, optional] This input will accept a 2D image or a 3D material to be used as a falloff map for the material’s specular highlights. When the input is a 2D image, the alpha channel is used to create the map while the color channels are discarded.

**Phong.BumpmapTex**
[white, optional] This input will accept a 2D image or a 3D material, then uses the RGB information as texture-space normals.

Each of these inputs multiplies the pixels in the texture map by the equivalently named parameters in the node itself. This provides an effective method for scaling parts of the material.

When nodes have as many inputs as this one does it is often difficult to make connections with any precision. Hold the Option or Alt key down while dragging the output from another node over the node tile, and keep holding Option or Alt when releasing the left mouse button. A small menu listing all of the inputs provided by the node will appear. Click on the desired input to complete the connection.

**Controls**

![Node UI](image.png)
Diffuse
Diffuse describes the base surface characteristics without any additional effects like reflections or specular highlights. In addition to defining the base color of an object, the diffuse color also defines the transparency of the object.

The alpha in a diffuse texture map can be used to make portions of the surface of any object the material is applied to transparent.

Diffuse Color
A material's Diffuse Color describes the base color presented by the material when it is lit indirectly or by ambient light. If a diffuse texture map is provided, then the color value provided here is multiplied by the color values in the texture.

Alpha
This slider sets the material's Alpha channel value. This affects diffuse and specular colors equally and affects the alpha value of the material in the rendered output. If a diffuse texture map is provided, then the alpha value set here is multiplied by the alpha values in the texture map.

Opacity
Reducing the material's Opacity will decrease the color and alpha values of the specular and diffuse colors equally, making the material transparent.

Specular
The parameters in the Specular section describe the look of the specular highlight of the surface. These values are evaluated in a different way for each illumination model.

Specular Color
Specular Color determines the color of light that reflects from a shiny surface. The more specular a material is, the glossier it appears. Surfaces like plastics and glass tend to have white specular highlights, whereas metallic surfaces like gold have specular highlights that inherit their color from the material color. If a specular texture map is provided, then the value provided here is multiplied by the color values from the texture.

Specular Intensity
Specular Intensity controls how strong the specular highlight is. If the specular intensity texture is provided, then this value is multiplied by the alpha value of the texture.

Specular Exponent
Specular Exponent controls the falloff of the specular highlight. The greater the value, the sharper the falloff, and the smoother and glossier the material appears. If the specular exponent texture is provided, then this value is multiplied by the alpha value of the texture map.

Transmittance
Transmittance controls the way light passes through a material. For example, a solid blue sphere will cast a black shadow, but one made of translucent blue plastic would cast a much lower density blue shadow.

There is a separate Opacity option. Opacity determines how transparent the actual surface is when it is rendered. Fusion allows for adjusting both opacity and transmittance separately. This might be a bit counter-intuitive to those who are unfamiliar with 3D software at first. It is possible to have a surface that is fully opaque but transmits 100% of the light arriving upon it, effectively making it a luminous/emissive surface.
**Attenuation**

Attenuation determines how much color is passed through the object. For an object to have transmissive shadows, set the attenuation to (1, 1, 1), which means 100% of green, blue, red light pass through the object. Setting this color to RGB (1, 0, 0) means that the material will transmit 100% of the red arriving at the surface but none of the green or blue light. This allows for “stained glass” shadows.

**Alpha Detail**

When the Alpha Detail slider is set to 0, the alpha channel of the object is ignored and the entire object casts a shadow. If it is set to 1, the alpha channel determines what portions of the object cast a shadow.

**Color Detail**

The Color Detail slider modulates light passing through the surface by the diffuse color + texture colors. Use this to throw a shadow that contains color details of the texture applied to the object. Increasing the slider from 0 to 1 brings in more of diffuse color + texture color into the shadow. Note that the alpha and opacity of the object is ignored when transmitting color, allowing an object with a solid alpha to still transmit its color to the shadow.

**Saturation**

The Saturation slider controls the saturation of the color component transmitted to the shadow. Setting this to 0.0 will result in monochrome shadows.

**Receives Lighting/Shadows**

These checkboxes control whether the material is affected by lighting and shadows in the scene. If turned off, the object will always be fully lit and/or unshadowed.

**Two Sided Lighting**

This makes the surface effectively two sided by adding a second set of normals facing the opposite direction on the backside of the surface. This is normally off to increase rendering speed, but it can be turned on for 2D surfaces or for objects that are not fully enclosed, to allow the reverse or interior surfaces to be visible as well.

Normally, in a 3D application only the front face of a surface is visible and the back face is culled, so that if a camera were to revolve around a plane in a 3D application, when it reached the backside, the plane would become invisible. Making a plane two sided in a 3D application is equivalent to adding another plane on top of the first but rotated by 180 degrees so the normals are facing the opposite direction on the backside. Thus, when you revolve around the back, you see the second image plane, which has its normals facing the opposite way.

Fusion does exactly the same thing as 3D applications when you make a surface two sided. The confusion about what two sided does arises because Fusion does not cull back-facing polygons by default. If you revolve around a one-sided plane in Fusion, you will still see it from the backside (but you are seeing the frontside duplicated through to the backside as if it were transparent). Making the plane two sided effectively adds a second set of normals to the backside of the plane.

**NOTE:** This can become rather confusing once you make the surface transparent, as the same rules still apply and produce a result, which is counter-intuitive. If you view from the frontside a transparent two-sided surface illuminated from the backside, it will look unlit.
Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

Reflect [3RR]

The Reflection node is used to add environment map reflections and refractions to materials. Control is offered over the face on and glancing strength, falloff, per channel refraction indexes and tinting. Several texture map inputs can modify the behavior of each parameter.

The Reflection node is usually combined with a standard lighting material such as Blinn, Cook Torrance, Phong or Ward by connecting the output of that node to the Reflection node’s background material input. Then a reflection texture is connected to the reflection texture input. This can be a 2D image, but is more frequently an environmental map created by the Sphere Map or Cube Map nodes.

Environment mapping is an approximation that assumes an object’s environment is infinitely distant from the object. It’s best to picture this as a cube or sphere with the object at the center. In particular, this infinite distance assumption means that objects cannot interact with themselves (e.g., the reflections on the handle of a teapot will not show the body of the teapot but rather the infinite environment map). It also means that if you use the same cubemap on multiple objects in the scene, those objects will not inter-reflect each other (e.g., two neighboring object would not reflect each other). If you want objects to reflect each other you need to render a cubemap for each.

For more information see Reflections and Refractions in this manual.

External Inputs

Reflect.BackgroundMaterial
[orange, optional] This input expects a 2D image or a 3D material. If a 2D image is provided, the node will treat it as a diffuse texture map applied to a basic material.

Reflect.Reflection.ReflectionTex
[green, optional] This input expects a 2D image or a 3D material. The RGB channels are used as the reflection texture, and the alpha is ignored.

Reflect.Reflection.ReflectionIntensityTex
[magenta, optional] This input expects a 2D image or a 3D material. The alpha channel of the texture is multiplied by the intensity of the reflection.

Reflect.Refraction.RefractionTex
[light blue, optional] This input expects a 2D image or a 3D material. The RGB channels are used as the refraction texture.

Reflect.BumpmapTex
[white, optional] This input will accept a 2D image or a 3D material, then uses the RGB information as texture-space normals.
Reflection

**Reflection Strength Variability**
This multi-button control can be set to Constant or By Angle for varying the reflection intensity, according to the relative surface orientation to the viewer. The following three controls are only visible when this control is set to By Angle.

**Glancing Strength**
[By Angle] Glancing Strength controls the intensity of the reflection for those areas of the geometry where the reflection faces away from the camera.

**Face On Strength**
[By Angle] Face On Strength controls the intensity of the reflection for those parts of the geometry that reflect directly back to the camera.

**Falloff**
[By Angle] Falloff controls the sharpness of the transition between the Glancing and Face On Strength regions. It can be considered to be analogous to applying gamma correction to a gradient between the Face On and Glancing values.

**Constant Strength**
[Constant Angle] This control is only visible when the reflection strength variability is set to Constant. In this case, the intensity of the reflection is constant regardless of the incidence angle of the reflection.
Refraction
If the incoming background material has a lower opacity than 1, then it is possible to use an environment map as refraction texture, and it is possible to simulate refraction effects in transparent objects.

Separate RGB Refraction Indices
When this checkbox is enabled, the Refraction Index slider will be hidden and three sliders for adjusting the refraction index of the Red, Green and Blue channels will appear in its place. This allows for simulation of the spectral refraction effects commonly seen in thick imperfect glass, for example.

Refraction Index
This slider controls how strongly the environment map will be deformed when viewed through a surface. The overall deformation is based on the incidence angle. Since this is an approximation and not a simulation, the results are not intended to model real refractions accurately.

Refraction Tint
The refraction texture is multiplied by the tint color for simulating color-filtered refractions. It can be used to simulate the type of coloring found in tinted glass, as seen in many brands of beer bottles, for example.

Stereo Mix [3SMM]

External Inputs

StereoMix.LeftMaterial
[orange, required] This input will accept a 2D image or a 3D material to be used as the material for the left eye rendering. If a 2D image is used, it will be converted to a diffuse texture map using the basic material type.

StereoMix.RightMaterial
[green, required] This input will accept a 2D image or a 3D material to be used as the material for the right eye rendering. If a 2D image is used, it will be converted to a diffuse texture map using the basic material type.

While the inputs can be either 2D images or 3D materials, the output will always be a material.
Controls

Swap
This option will swap both inputs of the node.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

Ward [3WD]

The Ward node is a basic illumination material that can be applied to geometry in the 3D scene. It describes how the object will respond to light, and provides a large number of texture map inputs to allow fine control over the diffuse, specular and bumpmap components of the material.

In particular, the Ward node is ideal for simulating brushed metal surfaces, as the highlight can be elongated along the U or V directions of the mapping co-ordinates. This is known as an Anisotropic highlight.

The Ward node outputs a 3D Material that can be connected to the material inputs on any 3D geometry node.

External Inputs

Ward.DiffuseTexture
[orange, optional] This input will accept a 2D image or a 3D material to be used as a specular color texture map.

Ward.SpecularColorTexture
[green, optional] This input will accept a 2D image or a 3D material to be used as a specular color texture map.

Ward.SpecularIntensityTexture
[magenta, optional] This input will accept a 2D image or a 3D material to be used as an intensity map for the material’s specular highlights. When the input is a 2D image, the alpha channel is used to create the map while the color channels are discarded.
Ward.SpreadUTexture
[light blue, optional] This input will accept a 2D image or a 3D material. The value of the Spread U option in the node’s controls will be multiplied against the pixel values in the material’s alpha channel.

Ward.SpreadVTexture
[white, optional] This input will accept a 2D image or a 3D material. The value of the Spread V option in the node’s controls will be multiplied against the pixel values in the material’s alpha channel.

Ward.BumpmapTexture
[white, optional] This input will accept a 2D image or a 3D material, then uses the RGB information as texture-space normals.

Each of these inputs multiplies the pixels in the texture map by the equivalently named parameters in the node itself. This provides an effective method for scaling parts of the material.

When nodes have as many inputs as this one does it is often difficult to make connections with any precision. Hold the Option or Alt key down while dragging the output from another node over the node tile, and keep holding Option or Alt when releasing the left mouse button. A small menu listing all of the inputs provided by the node will appear. Click on the desired input to complete the connection.

Controls
Diffuse
Diffuse describes the base surface characteristics without any additional effects like reflections or specular highlights. In addition to defining the base color of an object, the diffuse color also defines the transparency of the object. The alpha in a diffuse texture map can be used to make portions of the surface of any object the material is applied to transparent.

Diffuse Color
A material’s Diffuse Color describes the base color presented by the material when it is lit indirectly or by ambient light. If a diffuse texture map is provided, then the color value provided here is multiplied by the color values in the texture.

Alpha
This slider sets the material’s Alpha channel value. This affects diffuse and specular colors equally and affects the alpha value of the material in the rendered output. If a diffuse texture map is provided, then the alpha value set here is multiplied by the alpha values in the texture map.

Opacity
Reducing the material’s Opacity will decrease the color and alpha values of the specular and diffuse colors equally, making the material transparent.

Specular
The parameters in the Specular section describe the look of the specular highlight of the surface. These values are evaluated in a different way for each illumination model.

Specular Color
Specular Color determines the color of light that reflects from a shiny surface. The more specular a material is, the glossier it appears. Surfaces like plastics and glass tend to have white specular highlights, whereas metallic surfaces like gold have specular highlights that inherit their color from the material color. If a specular texture map is provided, then the value provided here is multiplied by the color values from the texture.

Specular Intensity
Specular Intensity controls how strong the specular highlight is. If the specular intensity texture is provided, then this value is multiplied by the alpha value of the texture.

Spread U
Spread U controls the falloff of the specular highlight along the U-axis in the UV-Map of the object. The smaller the value, the sharper the falloff, and the smoother and glossier the material appears in this direction. If the Spread U texture is provided, then this value is multiplied by the alpha value of the texture.

Spread V
Spread V controls the falloff of the specular highlight along the V-axis in the UV-Map of the object. The smaller the value, the sharper the falloff, and the smoother and glossier the material appears in this direction. If the Spread V texture is provided, then this value is multiplied by the alpha value of the texture.
Transmittance
Transmittance controls the way light passes through a material. For example, a solid blue sphere will cast a black shadow, but one made of translucent blue plastic would cast a much lower density blue shadow.

There is a separate Opacity option. Opacity determines how transparent the actual surface is when it is rendered. Fusion allows for adjusting both opacity and transmittance separately. This might be a bit counter-intuitive to those who are unfamiliar with 3D software at first. It is possible to have a surface that is fully opaque but transmits 100% of the light arriving upon it, effectively making it a luminous/emissive surface.

Attenuation
Attenuation determines how much color is passed through the object. For an object to have transmissive shadows, set the attenuation to (1, 1, 1), which means 100% of green, blue, red light pass through the object. Setting this color to RGB (1, 0, 0) means that the material will transmit 100% of the red arriving at the surface but none of the green or blue light. This allows for "stained glass" shadows.

Alpha Detail
When the Alpha Detail slider is set to 0, the alpha channel of the object is ignored and the entire object casts a shadow. If it is set to 1, the alpha channel determines what portions of the object cast a shadow.

Color Detail
The Color Detail slider modulates light passing through the surface by the diffuse color + texture colors. Use this to throw a shadow that contains color details of the texture applied to the object. Increasing the slider from 0 to 1 brings in more of diffuse color + texture color into the shadow. Note that the alpha and opacity of the object is ignored when transmitting color, allowing an object with a solid alpha to still transmit its color to the shadow.

Saturation
The Saturation slider controls the saturation of the color component transmitted to the shadow. Setting this to 0.0 will result in monochrome shadows.

Receives Lighting/Shadows
These checkboxes control whether the material is affected by lighting and shadows in the scene. If turned off, the object will always be fully lit and/or unshadowed.

Two Sided Lighting
This makes the surface effectively two sided by adding a second set of normals facing the opposite direction on the backside of the surface. This is normally off to increase rendering speed, but it can be turned on for 2D surfaces or for objects that are not fully enclosed, to allow the reverse or interior surfaces to be visible as well.

Normally, in a 3D application only the front face of a surface is visible and the back face is culled, so that if a camera were to revolve around a plane in a 3D application, when it reached the backside, the plane would become invisible. Making a plane two sided in a 3D application is equivalent to adding another plane on top of the first but rotated by 180 degrees so the normals are facing the opposite direction on the backside. Thus, when you revolve around the back, you see the second image plane, which has its normals facing the opposite way.
Fusion does exactly the same thing as 3D applications when you make a surface two sided. The confusion about what two sided does arises because Fusion does not cull back-facing polygons by default. If you revolve around a one-sided plane in Fusion you will still see it from the backside (but you are seeing the frontside duplicated through to the backside as if it were transparent). Making the plane two sided effectively adds a second set of normals to the backside of the plane.

**NOTE:** This can become rather confusing once you make the surface transparent, as the same rules still apply and produce a result that is counter-intuitive. If you view from the frontside a transparent two-sided surface illuminated from the backside, it will look unlit.

**Material ID**

This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.
Chapter 77

3D Texture Nodes

This chapter details the 3D Texture nodes available in the Fusion page.
Contents

BumpMap [3BU] 1504
Catcher [3CA] 1506
CubeMap [3CU] 1508
Falloff [3FA] 1510
Fast Noise Texture [3FN] 1512
Gradient 3D [3GD] 1514
Sphere Map [3SPM] 1516
Texture [TXR] 1518
Texture Transform [3TX] 1519
**BumpMap [3BU]**

The BumpMap node either converts a grayscale (height map) image into a bump map or takes a bump map created by the Create BumpMap node directly. The node outputs a material.

**External Inputs**

- **Bumpmap.ImageInput (white)**
  Receives the RGBA channels from an image for the bump calculation or an existing bump map.

**Controls**

This tab contains all parameters for the node.

- **The Source Image is a...**
  Toggle between HeightMap, which will create a bump map similar to the CreateBumpMap node, and BumpMap, which expects a bump map created by the CreateBumpMap node.

- **Filter Size**
  The process of generating the bump information is basically a Custom Filter. This multi-button control sets the filter size.

- **Extract height information from...**
  Set the channel from where to extract the grayscale information.
Clamp Normal.Z
Clips the lower values of the Blue channel in the resulting bump texture.

Filter Wrap Mode
Basically “wraps” the image at the borders, so the filter produces correct result when using seamless tileable textures.

Height Scale
Changes the contrast of the resulting values in the bump map. Increasing this value yields in a more visible bump map.

Bump map Texture Depth
Optionally converts the resulting bump texture into the desired bit depth.

Notes on Bump maps
There is some confusion of terminology with bumpmapping, depending on which papers/books/people you are reading/talking to. Here are Fusion conventions:

Height map
A grayscale image containing a height value per pixel

Bump map
An image containing normals stored in the RGB channels used for modifying the existing normals (usually given in tangent space)
Normal map

An image containing normals stored in the RGB channels used for replacing the existing normals (usually given in tangent or object space)

Catcher [3CA]

The Catcher material is used to "catch" texture-mode projections cast from Projector 3D and Camera 3D nodes. The intercepted projections are converted into a texture map and applied by the Catcher material to the geometry to which it is connected.

To understand the purpose of the Catcher node it helps to understand the difference between light-based projections and texture-based projections. A light-based projection simply adds the values of the RGB channels in the projected image to the diffuse texture of any geometry that lies within the projection cone. This makes it impossible to clip away geometry based on the alpha channel of an image when using light mode projections.

Imagine a scenario where you want to project an image of a building onto an image plane as part of a set extension shot. You first rotoscope the image to matte out the windows. This will make it possible to see the geometry of the rooms behind the wall in the final composite. When this image is projected as light, the alpha channel is ignored, so the matted windows remain opaque.

By connecting the Catcher to the diffuse texture map of the material applied to the image plane, and then switching the projection from Light or Ambient Light mode to Texture mode, Fusion knows to apply the projected image as a texture map. When using this technique, the windows would become transparent, and it would be possible to see the geometry behind the window.

The main advantages of this approach over light projection are that the Catcher can be used to project alpha onto an object, and it doesn’t require lighting to be enabled. Another advantage is that the Catcher is not restricted to the diffuse input of a material, making it possible to project specular intensity maps, or even reflection and refraction maps.

**NOTE:** The Catcher material requires a Projector 3D or Camera 3D node in the scene, set to project an image in Texture mode on the object to which the Catcher is connected. Without a projection, or if the projection is not set to Texture mode, the Catcher will simply make the object transparent and invisible.
External Inputs

This material node does not have any external inputs.

Controls

Enable
Use this checkbox to enable or disable the node.

Color Accumulation Mode
The Color Accumulation mode is used to control how the Catcher will combine the light from multiple projectors. It will have no affect on the results when only one projector is in the scene. This control is designed to work with the software renderer, and will have no affect when using the OpenGL renderer.

Alpha Accumulation Mode
The Alpha Accumulation mode is used to control how the Catcher will combine the alpha channels from multiple projectors. It will have no affect on the results when only one projector is in the scene. This control is designed to work with the software renderer, and will have no affect when using the OpenGL renderer.

Accumulation Threshold
The Accumulation Threshold can be used to exclude certain low values from the accumulation calculation. For example, when using the Median Accumulation mode, a threshold of 0.01 would exclude any pixel with a value of less than 0.01 from the median calculation.

Restrict by Projector ID
When active, the Catcher will only receive light from projectors with a matching ID. Projectors with a different ID will be ignored.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.
**CubeMap [3CU]**

The CubeMap node creates texture maps using separate images for each face of the cube. It can also extract the individual faces of the cube from a single image containing an unfolded cube in the Vertical or Horizontal Cross layouts.

A cube map is produced by mounting 6 cameras at 90 degrees angle of views to point up, down, left, right, front, and back.

The node provides options to set the reference coordinate system and rotation for the resulting texture map. The CubeMap node is typically used to produce environment maps for distant areas (such as skies or horizons) or reflection and refraction maps.

**External Inputs**

- **CubeMap.CrossImage**
  [white, required] This input is only visible when the node is set to the Vertical Cross or Horizontal Cross orientation. It expects a 2D image.

- **CubeMap.[DIRECTION]**
  [white, required] These six inputs are only visible when the node is set to the Separate Images orientation mode. Each input expects an image aligned to match the left, right, up, down, front and back faces.
Controls

Orientation
This multi-button control tells the node which type of input to expect for the cube map texture. Valid options are:

- **Separate Images**: This option exposes six inputs on the node, one for each face of the cube. If the separate images are not square or not of the same size, they will be rescaled into the largest 1:1 image that can contain all of them.

- **Vertical Cross**: This option exposes a single input on the node. The image should be an unwrapped texture of a cube containing all the faces organized into a Vertical Cross formation, where the height is larger than the width. If the image aspect of the cross image is not 3:4, the CubeMap node will crop it down so it matches the appropriate aspect ratio.

- **Horizontal Cross**: This option exposes a single input on the node. The image should be an unwrapped texture of a cube containing all the faces organized into a Horizontal Cross formation, where the width is larger than the height. If the image aspect of the cross image is not 4:3, the CubeMap node will crop it down so that matches the appropriate aspect ratio.

Coordinate System
This multi-button control sets the coordinate system used when converting the image into a texture.

- **Model**: This option orients the texture along the object local coordinate system.

- **World**: This option orients the resulting texture using the global or world coordinate system.

- **Eye**: This option aligns the texture map to the coordinate system of the camera or viewer.
Warn about bad dimensions
Selecting this checkbox will print a warning message into the console if the dimensions of the image provided do not meet the requirements of the selected orientation mode.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

Falloff [3FA]

The Falloff node blends two materials together based on the incidence angle between the object the material is applied to and the camera. This is useful when you wish to use one material for portions of the geometry that would reflect light directly back to the camera and a different material for parts that reflect light back into the scene.

External Inputs

Falloff.FaceOnMaterial
[orange, optional] This input expects a 2D image or a 3D material. If a 2D image is provided, it will be turned into a diffuse texture map using the basic material shader.

Falloff.GlancingMaterial
[green, optional] This input expects a 2D image or a 3D material. If a 2D image is provided, it will be turned into a diffuse texture map using the basic material shader.

While the inputs for this node can be images, the output will always be a material.
Controls

Color Variation

Two Tone
Two regular Color controls define the colors for Glancing and Face On.

Gradient
A Gradient control defines the colors for Glancing and Face On. This can be used for a multitude of effects, like creating Toon Shaders, for example.

Face On Color

Face On Color
The Face On Color defines the color of surface parts facing the camera. If the Face On texture map is provided, then the color value provided here is multiplied by the color values in the texture.

Face On Opacity
Reducing the material's opacity will decrease the color and alpha values of the Face On material, making the material transparent.
Glancing Color

Glancing Color
The Glancing Color defines the color of surface parts more perpendicular to the camera. If the Glancing material port has a valid input, then this input is multiplied by this color.

Glancing Opacity
Reducing the material’s opacity will decrease the color and alpha values of the Glancing material, making the material transparent.

Falloff
This value controls the transition between Glancing and Face On strength. It is very similar to a gamma operation applied to a gradient, blending one value into another.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

Fast Noise Texture [3FN]

The Fast Noise Texture node is the procedural resolution-independent version of the 2D Fast Noise node. It creates a noise texture directly as a material for usage with 3D nodes. It offers a 3D volumetric mode for creating seamless textures in conjunction with nodes providing UVW texture coordinates (like the UV Map node set to XYZtoUVW or Camera).

External Inputs

FastNoiseTexture.SourceMaterial
[orange, required] This input will accept a 2D image or a 3D material. This is modulated by the noise pattern.

Controls
Output Mode

- **2D**: Calculates the noise texture based on 2D texture coordinates (UV). This mode allows smoothly varying the noise pattern.
- **3D**: Calculates the noise texture based on 3D texture coordinates (UVW). Nodes like Shape 3D automatically provide a third texture coordinate, otherwise a 3D texture space can be created using the UV Map node. Does not support animation of the noise pattern.

Discontinuous

Normally, the noise function interpolates between values to create a smooth continuous gradient of results. Enable this checkbox to create hard discontinuity lines along some of the noise contours. The result will be a dramatically different effect.

Invert

Select this checkbox to Invert the noise, creating a negative image of the original pattern. This is most effective when Discontinuous is also enabled.

Detail

Increase the value of this slider to produce a greater level of detail in the noise result. Larger values add more layers of increasingly detailed noise without affecting the overall pattern. High values take longer to render but can produce a more natural result (not all graphics cards support higher detail levels in hardware).

Brightness

This control adjusts the overall Brightness of the noise map.

Contrast

This control increases or decreases the overall Contrast of the noise map. It can exaggerate the effect of the noise.

Scale

The feature scale of the noise map can be adjusted using the Scale slider, changing it from gentle variations over the whole image to a tighter overall texture effect. This value represents the scale along the UV axis.

Scale Z

(3D only) The Scale Z value scales the noise texture along the W-axis in texture space.

Seethe

(2D only) The Seethe control smoothly varies the 2D noise pattern.

Seethe Rate

(2D only) As with the Seethe control above, the Seethe Rate also causes the noise map to evolve and change. The Seethe Rate defines the rate at which the noise changes each frame, causing an animated drift in the noise automatically, without the need for spline animation.

Material ID

This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.
Gradient 3D [3GD]

With the Gradient 3D node it is possible to texture objects with a variety of gradient types. It offers many of the controls of the Background node. While it is not possible to transform the gradient directly in 3D space, it is orientable using the following nodes:

**Texture Transform Node**
The Texture Transform node can be used to adjust the mapping per pixel.

**UVMap Node**
The UV Map node can be used to adjust the mapping per vertex (use the XYZtoUVW mode). This has onscreen controls, so you can see what the gradient is doing. Using this node is recommended because it is faster to evaluate.

Working with the Gradient node may be a bit confusing at first. The gradient defaults to a linear gradient that goes from -1 to +1 along the Z-axis. All primitives in Fusion (Shape 3D) can output a third texture coordinate for UVW mapping.

Controls
**Gradient Type**

Determines the type of or pattern used for the gradient.

- **Linear**: A simple linear gradient.
- **Reflect**: Based on the Linear mode, this gradient will be mirrored at the middle of the textured range.
- **Square**: The gradient is applied using a square pattern.
- **Cross**: Similar to the Reflect mode, but it will use two axes to apply the gradient.
- **Radial**: The Radial mode uses a circular pattern to apply the gradient.

**Gradient**

The Gradient control consists of a bar where it is possible to add, modify and remove points of the gradient. Each point has its own color. It is possible to animate the color as well as the position of the point. Furthermore, a From Image modifier can be applied to the gradient to evaluate it from an image.

**Gradient Interpolation Method**

The gradient is linear interpolated from point to point in RGB color space by default. This can result in unwanted colors sometimes. Choosing another color space may provide a better result.

**Offset**

Allows panning through the gradient.

**Repeat**

Defines how the left and right border of the gradient is treated.

- **Once**: When using the Gradient Offset control to shift the gradient, the border colors will keep their values. Shifting the default gradient to the left will result in a white border on the left, while shifting it to the right will result in a black border on the right.
- **Repeat**: When using the Gradient Offset control to shift the gradient, the border colors will be wrapped around. Shifting the default gradient to the left will result in a sharp jump from white to black, while shifting it to the right will result in a sharp jump from black to white.
- **Ping Pong**: When using the Gradient Offset control to shift the gradient, the border colors ping pong back and forth. Shifting the default gradient to the left will result in the edge fading from white back to black, while shifting it to the right will result in the edge fading from black back to white.
Sub Pixel
Determines the accuracy with which the gradient is created.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

Sphere Map [3SPM]
The Sphere Map node allows the creation of a spherical texture map from an image. The input image should represent the texture information in a longitude/latitude format, where the X-axis represents 0–360 degrees longitude and the Y-axis represents –90 to +90 degrees latitude.

External Inputs

SphereMap.Image
[white, required] Receives the RGBA channels from an image output.

Controls
Angular Mapping
Adjusts the texture coordinate mapping so the poles are less squashed and areas in the texture get mapped to equal areas on the sphere. In other words, it turns the mapping of the latitude lines from a hemispherical fisheye to an angular fisheye. This mapping attempts to preserve area and makes it easier to paint on or modify a sphere map since the image is not as compressed at the poles.

Rotation
Offers controls to rotate the texture map.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.

The node expects an image with an aspect ratio of 2:1. Otherwise, the image is clamped according to the following rules:
- $2 \times \text{width} > \text{height}$: The width is fit onto the sphere and the poles will display clamped edges.
- $2 \times \text{width} < \text{height}$: The height is fit onto the sphere and there will be clamping about the 0 degree longitude line.

Sphere Map vs. Connecting the Texture to a Sphere Directly
You can connect a latlong (equirectangular) texture map directly to a sphere instead of piping it through the Sphere Map node first. This results in a different rendering if you set the start/end angle and latitude to less than 360°/180°. In the first case, the texture will be squashed. When using the Sphere Map node, the texture will be cropped. Compare:

![Comparison of Sphere Map vs. Connecting Texture Directly](image)

**NOTE:** If you pipe the texture directly into the sphere, it will also be mirrored horizontally. You can “fix” this by using a Transform node first.
Texture [TXR]

The Texture node can control the texture mapping of elements in a rendered image. The Texture-map image (connected to the green input) can be wrapped around objects to replace the current texture. The Texture node relies on the presence of U and V Map channels in 3D rendered images. If these channels are not present, this node has no effect.

Note: Background pixels may have U and V values of 0.0, which will set those pixels to the color of the texture’s corner pixel. To restrict texturing to specific objects, use an effect mask based on the alpha of the object, or its Object or Material ID channel.

For more information, see Chapter 56, “Understanding Image Channels and Noise Processing.”

External Inputs

CreateTexture.ImageInput
[orange, required] This input expects a 2D image.

Controls

Wrap Mode
If a texture is transformed in the texture space (using the controls below or the UV Map node), then it’s possible that areas beyond the image borders are mapped on the object. The Wrap Mode determines how the image is applied in these areas.

- **Wrap**: This wraps the edges of the image around the borders of the image.
- **Clamp**: The color at the edges of the images is used for texturing. This mode is similar to the Duplicate mode in the Transform node.
- **Black**: The image is clipped along its edges. A black color with alpha=0 is used instead.
- **Mirror**: The image is mirrored in both X and Y.

U/V Offset
These sliders can be used to offset the texture along the U and V coordinates.

U/V Scale
These sliders can be used to scale the texture along the U and V coordinates.
Texture Transform [3TX]

The TextureTransform node can be used to translate, rotate, and scale image textures on the input material. While the input can also be an image, the output will always be a material.

External Inputs

TextureTransform.MaterialInput
[orange, optional] This input expects a 2D image or 3D material.

Controls

NOTE: Not all Wrap modes will be supported by all graphics cards.
Translation

**U, V, W Translation**
These sliders will shift the texture along U, V, and W axes.

Rotation

**Rotation Order**
Use these buttons to set the order in which the rotation is applied.

**U, V, W Rotation**
In conjunction with the Rotation Order, these settings define the rotation around the UVW axis.

Scale

**U, V, W Scale**
Scales the texture along the according UVW axis.

Pivot

**U, V, W Pivot**
Sets the reference point for rotation and scaling.

Material ID
This slider sets the numeric identifier assigned to this material. This value will be rendered into the MatID auxiliary channel if the according option is enabled in the renderer.
Chapter 78

Blur Nodes

This chapter details the Blur nodes available in the Fusion page.
Contents

Blur [BLUR] 1523
Defocus [DFO] 1525
Directional Blur [DRBL] 1527
Glow [GLO] 1528
Sharpen [SHRP] 1531
Soft Glow [SGlo] 1533
Unsharp Mask [USM] 1535
VariBlur [VBL] 1536
Vector Motion Blur [VBL] 1537
Blur [BLUR]

The Blur node does exactly what its name implies — it blurs the input image. This is one of the most commonly used image processing operations.

Controls

NOTE: Since a perfect Gaussian filter would require examining an infinite number of pixels, all practical Gaussians are, of necessity, approximations. The algorithm Fusion uses is a highly-optimized approach that has many strengths, but can give rise to visible ringing around the edges in certain extreme cases. This ringing only appears when blurring float-depth images and is normally far below the limits of visibility, especially in final renders or HiQ mode, but may appear in subsequent processing. If you experience this, selecting the Multi-box filter may be a viable alternative.

Filter Type
The Filter Type button array allows for the selection of the filter to be applied to the image.

- **Box Blur**: This option applies a Box Blur effect to the whole image. This method is faster than the Gaussian blur but produces a lower quality result.
- **Soften**: Soften applies a general softening filter effect. This filter method is slower than the Gaussian filter and produces a lower quality result. It is included for compatibility with older node trees only.
- **Bartlett**: Bartlett applies a more subtle, anti-aliased blur filter.
- **Multi-box**: Multi-box uses a Box filter layered in multiple passes to approximate a Gaussian shape. With a moderate number of passes (e.g., four), a high quality blur can be obtained, often faster than the Gaussian filter and without any ringing.
- **Gaussian**: Gaussian applies a smooth, symmetrical blur filter, using a sophisticated constant-time Gaussian approximation algorithm. This mode is the default filter method.
**Color Channels (RGBA)**
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.

**NOTE:** This is not the same as the RGBA checkboxes found under the common controls. The Blur node takes these selections into account before it processes the image, so deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect.

In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

**Lock X/Y**
Locks the X and Y Blur sliders together for symmetrical blurring. This is checked by default.

**Blur Size**
Sets the amount of blur applied to the image. When the Lock X and Y control is deselected, independent control over each axis is provided.

**Clipping Mode**
This option sets the mode used to handle the edges of the image when performing domain of definition rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

- **Frame**
The default option is Frame, which automatically sets the node's domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

- **Domain**
Setting this option to Domain will respect the upstream domain of definition when applying the node's effect. This can have adverse clipping effects in situations where the node employs a large filter.

- **None**
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node's effect that would normally be outside the upstream DoD will be treated as black/transparent.

**Blend**
This is a cloned instance of the Blend slider in the Common Controls tab. Changes made to this control are simultaneously made to the one in the common controls.

The Blend slider mixes the result of the node with its input, blending back the effect at any value less than 1.0.
Examples
This is a comparison of Blur filters visualized as “cross-sections” of a filtered edge. As you can see, Box will create a linear ramp, while Bartlett creates a somewhat smoother ramp. Multi-box and Gaussian result in even smoother ramps that are virtually indistinguishable unless you zoom in really close on the slopes. As mentioned above, Gaussian will overshoot slightly and may result in negative values if used on floating-point images.

Defocus [DFO]

The Defocus node simulates the effects of an out-of-focus camera lens, including blooming and image flaring. It provides a fast but relatively inaccurate Gaussian mode, as well as a more realistic but much slower Lens mode.

Controls

Filter
Use this menu to select the exact method applied to create the defocus. Gaussian applies a fairly simplistic effect, while Lens mode will create a much more realistic defocus. Lens mode will take significantly longer than Gaussian.

Lock X/Y
When Lock X/Y is selected, this performs the same amount of defocusing to both the X- and Y-axis of the image. Deselect to obtain individual control.
**Defocus Size**
The Defocus Size control sets the size of the defocus effect. Higher values blur the image by greater amounts and produce larger blooms.

**Bloom Level**
The Bloom Level control determines the intensity and size of the blooming applied to pixels that are above the bloom threshold.

**Bloom Threshold**
Pixels with values above the set Bloom Threshold are defocused and have a glow applied (blooming). Pixels below that value are only defocused.

**Lens Type**
The basic shape that is used to create the “bad bokeh” effect. This can be refined further with the Angle, Sides and Shape sliders.

**Lens Angle**
Defines the rotation of the shape. Best visible with NGon lens types. Due to the round nature of a circle, this slider will have no visible effect when the Lens Type is set to Circle.

**Lens Sides**
Defines how many sides the NGon shapes will have. Best visible with NGon lens types. Due to the round nature of a circle, this slider will have no visible effect when the Lens Type is set to Circle.

**Lens Shape**
Defines how pointed the NGons are. Higher values will create a more pointed, starry look. Lower values create smoother NGons. Best visible with NGon lens types and Lens Sides between 5 and 10. Due to the round nature of a circle, this slider will have no visible effect when the Lens Type is set to Circle.

**Use OpenCL**
Introduced with Fusion's OpenCL supercomputing, this option renders the effect on the GPU rather than on the CPU. Depending on the graphics card used in the computer, this can boost the speed of the node by a factor of 30 and more.

**Clipping Mode**
This option sets the mode used to handle the edges of the image when performing domain of definition rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

**Frame**
The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

**Domain**
Setting this option to Domain will respect the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

**None**
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD will be treated as black/transparent.
Directional Blur [DRBL]

This node is used to create Directional and Radial blurs. It is useful for creating simulated motion blur and light ray type effects. Directional Blur affects all channels (RGBA).

Controls

Type
This button array is used to select the Type of directional blur to be supplied to the image.

Linear
Linear distorts the image in a straight line, resembling the scenery that appears in the window of a speeding train.

Radial
Radial will create a distortion that originates at some arbitrary center, radiating outward the way that a view would appear if one were at the head of the train looking forward.

Centered
The Centered button produces a similar result to linear, but the blur effect is equally distributed on both sides of the original.

Zoom
Zoom creates a distortion in the scale of the image smear to simulate the zoom streaking of a camera filming with a slow shutter speed.

Center X and Y
This coordinate control and crosshair affects the Radial and Zoom Motion blur types only. It is used to calculate the position from where the blurring effect starts.
Length
Length adjusts the strength and heading of the effect. Values lower than zero cause blurs to oppose the angle control. Values greater than the slider maximum may be typed into the slider’s edit box.

Angle
In both Linear modes, this control will modify the direction of the directional blur. In the Radial and Zoom modes, the effect will be similar to that of the camera spinning while looking at the same spot. If the setting of the length slider is other than zero, the effect will create a whirlpool effect.

Glow
This will add a Glow to the directional blur, which can be used to duplicate the effect of increased camera exposure to light caused by longer shutter speeds.

Clipping Mode
This option sets the mode used to handle the edges of the image when performing domain of definition rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

Frame
The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

Domain
Setting this option to Domain will respect the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

None
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD will be treated as black/transparent.

Glow [GLO]

A Glow is basically created by blurring an image, then brightening the blurred result and mixing it back with the original.

The Glow node provides a more convenient way to accomplish this effect, as well as a variety of variations on the theme. For example, a Bartlett glow is a high quality glow with smoother drop off, however, it is more processor-intensive at larger sizes.
Controls

Filter
Use these buttons to select the method of Blur used in the filter. The selections are described below.

Box
A simple but very fast Box filter.

Bartlett
Bartlett adds a softer, subtler glow with a smoother drop off but may take longer to render than Box.

Multi-box
Multi-box uses a Box filter layered in multiple passes to approximate a Gaussian shape. With a moderate number of passes (e.g., four), a high quality blur can be obtained, often faster than the Gaussian filter, and without any ringing.

Gaussian
Gaussian adds a soft glow, blurred by the Gaussian algorithm. This is the default method.

Blend
Blend adds a non-linear glow that is evenly visible in the whites and blacks.

Hilight
Hilight adds a glow without creating a halo in the surrounding pixels.

Solarize
Solarize adds a glow and solarizes the image.
**Color Channels (RGBA)**
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.

This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes. Deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect.

In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

**Lock X/Y**
When Lock X/Y is checked, both the horizontal and vertical glow amounts will be locked. Otherwise, separate amounts of blur may be applied to each axis.

**Glow Size**
Glow Size determines the size of the glow effect. Larger values expand the size of the glowing highlights of the image.

**Num Passes**
Only available in Multi-box mode. Larger values result in a smoother distribution of the effect but also increase render times. It’s good to find that thin line between desired quality and acceptable render times.

**Glow**
The Glow slider determines the intensity of the glow effect. Larger values tend to completely blow the image out to white.

**Clipping Mode**
This option sets the mode used to handle the edges of the image when performing domain of definition rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

**Frame**
The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

**Domain**
Setting this option to Domain will respect the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

**None**
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD will be treated as black/transparent.

**Blend**
This is a cloned instance of the Blend slider in the Common Controls tab. Changes made to this control are simultaneously made to the one in the common controls.

The Blend slider mixes the result of the node with its input, blending back the effect at any value less than 1.0.
Apply Mode

Three Apply Modes are available when it comes to applying the glow to the image.

- **Normal**: Default. This mode simply adds the glow directly over top of the original image.
- **Merge Under**: Merge Under places the glow beneath the image, based on the alpha channel. Threshold mode permits clipping of the threshold values.
- **Threshold**: This control clips the effect of the glow. A new range slider will appear. Pixels in the glowed areas with values below the low value will be pushed to black. Pixels with values greater than high will be pushed to white.
- **High-Low Range Control**: Only available in Threshold mode. Pixels in the glowed areas with values below the low value will be pushed to black. Pixels with values greater than high will be pushed to white.

Color Scale (RGBA)

These Scale sliders are normally a reveal control labeled Color Scale. They can be used to adjust the amount of glow applied to each color channel individually, thereby tinting the glow.

Glow Pre Mask

The Glow node supports pre-masking using the glow mask. A Glow Pre Mask filters the image before applying the glow. The glow is then merged back over the original image. This is different from a regular effect mask that clips the rendered result.

The Glow mask allows the glow to extend beyond the borders of the mask, while restricting the source of the glow to only those pixels within the mask.

To apply a glow mask, select Glow Mask instead of Effect Mask from the contextual menu when a Glow node is active. Glow masks are identical to Effects masks in every other respect.

**Sharpen [SHRP]**

The Sharpen node uses a convolution filter to enhance detail in an image.

Controls
**Color Channels (RGBA)**
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.

This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes, so deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect.

In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

**Lock X/Y**
This locks the X and Y Sharpen sliders together for symmetrical sharpening. This is checked by default.

**Amount**
This slider sets the amount of sharpening applied to the image. When the Lock X/Y control is deselected, independent control over each axis is provided.

**Clipping Mode**
This option sets the mode used to handle the edges of the image when performing domain of definition rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

**Frame**
The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

**Domain**
Setting this option to Domain will respect the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

**None**
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD will be treated as black/transparent.

**Blend**
This is a cloned instance of the Blend slider in the Common Controls tab. Changes made to this control are simultaneously made to the one in the common controls.

The Blend slider mixes the result of the node with its input, blending back the effect at any value less than 1.0.
Soft Glow [SGlo]

The Soft Glow node is similar to the Glow node but performs additional processing of the image to create a much softer, more natural glow.

This node is perfect for atmospheric haze around planets, skin tones, and simulating dream-like environments.

**NOTE:** The Glow node supports pre-masking using the Glow Pre Mask input on the node. A pre-mask limits the image before applying the glow. The glow is then is combined with the original image. This is different from a regular effect mask that limits the rendered result.

The Glow mask allows the glow to extend beyond the borders of the mask, while restricting the source of the glow to only those pixels within the mask.

**Controls**
**Filter**

Use these buttons to select the method of Blur used in the filter. The selections are described below.

- **Box**: A simple but very fast Box filter.
- **Bartlett**: Bartlett adds a softer, subtler glow with a smoother drop off but may take longer to render than Box.
- **Multi-box**: Multi-box uses a Box filter layered in multiple passes to approximate a Gaussian shape. With a moderate number of passes (e.g., four), a high quality blur can be obtained, often faster than the Gaussian filter and without any ringing.
- **Gaussian**: Gaussian adds a soft glow, blurred by the Gaussian algorithm. This is the default method.

**Color Channels (RGBA)**

The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.

This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes, so deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect.

In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

**Threshold**

This control is used to limit the affect of the soft glow. The higher the threshold, the brighter the pixel must be before it is affected by the glow.

**Gain**

The Gain control defines the brightness of the glow.

**Lock X/Y**

When Lock X/Y is checked, both the horizontal and vertical glow amounts will be locked. Otherwise, separate amounts of glow may be applied to each axis of the image.

**Glow Size**

Amount determines the size of the glow effect. Larger values expand the size of the glowing highlights of the image.

**Num Passes**

Only available in Multi-box mode. Larger values result in a smoother distribution of the effect but also increase render times. It’s good to find that thin line between desired quality and acceptable render times.

**Clipping Mode**

This option sets the mode used to handle the edges of the image when performing domain of definition rendering. This is profoundly important for node like Blur, which may require samples from portions of the image outside the current domain.

**Frame**

The default option is Frame, which automatically sets the node’s domain of definition to use the full frame of the image, effectively ignoring the current domain of definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.
Domain
Setting this option to Domain will respect the upstream domain of definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

None
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect that would normally be outside the upstream DoD will be treated as black/transparent.

Blend
This is a cloned instance of the Blend slider in the Common Controls tab. Changes made to this control are simultaneously made to the one in the common controls. The Blend slider mixes the result of the node with its input, blending back the effect at any value less than 1.0.

Color Scale (RGBA)
These Scale sliders are normally a reveal control labeled Color Scale. They can be used to adjust the amount of glow applied to each color channel individually, thereby tinting the glow.

Unsharp Mask [USM]
Unsharp masking is a technique used to sharpen only the edges within an image. This node is most often used to correct for blurring and loss of detail in low contrast images, for example, to extract useful detail from long exposure shots of far-away galaxies.

This filter extracts a range of frequencies from the image and blurs them to reduce detail. The blurred result is then compared to the original images. Pixels with a significant difference between the original and the blurred image are likely to be an edge detail. The pixel is then brightened to enhance it.

Controls

Color Channels (RGBA)
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.
This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes, so deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect.

In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

**Lock X/Y**
When Lock X/Y is checked, both the horizontal and vertical sharpen amounts will be locked. Otherwise, separate amounts of glow may be applied to each axis of the image.

**Size**
This control adjusts the size of blur filter applied to the extracted image. The higher this value, the more likely it is that pixels will be identified as detail.

**Gain**
The Gain control adjusts how much gain is applied to pixels identified as detail by the mask. Higher values will create a sharper image.

**Threshold Low and High**
This range control determines the frequencies from the source image to be extracted. Raising low values will eliminate dark pixels from the comparison. Pixels above the high value will have the full effect of the gain applied.

### VariBlur [VBL]

The VariBlur node gives a true Per-pixel Variable blur, using a second image to control the amount of blur for each pixel. It is somewhat similar in effect to the Depth Blur node but uses a different approach for cleaner results in many cases.

**Controls**

**NOTE:** The Blur Image input must be connected, or no blurring will be performed.
Method

**Soften**
This method varies from a simple Box shape to a Bartlett triangle to a decent-looking Smooth blur as Quality is increased. It is a little better at preserving detail in less-blurred areas than Multi-box.

**Multibox**
Similar to Soften, this gives a better Gaussian approximation at higher Quality settings.

**Defocus**
Not really a true defocus, this gives a flat, circular shape to blurred pixels that can approximate the look of a defocus.

**Quality**
Increasing Quality gives smoother blurs, at the expense of speed. Quality set to 1 uses a very fast but simple Box blur for all Method settings. A Quality of 2 is usually sufficient for low Blur Size values. 4 is generally good enough for most jobs unless Blur Size is particularly high.

**Blur Channel**
This selects which channel of the Blur Image controls the amount of blurring applied to each pixel.

**Lock X/Y**
When selected, only a Blur Size control is shown, and changes to the amount of blur are applied to both axes equally. If the checkbox is cleared, individual controls appear for both X and Y Blur Size.

**Blur Size**
Increasing this control will increase the overall amount of blur applied to each pixel. Those pixels where the Blur Image is black or non-existent will never be blurred, regardless of Blur Size.

---

**Vector Motion Blur [VBL]**

This node is used to create Directional blurs based on a Vector Channel.

This node will perform a 2D blur on the image, using a vector map produced by a 3D application. The vector map is typically two floating-point images, one channel specifies how far the pixel is moving in X, and the other specifies how far the pixel is moving in Y. These channels may be embedded in the image in the case of OpenEXR or RLA/RPF images, or may be provided as separate images using the node’s Vectors input.

The vector channels should use a float16 or float32 color depth, to provide + and – values.

A value of 1 in the X channel would indicate that pixel has moved one pixel to the right, while a value of –10 indicates ten pixels of movement to the left.
Controls

X Channel
Use this multi-button array to choose which channel of the image will provide the vectors for the movement of the pixels along the X-axis.

Y Channel
Use this multi-button array to choose which channel of the image will provide the vectors for the movement of the pixels along the Y-axis.

Flip X Channel
This checkbox can be used to flip, or invert, the X-vectors. A value of 5 for a pixel in the X-vector channel would become –5 when this checkbox is selected.

Flip Y Channel
This checkbox can be used to flip, or invert, the Y vectors. A value of 5 for a pixel in the Y-vector channel would become –5 when this checkbox is selected.

Lock Scale X/Y
Selecting this checkbox will provide access to separate sliders for X and Y Scale. By default only a single Scale slider is provided.

Scale/Scale X
This slider will be labeled Scale if the Lock Scale X/Y checkbox is not selected, otherwise it will be labeled Scale X. The vector channel value for a pixel is multiplied by the value of this slider. For example, given a scale of 2 and a vector value of 10, the result would be 20.

Scale Y
This slider will only appear if the Lock Scale X/Y checkbox is selected. Otherwise, it will be hidden, and use the same value set in the Scale slider above.
This chapter details the Color nodes available in the Fusion page.

Auto Gain [AG]

The Auto Gain node is used to automatically adjust the color range of an image so that the darkest and brightest pixels are set to user-selected values. By default, the darkest pixels in the image are pushed down to black, the brightest pixels are pushed to white and all of the pixels in between are stretched to cover the color range evenly.

This can be useful when compensating for variations in lighting, dealing with low contrast images, or visualizing the full color range of float images (though the Viewer’s View Normalized Image button is generally more suitable for this).

Controls

NOTE: Variations over time in the input image can cause corresponding variations in the levels of the result. For example, if a bright object moves out of an otherwise dark shot, the remaining scene will get suddenly brighter, as the remaining darker values are stretched to white. This also applies to sudden depth changes when Do Z is applied; existing objects may be pushed forward or backward when a near or far object enters or leaves the scene.

Do Z
Select the Do Z checkbox to apply the Auto Gain effect to the Z-channels. This can be useful for matching the ranges of one Z-channel to another, or to view a float Z-channel in the RGB values.

Range
This Range control is used to set the lowest and highest possible pixel value in the image. All color values in the image are rescaled to fit within this range.

Examples
Create a horizontal gradient with the Background node. Set one color to dark gray (RGB Values 0.2). Set the other color to light gray (RGB Values 0.8).

Add an Auto Gain node and set the Low value to 0.0 and the High to 0.5. This will cause the brightest pixels to be pushed down to 0.5 and the darkest pixels will get pushed to black. The remainder of the pixel values will be scaled between those limits.
Brightness Contrast [BC]

The Brightness Contrast node is used to adjust the gain, brightness, contrast, gamma and saturation of an image. The order of the controls represents the order in which each operation is applied (for example, gamma is applied before contrast but after gain). The Brightness Contrast is also reversible using the Forward and Reverse buttons. So color corrections, once applied, can be reversed further downstream.

For this to work best, make sure that your image is processed in 32bit floating point.

Controls

Color Channels (RGBA)
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.

This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes, so deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect.

In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

Gain
The pixel values are multiplied by the value of this control. A Gain of 1.2 will make a pixel that is R0.5 G0.5 B0.4 into R0.6 G0.6, B0.48 (i.e., 0.4 * 1.2 = 0.48). Gain affects higher values more than it affects lower values, so the effect will be strongest in the midrange and top range of the image.
Lift
While Gain basically scales the color values around black, Lift scales the color values around white. The pixel values are multiplied by the value of this control. A Lift of 0.5 will make a pixel that is R0.0 G0.0 B0.0 into R0.5 G0.5, B0.5, while leaving white pixels totally unaffected. Lift affects lower values more than it affects higher values, so the effect will be strongest in the midrange and low range of the image.

Gamma
Values higher than 1.0 will raise the Gamma (mid gray), whereas lower values will decrease it. The effect of this node is not linear and existing black or white levels will not be affected at all. Pure gray colors will be affected the most.

Contrast
Contrast is the range of difference between the light to dark areas. Increasing the value of this slider will increase the contrast, pushing color from the midrange toward black and white. Reducing the contrast will cause the colors in the image to move toward midrange, reducing the difference between the darkest and brightest pixels in the image.

Brightness
The value of the Brightness slider is added to the value of each pixel in the image. This control's affect on an image is linear so the effect will be applied identically to all pixels regardless of value.

Saturation
This control is used to increase or decrease the amount of Saturation in the image. A saturation of 0 has no color. All colors are grayscale.

Low and High
This range control is similar to the Gain control in some respects. If Low is anchored at 0.0 and the High value is reduced from 1.0, the effect is identical to increasing the gain. High values are multiplied by the inverse of the high value. (e.g., if high is 0.75, each pixel will be multiplied by 1/0.75 or 1.3333).

Leaving the high anchored at 1.0 and increasing the low is exactly the same as inverting the image colors and increasing the gain and inverting it back again. This pushes more of the image toward black without affecting the whites at all.

Direction
Forward applies all values normally. Reverse effectively inverts all values.

Clip Black/White
The Clip Black and Clip White checkboxes are used to clip out of range color values that can appear in an image when processing in floating-point color depth. Out of range colors are below black (0.0) or above white (1.0). These checkboxes will have no affect on images processed at 8-bit or 16-bit per channel, as such images cannot have out of range values.

Pre-Divide/Post-Multiply
Selecting the Pre-Divide/Post-Multiply checkbox will cause the image pixel values to be divided by the alpha values prior to the color correction, and then re-multiplied by the alpha value after the correction.

This helps to prevent the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.
Channel Booleans [BOL]

The Channel Booleans node can be used to apply a variety of mathematical and logical operations on the channels in an image. This node works by using one image’s channels to modify another image’s channels. If a foreground input is not available, selecting options that use color channels from the foreground will end up using the background input’s color channels instead.

**On the Color Channels Tab the Node Controls are Divided as Follows:**
On the left side are target channels for the image piped into the Channel Booleans (background input). The drop down to the right lets you choose whether you want to modify the BG image with its own channels (suffix BG after list name) or with the channels from another image, which must be piped into the foreground input on the Channel Booleans node (suffix FG in the drop-down list).

**Controls**

**Operation Type**
This drop-down box is used to select the mathematical method applied to the selected channels. Its settings are as follows:

**Copy**
Copy the value from one color channel to another. For example, copy the foreground red channel into the alpha channel to create a matte.

**Add**
Add the color values from color channel to channel.

**Subtract**
Subtract the color values of one color channel from another color channel.

**And**
Perform a logical AND on the color values from color channel to color channel. The foreground image will generally remove bits from the color channel of the background image.
Or
Perform a logical OR on the color values from color channel to color channel. The foreground image will generally add bits from the color channel of the background image.

0Exclusive Or
Perform a logical XOR on the color values from color channel to color channel. The foreground image will generally flip bits from the color channel of the background image.

Multiply
Multiply the values of a color channel. This will give the appearance of darkening the image as the values are scaled from 0 to 1. White has a value of 1 so the result would be the same. Gray has a value of 0.5 so the result would be a darker image or, in other words, an image half as bright.

Divide
Divide the values of a color channel. This will give the appearance of lightening the image as the values are scaled from 0 to 1.

Maximum
Compare the two images and take the Maximum, or brightest, values from each image.

Minimum
Compare the two images and take the Minimum, or darkest, values from each image.

Negative
Invert the FG input to make a Negative version of the image.

Solid
Solid sets a channel to a full value of 255. This is useful for setting the alpha to full value.

Clear
Clear sets a channel to a value of zero. This is useful for clearing the alpha.

Difference
Difference subtracts the greater color values of one color channel from the lesser values of another color channel.

Signed Add
Signed Add subtracts areas that are lower than mid-gray and adds areas that are higher than mid-gray, which is useful for creating effects with embossed gray images.

To Red, Green, Blue, Alpha
These menus represent the four color channels of the output image. Use the drop-down menu to select which channel from the source images will be used to produce the output channel.

The default setting simply copies the channels from the foreground channel. Select any one of the four color channels, as well as several auxiliary channels like Z-buffer, saturation, luminance and hue.
Auxiliary Channels

There are several auxiliary channels. Use these menus to select a source for the auxiliary channels of the output image. See Chapter 74, “3D Nodes,” for further details on auxiliary channels.

Enable Extra Channels

When the Enable Extra Channels checkbox is selected, the Channel Boolean node will be able to output images with channels beyond the usual RGBA. The remaining controls in this tab will become active and can be used to copy data into the auxiliary channels.

Examples

To copy the alpha channel of one image to its own color channels, set the red, green, and blue channels to Alpha BG. Set the Operation to Copy.

To copy the alpha channel from another image, set operation type to Alpha FG.

To replace the existing alpha channel of an image with the alpha of another image choose “Do Nothing” for To Red, To Green, and To Blue and “Alpha FG” for To Alpha. Pipe the image containing the alpha into the foreground input on the Channel Booleans node. Set Operation: “Copy.” The same operation can also be performed using the Matte Control node.

To combine any type of mask into an alpha for an image choose “Do Nothing” for To Red, To Green, and To Blue and “Matte” for To Alpha. Pipe the mask into the foreground input on the Channel Booleans node. Set Operation: “Copy.”

To subtract the red channel’s pixels of another image from the blue channel choose “Do Nothing” for To Red and To Green and “Red FG” for To Blue. Pipe the image containing the red channel to subtract into the foreground input on the Channel Booleans node. Set Operation: “Subtract.”

Color Corrector [CC]

The Color Corrector node is a comprehensive color node with histograms, matching and equalization, hue shifting, tinting and color suppression. The Color Corrector has two image inputs. Connect the image to be corrected to the primary input. The secondary input can be used as a reference for histogram matching.

Overview

Controls in the Color Correction node are separated into four separate categories: colors, levels, histogram and suppress. Selecting one of the category buttons from the array at the top of the Correction tab will cause that category’s controls to appear. Each category is described in detail below.
Colors Mode

Master/Shadows/Midtones/Highlights

This array of buttons determines the range of colors affected by the controls in this tab. For example, when the Shadows range is selected, any color adjustments made will affect only the darker pixels of the image.

The selected state of this button is maintained throughout the Colors, Levels, and Suppress sections of the Color Corrector node.

Adjustments made to the image in the Master channel are applied to the image after any changes made to the Highlight, Midtone, and Shadow ranges.

NOTE: The controls are independent for each color range. For example, adjusting the Gamma control while in Shadows mode will not change or affect the value of the Gamma control for the Highlights mode. Each control is independent and applied separately.

Color Wheel

The Color Wheel display provides a visual representation of adjustments made to Hue and Saturation, as well as any tinting applied to the image. Adjustments can be made directly on the display, or by entering values in the text boxes to the right of the color wheel.
Hue
The Hue control provides a method of shifting the hue of the image (or selected color range) through the color spectrum. The control value has an effective range between 0.0 and 1.0, which represents the angle of rotation in a clockwise direction. A value of 0.25 would be 90 degrees (90/360) and would have the effect of shifting red toward blue, green to red, and so on.
The degree of hue shifting can be entered directly into the text control, or by placing the mouse above the outer ring of the color control and dragging the mouse up or down. The outer ring will always show the shifted colors compared to the original colors shown in the center of the control.

Saturation
The Saturation control is used to adjust the intensity of the color values. A saturation of 0 produces gray pixels without any chroma or color component, whereas a value of 1.0 produces no change in the chroma component of the input image. Higher values will generate over-saturated values with a high color component.
Saturation values can be entered directly into the text control, or by dragging the mouse to the left and right on the outer ring of the color wheel control.

Tint/Strength
The Tint control is used to tint an image or selected color range. The values in this control go from 0 to 1.0, which indicate the angle of the tint color on the color wheel.
A value of 0.25 would indicate 90 degrees, which would be midway between green and yellow on the color wheel.
The Strength control determines how much tint is applied to the selected range of colors.
The tinting is represented in the Color Wheel control by small circles that show the color and strength of the tint. The Highlight Ranges marker is a black outline of a circle. The Midtones and Shadows are represented by gray circles. The Master Tint Marker is also black, but it has a white M in the center to distinguish it from the others.
The mouse can position the marker for each range only when the appropriate range is selected. For example, the Highlight Marker cannot be moved when the Master range is selected.
Holding down the Command or Ctrl key while dragging this control will allow you to make finer adjustments by reducing the control’s sensitivity to mouse movements. Holding the Shift key down will limit the movement of the marker to a single axis, allowing you to restrict the effect to either tint or strength.

Tint Mode

Fast/Full/Better
These three buttons are used to select the speed and quality of the algorithm used to apply the tint, hue and saturation adjustments. The default is Better, but for working with larger images, it may be desirable to use a faster method.

Hue
This slider is a clone of the Hue control shown in the color wheel above. The slider makes it easier to make small adjustments to the value with the mouse.
**Saturation**
This slider is a clone of the Saturation control shown in the color wheel above. The slider makes it easier to make small adjustments to the value with the mouse.

**RGB/Red/Green/Blue**
These buttons are the same buttons seen in the Histogram, Color and Levels sections of the Color Corrector node. When the red channel is selected, the controls in this tab will affect the red channel only, and so on.

The controls are independent, so switching to blue will not remove or eliminate any changes made to red, green or master. The animation and adjustments made to each channel are separate. These buttons simply determine what controls to display.

**Master RGB Contrast**
Contrast is the range of difference between the light to dark areas. Increasing the value of this slider will increase the contrast, pushing color from the midrange toward black and white. Reducing the contrast will cause the colors in the image to move toward midrange, reducing the difference between the darkest and brightest pixels in the image.

**Master RGB Gain**
The pixel values are multiplied by the value of this control. A Gain of 1.2 will make a pixel that is R0.5 G0.5 B0.4 into R0.6 G0.6, B0.48 (i.e., 0.4 * 1.2 = 0.48). Gain affects higher values more than it affects lower values, so the effect will be strongest in the midrange and top range of your image.

**Master RGB Lift**
While Gain basically scales the color values around black, Lift scales the color values around white. The pixel values are multiplied by the value of this control. A Lift of 0.5 will make a pixel that is R0.0 G0.0 B0.0 into R0.5 G0.5, B0.5, while leaving white pixels totally unaffected. Lift affects lower values more than it affects higher values, so the effect will be strongest in the midrange and lowrange of the image.

**Master RGB Gamma**
Values higher than 1.0 will raise the Gamma (mid gray) while lower values will decrease it. The effect of this node is not linear, and existing black or white levels will not be affected at all. Pure grays will be affected the most.

**Master RGB Brightness**
The value of the Brightness slider is added to the value of each pixel in your image. This control’s affect on an image is linear, so the effect will be applied identically to all pixels regardless of value.

**Reset All Color Changes**
Selecting this button will return all color controls in this section to their default values.
Levels Mode

Master/Shadows/Midtones/Highlights
This array is described in the Colors mode above.

Histogram Control
A Histogram is a chart that represents the distribution of color values in the scene. The chart reads from left to right, with the leftmost values representing the darkest colors in the scene and the rightmost values representing the brightest. The more pixels in an image with the same or similar value, the higher that portion of the chart will be.

Luminance is calculated per channel, therefore, the red, green, and blue channels all have their own histogram and the combined result of these comprise the Master Histogram.

To scale the histogram vertically, place the mouse pointer inside the control and drag the pointer up to zoom in or down to zoom out.

RGB/Red/Green/Blue
These buttons are used to select and display the histogram for each color channel or for the master channel.

Display Selector Toolbar
The Display Selector toolbar provides a method of enabling and disabling components of the histogram display. Hold the mouse pointer over the button to display a tooltip that describes the button's function.

Input Histogram
This enables or disables the display of the Input image's histogram.

Reference Histogram
This enables or disables the display of the Reference image's histogram.

Output Histogram
This enables or disables the display of the histogram from the post color corrected image.
Corrective Curve
This toggles the display of a spline used to visualize exactly how auto color corrections applied using a reference image are affecting the image. This can be useful when equalizing luminance between the input and reference images.

Low/Mid/High
These controls are used to adjust the input image's histogram, compressing or shifting the ranges of the selected color channel.

The controls can be adjusted by dragging the triangles beneath the histogram display to the left and right.

Shifting the high value toward the left (decreasing the value) will cause the histogram to slant toward white, shifting the image distribution toward white. The low value will have a similar effect in the opposite direction, pushing the image distribution toward black.

Threshold Output Low/High
The Threshold control can apply clipping to the image, compressing the histogram. Decreasing the level of the High control will reduce the value of pixels in the image, sliding white pixels down toward gray and gray pixels toward black.

Adjusting the Low control toward High will do the opposite, sliding the darkest pixels toward white.

If the low value was set to 0.1, pixels with a value of 0.0 would be set to 0.1 instead, and all other values would increase to accommodate the change. The best way to visualize the effect is to observe the change to the output histogram displayed above.

Reset All Levels
Clicking on this button will reset all of the controls in the Levels section to their defaults.

Histogram Mode
This Color Corrector mode produces a Histogram display of the input image. If a reference image is also provided, the histogram for the reference image is also displayed. The controls in this tab are primarily used to match one image to another, using either the Equalize or Match modes of the Color Corrector.

Float Images and Histogram Equalization or Matching
Use the histogram Matching or Equalization methods on a float image and the color depth of the output image will be converted to 16-bit integer. Two-dimensional histograms are not well suited to working with the extreme dynamic range of float images, so these operations will always revert to 16-bit integer processing.

Histogram Control
The Histogram Control is described in detail earlier in this node documentation, under the heading of the Levels Mode.

Keep/Equalize/Match Buttons
Each of these buttons enables a different type of color correction operation.

Keep
Keep produces no change to the image and the reference histogram is ignored.
**Equalize**
Selecting Equalize adjusts the source image so that all of the color values in the image are equally represented, in essence, flattening the histogram so that the distribution of colors in the image becomes more even.

**Match**
The Match mode modifies the source image based on the histogram from the reference image. It is used to match two shots with different lighting conditions and exposures so that they will appear similar.

When selected, the Equalize and Match modes reveal the following controls.

**Match/Equalize Luminance**
This slider affects the degree to which the Color Corrector node will attempt to affect the image based on its luminance distribution. When this control is zero (the default), matching and equalization are applied to each color channel independently and the luminance, or combined value of the three color channels, is not affected.

If this control has a positive value when equalizing the image, the input image’s luminance distribution will be flattened before any color equalization is applied.

If this control has a positive value when the correction mode is set to Match, the luminance values of the input are matched to the reference before any correction is applied to the R, G and B channels.

The Luminance and RGB controls can have a cumulative effect, and generally they are not both set to full (1.0) at the same time.

**Lock Red/Green/Blue**
When this checkbox is selected, color matching will be applied to all color channels equally. When the checkbox is not selected, individual controls for each channel will appear.

**Equalize/Match Red, Green, Blue**
The name of this control changes depending on whether the Equalize or Match modes have been selected. The slider can be used to reduce the amount of correction applied to the image to equalize or match it. A value of 1.0 causes the full effect of the equalize or match to be applied, whereas lower values moderate the result.

**8-Bit, 10-Bit, 16-Bit Buttons**
This array of buttons determines the level of color fidelity used when sampling the image to produce the histogram. 10-bit produces higher fidelity than 8-bit, and 16-bit produces higher fidelity than 10-bit.

**Smooth Out Correction Curves**
Often, color equalization and matching operations will introduce posterization in an image, which occurs because gradients in the image have been expanded or compressed so that the dynamic range between colors is not sufficient to display a smooth transition. This control can be used to smooth the correction curve, blending some of the original histogram back into the result for a more even transition.

**Snapshot Match**
Click this button to take a freeze of the current reference histogram, storing its current state as a Snapshot in memory. If the reference histogram is not snapshot, the reference histogram is updated from frame to frame. This can cause flickering and phasing of the correction as the node tries to match a changing source to a changing reference.
**Release Match**
Click on this button to release the current snapshot of the histogram and return to using the live reference input.

**Reset All Histogram Changes**
Selecting this button will remove all changes made to the histogram, returning the controls to default and setting the mode back to keep.

**Suppress Mode**
Color Suppression provides a mechanism for removing an unwanted color component from the image. The Color Wheel control is similar to that shown in the Colors section of the node, but this one is surrounded by six controls, each representing a specific color along the wheel.

To suppress a color in the selected range, drag the control that represents that color toward the center of the color wheel. The closer the control is to the center, the more that color will be suppressed from the image.

**Suppression Angle**
Use the Suppression Angle control to rotate the controls on the suppression wheel and zero in on a specific color.

**Reset All Suppression**
Clicking on this control resets the suppression colors to 1.0, the default value.

**Ranges Tab**
The Ranges tab contains the controls used to specify which pixels in an image are considered to be shadows and which are considered to be highlights. The midrange is always calculated as any pixels not already included in either the shadows or the highlights.
Result/Shadows/Midtones/Highlights
These buttons are used to select the color range displayed in the Viewers. They help to visualize the actual pixels that will be included in the range. When the Result button is selected, the image displayed by the color corrector in the views will be that of the color corrected image. This is the default.

Selecting one of the other buttons will switch the display to a grayscale image showing which pixels are part of the selected range. White pixels represent pixels that are considered to be part of the range and black pixels are not included in the range. For example, choosing Shadows would show pixels considered to be shadows as white and pixels that are not shadows as black. Mid gray pixels are only partly in the range and will not receive the full effect of any color adjustments to that range.

Spline Display
The extent of the ranges is selected by manipulating the spline handles. There are four spline points, each with one Bezier handle. The two handles at the top represent the start of the shadow and highlight ranges, whereas the two at the bottom represent the end of the range. The Bezier handles are used to control the falloff.

The midtones range has no specific controls since its range is understood to be the space between the shadow and the highlight ranges.

The X and Y text controls below the Spline display can be used to enter precise positions for the selected Bezier point or handle.

Channel
The Channel selection buttons shown in this tab can be used to examine the range of a specific color channel. By default, Fusion displays the luminance channel when the color ranges are examined.

Output the Range You See Now as Final Render
Selecting this checkbox will cause the monochrome display of the range shown in the Viewers to be output as the final render. Normally, the Color node will output the full RGBA image, even if the node was left to display one of the color ranges in the view instead. This control makes it possible to use the Color Corrector node to generate a range's matte for use as an effect mask in other nodes.
**Preset Simple/Smooth Ranges**
These two buttons can be used to return the spline ranges to either Smooth (default) or Simple (linear) settings.

**Options Mode**

![ColorCorrector1](image)

**Pre-Divide/Post-Multiply**
Selecting this option will divide the color channels by the value of the alpha before applying the color correction. After the color correction, the color values are re-multiplied by the alpha to produce a properly additive image. This is crucial when performing an additive merge or when working with CG images generated against black.

**Histogram Proxy Scale**
The Histogram Proxy Scale determines the level of precision used when creating and calculating histograms. Lower values represent higher precision and higher values produce a rougher, generalized histogram.

**Process Order**
This menu is used to select whether adjustments to the image’s gamma are applied before or after any changes made to the images levels.

**Color Curves [CCV]**

The Color Curves node is a spline-based node for performing Look Up Table (LUT) color manipulations. A separate spline is provided for each color channel. The effect can be animated or dissolved and can be applied to the image using RGB, YUV, YIQ, CMY or HLS color spaces.

The LUT view in the color corrector can be scaled using the + and - keys on the numeric keypad. The color curves LUT has full support for out of range values, pixels with color values above 1.0 or below 0.0.

The splines shown in this LUT view are also available from the Spline Editor, should a greater precision be required when adjusting the controls.
Controls

Mode
The Mode options change between Animated and Dissolve modes. The default mode is static, where adjustments to the curves are static. Setting the mode provides a change spline for each channel, allowing the color curve to be animated over time.

Dissolve mode is essentially obsolete and is included for compatibility reasons only.

Color Space
The splines in the LUT view can represent color channels from a variety of color spaces. The default is Red, Green and Blue. The options in this menu allow an alternate color space to be selected. A detailed description of the color spaces available here can be found in the online reference documentation for the Color Space node.

Color Channels (RGBA)
Use the Color Channel controls to select which channel's spline is currently active for editing. The labels of these controls will change to reflect the names of the channels for the current color space. Normally, they will read as Red, Green and Blue. If the Color Curves node is operating in YUV color space, they will read as Y, U, and V instead.

These controls do not restrict the effect of the node to a specific channel. They only select whether the spline for that channel is editable. These controls are most often used to ensure that adding or moving points on one channel's spline does not unintentionally affect a different channel's spline.
**Spline Window**
The Spline Window displays splines for each RGBA channel. These can be edited individually or as a group, depending on the color channels selected above.

The Spline default to a linear range, from 0 in, 0 out at the bottom left to the 1 in, 1 out Top right. In the default a color will process to the same value to the output. If a point is added in the middle at 0.5 in 0.5 out, and the point is moved up, this will raise the mid color of the image brighter.

The Spline curves allow for precise control over color ranges, so specific adjustments can be made without affecting other color values.

**In and Out**
Use the In and Out controls to manipulate the precise values of a selected point. To change a value, select a point and enter the in/out values desired.

**Pick**
Click on the Pick button and select a color from an image in the display to automatically set keypoints on the spline for the selected color. The new points will be drawn with a triangular shape and can only be moved vertically (if point is locked, only the Out value can change).

Points are only added to enabled splines. To add points only on a specific channel, disable the other channels before making the selection.

One use for this technique is white balancing an image. Use the Pick control to select a pixel from the image that should be pure gray. Adjust the points that appear so that the Out value is 0.5 to change the pixel colors to gray.

Use the contextual menu’s Locked Pick Points option to unlock points created using the Pick option, converting them into normal points.

**Match Reference**
Clicking on the Match Reference button will automatically set points on the curve to match an image provided in the second (reference) input of the Color Curves node.

**Sample Reference**
Clicking the Sample Reference button will sample the center scanline of the background image and create a LUT of its color values

**Number of Samples on Match Curve**
This slider determines how many points are used to match the curve to the range in the reference image.

**Pre-Divide/Post-Multiply**
Selecting this checkbox will cause the image’s pixel values to be divided by the alpha values prior to the color correction, and then re-multiplied by the alpha value after the correction. This helps to avoid the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.
Color Gain [CLR]

The Color Gain node contains options for adjusting the gain, gamma, saturation and hue of the image. Many of the controls provided by the Color Gain node are also found in the Color Corrector node, but this simpler node may render more quickly. One feature that distinguishes the Color Gain node from the color corrector is its balance controls. These can be used to adjust the tinting of the colors in the high, mids and lows.

Controls

**Lock R/G/B**
When selected, the Red, Green and Blue channel controls for each effect are combined into one slider. Alpha channel effects remain separate.

**Gain RGBA**
The Gain RGBA controls multiply the values of the image channel in a linear fashion. All pixels are multiplied by the same factor, but the effect will be larger on bright pixels and smaller on dark. Black pixels will not be changed (x * 0=0).

**Lift RGBA**
While Gain basically scales the color values around black, Lift scales the color values around white. The pixel values are multiplied by the value of this control. A Lift of 0.5 will make a pixel that is R0.0 G0.0 B0.0 into R0.5 G0.5, B0.5, while leaving white pixels totally unaffected.
Lift affects lower values more than it affects higher values, so the effect will be strongest in the midrange and lowrange of the image.

**Gamma RGBA**
The Gamma RGBA controls affect the brightness of the mid-range in the image. The effect of this node is non-linear. White and black pixels in the image are not affected when gamma is modified, whereas pure grays are affected most by changes to this parameter. Large value changes to this control will tend to push mid-range pixels into black or white, depending on the value used.

**Pre-Divide/Post-Multiply**
Selecting this checkbox will cause the image pixel values to be divided by the alpha values prior to the color correction, and then re-multiplied by the alpha value after the correction. This helps to avoid the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.

**Saturation Tab**

**RGB Saturation**
This setting controls the intensity of the colors in the image channels. A value of 0.0 will strip all of the color out of an image channel. Values greater than one will intensify the colors in the scene, pushing them toward primary colors.

**Balance Tab**
**CMY Brightness Highs/Mids/Darks**

This section of the Color Gain node offers controls for adjusting the overall balance of a color channel. Independent color and brightness controls are offered for the High, Mid and Dark ranges of the image.

Colors are grouped into opposing pairs from the two dominant color spaces. Red values can be pushed toward Cyan, Green values to Magenta and Blue to Yellow. Brightness can be raised or lowered for each of the channels.

By default, the Balance sliders can be adjusted by -1 to +1, but values outside of this range can be entered manually to increase the effect. A value of 0.0 for any slider indicates no change to the image channel. Positive and negative values indicate that the balance of the image channel has been pushed toward one color or the other in the pair.

**Hue Tab**

Use the Hue section of the Color Gain node to shift the overall hue of the image, without affecting the brightness or saturation. Independent control of the High, Mid and Dark ranges is offered by three sliders.

The following is the order of the hues in the RGB color space: Red, Yellow, Green, Cyan, Blue, Magenta and Red. Values above 0 push the hue of the image toward the right (red turns to yellow). Values below 0 push the hue toward the left (red turns to magenta). At -1.0 or 1.0, the hue completes the cycle and returns to its original value.

The default range of the hue sliders is -1.0 to +1.0. Values outside of this range can be entered manually.

**Ranges Tab**

The Ranges tab contains the controls used to specify which pixels in an image are considered to be shadows and which are considered to be highlights. The midrange is always calculated as any pixels not already included in either the shadows or the highlights.
Spline Display
The extent of the ranges is selected by manipulating the spline handles. There are four spline points, each with one Bezier handle. The two handles at the top represent the start of the shadow and highlight ranges, whereas the two at the bottom represent the end of the range. The Bezier handles are used to control the falloff.

The midtones range has no specific controls since its range is understood to be the space between the shadow and the highlight ranges. The X and Y text controls below the Spline display can be used to enter precise positions for the selected Bezier point or handle.

Preset Simple/Smooth Ranges
These two buttons can be used to return the spline ranges to either Smooth (default) or Simple (linear) settings.

Color Matrix [CMX]

The ColorMatrix allows for a vast number of operations to modify values individually in the different color channels.

Controls

Update Lock
When this control is selected, Fusion will not render the node. This is useful for setting up each value of the node, then turning Update Lock off in order to render it.

Matrix
This defines what type of operation actually takes place. The horizontal rows define the output values of the node, the vertical columns the input values. The “add” column allows for simple adding of values to the individual color channels. By default the output values are identical to the input values.

- 100% of the Red channel input is copied to the Red channel output.
- 100% of the Green channel input is copied to the Green channel output.
• 100% of the Blue channel input is copied to the Blue channel output.
• 100% of the Alpha channel input is copied to the Alpha channel output.
• We can also write the default settings as mathematical equations
  \[
  [R\ out] = 1 \times [R\ in] + 0 \times [G\ in] + 0 \times [B\ in] + 0 \times [A\ in] + 0
  
  [G\ out] = 0 \times [R\ in] + 1 \times [G\ in] + 0 \times [B\ in] + 0 \times [A\ in] + 0
  
  [B\ out] = 0 \times [R\ in] + 0 \times [G\ in] + 1 \times [B\ in] + 0 \times [A\ in] + 0
  
  [A\ out] = 0 \times [R\ in] + 0 \times [G\ in] + 0 \times [B\ in] + 1 \times [A\ in] + 0
  \]

**Invert**

Enabling this option will invert the Matrix. Think of swapping channels around, doing other operations with different nodes, and then copying and pasting the original ColorMatrix and setting it to Invert to get your channels back to the original.

**Example 1 – Invert**

If we want to do a simple invert or negative of the color values, but keep our alpha channel as it is, the matrix would look like this.

![ColorMatrix](image)

Observe the fact that we have to Add 1 to each channel to push the inverted values back into the positive numbers.

Let’s follow this example step by step by viewing the waveform of a 32-bit grayscale gradient.

• **01**: The original grayscale
• **02**: RGB set to -1. The values get inverted but fall below 0.

![Image](image1.png)

• **03**: Adding 1 to each channel keeps the inversion but moves the values back into a positive range.

![Image](image2.png)

---

**Example 2 – Brightness per Channel**

Let’s influence the brightness of each channel individually. This subtracts 0.2 from the red channel, adds 0.314 to the green channel and adds 0.75 to the blue channel while keeping Alpha as it is.

**Example 3 – Copying Values**

Of course we can also copy color values back and forth between individual channels. Let’s make the red channel contain the luminance values of the image based on thirds and the green channel contain the luminance values based on the proper black-and-white conversion method, whereas in the blue channel we use a third method based on getting more information from red and less from blue. We also lower the blue channel’s brightness by 0.1 and replace the alpha channel with the original blue channel.
Color Space [CS]

The Color Space node provides the ability to work on an image in a variety of alternate color space formats. By default, Fusion uses the RGB color space, and most nodes and displays interpret the primary channels of an image as Red, Green and Blue.

Changing the color space from RGB will cause most images to look odd, as Fusion’s viewers will still interpret the primary channels as Red, Green and Blue. For example, viewing an image converted to YUV in one of the Viewers will show the Y channel as Red, the U channel as Green and the V channel as Blue.

Several elements of the Fusion interface refer to the RGB channels directly. The four checkboxes used to restrict the effect of the node to a single color channel are one example. When a conversion is applied to an image, the labels of these elements remain R, G and B, but the values they represent are from the current color space. (Red is Hue, Green is Luminance, Blue is Saturation for a RGB to HLS conversion. The Alpha value is never changed by the color space conversion.)

Controls

Color Space Conversion
This button array has three options.

None
The Color Space node has no effect on the image.

To Color
The input image will be converted to the color space selected in the Color Type control found below.

To RGB
The input image will be converted back to the RGB color space from the type selected in the Color Type control below (for example, YUV to RGB).

Color Type
These buttons are used to select the color space conversion applied when the To Color conversion is selected.
HSV (Hue, Saturation and Value)
Each pixel in the HSV color space is described in terms of its Hue, Saturation and Value components. Value is defined as the quality by which we distinguish a light color from a dark one or brightness. Decreasing saturation roughly corresponds to adding white to a paint chip on a palette. Increasing value is roughly similar to adding black.

YUV (Luma, Blue Chroma and Red Chroma)
The YUV color space is used in the analog broadcast of PAL video. This format is often used to color correct images, due to its familiarity to a large percentage of video engineers. Each pixel is described in terms of its Luminance, Blue Chroma and Red Chroma components.

YIQ (Luma, In Phase and Quadrature)
The YIQ color space is used in the analog broadcast of NTSC video. This format is much more rare than YUV and almost never seen in production. Each pixel is described in terms of its Luminance, Chroma (in-phase or red-cyan channel) and Quadrature (magenta-green) components.

CMY (Cyan, Magenta and Yellow)
Although more common in print, the CMY format is often found in computer graphics from other software packages. Each pixel is described in terms of its Cyan, Magenta and Yellow components. CMY is non-linear.

HLS (Hue, Luminance and Saturation)
Each pixel in the HLS color space is described in terms of its Hue, Luminance and Saturation components. The differences between HLS and HSV color spaces are minor.

XYZ (CIE Format)
This mode is used to convert a CIE XYZ image to and from RGB color spaces. CIE XYZ is a weighted space, rather than a non-linear one, unlike the other available color spaces. Non-linear in this context means that equal changes in value at different positions in the color space may not necessarily produce the same magnitude of change visually to the eye.

Expressed simply, the CIE color space is a perceptual color system, with weighted values obtained from experiments where subjects were asked to match an existing light source using three primary light sources.

This color space is most often used to perform gamut conversion and color space matching between image display formats because it contains the entire gamut of perceivable colors.

Negative
The color channels are inverted. The color space remains RGBA.

BW
The image is converted to black and white. The contribution of each channel to the luminance of the image is adjustable via slider controls that appear when this option is selected. The default values of these sliders represent the usual perceptual contribution of each channel to an image’s luminance. The color space of the image remains RGBA.
Copy Aux [CPA]

CopyAux copies aux channel groups into RGBA channels. CopyAux is only available in Resolve Studio. It is mostly a convenience node as the copying can also be accomplished with more effort using a ChannelBoolean node. Although CopyAux has quite a few options, most of the time you will only adjust the channel to copy and ignore the rest.

Before Fusion 6.31, to access aux channels you used a ChannelBoolean to copy them into the RGBA channels. Often this would also involve a ChangeDepth node to make sure that the RGBA channels that were receiving the aux channel were float32. Now in Dimension, CopyAux accomplishes the same result in fewer mouse clicks, allowing you to work faster. Where ChannelBooleans deals with individual channels, CopyAux deals with channel groups. By default, the CopyAux node will automatically promote the depth of its output to match the depth of the aux channel.

CopyAux also supports static normalization ranges. The advantage of static normalization versus the dynamic normalization that Fusion’s viewers do is that colors remain constant over time. For example, if you are viewing Z or WorldPos values for a ball, you will see a smooth gradient from white to black. Now imagine that some other 3D object is introduced into the background at a certain time. Dynamic normalization will turn the ball almost completely white while the background object is now the new black. Dynamic normalization also causes flicker problems while viewing vector/disparity channels, which can make it difficult to compare the aux channels of two frames at different times visually.

Controls

Mode
Mode determines whether the aux channel is copied into the RGBA color channel or vice versa. Using this option, you can use one CopyAux to bring an aux channel into color, do some compositing operations on it, and then use another CopyAux to write the color back in the aux channel. When the Mode is set to "Color>Aux," all the inputs except AuxChannel are hidden.
**Aux Channel**

The Aux Channel is to be copied from or written to depending on the current mode. When the aux channel abcd has one valid component, it will be copied as aaa1, two valid components as ab01, three valid components as abc1, and four components as abcd. For example, the Z-channel will be copied as zzz1, texture coordinates as uv01, and normals as nxnynz1.

**Out Color Depth**

Out Color Depth controls the color depth of the output image. Most aux channels contain float values or, if they are integer valued, they can contain values beyond 255. When you copy float values into an int8 or int16 image, this can be a problem since negative values and values over 1.0 can get clipped. In addition, precision can be lost. This option determines what happens if the depth of RGBA channels of the input image is insufficient to contain the copied aux channel.

Be careful about copying float channels into integer image formats, as they can get clipped if you do not set up CopyAux correctly. For the purpose of this node, all aux channels are considered to be float32 except ObjectID/MaterialID, which are considered to be int16.

**Match Aux Channel Depth**

The bit depth of the RGBA channels of the output image will be increased to match the depth of the aux channel. In particular, this means that the RGBA channels of the output image will be either int16 or float32. It is wise to be careful when using this option as, for example, if you normally have int8 color channels, you will now be using 2x or 4x more memory for the color channels. In particular, the Z, Coverage, TextureCoordinate, Normal, Vector, BackVector, WorldPosition, and Disparity channels will always be output as float and the Material/ObjectID channels will be output as int16.

**Match Source Color Depth**

The bit depth of the RGBA channels of the output image will be the same as the input image. This can have some unexpected consequences. For example, if your input image is int8, the XYZ components of normals which are floating-point numbers in the [-1, 1] range will be clipped to a non-negative numbers [0, 1] range. As a more extreme example, consider what will happen to Z values. Z values are floating point numbers stored in the [-1e30, 0] range and they will all get truncated to the [0, 1] range, which means your Z-channel will be full of zeroes.

**Force Float32**

The bit depth of the RGBA channels of the output image will always be float32.

**Channel Missing**

Channel Missing determines what happens if a channel is not present. For example, this determines what happens if you chose to copy Disparity to Color and your input image does not have a Disparity aux channel.

**Fail**

The node fails and prints an error message to the console.

**Use Default Value**

This fills the RGBA channels with the default value of zero for everything except Z for which it is -1e30.
**Kill Aux Channels**

When this is checked, CopyAux will copy the requested channel to RGBA and then output a resulting image that is purely RGBA with all other channels being killed. This is useful if you want to increase the number of frames of CopyAux that can be cached for playback, for example to play back a long sequence of disparity. A handy tip is that you can use the “Kill Aux” feature also with just Copy Color > Color for a longer color playback.

![CopyAux node](image)

**Enable Remapping**

When remapping is enabled, the currently selected aux channel will be rescaled, linearly mapping the range according to the From and To slider selections as explained below. The Remapping options are applied before the conversion operation. This means you could set the From. Min/From. Max values to -1, 1 to rescale your normals into the [0, 1] range, or set them to [-1000, 0] to rescale your Z values from [-1000, 0] into the [0, 1] range before the clipping occurs.

Note that the Remapping options are per channel options. That means the default scale for normals can be set to [-1, +1] > [0, 1] and for Z it can be set [-1000, 0] > [0, 1]. When you flip between normals and Z, both options will be remembered. One way this could be useful is that you can set up all of your remapping ranges and save this as a setting that you can reuse. The remapping can be useful to squash the aux channels into a static [0, 1] range for viewing or, for example, if you wish to compress normals into the [0, 1] range in order to store them in an int8 image.

**From. Min**

This is the value of the aux channel that will correspond to To. Min.

**From. Max**

This is the value of the aux channel that will correspond to To. Max. It is possible to set the max value less than the min value to achieve a flip/inversion of the values.

**Detect Range**

This scans the current image to detect the min/max values and then sets the From. Min/From. Max Value controls to these values.

**Update Range**

This scans the current image to detect the min/max values and then enlarges the current [From. Min, From. Max] region so that it contains the min/max values from the scan.
**To. Min**
This is the minimum output value, which defaults to 0.

**To. Max**
This is the maximum output value, which defaults to 1.

**Invert**
After the values have been rescaled into the [To. Min, To. Max] range, this inverts/flips the range.

---

**Gamut [GMT]**

The Gamut node converts color from different gamuts to other color gamuts as well as removing or adding the appropriate gamma to entirely linearize incoming images.

---

**Controls**
**Source Space**
Source Space determines the input color space of the image. Leave this at “No Change” if you want to just add Gamma using the Output Space control.

**DCI-P3**
The DCI-P3 color space is most commonly used in association with DLP projectors, and is frequently provided as a color space available with 2K DLP projectors, and as an emulation mode for 10-bit LCD monitors such as the HP Dreamcolor. This color space is defined in the SMPTE-431-2 standard.

**Custom**
The Custom gamut allows you to describe the color space according to CIE 1931 primaries and white point, which are expressed as XY coordinates, as well as by gamma, limit and slope. For example, the DCI-P3 gamut mentioned above would have the following values if described as a Custom color space.

<table>
<thead>
<tr>
<th>Gamut</th>
<th>0.68</th>
<th>0.32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Primary</td>
<td>0.265</td>
<td>0.69</td>
</tr>
<tr>
<td>Blue Primary</td>
<td>0.15</td>
<td>0.06</td>
</tr>
<tr>
<td>White Point</td>
<td>0.314</td>
<td>0.351</td>
</tr>
<tr>
<td>Gamma</td>
<td>2.6</td>
<td>–</td>
</tr>
<tr>
<td>Linear Limit</td>
<td>0.0313</td>
<td>–</td>
</tr>
</tbody>
</table>

To understand how these controls work you could view the node attached to a gradient background in Waveform mode and observe how different adjustments modify the output.

**Output Space**
Output Space is the converted gamut to the desired color space. Leave this at No Change if you want to just remove Gamma using the Source Space control.

**Remove/Add Gamma**
Select these checkboxes to do the gamut conversion in a linear or non-linear gamma, or simply remove or add the appropriate gamma values without changing the color space.

**Pre-Divide/Post-Multiply**
Selecting this checkbox will cause the image’s pixel values to be divided by the alpha values prior to the color correction, and then re-multiplied by the alpha value after the correction. This helps to avoid the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.
Hue Curves [HCV]

The Hue Curves node allows you to adjust the color in an image using a series of spline curves. Splines are provided to control the image’s hue, saturation and luminance as well as each individual color channel. An additional set of curves allows you to apply suppression to individual color channels.

The advantage of the Hue Curves node over other color correction nodes in Fusion is that the splines can be manipulated to restrict the node’s effect to a very narrow portion of the image, or expanded to include a wide-ranging portion of the image. Additionally, these curves can be animated to follow changes in the image over time. Since the primary axis of the spline is defined by the image’s hue, it is much easier to isolate a specific color from the image for adjustment.

Controls

Mode
The Mode options changes between Animate and Dissolve modes. The default mode is Static, where adjustments to the curves are applied consistently over time. Setting the Mode to Animate or Dissolve allows for the color curve to be animated over time.

Dissolve mode is essentially obsolete and is included for compatibility reasons only.

Color Channel Checkboxes
These checkboxes define which Splines are editable and are included in the Pick Color process.

Any number of activated splines can be edited simultaneously, however in most cases it’s more convenient to have only the currently modified spline active to avoid unwanted changes to other splines.

When using the Pick Color button a point will be created on all active splines, representing the selected color.
**Spline Window**

This Look Up Table (LUT) control is the main interface element of the Hue Curves node, which hosts the various splines. In appearance the node is very similar to the Color Curves node, but in this case the horizontal axis represents the image’s hue, while the vertical axis represents the degree of adjustment. The Spline window shows the curves for the individual channels. It is basically a miniature Spline Editor. In fact, the curves shown in this window can also be found and edited in the Spline Editor.

The spline curves for all components are initially flat, with key points placed horizontally at each of the primary colors. From left to right these are: Red, Yellow, Green, Cyan, Blue, and Magenta. Due to the cyclical nature of the hue gradient, the leftmost key point in each curve is connected to the rightmost key point of the curve.

Right clicking in the LUT Control will display a contextual menu containing options for resetting the curves, importing external curves, adjusting the smoothness of the selected key points and more.

**In and Out**

Use the In and Out controls to manipulate the precise values of a selected point. To change a value, select a point and enter the in/out values desired.

**Pick**

Left clicking and dragging from the Pick Color button will change the current mouse cursor to an eyedropper. While still holding down the left mouse button, drag the cursor to a viewer to pick a pixel from a displayed image. This will cause key points, which are locked on the horizontal axis, to appear on the currently active curves. The key points will represent the position of the selected color on the curve. Use the contextual menu’s “Lock Selected Points” toggle to unlock points and restore the option of horizontal movement.

Points are only added to enabled splines. To add points only on a specific channel, disable the other channels before making the selection.

**Pre-Divide/Post-Multiply**

Selecting this checkbox will cause the image’s pixel values to be divided by the alpha values prior to the color correction, and then re-multiplied by the alpha value after the correction. This helps to avoid the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.

**OCIO CDL Transform [OCD]**

Fusion supports the Open Color IO workflow specified by Sony Imageworks. In general, the color pipeline is made up from a set of color transformations defined by OCIO-specific config files, commonly named with a “.ocio” extension, which allows users to easily share color settings within or between facilities. The path to the config file to be used is normally specified by a user-created environment variable called “OCIO,” though some tools allow overriding this. If no other *.ocio config files are located, the DefaultConfig.ocio file in Fusion’s LUTs directory will be used.
For in-depth documentation of the format's internals, please refer to the official pages on opencolorio.org.

The OCIO CDLTransform allows users to create, save, load, and apply CDL files.

**Controls**
Operation
Toggles between File and Controls. In File mode, standard ASC-CDL files can be loaded. In Controls mode, manual adjustments can be made to Slope, Offset, Power and Saturation, and the CDL file can be saved.

Direction
Toggles between Forward and Reverse. Forward applies the corrections specified in the node, while reverse tries to remove those corrections. Keep in mind that not every color correction can be undone.

Imagine all slope-values have been set to 0.0, resulting in a fully black image. Reversing that operation is not possible, neither mathematically nor visually.

Slope
Multiplies the color values; this is the same as Gain in the BrightnessContrast node

Offset
Adds to the color values; this is the same as Brightness in the BrightnessContrast node

Power
Applies a Gamma Curve. This is an inverse of the Gamma function of the BrightnessContrast node.

Saturation
Enhances or decreases the color saturation. This works the same as Saturation in the BrightnessContrast node.

Export File
Allows the user to export the settings as a CDL file.
Fusion supports the Open Color IO workflow specified by Sony Imageworks. In general, the color pipeline is made up from a set of color transformations defined by OCIO-specific config files, commonly named with a ".ocio" extension, which allows users to easily share color settings within or between facilities. The path to the config file to be used is normally specified by a user-created environment variable called "OCIO," though some tools allow overriding this.

If no other *.ocio config files are located, the DefaultConfig.ocio file in Fusion's LUTs directory will be used. For in-depth documentation of the format's internals, please refer to the official pages on opencolorio.org. The OCIOColorSpace allows for sophisticated color space conversions, based on an OCIO Config File. Sample configs can be obtained from opencolorio.org/downloads.html

The functionality of the OCIOFileTransform node is also available as a ViewLUT node from the ViewLUT menu.

**OCIO Config**
Displays a File > Open dialog to load the desired Config File.

**Source Space**
Based on the Config file, the available source color spaces will be listed here.
The content of this list is solely based on the loaded profile and hence can vary immensely.

**Output Space**
Based on the Config file, the available output color spaces will be listed here.
The content of this list is solely based on the loaded profile and hence can vary immensely.
OCIO FileTransform [OCF]

Fusion supports the Open Color IO workflow specified by Sony Imageworks.

In general, the color pipeline is made up from a set of color transformations defined by OCIO-specific config files, commonly named with a ".ocio" extension, which allows users to easily share color settings within or between facilities. The path to the config file to be used is normally specified by a user-created environment variable called "OCIO," though some tools allow overriding this.

If no other *.ocio config files are located, the DefaultConfig.ocio file in Fusion's LUTs directory will be used. For in-depth documentation of the format's internals, please refer to the official pages on opencolorio.org. The OCIOFileTransform allows the user to load and apply a variety of Look Up Tables.

The functionality of the OCIOFileTransform node is also available as a ViewLUT node from the ViewLUT menu.

Controls

LUT File
Displays a File > Open dialog to load the desired LUT.

CCC ID

Direction
Toggles between Forward and Reverse. Forward applies the corrections specified in the node, while Reverse tries to remove those corrections. Keep in mind that not every color correction can be undone. Imagine all slope values have been set to 0.0, resulting in a fully black image. Reversing that operation is not possible, neither mathematically nor visually.

Interpolation
Allows user to select the color interpolation to achieve the best quality/render time ratio.

The ViewLUT Version of the Node
Set Canvas Color [SCV]

Set Canvas Color is used to set the color of the workspace — all the area beyond the defined pixels within an image (the DoD). This area usually extends to infinity. By default, the canvas color used is black/no alpha (transparent).

Some nodes may change an image’s canvas color, for example, inverting a mask will change the mask’s canvas from black to white. Set Canvas Color allows you to control and override this.

Controls

Color Picker

Use these controls to adjust the Color and the Alpha value for the image’s canvas. It defaults to black with zero alpha.

White Balance [WB]

The White Balance node can be used to automatically remove color casts in the image caused by the incorrect setup of a camera, problems in a camera’s CCD, or bad lighting conditions. Correction can be done by selecting a color temperature, or by choosing a neutral color from the original image that exhibits the color cast to be corrected.
**IMPORTANT** When picking neutral colors using the Custom method, make sure you are picking from the source image, not the results of the White Balance node. This ensures that the image doesn’t change while you are still picking, and that the White Balance node gets an accurate idea of the original colors it needs to correct.

**Balance Tab**

Use this menu to select the Color Space of the source image, if it is known. This can make the correction more accurate since the node will be able to take the natural gamma of the color space into account as part of the correction. If the color space that the image uses is unknown, leave this menu at its default value.

**Method**

The White Balance node can operate using one of two methods, a Custom method and a color Temperature method.

**Custom**

The Custom method requires the selection of a pixel from the scene that should have been pure gray.

The node uses this information to calculate the color correction required to convert the pixel so that it actually is gray. When that correction is applied to the entire image, it generally white balances the entire shot.
**Temperature**

The color Temperature method requires that the actual color temperature of the shot be specified.

**Lock Black/Mid/White**

This checkbox locks the Black, Mid and White points together so that the entire image is affected equally. Unchecking the control will provide individual controls for white balancing each range separately. This control affects both methods equally.

**Black/Mid/White Reference**

These controls only appear if the Custom method is selected. They are used to select a color from a pixel in the source image. The White Balance node will color correct the image so that the selected color is transformed to the color set in the Result color picker below. Generally, this is gray. A color that is supposed to be pure gray but is not truly gray for one reason or another should be selected.

If the Lock Black/Mid/White checkbox is deselected, different references can be selected for each color range.

For example, try to select a pixel for the black and white references that is not clipped in any of the color channels. In the high end, an example would be a pixel that is light pink with values of 255, 240, 240. The pixel is saturated/clipped in the red, even though the color is not white. Similarly, a really dark blue-gray pixel might be 0, 2, 10. It is clipped in red as well, even though it is not black.

Neither example would be a good choice as a reference pixel because there would not be enough headroom left for the White Balance node.

**Black/Mid/White Result**

These controls only appear if the Custom method is selected. They are used to select the color to which the node will balance the reference color. This generally defaults to pure, midrange gray.

If the Lock Black/Mid/White checkbox is deselected, different results can be selected for each color range.

---

**Temperature Control**

![Temperature Control Diagram](image-url)
**Temperature Reference**
Use this control to set the color Temperature of the source image. If the Lock Black/ Mid/White checkbox is deselected, different references can be selected for each color range.

**Temperature Result**
Use this control to set the target color temperature for the image. If the Lock Black/Mid/White checkbox is deselected, different results can be selected for each color range.

**Use Gamma**
This checkbox selects whether the node will take the gamma of the image into account when applying the correction, using the default gamma of the color space selected in the menu at the top of the tab.

**Ranges Tab**

![Ranges Tab Image]

**Ranges**
Use the controls in the Ranges tab to customize the range of pixels in the image considered to be shadows, midtones, and highlights by the node. The use of the controls in this tab is documented in detail in the Color Corrector node documentation.
Chapter 80

Composite Nodes

This chapter details the Dissolve and Merge nodes available in the Fusion page.
## Dissolve [DX]
- Dissolve Node Introduction: 1583
- Inputs: 1583
- Typical Node Structure: 1584
- Resolution Handling: 1584
- Controls: 1584

## Merge [MRG]
- Merge Node Introduction: 1586
- Inputs: 1586
- Typical Node Structure: 1587
- Resolution Handling: 1587
- Controls: 1587
**Dissolve [DX]**

**Dissolve Node Introduction**

The Dissolve node is typically used to mix two images together, providing a gradual transition between two clips. A Background/Foreground slider controls the amount of mix between the foreground and background images. Dissolves are commonly used to transition between one clip and another and are a very common effect in editing. However, you can also use the extreme left and right positions of the Background/Foreground slider to switch between inputs.

Unlike all other nodes in Fusion, the Dissolve node does not require you to connect an image to the background, but lets you output either the background or foreground according to the setting of the Background/Foreground slider.

This quality makes it possible for you use the Dissolve node as an automatic layer switching tool when connected to background and foreground clips with different durations. Simply connect each clip to the background and foreground inputs respectively, and set the Background/Foreground slider to the input of shorter duration, to determine which is “on top.” After the last frame of that clip has ended, the Dissolve node automatically switches to the clip that’s connected to the other input.

In addition to the default dissolve, the Gradient Wipe setting of the Operation menu allows you to create arbitrary animated dissolve patterns based on the luminance of an image connected to the optional Gradient Wipe input. You can use this capability with images of geometric shapes or gradients of different kinds, movie clips of fire, water ripples, or rain, the Fast Noise node, or even particle systems you create within the Fusion page to create a variety of unique and creative transitions. Soft-edged effect masks may also be used to add to the possible effects.

Ultimately, animating the Background/Foreground control allows you to control the transition that’s being used to switch from the foreground input to the background, or vice versa.

**Inputs**

The Dissolve node provides three image inputs, all of which are optional:

- **Background**: The first of two images you want to switch between or mix together. Unlike most other nodes, it is not necessary to connect the background input before connecting the foreground input.

- **Foreground**: The second of two images you want to switch between or mix together. The Dissolve node works best when both foreground and background inputs are connected to images with the same resolution.

- **Gradient Map**: (Optional) The Gradient Map is required only when Gradient Wipe is selected.
Typical Node Structure

Dissolve nodes are typically connected in the following way, with two input images connected to the background and foreground inputs, and the output connected to the next node in the composition.

Resolution Handling

It is recommended to make sure that all images connected to the foreground, background, and gradient map inputs of the Dissolve node have the same resolution and the same pixel aspect. This is not required, however. But the result if you mix resolutions depends on how you set the Background/Foreground slider.

- If the input images are different sizes, but the Foreground/Background slider is set to full Foreground (all the way to the right) or full Background (all the way to the left), then the output resolution will be identical to the image resolution of the corresponding node input.
- If input images of different sizes are mixed together by setting the Background/Foreground slider somewhere in between, the output resolution will be set to the larger of the two input resolutions, to make sure there's enough room to encompass both images. In this case, you may experience undesirable resolution changes when the slider moves from full foreground or background to somewhere in-between.

For example, if you try to dissolve between a 4K image (connected to the background) and an 8K image (connected to the foreground) the output of the Dissolve node will be 4K when the slider is set to full Background, but will suddenly jump to 8K when set to full Foreground, or when mixed somewhere in between the foreground and background.

Controls
Primary Controls
These are the main controls that govern the Dissolve node’s behavior.

- **Operation pop-up**: The Operation menu contains one of seven different methods for mixing the Foreground and Background inputs. The two images are mixed together using the value of the Background/Foreground slider to determine the percentage each image contributes.
  - **Dissolve**: The standard Dissolve mode is the equivalent of a cross dissolve, one clip fades out as another clip fades in.
  - **Additive Dissolve**: Similar in look to a standard film dissolve, an Additive dissolve adds the second clip and then fades out the first one.
  - **Erode**: The Erode method transitions between the two images by growing the darkest areas of the background image to reveal the foreground image. The effect appears similar to a filmstrip burning out.
  - **Random Dissolve**: A randomly generated dot pattern is used to perform the mix of the images.
  - **Random Noise Dissolve**: A moving random dot pattern is used to perform the mix of the images.
  - **Gradient Wipe**: The dissolve is controlled by the luminance values of the image in the Gradient Map input. The edges of this dissolve can be softened. The density and the color of the border can be adjusted independently.
  - **SMPTE Wipe**: The SMPTE wipe is similar to the basic effect wipes found on many video effects switchers. There is a horizontal wipe and a vertical wipe provided. The wipes can have soft edges and borders added. The density and the color of the border can be adjusted independently.

- **Background/Foreground slider**: Defaults to Foreground. This control determines whether the output is the background image, the foreground image, or a mix between the two. The type of mix is determined by the Operation control. If one of the input images is not currently available, the other one will be output regardless of the setting of this slider.

Gradient/SMPTE wipe controls
The following controls appear only when Gradient Wipe or SMPTE Wipe are selected.

- **Wipe Style**: (SMPTE Wipe only) The drop-down list allows the selection of two wipe styles: Horizontal - Left to Right and Vertical - Top to Bottom. The direction of the wipes can be reversed by using the Invert Wipe checkbox.
- **Invert Wipe**: (SMPTE Wipe only) When checked, the direction of the wipe will be reversed.
- **Softness**: Use this control to soften the edge of the transition.
- **Border**: Select the Border to enable coloring of the transition’s edge and to reveal the associated controls. The effect is to create a border around the transition edge.
- **Border Softness**: (Only appears when Border is turned on) The Border Softness slider controls the width and density of the border. Higher values will create a denser border and lower values will create a thinner one.
- **Border Color**: (Only appears when Border is turned on) Use Border Color to select the color used in the border.
**Merge [MRG]**

**Merge Node Introduction**

The Merge node combines two images based on the alpha (opacity) channel associated with the one in front. This node takes two inputs – a background and a foreground image. The Operation mode determines which method is used to combine the foreground and background images, supporting the standard over, in, held out, atop, and xor methods for compositing images. Meanwhile, an Apply Mode pop-up lets you use different composite modes, transfer modes, or blend modes (whichever your preferred terminology) to combine the foreground against the background in different ways; this includes such standard modes as screen, dissolve, multiply, overlay, as well as many others.

The Merge node can perform both additive (premultiplied) and subtractive (non-premultiplied) compositing, depending on how your compositions and media is set up. However, you also have the flexibility of using the Additive/Subtractive slider to blend between additive and subtractive composite results, which has the bonus of providing solutions for problem edges in some cases.

Ordinarily, the foreground and background input connections determine the layer order of images composited with this node. However, you can also enable Z-Depth compositing if Z-channels are available in the input images. Z-merging compares the depth value of each pixel in each layer to determine which pixels should be in front and which should be in back.

**Inputs**

The Merge node provides three image inputs, all of which are optional:

- **Background**: The orange Background input is for the first of two images you want to composite together. You should connect the background input before connecting the foreground input. If you connect an image to the background without connecting anything to the foreground input, the Merge node will output the background image.

- **Foreground**: The green Foreground input is for the second of two images you want to composite together; that’s typically a foreground subject that should be in front of the background. If you connect an image to the foreground input without connecting anything to the background input first, the Merge node won’t output anything.

- **Effect Mask**: (Optional) The effect mask input lets you mask a limited area of the output image to be merged where the mask is white (where the foreground image shows in front of the background), letting the background image show through by itself where the mask is black.
**Typical Node Structure**

Merge nodes are typically connected in the following way, with two input images connected to the background and foreground inputs, and the output connected to the next node in the composition. In this example, the Effect Mask input is not used, as this is not typical.

![A typical Merge node structure](image)

**Resolution Handling**

While you can connect images of any resolution to the background and foreground inputs of the Merge node, the image that’s connected to the background input determines the resolution of the output.

**TIP:** If you want to change the resolution of the image connected to the background, you can use the Crop node to change the “canvas” resolution of the image without changing the size of the original image, or the Resize node to change both the resolution and the size of the image.

**Controls**

![Merge node controls](image)
Merge Tab
The merge tab contains most of the controls necessary for customizing most merge operations.

Foreground Sizing Controls
These controls let you adjust the sizing of the image connected to the foreground input, making it unnecessary to use a separate transform node to fit the foreground layer to match the background layer in simple compositions.

- **Center X and Y:** This control determines the position of the foreground image in the composite. The default is 0.5, 0.5, which centers the foreground image in the exact center of the background image. The value shown is always the actual position in normalized coordinates, multiplied by the reference size. See below for a description of the reference size controls.

- **Size:** Use this control to increase or decrease the size of the foreground image before it is composited over the background. The range of values for this slider is 0.0 to 5.0, but any value greater than 0 can be entered manually. A size of 1.0 gives a pixel-for-pixel composition, where a single pixel in the foreground is the same size as a single pixel in the background.

- **Angle:** Use this control to rotate the foreground image before it is combined with the background.

Compositing Mode and Adjustment Controls
The next six parameters control how the background and foreground input images are combined to create a single output image.

- **Apply Modes:** The Apply Mode setting determines the math used when blending or combining the foreground and background pixels.
  - **Normal:** The Default merge mode uses the foreground’s alpha channel as a mask to determine which pixels are transparent and which are not. When this is active, another menu shows possible operations, including: over, in, held out, atop, and xor.
  - **Screen:** Screen merges the images based on a multiplication of their color values. The alpha channel is ignored and layer order becomes irrelevant. The resulting color is always lighter. Screening with black leaves the color unchanged, whereas screening with white will always produce white. This effect creates a similar look to projecting several film frames onto the same surface. When this is active, another menu shows possible operations, including: over, in, held out, atop, and xor.
  - **Dissolve:** Dissolve mixes two image sequences together. It uses a calculated average of the two images to perform the mixture.
  - **Multiply:** Multiply the values of a color channel. This will give the appearance of darkening the image as the values are scaled from 0 to 1. White has a value of 1, so the result would be the same. Gray has a value of 0.5, so the result would be a darker image or, in other words, an image half as bright.
  - **Overlay:** Overlay multiplies or screens the color values of the foreground image, depending on the color values of the background image. Patterns or colors overlay the existing pixels while preserving the highlights and shadows of the color values of the background image. The background image is not replaced but is mixed with the foreground image to reflect the original lightness or darkness of the background image.
  - **Soft Light:** Soft Light darkens or lightens the foreground image, depending on the color values of the background image. The effect is similar to shining a diffused spotlight on the image.
- **Hard Light**: Hard Light multiplies or screens the color values of the foreground image, depending on the color values of the background image. The effect is similar to shining a harsh spotlight on the image.

- **Color Dodge**: Color Dodge uses the foreground’s color values to brighten the background image. This is similar to the photographical practice of dodging by reducing the exposure of an area of a print.

- **Color Burn**: Color Burn uses the foreground’s color values to darken the background image. This is similar to the photographical practice of burning by increasing the exposure of an area of a print.

- **Darken**: Darken looks at the color information in each channel and selects the background or foreground image’s color value, whichever is darker, as the result color. Pixels lighter than the merged colors are replaced, and pixels darker than the merged color do not change.

- **Lighten**: Lighten looks at the color information in each channel and selects the background or foreground image’s color values, whichever is lighter, as the result color value. Pixels darker than the merged color are replaced, and pixels lighter than the merged color do not change.

- **Difference**: Difference looks at the color information in each channel and subtracts the foreground color values from the background color values or the background from the foreground, depending on which has the greater brightness value. Merging with white inverts the color. Merging with black produces no change.

- **Exclusion**: Exclusion creates an effect similar to, but lower in contrast than, the Difference mode. Merging with white inverts the base color values. Merging with black produces no change.

- **Hue**: Hue creates a result color with the luminance and saturation of the background color values and the hue of the foreground color values.

- **Saturation**: Saturation creates a result color with the luminance and hue of the base color and the saturation of the blend color.

- **Color**: Color creates a result color with the luminance of the background color value and the hue and saturation of the foreground. This preserves the gray levels in the image and is useful for coloring monochrome images.

- **Luminosity**: Luminosity creates a result color with the hue and saturation of the background color values and the luminance of the foreground color values. This mode creates an inverse effect from that of the Color mode.

**Operator Modes**: This menu is used to select the Operation mode of the merge. Changing the Operation mode changes how the foreground and background are combined to produce a result. This pop-up menu is only visible when the Merge node’s Apply mode is set to either Normal or Screen.

For an excellent description of the math underlying the Operation modes, read Compositing Digital Images, Porter, T., and T. Duff, SIGGRAPH 84 proceedings, pages 253-259. Essentially, the math is as described below. Note that some modes not listed in the Operator drop-down (Under, In, Held In, Below) are easily obtained by swapping the foreground and background inputs (with Command-T or Ctrl-T) and choosing a corresponding mode. The formula used to combine pixels in the merge is always $fg \times x + bg \times y$. The different operations determine exactly what x and y are, as shown in the description for each mode.
The Operator Modes are as follows:

- **Over**: The Over mode adds the foreground layer to the background layer by replacing the pixels in the background with the pixels from the Z wherever the foreground’s alpha channel is greater than 1.
  \[ x = 1, \ y = 1-\text{foreground alpha} \]

- **In**: The In mode multiplies the alpha channel of the background input against the pixels in the foreground. The color channels of the foreground input are ignored. Only pixels from the foreground are seen in the final output. This essentially clips the foreground using the mask from the background.
  \[ x = \text{background alpha}, \ y = 0 \]

- **Held Out**: Held Out is essentially the opposite of the In operation. The pixels in the foreground image are multiplied against the inverted alpha channel of the background image. Accomplish exactly the same result using the In operation and a Matte Control node to invert the matte channel of the background image.
  \[ x = 1-\text{background alpha}, \ y = 0 \]

- **ATop**: ATop places the foreground over the background only where the background has a matte.
  \[ x = \text{background alpha}, \ y = 1-\text{foreground alpha} \]

- **XOr**: XOr combines the foreground with the background wherever either the foreground or the background have a matte, but never where both have a matte.
  \[ x = 1-\text{background alpha}, \ y = 1-\text{foreground alpha} \]

- **Subtractive/Additive slider**: This slider controls whether Fusion performs an Additive merge, a Subtractive merge, or a blend of both. This slider defaults to Additive merging for most operations, assuming the input images are pre-multiplied (which is usually the case). If you don’t understand the difference between Additive and Subtractive merging, here’s a quick explanation.
  - An Additive merge is necessary when the foreground image is pre-multiplied, meaning that the pixels in the color channels have been multiplied by the pixels in the alpha channel. The result is that transparent pixels are always black, since any number multiplied by 0 is always going to be 0. This obscures the background (by multiplying with the inverse of the foreground alpha), then simply adds the pixels from the foreground.
  - A Subtractive merge is necessary if the foreground image is not pre-multiplied. The compositing method is similar to an additive merge, but the foreground image is first multiplied by its own alpha, to eliminate any background pixels outside the alpha area.

While the Additive/Subtractive option could easily have been a checkbox to select one mode or another, the Merge node lets you blend between the Additive and Subtractive versions of the merge operation, an operation that is occasionally useful for dealing with problem composites with edges that are calling attention to themselves as too bright or too dark.

For example, using Subtractive merging on a pre-multiplied image may result in darker edges, whereas using Additive merging with a non-premultiplied image will cause any non-black area outside the foreground’s alpha to be added to the result, thereby lightening the edges. By blending between Additive and Subtractive, you can tweak the edge brightness to be just right for your situation.
• **Alpha Gain slider**: Alpha Gain linearly scales the values of the foreground's alpha channel. In Subtractive merges, this controls the density of the composite, similarly to Blend. In Additive merges, this effectively reduces the amount that the background is obscured by, thus brightening the overall result. In an Additive merge with Alpha Gain set to 0.0, the foreground pixels are simply added to the background.

• **Burn In slider**: The Burn In control adjusts the amount of alpha used to darken the background, without affecting the amount of foreground added in. At 0.0, the merge behaves like a straight alpha blend, whereas at 1.0, the foreground is effectively added onto the background (after alpha multiplication if in Subtractive mode). This gives the effect of the foreground image brightening the background image, as with Alpha Gain. In fact, for Additive merges, increasing the Burn In gives an identical result to decreasing Alpha Gain.

• **Blend slider**: This is a cloned instance of the Blend slider in the Common Controls tab. Changes made to this control are simultaneously made to the one in the common controls. The Blend slider mixes the result of the node with its input, blending back the effect at any value less than 1.0. In this case it will blend the background with the merged result.

**Additional Controls**
The remaining controls let you fine-tune the results of the above settings.

• **Filter Method**: For input images that are being resized, this setting lets you choose the filter method used to interpolate image pixels when resizing clips. Defaults to Linear. Different settings work better for different kinds of resizing. Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter, however the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.
  - **Nearest Neighbor**: This skips or duplicates pixels as needed. This produces the fastest but crudest results.
  - **Box**: This is a simple interpolation resize of the image.
  - **Linear**: This uses a simplistic filter, which produces relatively clean and fast results.
  - **Quadratic**: This filter produces a nominal result. It offers a good compromise between speed and quality.
  - **Cubic**: This produces better results with continuous tone images but is slower than Bi-Cubic. If the images have fine detail in them, the results may be blurrier than desired.
  - **Catmull-Rom**: This produces good results with continuous tone images that are resized down. Produces sharp results with finely detailed images.
  - **Gaussian**: This is very similar in speed and quality to Bi-Cubic.
  - **Mitchell**: This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.
  - **Lanczos**: This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.
  - **Sinc**: This is an advanced filter that produces very sharp, detailed results, however it may produce visible 'ringing' in some situations.
  - **Bessel**: This is similar to the Sinc filter but may be slightly faster.
  - **Window Method**: Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.
- **Hanning**: This is a simple tapered window.
- **Hamming**: Hamming is a slightly tweaked version of Hanning.
- **Blackman**: A window with a more sharply tapered falloff.
- **Kaiser**: A more complex window, with results between Hamming and Blackman.

![Resize Filters from left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, and Bessel](image)

- **Edges buttons**: Four buttons let you choose how to handle the space around images that are smaller than the current DoD of the canvas as defined by the resolution of the background image.
  - **Canvas**: The area outside of the frame is set to the current color/opacity of the canvas. If you want to change what value this is, you can attach a Set Canvas Color node between the image connected to the foreground input and the foreground input itself, using Set Canvas Color to choose a color and/or transparency setting with which to fill the canvas.
  - **Wrap**: Creates a “video wall” effect by duplicating the foreground image as a grid.
  - **Duplicate**: Duplicates the outermost pixels along the edge of the foreground image, duplicating them to stretch out up, down, left, and right from each side to reach the end of the DoD.
  - **Mirror**: Similar to duplicate, except that every other iteration of the foreground image is flipped and flopped to create a repeating pattern.

- **Invert Transform**: Select the Invert Transform control to invert any position, rotation or scaling transformation. This option is useful when connecting the merge to the position of a tracker for the purpose of match moving.
- **Flatten Transform**: The Flatten Transform option prevents this node from concatenating its transformation with subsequent nodes. The node may still concatenate transforms from its input, but it will not concatenate its transformation with the node at its output.
- **Reference Size**: The controls under the Reference Size reveal do not directly affect the image. Instead they allow you to control how Fusion represents the position of the Merge node’s center.
  Normally, coordinates are represented as values between 0 and 1, where 1 is a distance equal to the full width or height of the image. This allows for resolution independence, because the size of the image can be changed without having to change the value of the center.

One disadvantage to this approach is that it complicates making pixel accurate adjustments to an image. To demonstrate, imagine an image that is 100 x 100 pixels in size. To move the center of the foreground element to the right by 5 pixels, we would change the X value of the merge center from 0.5, 0.5 to 0.55, 0.5. We know the change must be 0.05 because 5/100 = 0.05.

If you specify the dimensions of the background image in the Reference Size controls, this changes the way the Center control values are displayed so that it shows the actual pixel positions in its X and Y fields.

Extending the example, set the width and height to 100 each and the center will now be shown as 50, 50, and we would move it 5 pixels toward the right by entering 55, 50.
Internally, the Merge node still stores this value as a number between 0 to 1 and, if the center control’s value were to be queried via scripting or the center control were to be published for use by other nodes, the original normalized value would be retrieved. The change is only visible in the value shown for merge center in the node control.

- **Use Frame Format Settings**: Select this to force the merge to use the composition’s current frame format settings to set the reference width and reference height values.
- **Width and Height**: Set these sliders to the width and height of the image to change the way that Fusion displays the values of the Merge node’s center control.

Channels Tab

![Channels Tab Image]

The Channels tab has controls that let the Merge node use Z-channels embedded within each image to define what’s in front and what’s behind during a Merge operation. The following controls let you customize the result.

- **Perform Depth Merge checkbox**: Off by default. When turned on, the Z-channel of both images will be used to determine the composite order. Alpha channels are still used to define transparency, but the values of the Z-Depth channels will determine the ordering of image elements, front to back. If a Z-channel is not available for either image, the setting of this checkbox will be ignored, and no depth compositing will take place. If Z-Depth channels are available, turning this checkbox off disables their use within this operation.
- **Foreground Z-Offset slider**: Sets an offset applied to the foreground image’s Z value. Click the Pick button to pick a value from a displayed image’s Z-channel, or enter a value using the slider or input boxes. Raising the value causes the foreground image’s Z-channel to be offset further away along the Z-axis, whereas lowering the value causes the foreground to move closer.
- **Subtractive/Additive slider**: When Z-compositing, it is possible for image pixels from the background to be composited in the foreground of the output because the Z-buffer for that pixel is closer than the Z of the foreground pixel. This slider controls whether these pixels are merged in an Additive or a Subtractive mode, in exactly the same way as the comparable slider in the Merge tab.

When merged over a background of a different color, the original background will still be visible in the semi-transparent areas. An Additive merge will maintain the transparencies of the image but will add their values to the background.
Chapter 81

Generator Nodes

This chapter details the Generator nodes available in the Fusion page.

Background [BG]

The Background node can be used to produce anything from simple color backgrounds to complex loopable gradients.

Color Tab

Mode

This control is used to select the mode used by the Background node when the image is generated. Four selections are available.

- **Solid Color**: This default creates a single color image.
- **Horizontal**: This creates a two color horizontal gradation.
- **Vertical**: This creates a two color vertical gradation.
- **Four Corner**: This creates a four color corner gradation.
Gradient
This creates a background from a custom gradient.

Color
These controls are used to select the color of the Background node. Depending on the mode selected, one to four color controls will be displayed to create linear color ramp backdrops. Select one and pick a color from the preset menu or create them. Alternatively, enter values in RGB via the keyboard by clicking in the values box and typing in the value. Each color has its own alpha value slider to adjust the transparency of each color.
Image Tab

The controls in this tab are used to set the resolution, color depth and pixel aspect of the image produced by the node.

Process Mode

Use this menu control to select the Fields Processing mode used by Fusion to render changes to the image. The default option is determined by the Has Fields checkbox control in the Frame Format preferences.

Global In and Out

Use this control to specify the position of this node within the project. Use Global In to specify on which frame that the clip starts and Global Out to specify on which frame this clip ends (inclusive) within the project’s Global Range.

The node will not produce an image on frames outside of this range.

Use Frame Format Settings

When this checkbox is selected, the width, height and pixel aspect of the image created by the node will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

Width/Height

This pair of controls is used to set the Width and Height dimensions of the image to be created by the node.

Pixel Aspect

This control is used to specify the Pixel Aspect ratio of the created images. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor) and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).
Depth

The Depth button array is used to set the pixel color depth of the image created by the Creator node. 32-bit pixels require 4 times the memory of 8-bit pixels, but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

Right-click on the Width, Height or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height and pixel aspect to the values for that format accordingly.

Day Sky [DS]

The DaySky generator is a practical implementation of the research paper, A Practical Analytical Model for Daylight, by Preetham, Shirley, and Smits. A copy of the original paper can be found at the website for the Visual Simulation Group at the University of Utah [https://www.cs.utah.edu/~shirley/papers/sunsky/sunsky.pdf].

This node aims to produce a simulation of the daylight produced at a specific time and location on the earth, and generates a high dynamic range image that represents a map of that light. It is not a sky generator, although it could be combined with a cloud generator or noise node to produce one.

Controls

Latitude, Longitude

Use these sliders to specify the Latitude and Longitude used to create the Day Sky simulation.
**Day, Month, Time**
Use these controls to specify the Day, Month, and Time for the DaySky simulation.

**Turbidity**
Turbidity causes light to be scattered and absorbed rather than transmitted in straight lines through the simulation. Increasing the turbidity will give the sky simulation a murky feeling, as if smoke or atmospheric haze were present.

**Do Tone Mapping**
Deselect this checkbox to disable any tone mapping applied to the simulation. Since the simulation is calculated in 32-bit floating-point color space, it generates color values well above 1.0 and well below 0.0. Tone Mapping is a process that takes the full dynamic range of the resulting simulation and compresses the data into the desired exposure range while attempting to preserve as much detail from the highlights and shadows as possible.

Generally, this option should only be deselected if the resulting image will later be color corrected as part of a floating-point color pipeline.

**Exposure**
Use this control to select the exposure used for Tone Mapping.

**Advanced Tab**

**Horizon Brightness**
Use this control to adjust the brightness of the horizon relative to the sky.

**Luminance Gradient**
Use this control to adjust the width of the gradient separating the horizon from the sky.

**Circumsolar Region Intensity**
Use this control to adjust the intensity or brightness of the sky nearest to the sun.

**Circumsolar Region Width**
Use this control to adjust the width or size of the area in the sky affected by the sun.

**Backscattered Light**
Use this control to increase or decrease the amount of backscatter light in the simulation.
Image Tab

The controls in this tab are used to set the resolution, color depth, and pixel aspect of the image produced by the node.

![Image Tab controls](image)

**Process Mode**

Use this menu control to select the Fields Processing mode used by Fusion to render changes to the image. The default option is determined by the Has Fields checkbox control in the Frame Format preferences.

**Global In and Out**

Use this control to specify the position of this node within the project. Use Global In to specify on which frame that the clip starts and Global Out to specify on which frame this clip ends (inclusive) within the project's Global Range.

The node will not produce an image on frames outside of this range.

**Use Frame Format Settings**

When this checkbox is selected, the width, height, and pixel aspect of the image created by the node will be locked to values defined in the composition's Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

**Width/Height**

This pair of controls is used to set the Width and Height dimensions of the image to be created by the node.

**Pixel Aspect**

This control is used to specify the Pixel Aspect ratio of the created images. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor) and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).
Depth
The Depth button array is used to set the pixel color depth of the image created by the Creator node. 32-bit pixels require 4 times the memory of 8-bit pixels, but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

Right-click on the Width, Height, or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height, and pixel aspect to the values for that format accordingly.

Fast Noise [FN]

The Fast Noise node is a very fast and flexible Perlin Noise generator. It can be useful for a wide range of effects, from clouds and swirling fog to waves, water caustics, stylized fire, and smoke and other organic textures. It is also invaluable as a noise source for other effects, such as heat shimmer, particle systems and dirtiness maps.

Controls

Discontinuous
Normally, the noise function interpolates between values to create a smooth continuous gradient of results. Enable this checkbox to create hard discontinuity lines along some of the noise contours. The result will be a dramatically different effect.

Inverted
Select this checkbox to invert the noise, creating a negative image of the original pattern. This is most effective when Discontinuous is also enabled.
**Center**  
Use the Center coordinate control to pan and move the noise pattern.

**Detail**  
Increase the value of this slider to produce a greater level of detail in the noise result. Larger values add more layers of increasingly detailed noise without affecting the overall pattern. High values take longer to render but can produce a more natural result.

**Brightness**  
This control adjusts the overall brightness of the noise map, before any gradient color mapping is applied. In Gradient mode, this has a similar effect to the Offset control.

**Contrast**  
This control increases or decreases the overall Contrast of the noise map, prior to any gradient color mapping. It can exaggerate the effect of the noise, and widen the range of colors applied in Gradient mode.

**Lock and Scale X/Y**  
The size of the noise map can be adjusted using the Scale slider, changing it from gentle variations over the whole image to a tighter overall texture effect. The Scale slider can be separated into independent X- and Y-axis scale sliders by clicking on the Lock X/Y checkbox immediately above, which can be useful for a brushed-metal effect.

**Angle**  
Use the Angle control to rotate the noise pattern.

**Seethe**  
Adjust this thumbwheel control to interpolate the noise map against a different noise map. This will cause a crawling shift in the noise, like it was drifting or flowing. This control must be animated to affect the gradient over time, or you can use the Seethe Rate control below.

**Seethe Rate**  
As with the Seethe control above, the Seethe Rate also causes the noise map to evolve and change. The Seethe Rate defines the rate at which the noise changes each frame, causing an animated drift in the noise automatically, without the need for spline animation.
Two Color
A simple two color gradient is used to color the noise map. The noise function will smoothly transition from the first color into the second.

Gradient
The Advanced Gradient control in Fusion is used to provide much more control over the color gradient used with the noise map.
**Image Tab**

The controls in this tab are used to set the resolution, color depth, and pixel aspect of the image produced by the node.

**Process Mode**

Use this menu control to select the fields processing mode used by Fusion to render changes to the image. The default option is determined by the Has Fields checkbox control in the Frame Format preferences.

**Global In and Out**

Use this control to specify the position of this node within the project. Use Global In to specify on which frame that the clip starts and Global Out to specify on which frame this clip ends (inclusive) within the project’s Global Range.

The node will not produce an image on frames outside of this range.

**Use Frame Format Settings**

When this checkbox is selected, the width, height and pixel aspect of the image created by the node will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

**Width/Height**

This pair of controls is used to set the Width and Height dimensions of the image to be created by the node.

**Pixel Aspect**

This control is used to specify the Pixel Aspect ratio of the created images. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor) and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).
**Depth**

The Depth button array is used to set the pixel color depth of the image created by the Creator node. 32-bit pixels require 4 times the memory of 8-bit pixels, but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

Right-click on the Width, Height or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height and pixel aspect to the values for that format accordingly.

**Mask Map Inputs**

These external connections allow you to use masks to control the value of the Noise Detail and Brightness controls individually for each pixel. This can allow some interesting and creative effects.

**Noise Detail Map**

A soft-edged mask connected to the Noise Detail Map will give a flat noise map (zero detail) where the mask is black, and full detail where it is white, with intermediate values smoothly reducing in detail. It is applied before any gradient color mapping. This can be very helpful for applying maximum noise detail in a specific area, while smoothly falling off elsewhere.

**Noise Brightness Map**

A mask connected to this input can be used to control the noise map completely, such as boosting it in certain areas, combining it with other textures, or if Detail is set to 0, replacing the Perlin Noise map altogether.

**Mandelbrot [MAN]**

This node creates an image pattern based on the Mandelbrot fractal theory set.

**Generation Tab**
**Position X and Y**
This designates the image’s horizontal and vertical position or seed point.

**Zoom**
Zoom magnifies the pattern in or out. Every magnification is recalculated so that there is no practical limit to the zoom.

**Escape Limit**
Defines a point where the calculation of the iteration is aborted. Low values lead to blurry halos.

**Iterations**
This determines the repetitiveness of the set. When animated, it simulates a growing of the set.

**Rotation**
This rotates the pattern. Every new angle requires recalculation of the image.

---

**Color Tab**

![Color Tab Image](image_url)

**Grad Method**
Use this control to determine the type of gradation applied at the borders of the pattern.

**Continuous Potential**
This causes the edges of the pattern to blend to the background color.

**Iterations**
This causes the edges of the pattern to be solid.

**Gradient Curve**
This affects the width of the gradation from the pattern to the background color.

**R/G/B/A Phase/Repetitions**
Set the color values of the pattern generators.
Image Tab

The controls in this tab are used to set the resolution, color depth and pixel aspect of the image produced by the node.

Process Mode
Use this menu control to select the Fields Processing mode used by Fusion to render changes to the image. The default option is determined by the Has Fields checkbox control in the Frame Format preferences. Global In and Out

Use this control to specify the position of this node within the project. Use Global In to specify on which frame that the clip starts and Global Out to specify on which frame this clip ends (inclusive) within the project’s Global Range.

The node will not produce an image on frames outside of this range.

Use Frame Format Settings
When this checkbox is selected, the width, height and pixel aspect of the image created by the node will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

Width/Height
This pair of controls is used to set the Width and Height dimensions of the image to be created by the node.

Pixel Aspect
This control is used to specify the Pixel Aspect ratio of the created images. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor) and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).
**Depth**

The Depth button array is used to set the pixel color depth of the image created by the Creator node. 32-bit pixels require 4 times the memory of 8-bit pixels, but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

Right-click on the Width, Height or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height, and pixel aspect to the values for that format accordingly.

**Plasma [PLAS]**

This background generation node uses four circular patterns to generate images similar to Plasma. It is useful as a deforming pattern for the Shadow and Deform nodes and to create a variety of other useful shapes and patterns. See also the Fast Noise node.

**Circles Tab**
**Scale**
The Scale control is used to adjust the size of the pattern created.

**Operation**
The options in this menu determine the mathematical relationship between the four circles whenever they intersect.

**Circle Type**
Select the type of circle to be used.

**Circle Center**
Report and change the position of the circle center.

**Circle Scale**
Determine the size of the circle to be used for the pattern.

**Color Tab**

![Color Tab Image]

**Phase**
Phase changes the color phase of the entire image. When animated, this creates psychedelic color cycles.

**R/G/B/A Phases**
Changes the phase of the individual color channels and the alpha. When animated, this creates color cycling effects.
**Image Tab**

The controls in this tab are used to set the resolution, color depth, and pixel aspect of the image produced by the node.

![Image Tab](image.png)

**Process Mode**

Use this menu control to select the Fields Processing mode used by Fusion to render changes to the image. The default option is determined by the Has Fields checkbox control in the Frame Format preferences.

**Global In and Out**

Use this control to specify the position of this node within the project. Use Global In to specify on which frame that the clip starts and Global Out to specify on which frame this clip ends (inclusive) within the project’s Global Range.

The node will not produce an image on frames outside of this range.

**Use Frame Format Settings**

When this checkbox is selected, the width, height and, pixel aspect of the image created by the node will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the image produced by the node will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

**Width/Height**

This pair of controls is used to set the Width and Height dimensions of the image to be created by the node.

**Pixel Aspect**

This control is used to specify the Pixel Aspect ratio of the created images. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor) and an aspect of 0.9:1 would create a slightly rectangular pixel (like an NTSC monitor).
Depth
The Depth button array is used to set the pixel color depth of the image created by the Creator node. 32-bit pixels require 4 times the memory of 8-bit pixels, but have far greater color accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range for representing colors that are brighter than white or darker than black.

Right-click on the Width, Height, or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height, and pixel aspect to the values for that format accordingly.

Text Plus [TXT+]

Fusion’s Text node is an advanced character generator capable of 3D transformations, multiple styles, and several layers of shading. Text can be laid out to a user-defined frame, circle, or along a path.

Any True Type or Postscript 1 font installed on the computer can be used to create text. Support for multibyte and Unicode characters allows text generation in any language, including right to left and vertically oriented text.

This node generates a 2D image. To produce extruded 3D text with optional beveling, see the Text 3D node.

Text Tab
Size
This control is used to increase or decrease the size of the text. This is not like selecting a point size in a word processor. The size is relative to the width of the image.

Font
The Font controls are used to select the font used by Fusion to create the text. Fusion has limited support for third-party font managers. Fonts managed by a third-party font manager may need to move the Mac OS X or Windows Fonts folder.

Underline and Strikeout
These checkboxes enable the addition of emphasis styles to the font used.

Styled Text
The edit box in this tab is where the text to be created is entered. Any common character can be typed into this box. The common OS clipboard shortcuts (Command-C or Ctrl-C to copy, Command-X or Ctrl-X to cut, Command-V or Ctrl-V to paste) will also work, however right-clicking on the edit box displays a custom contextual menu.

The Styled Text contextual menu has the following options.

Animate
Use this command to set to a keyframe on the entered text and animate the content over time.

Character Level Styling
This command enables Character Level Styling, which will place a set of controls in the Modifiers tab. Use these controls to affect changes in the font, color, size and transformations applied to individual characters.

Comp Name
Comp Name puts the name of the composition in the edit box and is generally used to create slates.

Follower
Follower is a text modifier that can be used to ripple animation applied to the text across each character in the text. See Text Modifiers at the end of this chapter.

Publish
Publish the text for connection to other text nodes.

Text Scramble
A text modifier ID is used to randomize the characters in the text. See Text Modifiers at the end of this chapter.

Text Timer
A text modifier is used to count down from a specified time or to output the current date and time. See Text Modifiers at the end of this chapter.

Time Code
A text modifier is used to output Time Code for the current frame. See Text Modifiers at the end of this chapter.

Connect To
Use this option to connect the text generated by this Text node to the published output of another node.
**Write On**
This range control is used to quickly apply simple Write On and Write Off effects to the text. To create a Write On effect, animate the End portion of the control from 1 to 0 over the length of time required. To create a Write Off effect, animate the Start portion of the range control from 0 to 1.

**International Font Controls**
This drop-down menu can be used to select a language specific to a subset of a font.

**Direction**
This menu provides options for determining the Direction in which the text is to be written.

**Line Direction**
These menu options are used to determine the text flow from top-bottom, bottom-top, left-right, or right-left.

**Force Monospaced**
This slider control can be used to override the kerning (spacing between characters) that is defined in the font. Setting this slider to zero (the default value) will cause Fusion to rely entirely on the kerning defined with each character. A value of one will cause the spacing between characters to be completely even, or monospaced.

**Do Font Defined Kerning**
This enables kerning as specified in the true type font and is on by default.

**Advanced Font Controls**
Leave the Font Defined Glyphs, Reordering and Ligation checkbox selected unless instructed to do otherwise by support.

**Manual Font Kerning/Placement**
Right-clicking on this label will display a contextual menu that can be used to animate the kerning of the text. See the Toolbar section of this node’s documentation later in this chapter for details on manual kerning.
The controls used to position the text are located in the Layout Tab. One of four layout types can be selected using the button array.

**Point**
Point layout is the simplest of the layout modes. Text is arranged around an adjustable center point.

**Frame**
Frame layout allows you to define a rectangular frame used to align the text. The alignment controls are used to justifying the text vertically and horizontally within the boundaries of the frame.

**Circle**
Circle Layout places the text around the curve of a circle or oval. Control is offered over the diameter and width of the circular shape. When the layout is set to this mode, the Alignment controls determine whether the text is positioned along the inside or outside of the circle’s edge, and how multiple lines of text are justified.

**Path**
Path layout allows you to shape your text along the edges of a path. The path can be used simply to add style to the text, or it can be animated using the Position on Path control that appears when this mode is selected.
**Center X, Y and Z**  
These controls are used to position the center of the layout element in space. X and Y are onscreen controls and Center Z is a slider in the node controls.

**Size**  
This slider is used to control the scale of the layout element.

**Layout Rotation**  
Select this checkbox and another set of options appears to set the Rotation options of the text.

**Rotation Order**  
This button array allows you to select the order in which 3D rotations are applied to the text.

**Angle X, Y and Z**  
These Angle controls can be used to adjust the angle of the Layout element along any axis.

**Width and Height**  
The Width control is visible when the Layout mode is set to Circle or Frame. The Height control is only visible when the Layout mode is set to Frame. They are used to adjust the dimensions and aspect of the Layout element.

**Perspective**  
This slider control is used to add or remove Perspective from the rotations applied by the Angle X, Y, and Z controls.

**Fit Characters**  
This menu control is only visible when the Layout type is set to Circle. This menu is used to select how the characters are spaced to fit along the circumference.

**Position On Path**  
The Position On Path control is used to control the position of the text along the path. Values less than zero or greater than one will cause the text to move beyond the path in the same direction as the vector of the path between the last two keyframes.

**Background Color**  
This label only appears when the Layout type is set to Path. It is used to provide access to a contextual menu that provides options for connecting the path to other paths in the node tree, and animating the shape of the path over time.

The text generated by this node is normally rendered against black. This color picker control can be used to set a new background color.

**Right-Click Here for Shape Animation**  
Consult the Motion Paths chapter of this manual for details.

**Horizontal and Vertical Alignment**  
Two identical sets of controls are used to control Vertical and Horizontal Alignment of the text. Use the first array of buttons to choose the alignment of the text. The slider beneath controls the justification.
Transform Tab

There are three buttons to determine the portion of the text affected by the transformations applied in this tab. Transformations can be applied to line, word and character levels simultaneously. This menu is only used to keep the number of visible controls to a reasonable number.

Characters
Each character of text is transformed along its own center axis.

Words
Each word is transformed separately on the word’s center axis.

Lines
Each line of the text is transformed separately on that line’s center axis.

Spacing
The Spacing slider is used to adjust the amount of space between each line, word or character. Values less than one will usually cause the characters to begin overlapping.

Pivot X, Y and Z
This provides control over the exact position of the axis. By default, the axis is positioned at the calculated center of the line, word or character. The Axis control works as an offset, such that a value of 0.1, 0.1 in this control would cause the axis to be shifted downward and to the right for each of the text elements. Positive values in the Z-axis slider will move the axis farther along the axis (away from the viewer). Negative values will bring the axis of rotation closer.
**Rotation Order**
These buttons are used to determine the order in which transforms are applied. X, Y and Z would mean that the rotation is applied to X, then Y, and then Z.

**Angle X, Y and Z**
These controls can be used to adjust the angle of the text elements in any of the three dimensions.

**Shear X and Y**
Adjust these sliders to modify the slanting of the text elements along the X- and Y-axis.

**Size X and Y**
Adjust these sliders to modify the size of the text elements along the X- and Y-axis.

**Shading Tab**
The Shading tab provides controls to adjust the shading, texture and softness of the text. Transformations can be controlled from this tab as well, applying additional transformations to as many as eight separate text shading elements independently. The Number menu is used to select the element affected by adjustments to the controls in this tab.
Name
This text label can be used to assign a more descriptive name to each shading element.

Enabled
Select this checkbox to enable or disable each layer of shading elements. Element 1 is enabled by default. The controls for a shading element will not be displayed unless this checkbox is selected.

Opacity
The Opacity slider controls the overall transparency of the shading element. It is usually better to assign opacity to a shading element than to adjust the alpha of the color applied to that element.

Priority Back/Front
This slider determines the layer’s order for the shading elements, also known as the Z-order. Slide the control to the right to bring an element closer to the front. Move it to the left to tuck one shading element behind another.

Overlap
This menu is used to select how the renderer deals with an Overlap between two characters in the text.

Composite
This Overlap option will merge the shading over top of itself.

Solid
This option sets the pixels in the overlap region to pure opaque.

Transparent
This option sets the pixels in the overlap region to pure transparent.

Element Type (Buttons)
There are four options available from this menu, providing control over how the shading element is applied to the text. Different controls will appear below depending on the element type selected.

Text Fill
The shading element is applied to the entire text. This is the default mode.

Text Outline
The shading element is drawn as an outline around the edges of the text.

Border Fill
The shading element fills a border surrounding the text. Five additional controls are provided with this shading mode.

Border Outline
The Border Outline mode draws an outline around the border that surrounds the text. It offers several additional controls.

Overlap
(All Types) Overlap is used to determine how the shading is handled when portions of the same shading element overlap. Setting this menu to transparent will cause the pixels’ color and alpha channels to be set to 0 (transparent).
**Thickness**
(Outline only) Use this slider control to adjust the thickness of the outline. Higher values equal thicker outlines.

**Adapt Thickness To Perspective**
(Outline only) Selecting this checkbox will cause your outline to become thinner where the text is farther away from the camera, and thicker where it is closer. This will create a much more realistic outline for text transformed in 3D but takes significantly longer to render.

**Outside Only**
(Outline only) Selecting this checkbox will cause the outline to be drawn only on the outside edge of the text. By default the outline is centered on the edge and partially overlaps the text.

**Join Style**
(Outline only) This menu provides options for how the corners of the outline are drawn. Options include Sharp, Rounded, and Beveled.

**Line Style**
(Outline only) This menu offers additional control over the style of the line. In addition to the default solid line, a variety of dash and dot patterns are available.

**Shape**
(Border Fill only) Shape creates a solid rectangular image around the character.

**Shape**
(Border Outline only) Creates a rectangular outline around each character.

**Level**
(Border Fill only) This is used to control the portion of the text border filled.

**Text**
This draws a border around the entire text.

**Line**
This draws a border around each line of text.

**Word**
This draws a border around each word.

**Character**
This draws a border around each character.

**Extend Horizontal and Extend Vertical**
(Border only) Use this slider to change the dimensions of each border.

**Round**
(Border only) This slider is used to round off the edges of the border.

**Color Types**
In addition to solid shading, it is also possible to map an external image onto the text. This menu is used to determine if the color of the shading element is derived from a user-selected color or if it comes from an external image source. Different controls will be displayed below depending on the Color Type selected.
**Solid Mode**
When the Type menu is set to Solid mode, color selector controls are provided to select the color of the text.

**Image Mode**
The output of a node in the node tree will be used to texture the text. The node used is chosen using the Color Image control revealed when this option is selected.

**Color Image**
(Image Mode only) This Color Image text box is used to enter the name of the node in the node tree that will provide the image. You can type the name in with the keyboard, drag the node from the node tree into the text box, or right-click and select Connect To from the contextual menu to select the image to be used.

**Image Size**
(Image Mode only) The Image Size menu is used to select how the image is mapped to the text.

**Full Image**
This option applies the entire image to the text.

**Text**
This option applies the image to fit the entire set of text.

**Line**
This option applies the image per line of text.

**Word**
This option applies the image per each word of text.

**Character**
This option applies the image per individual character.

**Softness X and Y**
These sliders control the softness of the text outline used to create the shading element. Control is provided for the X- and Y-axis independently.

**Softness On Fill Color Too**
Selecting this checkbox will cause blur (softness) to be applied to the shading element as well. The effect is best seen when applied to a shading element colored by an external image.

**Softness Glow**
This slider will apply a glow to the softened portion of the shading element.

**Softness Blend**
This slider controls the amount that the result of the softness control is blended back with the original. It can be used to tone down the result of the soften operation.

**Transform Controls**
Selecting the Transform button in the Shading tab will display controls for performing transformations to the shading elements. These controls work in exactly the same way as their equivalents in the Alignment and Layout Tabs, with the addition of a Center Offset control.
**Offset X, Y and Z**
These controls are used to apply offset from the text’s global center (as set in the Layout tab) for the shading elements. A value of X0.0, Y0.1 in the coordinate controls would place the shading element center 10 percent of the image further down the screen along the Y-axis. Positive values in the Z-Offset slider control will push the center farther away from the camera, while positive values will bring it closer to the camera.

**Tabs Tab**
The controls in the Tabs area are used to configure the horizontal screen positions of 8 separate tab stops. Any tab characters in the text will conform to these positions.
Because the Tab key is used by Fusion to advance to the next control, it is not possible to enter a tab directly into the Styled Text input. Enter a tab using one of the following methods.

**Copy and Paste**
Copy a tab from another document, such as Notes on macOS or Notepad on Windows, and paste it into the text box.

**Position**
This control is used to set the horizontal position of the tab in the frame. The values range from 0.0 to 1.0, where 0 is the far left side and 1 is the far right side of the frame. The position of the tab will be indicated in the Viewer by a thin vertical white line when the Text node is selected and the Tabs tab is open.

**Alignment**
Each tab can be set to either left aligned, right aligned or centered. This slider ranges from -1.0 to 1.0, where -1.0 is a left aligned tab, 0.0 is a centered tab and 1.0 is a right aligned tab. Small white boxes at the top of the tab lines indicate that there are tabs present in the node tree. Clicking within these boxes will toggle the alignment of the tab between the three states.

**Rendering Tab**

**Image Shading Sampling**
Use this button array to select the sampling type for shading rendering and transformations. The default of Pixel shading is sufficient for 90% of tasks. To reduce detectable aliasing in the text, set the sampling type to Area. This is slower but may produce better quality results. A setting of None will render faster, but with no additional sampling applied, so the quality will be lower.

**Image Shading Edges**
Use this button array to choose how transformations applied to image shading elements are handled when they wrap off the text’s edges.

**Sort Shading Elements**
This button selection determines the ordering of the shading elements. The default is By Priority, which organizes the shading elements back to front, according to the priority back/front slider in each shading element’s controls.
Selecting the By Depth (Z-Position) option will re-organize these according to each element’s Z-position, as set by the element’s transformations.
Clip Characters Behind Camera
This checkbox determines whether characters that go beyond the plane of the camera will be clipped, or if they will reflect back toward the center of the image. This should normally be enabled for clipping, but some interesting effects can be produced when clipping is disabled.

Anti-Aliasing
This slider is used to increase or decrease the amount of anti-aliasing applied to the text. Higher values mean exponentially longer render times, while lower values reduce render times at the expense of quality.

Render to Flash File
Click this button to render the output of the Text node to an Adobe Flash file.

Library Tab
The Shading Library is used to store and retrieve the settings of a Text node for easy re-use.

Put
To add a new text element to the library, click on the Put button. All of the current settings for the node will be saved according to the name assigned. A thumbnail will appear in the Shading Library showing how that style looks on the letter A.

Get
Click on a shading element in the library, then click on the Get button to apply those settings to the current node. Get will replace all of the text as well as the style.

Shading
Clicking on Shading will replace the shading elements only, without affecting the text entered. Right-click in the Shading Library window for a list of display options.

Text+ Toolbar
When the Text node is selected, a toolbar will appear in the Viewer.

Allow Typing In Preview Window
Enable this button to type and edit text directly in the Viewer, click on the text to produce a cursor that can be positioned within the text. The cursor can be moved using the arrow keys. Type normally.

Allow Manual Kerning
This button enables Manual Kerning, which overrides the automatic kerning normally applied to text. A small red dot will appear beneath each character of text in the Viewer. Drag on the dot to
reposition a character. Also select multiple characters and move them together. Hold the Option or Alt key down while dragging to constrain motion to a single axis.

Use the arrow keys on the keyboard to make manual adjustments to the position of the selected characters. Hold the Command or Ctrl key down while pressing arrow keys to move the character in smaller increments. Shift will move the characters in larger increments.

To animate the position of each character, right-click on the control label Manual Font Kerning/Placement beneath the Text tab’s Advanced Font controls and select Animate from the contextual menu. A new key will be set on the animation spline each time a character is moved. All characters are animated with the same spline, as with polyline mask animation.

**No Text Outline**
This button disables the drawing of any outline around the edges of the text. The outline is not a part of the text. It is an onscreen control used to help identify the position of the text.

**Text Outline Outside Frame Only**
This button draws an outline around the edges of text, which is outside the visible frame. This is useful for locating text that has moved off screen and is no longer rendering a visible result.

**Show Always Text Outline**
This button draws an outline around the edges of text at all times, whether the text is visible within the frame or not.

**Modifiers**

**Character Level Styling**
The Character Level Styling modifier only works on Text+ nodes. You can then select individual characters directly in your view and apply different text attributes to them. Think of larger capitals at the beginning of each line, different fonts in one word, colored highlighting, and more.
It can be applied by right-clicking into the Styled Text field of a Text+ node and selecting Character Level Styling.

Character Level Styling can only be directly applied to Text+ nodes, not to Text 3D nodes. However, styled text from a Text+ node can be applied to a Text 3D node by means of copying the Text+, right-clicking on the Text 3D and choosing Paste Settings.

Text Tab

Text Controls, Alignment, Transform and Shading Tab
For details see the Text+ node documentation.

Clear Character Styling on Selection
All changes made to the currently selected Characters will be reset.

Clear all Character Styling
All character attributes will be reset to their original values.

Comp Name
The Comp Name only works on Text+ nodes. It sets the Styled text to become the current Composition Name. This is quite useful to automate burn-ins for daily renderings. See also the TimeCode modifier. It can be applied by right-clicking into the Styled text field of a Text+ node and selecting Comp Name.

Controls
This Modifier Has No Controls
For further details see the Text+ node documentation.

Follower
The Follower only works on Text and Text3D nodes. This node allows for a plethora of cool motion graphics effects. The basic idea is that you animate the parameters of a single character and the other characters will follow that animation with a delay. It can be applied by right-clicking into the Styled Text field of a Text node and selecting Follower.
Timing Tab

Range
Allows the user to select if all characters should be influenced or only a selected range. You can drag-select a range of characters directly on the screen.

Order
Determines in which order the Characters are influenced. Notice that empty spaces are counted as characters as well. Available options are:

- **Left to right:** The animation ripples from left to right through all characters.
- **Right to left:** The animation ripples from right to left through all characters.
- **Inside out:** The animation ripples symmetrically from the center point of the characters toward the margin.
- **Outside in:** The animation ripples symmetrically from the margin toward the center point of the characters.
- **Random but one by one:** The animation is applied to randomly selected characters but only influences one character at a time.
- **Completely random:** The animation is applied to randomly selected characters, influencing multiple characters at a time.
- **Manual curve:** The affected characters can be specified by sliders.

Delay Type
Determines what sort of delay is applied to the animation. Available options are:

- **Between Each Character:** The more characters there are in your text, the longer the animation will take to the end.
- **Between First and Last Character:** No matter how many characters are in your text, the animation will always be completed in the selected amount of time.

Clear all Character Styling
All character attributes will be reset to their original values.

Text Controls, Alignment, Transform and Shading Tab
In these tabs, the actual animation for the characters is done. Observe that simply changing a value in these tabs will have no influence at all. The value needs to be animated for the effect to show.

For a detailed description on the various parameters, see the Text+ node documentation.
Text Scramble

The Text Scramble only works on Text+ nodes. It scrambles the Text around, randomly replacing the characters with others from a user definable set. It can be applied by right-clicking into the Styled text field of a Text+ node and selecting TextScramble.

Randomness

Defines how many characters are exchanged randomly. A value of 0 will change no characters at all. A value of 1 will change all characters in the text. Animating this thumbwheel to go from 0 to 1 will gradually exchange all characters.

Input Text

This reflects the original Text in the Text+ Styled Text. Text can be entered either here on in the Text+ node.

Animate On Time

When set, the characters will get scrambled randomly on every new frame. This switch has no effect when Randomness is set to 0.

Animate On Randomness

When set, the characters will get scrambled randomly on every new frame, when the Randomness thumbwheel is animated.

This switch has no effect when Randomness is set to 0.

Don’t Change Spaces

When set, the length of the single words will stay the same, though their characters get scrambled around.

Substitute Chars

Defines which characters are used to scramble the text.

Text Timer

The Text Timer only works on Text+ nodes. It makes the Text+ node either a Countdown, a Timer or a Clock. This is quite useful for on screen real-time displays or to burn in the creation time of a frame into the picture.

It can be applied by right-clicking into the Styled text field of a Text+ node and selecting TextScramble.

Mode

Sets the mode the timer is working in. In Clock mode the current system time will be displayed.
**Hrs, Mins, Secs (Switches)**
Defines which parts of the clock should be shown on screen.

**Hrs, Mins, Secs (Sliders)**
Set the start time for the Countdown and Timer mode.

**Start**
Starts the Counter or Timer. Toggles to Stop once the timer is running.

**Reset**
Resets the Counter and Timer to the values set by the sliders.

**Time Code**
The Time Code only works on Text+ nodes. It sets the Styled text to become a counter based on the current frame. This is quite useful to automate burn-ins for daily renderings.

It can be applied by right-clicking into the Styled text field of a Text+ node and selecting Time Code.

**Hrs, Mins, Secs, Frms, Flds**
Activate or de-activate these options to customize the time code display to show hours, minutes, seconds, frames, and fields respectively. Activating Frames only will give you a plain frame counter.

**Start Offset**
Introduce a positive or negative offset to Fusion’s current time to match up with existing time codes.

**Frames per Second**
This should match with your Composition’s FPS setting to provide accurate time measurement.

**Drop Frame**
Activate this checkbox to match the time code with footage that has drop frames, for example, certain NTSC formats.
Chapter 82

DeepPixel Nodes

This chapter details DeepPixel nodes found in the Fusion page.
Contents

Ambient Occlusion [SSAO] 1631
Depth Blurred 1634
Fog 1636
Shader 1637
Texture 1639
Ambient Occlusion [SSAO]

Ambient Occlusion (AO) is the lighting caused when a scene is surrounded by a uniform diffuse spherical light source. Think of the scene as being surrounded by a humongous sphere that uniformly emits light from its surface. AO captures the low frequency lighting. It does not capture sharp shadows or Diffuse or Specular lighting. For this reason, AO is usually combined with Diffuse and Specular lighting to create a full lighting solution.

The Ambient Occlusion node generates global lighting effects in 3D-rendered scenes as a post effect. It approximates expensive raytraced global illumination quickly. Being a post effect, it exposes similar aliasing issues like the Shader, Texture, and VolumeFog nodes. Hence, artifacts may appear in certain situations.

Usage

The AO node rarely works out of the box, but requires some tweaking. The setup process involves adjusting the KernelRadius and NumberOfSamples to get the desired affect.

The KernelRadius depends on the natural ‘scale’ of the scene. Initially there might appear to be no AO at all. At this point either the KernelRadius is too small or too big and working values have to be found.

Inputs

- **Image (required):** Requires RGBA, Z-Depth and Normals.
- **Scene (required):** The Scene or 3D Camera the image was rendered with.

If any of these are not supplied, the node will fail with a descriptive error.
Controls

**Output Mode**
- **Color:** The incoming image with Ambient Occlusion applied
- **AO:** Outputs the pure Ambient Occlusion as a grayscale image.

White corresponds to regions in the beauty pass that should be bright, while black correspond to regions that should be darker. This allows you to create a lighting equation by combining separate ambient/diffuse/specular passes. Having the AO as a separate buffer allows for creative freedom to combine the passes in various ways.

**Kernel Type**
To determine the AO, rays are cast outward from a point on the surface being shaded outwards to a large enclosed sphere.

The number of unoccluded rays, that is those rays that reach the sphere, determines the AO factor.

**Hemisphere**
Rays are cast toward a hemisphere oriented to the surfaces normal. This option is more realistic than “Sphere” and should be used unless there is a good reason otherwise.

Flat surfaces will receive 100% ambient intensity, while other parts will be darkened.

**Sphere**
Rays are cast toward a sphere centered about the point being shaded. This option is provided to produce a stylistic effect. Flat surfaces will receive 50% ambient intensity, while other parts will be made darker or brighter.
**Number of Samples**
Increase the number of samples until artifacts in the AO pass disappear. Higher values can generate better results but also increase render time.

**Kernel Radius**
The Kernel Radius controls the size of the filter kernel in 3D space. For each pixel, it controls how far one searches in 3D space for occluders. Most likely, the Filter Kernel is finicky and may need to be adjusted manually for each individual scene.

If made too small, nearby occluders can be missed. If made too large, the quality of the AO will decrease and the number of samples needs to be increased dramatically to get the quality back.

This value is dependent on the scene Z-depth. That means with huge Z values in the scene, the kernel size needs to be large as well. With tiny Z values, a small kernel size like 0.1 should be sufficient.

**Lift/Gamma/Tint**
Used to adjust the AO for artistic effects.

**Use OpenCL**
Ambient Occlusion is very slow on the CPU but performs much better on the GPU. Activate this switch to utilize the OpenCL power of your graphics card.

**TIP:** Combining multiple AO passes with different kernel radii can produce better effects.
Known Issues
- **Transparency/Translucency**: AO is designed to work with opaque objects. There will be two kinds of problems: those with transparent receivers and those with transparent occluders. You can work around some of these problems by splitting out the transparent/translucent objects into separate scenes and only computing AO on the opaque objects.
- **Particles**: Do not use AO on particles, unless the particles are solid opaque geometry. This is just the transparency problem again. Antialiased edges (another form of transparency) will also cause problems with AO. There’s not much you can do about this.
- **Supersampling**: See Antialiased edges. In order for this to work, the AO needs to be computed in the big image before it is downscaled to the final image.
- **View Dependence**: AO methods work in view space and the results are view dependent. This is a limitation of the technique itself. This means the amount of darkening can vary depending on the view location when in reality it should be constant. If at a point on an object the AO is 0.5, moving the camera could change it to 0.4.
- **Baking of AO**: The UV renderer can be used to bake AO into the textures on models.

Depth Blurred

The Depth Blur node is primarily used to create focal length or depth-of-field effects. It blurs 3D rendered images based on included Z-channel values, and can also be used for general per-pixel blurring effects by means of the Blur Channel controls. If the Blur Image input is connected, channels from that image will be used to control the blur.

Controls
Filter
These buttons are used to select the filter used for applying the blur.

Box
This applies a depth-based box blur effect to the image.

Soften
This applies a depth-based general softening filter effect.

Super Soften
This applies a depth-based high quality softening filter effect.

Blur Channels
Select one of these options to determine the channel used to control the level of blur applied to each pixel. The channel from the main image input is used, unless a node is connected to the node’s Blur Image input on the node tree.

Lock X/Y
When toggled on, this control locks the X and Y Blur sliders together for symmetrical blurring.

Blur Size
This slider is used to set the strength of the horizontal and vertical blurring applied to the image.

Focal Point
This control is only visible when the Blur channel is set to use the Z-buffer.
Use this control to select the distance of the simulated point of focus. Lowering the value causes the Focal Point to be closer to the camera, raising the value causes the Focal Point to be farther away.
Drag the Pick button (the pointer changes to a dropper) over the displayed image and select a Z-buffer value. If the image does not contain a valid Z-buffer, no change will occur in the value.

Depth of Field
This control is used to determine the depth of the area in focus. The focal point is positioned in the middle of the region and all pixels with a Z-value within the region stay in focus. For example, if the focal point was selected from the image and set to a value of 300, and the depth of field is set to 200, any pixel with a Z-value between 200 and 400 would remain in focus.

Z Scale
Scales the Z-buffer value by the selected amount. Raising the value causes the distances in the Z-channel to expand. Lowering the value causes it to contract. This is useful for exaggerating the depth effect. It can also be used to soften the boundaries of the blur. Some images with small depth values may require the Z-scale to be set quite low, below 1.0.
Fog

The Fog node is used to create simulated fog effects on 3D rendered images that contain a valid Z-buffer channel. The fog can be placed in front of or behind various elements of a rendered image based on the selected Z-channel planes.

The second image input on the Fog node can be used to provide an image that is used as the source of the fog. If no image is provided, the fog consists of a single color. Generally, a noise map of some sort is provided here.

Controls

**Z-Buffer Near Plane and Far Plane**
These controls are used to select the extents of the fog within the scene. To pick a value, drag the Pick button to an area on the image being viewed where the plane is to be located.

The Near Plane is used to select the depth where the fog thins out to nothing. The Far Plane is used to select the depth at which the fog becomes opaque.

**Z Depth Scale**
This option scales the Z-buffer values by the selected amount. Raising the value causes the distances in the Z-channel to expand, whereas lowering the value causes it to contract. This is useful for exaggerating the fog effect.
**Fog Color**
This option displays and controls the current fog color. Alpha adjusts the fog’s transparency value.

**Fog Opacity**
Use this control to adjust the opacity of the fog.

---

**Shader**

The Shader node can control the lighting, reflection mapping and 3D shading of elements in a rendered image. The reflection map image (connected to the green input) can be projected onto all elements in the scene or to elements selected by the Object and Material ID channels in the common controls. Effect masking can also be used to limit the effect of this node.

The Shader node relies on the presence of the X, Y, and Z normal map channels in 3D rendered images. If these channels are not present, this node has no effect.

---

**Light Tab**

**Ambient**
Ambient controls the amount of Ambient color present in the scene or for the selected object. This is a base level of light, added to all pixels, even in completely shadowed areas.

**Diffuse**
This option controls the amount of Diffuse color present in the scene or for the selected object. This is the normal color of the object, reflected equally in all directions.

**Specular**
This option controls the amount of Specular color present in the scene or for the selected object. This is the color of the glossy highlights reflected toward the eye from a light source.
**Reflection**
This option controls the amount of Reflection contribution in the scene or for the selected object. High levels make objects appear mirrored, low levels overlay subtle reflections giving a polished effect. It has no effect if no reflection map is connected.

**Reflection Type**
Select from these three buttons to determine the type of reflection mapping used to project the image in the second input.

**Screen**
Screen causes the reflection map to appear as if it were projected on to a screen behind the point of view.

**Spherical**
Spherical causes the reflection map to appear as if it were projected on to a huge sphere around the whole scene.

**Refraction**
Refraction causes the reflection map to appear as if it were refracting or distorting according to the geometry in the scene.

**Equator Angle**
Equator Angle controls the left to right angle of the light generated and mapped by the Shader node for the scene or the selected object.

**Polar Height**
Polar Height controls the top to bottom angle of the light generated and mapped by the Shader node for the scene or the selected object.

**Shader Tab**
Edit Diffuse and Specular
Toggle these controls on to enable editing of the Shader curves for the individual channels in the Shader spline window.

In and Out
These options are used to display and edit point values on the spline.

Specular Color
Use the Diffuse curve to manipulate the diffuse shading and the Specular curve to affect the specular shading. Drag a box over a number of points to group select them. Right-clicking displays a menu with options for adjusting the spline curves.

Texture
The Texture node can control the texture mapping of elements in a rendered image. The texture-map image (connected to the green input) can be wrapped around objects to replace the current texture. The Texture node relies on the presence of U and V Map channels in 3D rendered images. If these channels are not present, this node has no effect.

NOTE: Background pixels may have U and V values of 0.0, which will set those pixels to the color of the texture’s corner pixel. To restrict texturing to specific objects, use an effect mask based on the alpha of the object, or its Object or Material ID channel.

Texture Tab
Swap UV
When this checkbox is selected the U and V channels of the source image are swapped.
**Flip Horizontal and Vertical**
The texture-map image is flipped horizontally and/or vertically when this control is toggled on.

**Rotate 90**
The texture-map image is rotated 90 degrees when this checkbox is enabled.

**U and V Scale**
These controls change the scaling of the U and V coordinates used to map the texture. Changing these values effectively enlarges and shrinks the texture map as it is applied.

**U and V Offset**
Adjust these controls to offset the U and V coordinates. Changing the values causes the texture to appear to move along the geometry of the object.
Chapter 83

Effect Nodes

This chapter details the Effect nodes in the Fusion page.
## Contents

<table>

</table>
**Highlight [HIL]**

The Highlight filter creates star-shaped highlights in bright regions of the image, similar to a lens star filter effect.

**Settings Tab**

**Low and High**
This range control designates the range of Luminance values in the image that will generate highlights. Values less than the Low value will not receive highlights. Values above the High value will receive the full highlight effect.

**Curve**
The Curve value changes the drop off over the length of the highlight. Higher values will cause the brightness of the flares to drop off closer to the center of the highlight, whereas lower values will drop off farther from the center.

**Length**
This designates the Length of the flares from the highlight.

**Number of Points**
This determines the Number of flares emanating from the highlight.

**Angle**
Use this control to rotate the highlights.

**Merge Over**
When this checkbox is on, it will overlay the effect on the original image. With the checkbox off, the output will be the highlights only. This is useful for downstream color correction of the highlights.
Color Scale Tab

Red, Green and Blue Scale
Moving the sliders of one or all of these channels down will change the falloff color of the highlight.

Alpha Scale
Moving the Alpha slider down will make highlight falloff more transparent.

Highlight Masks
The Highlight node offers an additional mask input called the Highlight Mask. This is a pre-mask that determines what pixels can be affected by the highlight before the highlight is applied. Unlike regular masks, it will not crop off highlights from source pixels when the highlight extends past the masks edges.

Hot Spot [HOT]

The Hot Spot node is used to create lens flare, spotlight and burn/dodge effects of various types.

In the real world, lens flares occur when extremely bright light sources present in the scene by the reflections are reflected off elements inside the lens of the camera. One might see lens flares in a shot when viewing a strong light source through a camera lens, like the sun or a bright star.
Hot Spot Tab

**Primary Center X and Y**
This is the position of the Primary Hot Spot within the scene. Secondary lens elements and reflections are positioned relative to the position of the primary.

**Primary Strength**
This control determines the brightness of the primary hotspot.

**Hotspot Size**
This control determines the diameter of the primary hotspot. A value of 1.0 represents a circle the full width of the image.

**Aspect**
This controls the Aspect of the spot. A value of 1.0 produces a perfectly circular hotspot. Values above 1.0 will elongate the circle horizontally and values below 1.0 will elongate the circle vertically.

**Aspect Angle**
This control can be used to rotate the primary hotspot.

**Secondary Strength**
This control determines the strength, which is to say the brightness, of the secondary hotspot. The secondary hotspot is a reflection of the primary hotspot. It will always be positioned on the opposite side of the image from the primary hotspot.

**Secondary Size**
This determines the size of the secondary hotspot.

**Apply Mode**
This control determines how the hotspot affects the underlying image.

**Add (Burn)**
This causes the spots created to brighten the image.
**Subtract (Dodge)**
This causes the spots created to dim the image.

**Multiply (Spotlight)**
This causes the spots created to isolate a portion of the image with light and to darken the remainder of the image.

**Occlude**
Use this button array to select which channel of the image connected to the Hotspot node’s Occlusion input is used to provide the occlusion matte.

Occlusion happens when the source of the hotspot is blocked by something between it and the camera. When the source of a hotspot is occluded, the hotspot simply winks out.

Occlusion can be controlled from Alpha or R, G, or B channels of any image connected to the Occlusion input on the node’s tile. The white pixels in the image will occlude the hotspot. Gray pixels will partially suppress the hotspot.

**Lens Aberration**
Aberration changes the shape and behavior of the primary and secondary hotspots.

**In and Out Modes**
Elongates the shape of the hotspot into a flare. The hotspot stretches toward the center of the image when in In mode, stretching toward the corners when in Out mode.

**Flare In and Flare Out Modes**
This option is a lens distortion effect that is controlled by the movement of the lens effect. Flare In will cause the effect to become more severe the closer the hotspot gets to the center. Flare Out causes the effect to increase, as the hotspot gets closer to the edges of the image.

**Lens**
This mode emulates a round, ringed lens effect.

**Aberration**
The Aberration slider controls the overall strength of the lens aberration effect.

**Color Tab**
Color Channel and Mix
When selected, these checkbox controls enable the editing of the chosen splines in the LUT below.

Red, Green, Blue and Alpha Splines
The Red, Green, Blue, and Alpha splines are used to adjust the color of the spotlight along the radius of the hotspot.

The vertical axis represents the intensity or strength of the color channel, from a value of 0 at the bottom to 1 at the top. The horizontal axis represents the position along the radius of the hotspot, from the outside edge on the left to the inside on the right.

So the default curve of the node indicates that the red, green, blue, and alpha channels all have a linear falloff from the outside edge of the curve to the inside edge.

Mix Spline
The Mix spline is used to determine the influence of the controls that the Radial tab will have along the radius of the hotspot. The horizontal axis represents the position along the circle’s circumference, with 0 being 0 degrees and 1.0 being 360 degrees. The vertical axis represents the amount of the radial hotspot to blend with the color hotspot. A value of 0 is all radial hotspot, while a value of 1.0 is all color hotspot.

**NOTE:** Right-clicking in the LUT will display a contextual menu with options related to modifying spline curves.

A complete description of LUT editor controls and options can be found in Chapter 82, “LUT Nodes.”

Radial Tab

Radial On
When selected, this control enables the Radial splines. Otherwise, the radial matte created by the splines is not applied to the hotspot, and the Mix spline in the color controls will have no effect on the hotspot.
Radial Length and Radial Density Splines
The key to these splines is realizing that the LUT Editor’s horizontal axis represents a position around the circumference of the hotspot. A value of 0.0 is 0 degrees and 1.0 is 360 degrees. With that in mind, the length determines the radius of the light making up the hotspot along the circumference, and the density represents how bright the light is along the circumference.

Radial Repeat
This control will repeat the effect of the radial splines by X number of times. For example, a repeat of 2.0 causes the spline to take effect between 0 and 180 degrees instead of 0 and 360, repeating the spline again between 180 and 360.

Length Angle
This control will rotate the effect of the Radial Length spline around the circumference of the hotspot.

Density Angle
This control will rotate the effect of the Radial Density spline around the circumference of the hotspot.

NOTE: Right-clicking in the spline area will display a contextual menu containing options related to modifying spline curves.

A complete description of LUT Editor controls and options can be found in Chapter 82, “LUT Nodes.”

L1, L2 and L3 Tab
**Lens Reflect 1-3**
When selected, the reflection caused by the element is enabled.

**Element Strength**
This determines the brightness of element reflections.

**Element Size**
This determines the size of element reflections.

**Element Position**
This determines the distance of element reflections from the axis. The axis is calculated as a line between the hotspot position and the center of the image.

**Element Type**
Use this array of buttons to choose the shape and density of the element reflections. The presets available are described below.

- **Circular**
  This creates slightly soft-edged circular shaped reflections.

- **Soft Circular**
  This creates very soft-edged circular shaped reflections.

- **Circle**
  This creates a hard-edged circle shape.

- **NGon Solid**
  This creates a filled polygon with a variable number of sides.
**NGon Star**
This creates a very soft-edged star shape with a variable number of sides.

**NGon Shaded Out**
This creates soft-edged circular shapes.

**NGon Shaded In**
This creates a polygon with a variable number of sides, which has a very soft reversed (dark center, bright radius) circle.

**NGon Angle**
This control is used to determine the angle of the NGon shapes.

**NGon Sides**
This control is used to determine the amount of sides used when the Element Type is set to Ngon Star, Ngon Shaded Out, and Ngon Shaded In.

**NGon Starriness**
This control is used to bend polygons into star shapes. The higher the value the more star-like the shape.

**Lens Color Controls**
These controls determine the color of the lens that affects the colors of the reflections. To choose a lens color, pick one from a displayed image, or enter RGBA values using the sliders or input boxes.

## Pseudo Color [PSCL]

The Pseudo Color node provides the ability to produce variations of color based on waveforms generated by the node’s controls. Static or animated variances of the original image can be produced. The node’s controls are separated into four identical tabs, one for each of the color channels.

### R/G/B/A Tabs

![Pseudo Color Node Diagram](image-url)
**Color Check Box**  
When selected, the Pseudo Color node will affect this color channel.

**Wrap**  
When selected, waveform values that exceed allowable parameter values will be wrapped to the opposite extreme.

**High and Low**  
High and Low determine the range to be affected by the node in a specific color channel.

**Soft Edge**  
This slider determines the soft edge of color transition.

**Waveform**  
This selects the type of Waveform to be created by the generator. Four waveforms are available: Sine, Triangle, Sawtooth and Square.

**Frequency**  
This controls the Frequency of the waveform selected. Higher values will increase the number of occurrences of the variances.

**Phase**  
This modifies the Phase of the waveform. Animating this control will produce color cycling effects.

**Mean**  
This determines the level or Mean value of the waveform selected. Higher values will increase the overall brightness of the channel until the allowed maximum is reached.

**Amplitude**  
Amplitude increases or decreases the overall power of the waveform.

---

**Shadow [SH]**

Shadow is a versatile node used in the creation of shadows that are based on the alpha channel information from an image. It is also possible to use an additional image to control the shadow's apparent depth.

The Shadow node is designed to cast simple 2D shadows. Use a Spotlight node and an Image Plane node for full 3D shadow casting.
Controls

Shadow Offset
This control sets the apparent distance of the shadowed object from the background. Adjusting the position of the Shadow Offset crosshair in the views is the quickest way to create simple drop shadows.

Softness
Softness controls how blurry the shadow’s edges appear. The further the background is from the object, the fuzzier it becomes.

Shadow Color
Use this control to select the color of the shadow. The most realistic shadows are usually the ones that are not totally black and razor sharp.

Light Position
This control sets the position of the light relative to the shadow-casting object. The Light Position is only taken into consideration when the Light Distance slider is NOT set to infinity (1.0).

Light Distance
This slider will vary the apparent distance of the light between infinity (1.0) and being at zero distance from the shadow-casting object. The advantage of setting the Light Distance is that the resulting shadow is more realistic-looking with the further parts of the shadow being longer than those that are closer.

Minimum Depth Map Light Distance
This control is active when an image is connected to the shadow’s Depth Map input. The slider is used to control the amount that the depth map contributes to the Light Distance. Dark areas of a depth map make the shadow deeper. White areas bring it closer to the camera.
Z Map Channel
This menu is used to select which color channel of the image connected to the node’s Z Map input will be used to create the shadows depth map. Selections exist for the RGB and A, Luminance, and Z-buffer channels.

Output
The Output image can either contain the image with shadow applied or the shadow only. Changing the setting in the output drop-down list controls which mode will be used. This method is useful when color correction, perspective, or other effects need to be applied to the resulting shadow before it is merged back with the object.

For example, Shadow Alpha controls the shadow’s degree of transparency.

Trails [TRLS]

The Trails node is used to create a ghost-like after-trail of the image. This creates an interesting effect when applied to moving images with an alpha channel. Unlike a directional blur, only the preceding motion of an image is displayed as part of the effect.

Controls
Restart
This control clears the image buffer and displays a clean frame, without any of the
ghosting effect.

Preroll
This will make the Trails node pre-render the effect by the number of frames on the slider.

Reset/Pre-Roll on Render
When this checkbox is enabled, the Trails node will reset itself when a preview or final render is
initiated. It will Pre-roll the designated number of frames.

This Time Only
Selecting this checkbox will make the pre-roll use this current frame only and not the
previous frames.

Number of Pre-roll Frames
This determines the number of frames to pre-roll.

Lock RGBA
When selected, this checkbox allow the Gain of the color channels to be controlled
independently. This allows for tinting of the Trails effect.

Lock Scale X/Y
When selected, this checkbox allows the X- and Y-axis scaling of the image buffer to be
manipulated separately for each axis.

Lock Blur X/Y
When selected, this checkbox allows the blurring of the image buffer to be controlled
separately for each axis.

Gain
The Gain control affects the overall intensity and brightness of the image in the buffer. Lower
values in this parameter will create a much shorter, fainter trail, whereas higher values will
create a longer, more solid trail.

Rotate
The Rotate control rotates the image in the buffer before the current frame is merged into
the effect.

Offset X/Y
These controls offset the image in the buffer before the current frame is merged into the effect.
Control is given over each axis independently.

Scale
The Scale control resizes the image in the buffer before the current frame is merged into
the effect.

Blur Size
The Blur Size control applies a blur to the image in the buffer before the current frame is
merged into the effect.
Apply Mode
This menu is used to determine the method used by the Trails node when merging one sample over another. The methods in this menu are documented more completely in the Merge node's documentation in Chapter 72, "Composite Nodes."

Operator Mode
This menu is used to select to determine how the foreground and background are combined to produce a result. The menu will only be visible when the node's Apply mode is set to Normal.

For an excellent description of the math underlying the operation modes, read Compositing Digital Images, Porter, T., and T. Duff, SIGGRAPH 84 proceedings, pages 253-259. Essentially, the math is as described below. Note that some modes not listed in the Operator dropdown (Under, In, Held In, Below) are easily obtained by swapping the foreground and background inputs (with Command-T or Ctrl-T and choosing a corresponding mode.

The formula used to combine pixels in the merge is always \( \text{fg} \cdot x + \text{bg} \cdot y \). The different operations determine exactly what \( x \) and \( y \) are, as shown in the description for each mode.

Over
The Over mode adds the foreground layer to the background layer by replacing the pixels in the background with the pixels from the Z wherever the foreground's alpha channel is greater than 1.

\[ x = 1, \ y = 1 - \text{foreground alpha} \]

In
The In mode multiplies the alpha channel of the background input against the pixels in the foreground. The color channels of the foreground input are ignored. Only pixels from the foreground are seen in the final output. This essentially clips the foreground using the mask from the background.

\[ x = \text{background alpha}, \ y = 0 \]

Held Out
Held Out is essentially the opposite of the In operation. The pixels in the foreground image are multiplied against the inverted alpha channel of the background image. Accomplish exactly the same result using the In operation and a Matte Control node to invert the matte channel of the background image.

\[ x = 1 - \text{background alpha}, \ y = 0 \]

ATop
ATop places the foreground over the background only where the background has a matte.

\[ x = \text{background alpha}, \ y = 1 - \text{foreground alpha} \]

XOr
XOr combines the foreground with the background wherever either the foreground or the background have a matte, but never where both have a matte.

\[ x = 1 - \text{background alpha}, \ y = 1 - \text{foreground alpha} \]

Subtractive/Additive, Alpha Gain, Burn In
For details on these controls and their effect, consult the documentation for the Merge node in Chapter 72, "Composite Nodes."

Merge Under
This merges the current image under the generated trail, rather than the usual, over top operation.
**TV [TV]**

The TV node is a simple node designed to mimic some of the typical flaws seen in analog television broadcasts and screens.

**Controls**

Scan Lines
This slider is used to emulate the interlaced look by dropping lines out of the image. Setting it to black, with a transparent alpha, drops a line. A value of 1 (default) will drop every second line. A value of 2 shows one line, then drops the second and third and repeats. A value of zero turns off the effect.

Horizontal
Use this slider to apply a simple Horizontal offset to the image.

Vertical
Use this slider to apply a simple Vertical offset to the image.

Skew
This slider is used to apply a diagonal offset to the image. Positive values skew the image to the top left. Negative values skew the image to the top right. Pixels pushed off frame wrap around and reappear on the other side of the image.

Amplitude
The Amplitude slider can be used to introduce smooth sine wave-type deformation to the edges of the image. Higher values will increase the intensity of the deformation. Use frequency to determine how often the distortion is repeated.

Frequency
The Frequency slider sets the frequency of the sine wave used to produce distortion along the edges of the image when the amplitude control is greater than 1.
**Offset**

Use Offset to adjust the position of the sine wave, causing the deformation applied to the image via the Amplitude and Frequency controls to see across the image.

**Noise Tab**

**Power**

Increase the value of this slider above 0 to introduce noise into the image. The higher the value, the stronger the noise.

**Size**

Use this slider to scale the noise map larger.

**Random**

If this thumbwheel control is set to 0, the noise map will be static. Change the value over time to cause the static to change from frame to frame.

**Roll Bar Tab**

**Bar Strength**

At the default value of 0 no bar is drawn. The higher the value, the darker the area covered by the bar will become.

**Bar Size**

Increase the value of this slider to make the bar taller.

**Bar Offset**

Animate this control to scroll the bar across the screen.
Chapter 84

Film Nodes

This chapter details the Film nodes available in the Fusion page.
Contents

Cineon Log [LOG] 1660
Film Grain [FGR] 1662
Grain [GRN] 1665
Light Trim [LT] 1668
Remove Noise [RN] 1668
Cineon Log [LOG]

The Cineon Log node is used to convert image data from logarithmic to linear. Use this node if the log-lin conversion was bypassed in a Cineon Loader to return processing to Linear.

Controls

Mode
These buttons offer two options, one for converting log images to linear and one for converting linear images to logarithmic.

Lock RGB
When selected, the settings in this tab will affect all of the color channels equally.
De-select this control to convert the red, green and blue channels of the image using separate settings for each channel.

Black Level and White Level
Use this control to set the black point and white point in the log image before converting. Pixels with values in log space below the Black Level will become out of range values below 0.0. Pixels with values above the White Level will become out of range values above 1.0 after conversion.

When processing in floating point color space, the out of range values stored in the Cineon format are preserved through the conversion. In 16-bit or 8-bit mode, the out of range values are clipped.
Soft Clip (Knee)
The Soft Clip control is used to draw values that are out of range back into the image. This is done by smoothing the conversion curve at the top and bottom of the curve, allowing more values to be represented.

Applying a soft clip of any value other than 1 will immediately cause the node to process at 16-bit integer, eliminating all out of range values that do not fit within the soft clip.

Film Stock Gamma, Conversion Gamma and Conversion Table
These controls are used to set the response curves of the logarithmic data during conversion. In addition to the settings above, a custom ASCII file Look Up Table can be created with specific conversion values. The ASCII LUT file can be loaded using the File Folder Icon button.

Black Rolloff
Since a mathematical log() operation on a value of zero or lower will result in invalid values, Fusion will clip values below 1e-38 (0 followed by 38 zeros) to 0 to ensure correct results. This is almost never an issue, since values that small have no visual impact on an image. To see such tiny values you would have to add three Brightness Contrast nodes, each with a gain set to 1,000,000. Even then the values would hover very close to zero.

We have seen processes where instead of cropping these very small values, they are instead scaled. So values between 0.0 and 1e-16 are scaled between 1e-18 and 1e-16. The idea is to crush the majority of the visual range in a float image into values very near to zero, then expand them again, forcing a gentle ramp to produce a small ramp in the extreme black values. Should you find yourself facing a color pipeline using the process, here is how you can mimic it with the help of a Custom node.

The process involves converting the log image to linear with a very small gamma and a wider than normal black level to white level (e.g., conversion gamma of 0.6, black of 10, white of 1010). This will crush most of the images range into very very small values. This is followed by a Custom node (described below), then by a linear to log conversion that reverses the process, but uses a slightly higher black level. The difference between the black levels defines the falloff range.

Since this will lift the blacks, the image is usually then converted back to linear one more time, using more traditional values (i.e., 95-685) to reset the black point.

The Custom node should use the following equation in the red, green, and blue expressions:

\[
\text{if (c1< 1e-16, 1e-18 + (c1/1e-16)*(1e-16 - 1e-18), c1)}
\]

Falloff Comparison

The falloff from the native Fusion process
The falloff from the ramped clipping process

**Film Grain [FGR]**

The Film Grain node takes a new approach to grain, which should be more closely aligned with the grain profiles of modern film stocks. This provides you with more control over the final appearance of the grain.

**NOTE:** The Film Grain node does not replace the original Grain node, which is still provided to allow older compositions to load and render, but in almost every case, use of the new Film Grain node is now encouraged.

**Controls**
**Complexity**
The complexity of the Grain indicates the number of ‘layers’ of grain applied to the image. With a complexity of 1, only one grain layer is calculated and applied to the image. When complexity is set to 4, the node calculates four separate grain layers and applies the mean combined result of each pass to the final image. Higher complexities produce visually more complex results, without the apparent regularity often perceivable in digitally-produced grain.

**Alpha Multiply**
When the Alpha Multiply checkbox is enabled, the Film Grain node will multiply its results by the source images alpha channel. This is necessary when working with post multiplied images to ensure that the grain does not affect areas of the image where the alpha is 0.0 (transparent).

**NOTE:** Since it is impossible to say what the final value of semi-transparent pixels in the image are until after they are composited with their background, you should avoid applying log-processed grain to the elements until after they have been composited. This will ensure that the strength of the grain is accurate.

**Log Processing**
When this checkbox is enabled (default), the grain applied to the image will have its intensity applied non-linearly to match the grain profile of most film. Roughly speaking, the intensity of the grain will increase exponentially from black to white. When this checkbox is disabled the grain will be applied uniformly, regardless of the brightness of the affected pixel.

One of the primary features of grain in film is that the appearance of the grain varies radically with the exposure, so that there appears to be very little grain present in the blacks, with the amount and deviation of the grain increasing as the pixels exposure increases. In a film negative the darkest portions of the developed image will appear completely opaque, and this obscures the grain. As the negative becomes progressively clearer, more of the grain becomes evident in the result. Chemical differences in the response to light of the red, green, and blue layers of the film also cause each color component of the film to present a different grain profile, typically with the blue channel presenting the largest amount of grain.

As a result, the most important control in the new Film Grain node is the Log Processing checkbox, which should be enabled when matching film, and disabled when working with images that require a more linear grain response. Having this checkbox enabled will closely mimic the results of preceding the old grain node with a Linear > Log conversion and following with a Log > Linear conversion immediately after.

**Seed**
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Monochrome**
When the Monochrome checkbox is enabled (default) the grain will be applied to the red, green, and blue color channels of the image equally. When deselected, individual control over the Size, Strength and Roughness of the grain in each channel becomes possible.

**Lock Size X/Y**
Deselect the Lock Size X/Y checkbox to control the size of the Grain along the X- and Y-axis individually.
Size
The Grain Size is calculated relative to the size of a pixel, so that changing the resolution of the image does not impact the relative appearance of the grain. The default Grain Size of 1.0 will produce grain kernels that cover roughly 2 pixels.

Strength
Grain is expressed as a variation from the original color of a pixel. The stronger the grain’s strength, the wider the possible variation from the original pixel value. For example, given a pixel with an original value of \( p \), and a Grain node with complexity=1 size=1; roughness=0; log processing=off; the grain will produce an output value of \( p \pm \) strength. In other words, a pixel with a value of 0.5 with a grain strength of 0.02 could end up with a final value between 0.48 and 0.52.

Once again, that’s a slight over simplification, especially when the complexity exceeds 1. Enabling the Log Processing checkbox will also cause that variation to be affected such that there will be less variation in the blacks and more variation in the whites of the image.

NOTE: When visualizing the effect of the grain on the image, the more mathematically inclined may find it helps to picture a sine wave, where each lobe of the sine wave covers 1 pixel when the Grain Size is 1.0. The Grain Size controls the frequency of the sine wave, while the Grain Strength controls its amplitude. Again, this is something of an oversimplification.

Roughness
The Roughness slider applies low frequency variation to give the impression of clumping in the grain. Try setting the Roughness to 0, and you will observe that the grain produced has a very even luminance variation across the whole image. Increase the roughness to 1.0 and you will observe the presence of “cellular” differences in the luminance variation.

Offset
The Offset control helps to match the intensity of the grain in the deep blacks by offsetting the values before the intensity (strength) of the grain is calculated. So an offset of 0.1 would cause a pixel with a value of 0.1 to receive grain as if its value was actually 0.2.

Processing Examples

Log Processing On

In the default setting, the different amounts of Grain are applied to the blacks and the whites of the image.
Log Processing Off

When Log processing is off, the Grain is applied evenly to the entire image, as shown here.

Grain [GRN]

The Grain node offers comprehensive film grain emulation. This is useful for introducing simulated grain into a video or computer-generated image and matching existing grain in a given scene.

Grain Tab

Power
This slider determines the strength of the grain. A higher value increases visibility, making the grain more prevalent.
**RGB Difference**  
Separate Red, Green and Blue sliders are used to modify the strength of the effect on a per channel basis.

**Grain Softness**  
This slider controls the blurriness or fuzziness of the grain. Smaller values cause the grain to be more sharp or coarse.

**Grain Size**  
This slider determines the size of the grain particles. Higher values increase the grain size.

**Grain Spacing**  
This slider determines the density or amount of grain per area. Higher values cause the grain to appear more spaced out.

**Aspect Ratio**  
This slider adjusts the aspect of the grain so that it can be matched with anamorphic images.

**Alpha-Multiply**  
When enabled, this checkbox will multiply the image by the alpha, clearing the black areas of any grain effect.

### Spread Tab

**Edit RGB Checkboxes**  
Separate red, green, and blue to enable the custom curves for each channel. More grain would appear in the blue channel than the red, and the green channel would receive the least. This curve mimics usual film responses. Right-clicking in the spline area will display a contextual menu containing options related to modifying spline curves. A complete description of the LUT Editor control and its options can be found in Chapter 82, “LUT Nodes.”

**In and Out**  
This control gives direct editing of points on the curve by setting In/Out point values.
Examples

Default Spread

In the default setting, the Grain is applied evenly to the entire image as shown here. However, film often shows a different amount of grain in the blacks, mids and whites.

Bell Shaped Spread

Setting a bell shape is often a good starting point to create more realistic looking grain. Here we have a non-uniform distribution with different amounts of grain in the red, green, and blue channel as well.

In both examples, the Grain’s power has been over-exaggerated to show the effect a bit better.
Light Trim [LT]

This node emulates film scanner light trims. By design, this node works best with logarithmic data, such as the images stored by the Cineon file system. When logarithmic data is provided, the Light Trim node can be used to increase or decrease the apparent exposure level of the image.

Controls

Lock RGBA
When selected, the Lock RGBA control collapses control of all image channels into one slider. This selection is on by default. To manipulate the various color channels independently, de-select this checkbox.

Trim
This slider shifts the color in film, optical printing and lab printing points. 8 points equal one stop of exposure.

Remove Noise [RN]

The Remove Noise node provides simple noise management. The basic principle of its operation is the node blurs the image channels, then compares the blurred image to the original to extract the noise. A sharpness is then applied to the image, except where noise was detected.

To use this node, view the image and look at the red channel. Then increase the Red Softness until the grain appears to be gone. Next, increase the sharpness until the detail reappears, but stop before the grain reappears. Repeat for the green and blue channels.
Controls / Color

Method
Use these buttons to choose whether the node processes color using Color or Chroma methods. This will also give you a different set of control sliders.

Lock
This checkbox will link the Softness and Detail sliders of each channel together.

Softness Red, Green and Blue
The Softness sliders determine the amount of blur applied to each channel of the image. In Chroma mode you have sliders for the softness in the Luminance and Chrominance channels respectively.

Detail Red, Green and Blue
The Sharpness sliders determine how much detail is reintroduced into each channel after each channel is softened. In Chroma mode you have sliders for Luminance and Chrominance channels respectively.

Controls / Chroma

Method
The same principle applies as with the RGB Controls, but in this case the Luminance and Chrominance channels are influenced.
Chapter 85

Filter Nodes

This chapter details the Filter node available in the Fusion page.
Contents

CreateBumpMap 1672
Custom Filter Node 1673
ErodeDilate Node 1675
Filter Node 1676
Rank Filter Node 1678
CreateBumpMap

The Create Bumpmap node converts a grayscale (height map) image into a bump map. Check the notes for the naming conventions used in Fusion. Since the resulting bump vector information is represented as RGB, it’s possible to modify them using all the image processing nodes in Fusion. Use the Create BumpMap node for applying to a material.

![CreateBumpMap node](image)

**Input Port**

CreateBumpMap.Input (white): Receives the RGBA channels from an image output for the bump calculation.

**Controls**

This tab contains all parameters for the node.

**Filter Size**

The process of generating the bump information is basically a Custom Filter. This multi-button control sets the filter size.

**Height Source**

Set the channel from where to extract the grayscale information from.

**Clamp Normal.Z**

Clips the lower values of the blue channel in the resulting bump texture.

**Filter Wrap Mode**

Basically wraps the image at the borders, so the filter produces correct result when using seamless tileable textures.

**Height Scale**

Changes the contrast of the resulting values in the bump map. Increasing this value yields in a more visible bump map.
**Bump Map Texture Depth**  
Optionally converts the resulting bump texture into the desired bit depth.

**Notes on Bump Maps**  
This tab contains all parameters for the node.

**Height Map**  
A grayscale image containing a height value per pixel.

**Bump Map**  
An image containing normals stored in the RGB channels used for modifying the existing normals (usually given in tangent space).

**Normal Map**  
An image containing normals stored in the RGB channels used for replacing the existing normals (usually given in tangent or object space).

---

**Custom Filter Node**

![Custom Filter Node](image)

The Custom node is used to apply custom convolution filters to images. A custom convolution filter can give a wide variety of image effects. For example, emboss, relief, sharpen, blurring and edge detection are all convolution filters. There are many supplied custom filters in the Filters directory that can be loaded by right-clicking on the control header and selecting Settings > Load from the context menu.

A Kernel filter is an array (or grid) of either 3 x 3, 5 x 5, or 7 x 7 values. The center of the array represents the current pixel, and entries nearby represent adjacent pixels. A value of 1 applies the full value of the pixel to the filter. A value of 0 ignores the pixel's value. A value greater than one multiplies the pixel's effect on the result. Negative values can also be entered, where the value of the pixel will be subtracted from the average. Only integer values can be entered; 0.5 is not valid.

For example, a filter with the values...

```
0 0 0  
0 1 0  
0 0 0  
```

...will have zero effect from its neighboring pixels and the resulting image would be unchanged. A blurring effect would be...

```
1 1 1  
1 1 1  
1 1 1  
```
...where the neighboring pixels are averaged with the center, resulting in a softening effect.

\[
\begin{bmatrix}
-5 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 5 \\
\end{bmatrix}
\]

This example will subtract five times the value from the top left and add five times the value from the lower right. If parts of the image that is processed are very smooth in color, the neighboring values will be very similar. In parts of the image where the pixels are different (e.g., an edge), the results will be different and tend to highlight or emboss edges in the image.

Using the values...

\[
\begin{bmatrix}
1 & 1 & 1 \\
1 & 1 & 1 \\
1 & 1 & 1 \\
\end{bmatrix}
\]

...in a filter and sliding Normalize to Positive will make the image go brighter or glow, simulating film over-exposure.

Using the values...

\[
\begin{bmatrix}
-1 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 1 \\
\end{bmatrix}
\]

...in a filter and sliding Floor Level to Positive will look like a Relief filter.

**Controls**

![CustomFilter1 Controls](image)

**Color Channels (RGBA)**

The color corrector defaults to operating on R, G, B, and A channels. Selective channel editing is possible by clicking the checkboxes beside each channel, making selected channels active or inactive.

This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes. Deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect. In contrast, these controls under the Common Controls tab are applied after the node has processed.
Matrix Size
Use this drop-down to set the size of the filter at 3 x 3 pixels, 5 x 5 pixels, or 7 x 7 pixels, thus setting the radius of the pixels sampled. The larger the size, the more time it takes to render.

Update Lock
When this control is selected, Fusion will not render the filter. This is useful for setting up each value of the filter, then turning Update Lock off and rendering the filter.

Filter Matrix
The Filter Matrix control is a 7 x 7 grid of text boxes where a number is entered to represent how much influence each pixel has on the overall convolution filter. The text box in the center represents the pixel that is processed by the filter. The text box to the left of the center represents the pixel to the immediate left, and so forth.

The default Matrix size is 3 x 3. Only the pixels immediately adjacent to the current pixel will be analyzed. If a larger Matrix size is set, more of the text boxes in the grid will be enabled for input.

Normalize
This controls the amount of filter normalization that is applied to the result. Zero will give a normalized image. Positive values will brighten or raise the level of the filter result. Negative values will darken or lower the level.

Floor Level
This will add or subtract a minimum, or Floor Level, to the result of the filtered image. Zero will not add anything to the image. Positive values will add to the filtered image and negative values will subtract from the image.

ErodeDilate Node
This simple node erodes or dilates the image, depending on whether the Amount slider is set to a negative or positive value.

Controls
**Color Channels (RGBA)**
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive. This is not the same as the RGBA checkboxes found under the common controls. The node takes these controls into account before it processes. Deselecting a channel will cause the node to skip that channel when processing, speeding up the rendering of the effect. In contrast, the channel controls under the Common Controls tab are applied after the node has processed.

**Lock X/Y**
The Lock X/Y checkbox is used to separate the Amount slider into amount X and amount Y, allowing a different value for the effect on each axis.

**Amount**
A negative value for Amount causes the image to erode. Eroding simulates the effect of an underexposed frame, shrinking the image by growing darker areas of the image so that they eat away at brighter regions.

A positive value for Amount causes the image to dilate, similar to the effect of overexposing a camera. Regions of high luminance and brightness grow, eating away at the darker regions of the image. Both techniques will eradicate fine detail in the image and tend to posterize fine gradients.

**Filter Node**

The Filter node contains several pre-set filters, enabling a variety of effects, from radically changing the look of an image to adding subtle randomly-generated film grain.

**Controls**

The Filter node contains several pre-set filters, enabling a variety of effects, from radically changing the look of an image to adding subtle randomly-generated film grain.
**Filter Type**
This drop-down control provides a selection of filter types. The options are displayed below.

**Relief**
This appears to press the image into metal, such as an image on a coin. The image will appear to be bumped and overlaid on gray.

**Emboss Over**
Embosses the image over top of itself, with adjustable highlight and shadow height and direction.

**Noise**
Uniformly adds noise to images. This is often useful for 3D computer-generated images that need to be composited with live action as it reduces the squeaky clean look that is inherent in rendered images. The frame number acts as the random generator seed. Therefore, the effect is different on each frame and is repeatable.

**Defocus**
This filter type blurs the image.

**Sobel**
Sobel is an advanced edge detection filter. Used in conjunction with a Glow filter, it creates amazing neon light effects from live action or 3D rendered images.

**Laplacian**
Laplacian is a very sensitive edge detection filter that produces a finer edge than the Sobel filter.

**Grain**
Adds noise to images similar to the grain of film (mostly in the mid-range). This is useful for 3D computer-generated images that need to be composited with live action as it reduces the squeaky clean look that is inherent in rendered images. The frame number acts as the random generator seed. Therefore, the effect is different on each frame and is repeatable.

**Color Channels (RGBA)**
The filter defaults to operating on R, G, B, and A channels. Selective channel filtering is possible by clicking the checkboxes beside each channel to make them active or inactive.

**Power**
Values range from 1 to 10. It proportionately increases the amount by which the selected filter affects the image. This does not apply to Laplacian filter type.

**Angle**
This control has a range from 0 to 315 degrees and changes the effect in increments of 45 degrees. This only applies to the Relief and Emboss filters.

**Median**
Depending on which Filter Type is selected, the control may appear. It varies the Median filter’s effect. A value of 0.5 will produce the true median result, as it will find the middle values. A value of 0.0 will find the minimums and 1.0 will find the maximums. Applies to the Median filter only.
**Seed**
This control is only visible when applying the Grain or Noise filter types. The Seed slider can be used to ensure that the random elements of the effect are seeded with a consistent value. The randomizer will always produce the same result given the same seed value.

**Animated**
This control is only visible when applying the Grain or Noise filter types. Select the checkbox to cause the noise or grain to change from frame to frame. To produce static noise, remove the selection from this checkbox.

**Rank Filter Node**

The Rank Filter is a very simple node. This filter examines nearby pixels, sorts the pixels by value, and then replaces the color of all the pixels examined by the color of the pixel with the specified rank.

For example, a Rank filter with a size of 1 will sample 9 adjacent pixels for their values. The following shows some example values, sorted by value:

```
0.0
0.4
0.4
0.5
0.5
0.7
0.7
0.7
```

A Blur filter with the same size would average these values together to produce a value of 3.9. A Rank filter lets you choose a value from the list to select. For example, a rank of four would select the fourth item in the list, producing a value of 0.5.

A Median filter is simply a linear Rank filter that selects the median, or middle value, from the list of sorted values.

**Controls**
**Size**
This control determines the Size in pixels of the area sampled by the filter. A value of 1 will sample only the pixels immediately adjacent to the center pixel, while larger values sample from a larger area.

Small values are excellent for removing salt and pepper style noise, while larger values produce an effect similar to water color paintings.

**Rank**
The Rank determines which value from the sampled values will be chosen, where 0 is the lowest value and 1 is the brightest.
Chapter 86

Flow Nodes

This chapter details the Sticky Note and Underlay nodes available in the Fusion page.
Contents

Sticky Note [NTE] 1682
Underlay [UND] 1683
Sticky Note [NTE]

Sticky Notes are a useful way of providing notes, comments and history for a specific area of a comp. By changing their size and color, they can provide unobtrusive comments or crucial notices, as required. Sticky Notes make a good complement to the Comments tab.

Usage

To create a Sticky Note, click somewhere in the Node Editor where you want a Sticky Note to appear. Then, press Shift-Spacebar, type “sticky,” and press the Return key when the Sticky Note appears in the Select Tool window. The new Sticky Note will be created with its title bar centered on the last click position. Alternately, you can open the Effects Library, open the Tools > Node Editor category, and click or drag the Sticky Notes node to create a new one.

Like Groups, Sticky Notes are created in a smaller, collapsed form. They can be expanded by double-clicking anywhere on them, or by clicking the icon in the top right corner. Once expanded, they can be resized by dragging on any side or corner. To collapse them again, click the icon in the top right corner once more.

Sticky Notes can be renamed, deleted, copied, and pasted and have their node color and text color changed, using the Node Editor’s contextual menu like any other node. It is also possible to lock them to prevent editing.

To edit the text in a Sticky Note, first expand it by double-clicking anywhere on the note, then click below its title bar. If the note is not locked, the text will become editable.
Underlay [UND]

Underlays are a convenient method of visually organizing areas of a composition. As with Groups, Underlays can improve the readability of a comp by separating it into labeled functional blocks. While Groups are designed to streamline the look of a comp by collapsing complex layers down to single nodes, Underlays highlight, rather than hide, and do not restrict outside connections.

Usage

As with conventional nodes, an Underlay can be added to a comp by selecting it from the Nodes menu, in the Node category, or from the Node Editor’s Add Node contextual menu. The new Underlay will be created with its title bar centered on the last click position.

Underlays can be resized by dragging on any side or corner. This will not affect any nodes.

Underlays can also be used as simple selection groups. Activating an Underlay, by clicking on its title, will select all the tools contained wholly within it as well, allowing the entire set to be moved, duplicated, passed-through, and so on.
Chapter 87

Flow Organizational Nodes

This chapter details the Group, Macro, and Pipe Router nodes, which are designed to help organize your compositions, making the flow easier to see and understand.
Contents

Groups [NTE] 1686
Macro [-/-] 1687
Pipe Router [-/-] 1688
Groups [NTE]

Groups can be used to neatly organize your comps, especially by putting together multiple nodes.

Usage

- To group nodes, select them and either press Command-G or Ctrl-G or right-click and select Group from the contextual menu. Press Command-E or Ctrl-E to either Expand or Collapse a selected Group.

- Right-click and select Ungroup from the contextual menu to ungroup all nodes.

- When opened, Groups will hover over existing elements, allowing editing of the enclosed nodes.
Macro [-/-]

Macros can be used to combine multiple nodes and expose a user-definable set of controls. They are meant as a fast and convenient way for building your own customized nodes.

Usage

Creating a Macro
To create a Macro, select the nodes intended for the macro, right-click on any of them and select Macro > Create Macro from the contextual menu.

Macro Editor
The Macro Editor then allows you to specify and rename the controls that shall be exposed in the final macro.

In this example we only expose the Threshold and Gain sliders of a Softglow node, which is sandwiched between two ChannelBooleans.

After setting up the Macro to your liking, type in a name in the Macro Name field and select File > Save.
To add the Macro to your node tree, right-click anywhere on the node tree and select Macro > [NameOfYourMacro] from the contextual menu.

The Final Macro

The final Macro looks and behaves just like any other node in Fusion.

As another example, you could take a single ChannelBoolean, set it to Add mode, and make it into a macro exposing no controls at all, thus creating the equivalent of a Add Node like the one that can be found in programs like Shake.

Pipe Router [/-/]

Pipe Routers can be used to neatly organize your comps by creating diversions in your pipes to make them better visible and help you understand the flow more easily. Pipe Routers do not have any influence on render times.

Usage
Pipe Router

To insert a Router in your pipe, Option or Alt left-click on the pipe and place the Router anywhere on the node tree.

Though Routers have no actual controls, they still can be used to add comments to your comp.

![An example comment in a PipeRouter node](image)

Chapter – 87  Flow Organizational Nodes
Chapter 80

Fuses

This chapter introduces Fuses, scriptable plug-ins that can be used within the Fusion page.
## Contents

<table>
<thead>
<tr>
<th>Fuses [FUS]</th>
<th>1692</th>
</tr>
</thead>
</table>
Fuses [FUS]

Fuses are scriptable plug-ins. They can be edited within Fusion by pressing the Edit button, and will compile on-the-fly when clicking on Reload.

Fuses are a great way to prototype plug-ins or to deal with experimental code. Please refer to the SDK for further information.
This chapter details the MediaIn, MediaOut and Saver nodes within the Fusion page.
Contents

Medialn Node 1695
MediaOut Node 1698
Saver Node 1698
MediaIn Node

The MediaIn node shows the input to the Fusion page from the Edit page and is also used to select and load footage from the hard drive or network storage.

Each visible clip in a timeline appears in the Fusion page as a single MediaIn node connected by default to a MediaOut node. Clips that are not visible because they’re on lower tracks with full opaque clips above them are ignored.

These very-simple default compositions are referred to unofficially in this manual as “single-clip compositions.”

In this workflow, the MediaIn node represents the image that’s fed to the Fusion page for further work, and the MediaOut node represents the final output that’s fed onward to the Color page for grading.

When you add a clip from the Media Pool or from your file system directly into a composition, the resulting MediaIn node has more options than clips that were originally in the Timeline. This makes it easier to trim that clip’s media, to hold the first or last frame for a longer duration than the original media, or to reverse or loop the clip to get more range for your composition.

Tools Tab
• **Clip Name:** Displays the name of that clip.

• **Global In and Out:** These controls are only shown when using the MediaIn node to bring a Media Pool or Storage clip directly into the Node Editor. Use this control to specify the position of this node within the project. Use Global In to specify the frame on which that the clip starts and Global Out to specify the frame on which this clip ends within the project’s global range. The node will not produce an image on frames outside of this range.

If the Global In and Out values are decreased to the point where the range between the In and Out values is smaller than the amount of available frames in the clip, Fusion will automatically trim the clip by adjusting the Clip Time range control. If the global in/out values are increased to the point where the range between the In and Out values is larger than the amount of available frames in the clip, Fusion will automatically lengthen the clip by adjusting the Hold First/Last Frame controls. Extended frames are visually represented in the range control by changing the color of the held frames to purple in the control.

To slip the clip in time or move it through the project without changing its length, place the mouse pointer in the middle of the range control and drag it to the new location, or enter the value manually in the Global In value control.

• **Process Mode:** Lets you choose whether the clip represented by that node will be processed as Full Frames, or via one of the specified interlaced methods.

• **MediaID:** An ID assigned by DaVinci Resolve for that clip.

• **Layer:** In the case of Compound Clips, this identifies the layer of the clip.

• **Trim:** The Trim range control is used to trim frames from the start or end of a clip. Adjust the Trim In to remove frames from the start and Trim Out to specify the last frame of the clip. The values used here are offsets. A value of 5 in Trim In would use the fifth frame in the sequence as the start, ignoring the first four frames. A value of 95 would stop loading frames after the ninety-fifth.

• **Hold First Frame/Hold Last Frame:** The Hold First Frame and Hold Last Frame controls will hold the first or last frame of the clip for the specified amount of frames. Held frames are included in a loop if the footage is looped.

• **Reverse:** Select this checkbox to reverse the footage so that the last frame is played first and the first frame played last.

• **Loop:** Select this checkbox to loop the footage until the end of the project. Any lengthening of the clip using Hold First/Last Frame or shortening using Trim In/Out is included in the looped clip.

---

**Source Color Space**

The Source Color Space is used to set the color space of the source footage. It includes options for setting the color space type and the specific color space profile, such as Wide Gamut RGB.

---

Chapter – 89 I/O Nodes 1696
Sets the Color Space of the footage to help achieve a linear workflow.

Unlike the Gamut node, this doesn’t perform any actual color space conversion, but rather adds the source space data into the metadata, if that metadata doesn’t already exist. The metadata can then be used downstream by a Gamut node with the From Image option, or in a MediaOut node, if explicit output spaces are defined there.

- **Auto**: Passes along any metadata that might be in the incoming image.
- **Space**: Allows the user to set the Color Space from a variety of options.

### Source Gamma Space

Determines the Gamma Space of the footage and gives the option to remove the Gamma Curve to help achieve a linear workflow.

- **Auto**: Passes along any metadata that might be in the incoming image.
- **Space**: Allows the user to set the Gamma Space from a variety of options.
- **Log**: Brings up the Log/Lin settings, similar to the Cineon node.

### Remove Curve

Depending on the selected Gamma Space or on the Gamma Space found in Auto mode, the associated Gamma Curve is removed from, or a log-lin conversion is performed on, the material, effectively converting it to a linear output space.
MediaOut Node

The MediaOut node represents the final composition output of the Fusion page that’s fed onward to the Color page for grading.

The composition output by the Fusion page’s MediaOut nodes are propagated via the Color page’s source inputs, with the sole exception that if you’ve added plug-ins to that clip in the Edit page, then the handoff from the Fusion page to the Color page is as follows:

Fusion Effects  Edit Page Plug-ins  Color Effects

Saver Node

The Saver node is responsible for writing the results of a composition to disk. It can be inserted into a composition at any point. The Saver node node can also be used to add scratch track audio to your node tree, which can be heard during interactive playback.

A composition can contain any number of Saver nodes, and Savers can be placed at any point in the node tree.
Filename
Use the Filename dialog to select the name and path of the rendered image output. Click on the yellow folder icon to display a file browser to select a folder and filename to be used for output.

Sequence numbering is automatically added to the filename when rendered. For example, if `c\renders\image.tga` is entered as the filename and 30 frames of output is rendered, the files will automatically be numbered as `image0000.tga`, `image0001.tga`, `image0003.tga`... and so on. Four digit padding is automatically used for numbers lower than 10000.

Specify the number of digits to use for padding the sequence number by explicitly entering the digits into the filename.

For example, `image000000.tga` would apply 6 digit padding to the numeric sequence, `image.001.tga` would use 3 digit padding and `image1.tga` would use none.

Frame Offset
This thumbwheel control can be used to set an explicit start frame for the number sequence applied to the rendered filenames. For example, if Global Start is set to 1 and frames 1-30 are rendered, files will normally be numbered 0001-0030. If the Frame Offset is set to 100, the rendered output would be numbered from 100-131.

Export Tab

Clipping Mode
These radio buttons define how the edges of image should be treated. This can also be called source image clipping.

They default to Frame, which will provide the same behavior as previous versions of Fusion. Since this option will clip to the parts of the image visible within its visible dimensions, it will break any infinite-workspace behavior.

If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent. None does not perform any source image clipping at all.

This means that any data that would normally be needed outside the upstream DoD will be treated as black/transparent. Be aware that this might create humongous images which can consume a huge amount of disk space. So you should use this option only if really needed.

For more information about ROI, DoD and Infinite Workspace, see Chapter 60, “Using Viewers.”
**Save Alpha to Color**

When selected, this control will cause the alpha channel to be saved into the color channels as a grayscale image. This will completely overwrite any existing color information.

**Format Tab**

The Format tab contains information, options, and settings specific to the image format being saved. The controls for a TGA sequence will be entirely different from the ones displayed when a DPX file is saved.

TGA and DPX are displayed on the right for reference.

When the Saver node is set to DPX, it’s important to understand the reason for the “Data is Linear” option. When saving log data into a DPX, and not using the Saver node’s own lin-log conversion (that is, Bypass Conversion is checked), the “Data is Linear” option should be off. This indicates whether the reason for checking Bypass Conversion is because the data is linear, or whether it’s already log.

If “Data is Linear” is enabled, then the DPX is marked in its header as containing linear data. In turn, that means that when the DPX is loaded back into Fusion, or into other apps that evaluate the header, those apps will think the data is linear, and will not perform any log-lin conversion.
The Magic Comp Variable

As you can see in the screenshots, the pathnames in this example start with Comp:\.

The Comp variable in Fusion works for Loaders and Savers and helps you to keep your work organized. Comp:\ stands for the folder your actual composition is stored in.

So as long as all your source footage is stored in subfolders of your Comp folder, Fusion will find that footage regardless of the actual hard drive or network share name.

You could, for example, copy an entire shot from the network to your local drive, set up your Loaders and Savers to use the Comp variable, work all your magic locally (i.e., set up your composition), and then copy just the composition back to the server and issue a net-render. All render slaves will automatically find the source footage.

Some examples:

Your composition is stored in:
X:\Project\Shot0815\Fusion\Shot0815.comp

Your source footage sits in:
X:\Project\Shot0815\Fusion\Greenscreen\0815Green_0000.dpx

The relative path in the MediaIn node would then be:
Comp:\Greenscreen\0815Green_0000.dpx

If your source footage is stored in:
X:\Project\Shot0815\Footage\Greenscreen\0815Green_0000.dpx

The relative path in the MediaIn node would then be:
Comp:\..\Footage\Greenscreen\0815Green_0000.dpx

Observe how the two dots .. set the directory to go up one folder. Pretty much the same like CD .. in a command shell window.
Chapter 90

LUT Nodes

This chapter details the LUT nodes available in the Fusion page.
Contents

File LUT [FLU] 1704
LUT Cube Analyzer [LCA] 1705
LUT Cube Apply [LCP] 1706
LUT Cube Creator [LCC] 1707
**File LUT [FLU]**

The File LUT node applies a Look up Table (LUT) to the image, either a simple 1D LUT or a supported 3D LUT. Unlike the Color Curves node, it does not use a spline-based LUT. Instead, it loads the LUT from a file stored on the system or network.

This approach has two advantages. The first is that the only part of the LUT stored in the composition is the path to the file. Since LUT files can be very large, this can dramatically reduce the file size of a composition when several LUTs are present. The second advantage is that it becomes possible to adjust all File LUT nodes using the same file at the same time, simply by changing the contents of the LUT. This can be useful when the same LUT-based color correction is applied in many different compositions.

**Controls**

**LUT File**

Use this control to select the path to the file describing the LUT. Currently, this node supports LUTs exported from Fusion in .LUT and .ALUT formats, Shake’s LUT format, and a number of 3D LUT formats as well. The node will fail with an error message on the Console if it is unable to find or load the specified file.

**Color Space**

Use this control to change the color space the LUT is applied in. The default is to apply the curves described in the LUT to the RGB color space, but options for YUV, HLS, HSV and others are also available.

**Pre-Divide/Post-Multiply**

Selecting the Pre-Divide/Post-Multiply checkbox will cause the image pixel values to be divided by the alpha values prior to applying the LUT, and then re-multiplied by the alpha value after the correction.

This helps to prevent the creation of illegally additive images, particularly around the edges of a blue/green key or when working with 3D rendered objects.
LUT Cube Analyzer [LCA]

The LUT Cube Analyzer takes an image created by the LUT Cube Creator as an input and allows the user to create a 3D LUT file in ALUT3, ITX or 3DL format.

Feeding the original image into the node would result in an unaltered or 1:1 LUT file.

You can, however, modify, grade and color correct the original cube image with as many nodes as you like and feed the result into the LUT Cube Analyzer. This will create a LUT that exactly resembles your color pipeline.

Usage

Connect the output of any node modifying an image that was created with the LUT Cube Creator to the input of the Analyzer, view the Analyzer, select the desired output format, specify a filename, and press Write File to create the 3D LUT.

Controls

Type
Select the desired output format of the 3D LUT.

Filename
Specify a path and name the LUT file is written to.

Write File
Press this button to generate the 3D LUT file based on the settings above.
LUT Cube Apply [LCP]

The LUT Cube Apply takes an image created by the LUT Cube Creator as the Foreground input and applies that LUT to the image connected to the Background input. Feeding the original image into the node would result in an unaltered or 1:1 output.

You can, however, modify, grade and color correct the original cube image with as many nodes as you like and feed the result into the LUT Cube Apply. Or, take a LUT image that has been graded beforehand to apply the LUT without having to write an actual 3D LUT using the LUT Cube Analyzer.

Usage

Connect any image that is meant to be modified according to the LUT to the Background input of the node. Connect a LUT Cube image to the Foreground input of the node.

Settings

Use OpenCL

If your graphics card supports OpenCL, enabling this option will tremendously speed up the processing on this node.
LUT Cube Creator [LCC]

The LUT Cube Creator creates an image for further use with the LUT Cube Analyzer or LUT Cube Apply. The output can be graded, color corrected, or modified with any tool inside and outside of Fusion. If working outside Fusion, make sure to keep the image in 32-bit floating point to preserve color accuracy.

Controls

Type
- **Horizontal**: Creates a long, horizontal strip representing a color cube.
- **Vertical**: Creates a long, vertical strip representing a color cube.
- **Rect**: Creates a rectangular image, as depicted below, representing a color cube.

Size
Determines the resolution of the color cube.

**NOTE**: Higher resolutions yield more accurate results but are also more memory and computational extensive.

Common values for color cubes are $17 \times 17 \times 17$ or $33 \times 33 \times 33$, or in a mathematical fashion $n^2+1$. 
**Use OpenCL**

If your graphics card supports OpenCL, enabling this option will speed up the processing on this node.

A Cube Image created with the "Rect" type

The resulting Color Cube
Chapter 91

Mask Nodes

This chapter details the Mask nodes available in the Fusion page.
<table>

Common Mask Controls [CMC]

Common Controls can be found in every Mask node. This chapter is therefore valid for all Mask nodes.

Common Mask Controls

Although each mask has its own set of controls unique to that mask type, several of the controls shown are common for all types of masks. The controls listed here are generally found on all masks.

Show View Controls

Use the Show View Controls checkbox to disable the display of the Mask controls in the Viewer. Polyline centers, angles, and other controls will not be displayed, even when the node is selected.

Level

The Level control designates the transparency level of the pixels in the Mask channel. When the value is 1.0, the effect mask is completely opaque (unless it has a soft edge). Lower values will cause the mask to be partially transparent. The result is identical to lowering the blend control of an effect.

NOTE: Lowering the level of a mask will lower the values of all pixels covered by the mask in the Mask channel. For example, if a Circle mask is placed over a Rectangle mask, lowering the level of the Circle mask will lower the values of all of the pixels in the Mask channel, regardless of the fact that the Rectangle mask beneath it is still opaque.
Filter
This control selects the filtering algorithm to be used when applying Soft Edge to the mask.

Box
This is the fastest method, but at reduced quality. This is best suited for very small amounts of blur.

Bartlett
Otherwise known as a Pyramid filter, Bartlett makes a good compromise between speed and quality.

Multi-box
When selecting this filter, the Num Passes slider appears to let you control the quality. At 1 and 2 passes, results are identical to Box and Bartlett, respectively. At 4 and above, results are usually as good as Gaussian, in less time and with no edge “ringing.”

Gaussian
The default filter, this uses a true Gaussian approximation and gives excellent results, but it is a little slower than the other filters. In some cases, it can produce extremely slight edge “ringing” on floating-point pixels.

Soft Edge
Use the Soft Edge slider to blur (feather) the edges of the mask, using the selected filter. Higher values will cause the edge to fade off well beyond the boundaries of the mask. A value of 0.0 will create a crisp, well-defined edge.

Border Width
The Border Width control adjusts the thickness of the mask’s edge. When the Solid checkbox is toggled on, the border thickens or narrows the mask. When the mask is not solid, an outline of the mask shape is drawn and the thickness of the outline is handled with this control.

Paint Mode
Although each mask has its own set of controls unique to that mask type, several of the controls shown are common for all types of masks. The controls listed here are generally found on all masks.

Merge
Merge is the default for all masks. The new mask is merged together with the input mask.

Add
The mask’s values are added to the input mask’s values.
**Subtract**  
In the intersecting areas, the new mask values are subtracted from the input mask’s values.

**Minimum**  
The input mask’s values are compared to the new mask, and the lowest (minimum) value is taken.

**Maximum**  
The input mask’s values are compared to the new mask, and the highest (maximum) value is taken.

**Average**  
This calculates the average (half the sum) of the new mask and the input mask.

**Multiply**  
This multiplies the values of the input mask by the new mask’s values.

**Replace**  
The new mask completely replaces the input mask wherever they intersect. Areas that are zero (completely black) in the new mask do not affect the input mask.

**Invert**  
Areas of the input mask that are covered by the new mask are inverted; white becomes black and vice versa. Gray areas in the new mask are partially inverted.

**Copy**  
This mode completely discards the input mask and uses the new mask for all values.

**Ignore**  
This mode completely discards the new mask and uses the input mask for all values.

**Invert**  
Selecting this checkbox inverts the entire mask. This differs from the Invert Paint mode in that it affects all pixels, regardless of whether they are covered by the new mask or not.

**Solid**  
When the Solid checkbox is enabled, all areas completely enclosed by the mask will be filled solid white. Turning off the checkbox will treat the mask as an outline, with the width of the outline determined by the Border Width control. This checkbox is enabled by default.

**Center**  
All masks have a center, with the exception of the common controls found on Creator nodes, such as Background and Fast Noise.
**Process Mode**

Use this menu control to select the Fields Processing mode used by Fusion to render changes to the mask. The default option is determined by the Has Fields checkbox control in the Frame Format preferences.

**Use Frame Format Settings**

When this checkbox is selected, the width, height, and pixel aspect of the mask created will be locked to values defined in the composition’s Frame Format preferences. If the Frame Format preferences change, the resolution of the mask produced will change to match. Disabling this option can be useful to build a composition at a different resolution than the eventual target resolution for the final render.

**Width and Height**

This pair of controls is used to set the Width and Height dimensions of the mask to be created.

**Pixel Aspect**

This control is used to specify the Pixel Aspect ratio of the created mask. An aspect ratio of 1:1 would generate a square pixel with the same dimensions on either side (like a computer display monitor) and an aspect of 0.91 would create a slightly rectangular pixel (like an NTSC monitor).

**Depth**

The Depth button array is used to set the pixel color depth of the image created by the mask. 32-bit pixels require four times the memory of 8-bit pixels but have far greater accuracy. Float pixels allow high dynamic range values outside the normal 0..1 range, for representing colors that are brighter than white or darker than black.

**NOTE:** Right-click on the Width, Height, or Pixel Aspect controls to display a menu listing the file formats defined in the preferences Frame Format tab. Selecting any of the listed options will set the width, height, and pixel aspect to the values for that format.
The Bitmap Mask allows images from the node tree to act as masks for nodes and effects. Bitmap masks can be based on values from any of the color, alpha, hue, saturation, luminance, and auxiliary coverage channels of the image. Nodes can also be masked based on the Object or Material ID of a 3D rendered image (provided those channels were included when the file was rendered).

The output of any node can be connected directly to another node’s Effect Mask input. The Bitmap Mask node is not required for many common tasks. If the output is connected directly, the Common Controls tab for the masked node will display a control to select which channel of the mask image is used to create the mask.

However, Bitmap Mask nodes may still be required to connect to other mask inputs on some nodes, such as Garbage Mattes and Pre-Masks. Also, using a Bitmap Mask node between the mask source and the target node provides additional options that would not be available when connecting directly, such as combining masks, blurring the mask or clipping its threshold.

Many of the controls found in this Mask node are common to all Mask nodes. These controls are documented at Common Mask Controls.

**Controls**

**Level, Filter, Soft Edge and Border Width**

Please refer to the Common Mask Controls.
Fit Input
This control defines how the image source is treated if it does not fit the dimensions of the generated mask.

Imagine a 720x576 image source being used to generate a 1920x1080 mask.

In the following section we refer to image source as being the 720x576 image (yellow) and mask as being the mask that is actually generated (gray).

Crop
If the image source is smaller than the generated mask it will be placed according to the X/Y controls, masking off only a portion of the mask. If the image source is bigger than the generated mask it will be placed according to the X/Y controls and cropped off at the borders of the mask.

Stretch
The image source will be stretched in X and Y to accommodate the full dimensions of the generated mask. This might lead to visible distortions of the image source.

Inside
The image source will be scaled uniformly until one of its dimensions (X or Y) fits the inside dimensions of the mask. Depending on the relative dimensions of the image source and mask background, either the image source’s width or height may be cropped to fit the respective dimension of the mask.
**Width**
The image source will be scaled uniformly until its width (X) fits the width of the mask. Depending on the relative dimensions of the image source and mask, the image source’s Y-dimension might not fit the mask’s Y-dimension, resulting in either cropping of the image source in Y or the image source not covering the mask’s height entirely.

**Height**
The image source will be scaled uniformly until its height (Y) fits the height of the mask. Depending on the relative dimensions of the image source and mask, the image source’s X-dimension might not fit the mask’s X-dimension, resulting in either cropping of the image source in X or the image source not covering the mask’s width entirely.

**Outside**
The image source will be scaled uniformly until one of its dimensions (X or Y) fits the outside dimensions of the mask. Depending on the relative dimensions of the image source and mask, either the image source’s width or height may be cropped or not fit the respective dimension of the mask.
Other Controls

Channel
Use this control to select the Channel of the input image used to create the mask. Choices include the red, green, blue, and alpha channels, the hue, luminance, or saturation values, or the auxiliary coverage channel of the input image (if one is provided).

Threshold Low/High
The Threshold range control can be used to clip the bitmap image. Increasing the value of the low control will clip pixels below the specified value to black (0.0). Decreasing the high value will force pixels higher than the specified value to white (1.0).

Use Object/Use Material
This control has no affect unless the input image contains a Material or Object ID channel. When toggled on, the selected Object ID and/or Material ID is used to create a mask based on the selected object or material. When toggled off, the regular color channels will generate the mask.

Image Tab
Please refer to the Common Mask Controls.

B-Spline Mask [BSP]

A B-spline Mask is identical to a Polygon Mask in all respects except one. Where Polygon masks use Bezier splines, this Mask node uses B-splines. Where Bezier splines employ a main point and two handles to manage the smoothing of the spline segment, a B-spline requires only a single point. This means that a B-spline shape requires far fewer control points to create a nicely smoothed shape.

The smoothness of a B-spline is determined by the tension of the control points. To adjust the tension of a B-spline’s control points, select the point, hold down the W key and drag the mouse pointer to the left and right to increase or decrease the tension of the curve through that point.

Many of the controls found in this Mask node are common to all Mask nodes. These controls are documented at Common Mask Controls.
Controls

Level, Filter, Soft Edge and Border Width
Please refer to the Common Mask Controls.

Size
Use the Size control to adjust the scale of the B-spline effect mask, without affecting the relative behavior of the points that compose the mask or setting a keyframe in the mask animation.

X, Y and Z Rotation
Use these three controls to adjust the rotation angle of the effect mask along any axis.

Fill Method
The Fill Method drop-down menu offers two different techniques for dealing with overlapping regions of a polyline. If overlapping segments in a mask are causing undesirable holes to appear, try switching the setting of this control from Alternate to Non Zero Winding.

Right Click Here for Shape Animation
By default, all B-spline masks are animated when they are created. The initial keyframe is set to the current time and any changes to the shape at different times will create new keys.

Right-clicking on this label will display a contextual menu that offers options for removing or re-adding animation to the mask, or publishing and connecting the masks together.

Adding Points
Adding Points to a B-spline effect mask is relatively simple. Immediately after creating the mask there are no points, but the mask will be in Click Append mode. Simply click once in the Viewer wherever a point is required for the mask. Continue clicking to draw the shape of the mask.

When the shape is complete, click on the initial point again to close the mask.

When the shape is closed, the mode of the polyline will change to Insert and Modify. This allows for the adjusting and adding of additional points to the mask by clicking on segments of the polyline. To lock down the mask’s shape and prevent accidental changes, switch the Polyline mode to Done using the Polyline toolbar or contextual menu.
When a B-spline mask is added to a node, a toolbar will appear in the view with buttons that offer easy access to the modes and nodes. Hold the mouse pointer over any button in the toolbar to display a tooltip that describes that button’s function.

Change the way the toolbar is displayed by right-clicking on the toolbar and selecting from the options displayed in the toolbar’s contextual menu.

The functions of the buttons in this toolbar are explained in depth in the Polylines section.

**Image Tab**

Please refer to the Common Mask Controls.

**Ellipse Mask [ELP]**

The Ellipse Mask is most useful for masking round objects. It is a circle by default, but independent control is offered over the width, height, and angle, providing for a wide variety of ellipsoidal shapes.

Many of the controls found in this Mask node are common to all Mask nodes. These controls are documented at Common Mask Controls.
Controls

![Control Panel Image]

**Level, Filter, Soft Edge and Border Width**
Please refer to the Common Mask Controls.

**Width**
This control allows independent control of the ellipse mask’s Width. In addition to the slider in the mask’s controls, interactively drag the width (left or right edge) of the mask on the view using the pointer. Any changes will be reflected on this control.

**Height**
Height allows independent control of the ellipse mask’s height. In addition to the slider in the mask’s controls, interactively drag the height (top or bottom edge) of the mask on the view using the pointer. Any changes will be reflected on this control.

To change the mask’s size without affecting the aspect ratio, drag the on screen control between the edges (diagonal). This will modify both the width and height proportionately.

**Angle**
Change the rotational angle of the mask by moving the Angle control left or right. Values can be entered in the input boxes provided. Alternately, use the onscreen controls by dragging the little circle at the end of the dashed angle line to interactively adjust the rotation of the ellipse.

**Image Tab**
Please refer to the Common Mask Controls.

![Image Tab Image]
Mask Paint [PNM]

The Mask Paint node allows direct painting on mask images, using the mouse pointer as if it was a paintbrush. In addition to regular paint strokes, it is possible to apply basic primitive shapes and polyline style strokes.

Each stroke can have a duration that lasts for the entire project, a single frame or field, or an arbitrary number of fields. The strokes can have independent durations in the Timeline for easy manipulation of time. Alternatively, Multistrokes is a faster but non-editable way for doing many mask cleanup paint tasks.

Controls

As the Paint Mask node is fundamentally identical to the Paint node, see the Paint node and the Paint and Rotoscoping chapter for more details on the many options and capabilities available. The only difference is that, as Paint Mask operates on single-channel mask images, there is no Channel Selector control and all color controls have only a single Alpha value.

Mask Tab
Image Tab

Please refer to the Common Mask Controls.

Polygon Mask [PLY]

The Polygon Mask is most useful for masking objects that do not have a regular shape. When first added to a node, the Polygon mask consists of only Center and Angle controls, which are visible onscreen. Points are added to the polyline by clicking in the Viewer. Each new point is connected to the last one created.

Controls

Level, Filter, Soft Edge and Border Width

Please refer to the Common Mask Controls.
Size
Use the Size control to adjust the scale of the Polygon effect mask, without affecting the relative behavior of the points that compose the mask or setting a keyframe in the mask animation.

X, Y and Z Rotation
Use these three controls to adjust the rotation angle of the effect mask along any axis.

Fill Method
The Fill Method drop-down menu offers two different techniques for dealing with overlapping regions of a polyline. If overlapping polyline segments in a mask are causing undesirable holes in the mask, try switching the setting of this control from Alternate to Non Zero Winding.

Right Click Here for Shape Animation
By default, all polyline masks are animated when they are created. The initial keyframe is set to the current time and any changes to the shape at different times will create new keys.

Right-clicking on this label will display a contextual menu that offers options for removing or re-adding animation to the mask, or publishing and connecting masks together.

Adding Points
Adding Points to a polygonal effect mask is relatively simple. Immediately after creating the mask there are no points, but the mask will be in Click Append mode. Simply click once in the Viewer wherever a point is required for the mask. Continue clicking to draw the shape of the mask. When the shape is complete, click on the initial point again to close the mask.

When the shape is closed, the mode of the polyline will change to Insert and Modify. This allows for the adjusting and adding of additional points to the mask by clicking on segments of the polyline. To lock down the mask’s shape and prevent accidental changes, switch the Polyline mode to Done using the Polyline toolbar or contextual menu.

When a Polygon mask is added to a node, a toolbar will appear in the view with buttons that offer easy access to modes and nodes. Hold the mouse pointer over any button in the toolbar to display a tooltip that describes that button’s function.

Change the way the toolbar is displayed by right-clicking on the toolbar and selecting from the options displayed in the toolbar’s contextual menu. The functions of the buttons in this toolbar are explained in depth in the Polylines chapter.

Image Tab
Please refer to the Common Mask Controls.
Ranges Mask [RNG]

Similar to Bitmap Mask, the Range Mask allows images from the node tree to act as masks for nodes and effects. Instead of creating a simple luminance-based mask from a given channel, Range allows spline-based selection of low, mid and high ranges, akin to Color Corrector.

Controls

**Level, Filter, Soft Edge and Border Width**
Please refer to the Common Mask Controls.

**Shadows/Midtones/Highlights**
These buttons are used to select which range will be output by the node as a mask. White pixels represent pixels that are considered to be part of the range and black pixels are not included in the range. For example, choosing Shadows would show pixels considered to be shadows as white and pixels that are not shadows as black. Mid gray pixels are only partly in the range and will not receive the full effect of any color adjustments to that range.
Channel
The Channel selection buttons shown in this tab can be used to extract a mask from the range of a specific color channel. By default, Fusion uses the luminance channel when the color ranges are examined.

Spline Display
The extent of the ranges is selected by manipulating the spline handles. There are four spline points, each with one Bezier handle. The two handles at the top represent the start of the shadow and highlight ranges, whereas the two at the bottom represent the end of the range. The Bezier handles are used to control the falloff.

The midtones range has no specific controls, since its range is understood to be the space between the shadow and the highlight ranges. In other words, after low and high masks have been applied, midtones is everything else.

The X and Y text controls below the Spline Display can be used to enter precise positions for the selected Bezier point or handle.

Presets
This sets the splines to two commonly-used configurations. Simple gives a straightforward linear-weighted selection, while Smooth uses a more natural falloff.

Image Tab
Please refer to the Common Mask Controls.

Rectangle Mask [REC]
The Rectangle Mask creates a simple square or rectangular effect mask. Many of the controls found in this Mask node are common to all Mask nodes. These controls are documented at Common Mask Controls.
Controls

Level, Filter, Soft Edge and Border Width
Please refer to the Common Mask Controls.

Width and Height
Use these controls to change the X or Y scale of the rectangular effect mask independently of each other. Alternatively, drag the edges of the rectangle in the Viewer to interactively adjust its size.

Corner Radius
Corner Radius allows the corners of the rectangle mask to be rounded. A value of 0.0 is not rounding at all, which means that the rectangle has sharp corners. A value of 1.0 will apply the maximum amount of rounding to the corners.

Angle
Change the rotation angle of an effect mask by moving the Angle control left or right. Values can be entered in the provided input boxes. Alternately, use the onscreen controls by dragging the little circle at the end of the dashed angle line to interactively adjust the rotation of the ellipse.

Image Tab
Please refer to the Common Mask Controls.
Triangle Mask [TRI]

The Triangle Mask is unique in that it has no Center, Size or Angle control. Unlike most other types of masks, all three points of the triangle may be attached to a tracker or motion path. Complex effect masking is possible using trackers and other nodes’ paths to manipulate the triangle shape.

Many of the controls found in this Mask node are common to all Mask nodes. These controls are documented at Common Mask Controls.

Controls

**Level, Filter, Soft Edge and Border Width**

Please refer to the Common Mask Controls.

**Point 1, Point 2, Point 3**

These controls indicate the position of the three corners of the triangle. Each point can be published, connected to other controls, animated with a path, or attached to trackers. To perform any of these tasks, right-click on the Position control in the mask controls, or directly on the point in the Viewer, and select the appropriate option from the contextual menu.

Image Tab

Please refer to the Common Mask Controls.
Wand Mask [WND]

The Wand Mask provides the ability to mask an image based on a magic wand-style selection, similar to the magic wand tools found in traditional 2D paint applications. As with a Bitmap mask, any image in the composition can be used as a source for the mask. Generally, the default is most useful, where the source image is the input of the node to which the mask is applied.

**NOTE:** When adding a Wand mask to a node, a crosshair will appear in the Viewers. This crosshair should be positioned in the image to select the color used to create the Wand mask. The mask itself is created by examining the color of the pixel beneath the selection point and adding that color to the mask. The mask then expands to examine the pixels surrounding the selection point. If the surrounding pixels are the same color, they are also added to the mask. The mask stops expanding when no connecting pixels fall within the color range of the mask. The node to be used as the image source for the mask should be connected to the Source (orange) input on the node tree. As with other masks, the Effect Mask (blue) input is used to combine the wand’s result with other Mask nodes. Many of the controls found in this Mask node are common to all Mask nodes. These controls are documented at Common Mask Controls.

**Controls**

**Level, Filter, Soft Edge and Border Width**
Please refer to the Common Mask Controls.

**Selection Point**
The Selection Point is a pair of X and Y coordinates that determine from where in the source image the Wand mask derives its initial color sample. This control is also seen as a crosshair in the Viewers. The selection point can be positioned manually, connected to a tracker, path, or other expressions.
**Color Space**
The Color Space button group determines the color space used when selecting the source color for the mask. The Wand mask can operate in RGB, YUV, HLS, or LAB color spaces.

**Channel**
The Channel button group is used to select whether the color that is masked comes from all three color channels of the image, the alpha channel, or from an individual channel only.

The exact labels of the buttons will depend on the color space selected for the Wand Mask operation. If the color space is RGB, the options will be R, G, or B. If YUV is the color space, the options will be Y, U, or V.

**Range**
The Range slider controls the range of colors around the source color that will be included in the mask. If the value is left at 0.0, only pixels of exactly the same color as the source will be considered part of the mask. The higher the value, the more that similar colors in the source will be considered to be wholly part of the mask.

**Range Soft Edge**
The Range Soft Edge determines the falloff range of the colors selected. Any pixel within the range defined above will be treated as 100% within the mask. If the soft range is set to 0.0, no other pixels will be considered for the mask. Increasing the soft range will increase the number of colors close to, but not quite within, the range that will be included in the mask. These pixels will be semi-transparent in the mask.

**Image Tab**
Please refer to the Common Mask Controls.
Chapter 92

Matte Nodes

This chapter details the Matte nodes available in the Fusion page.

**Alpha Divide [ADV]**

As the name gives away, the Alpha Divide’s sole purpose is to divide an incoming image by its Alpha Channel.

This node has no controls

**Alpha Multiply [AMI]**

As the name gives away, the AlphaMultiply’s sole purpose is to multiply an incoming image with its Alpha Channel.

This node has no controls

**Chroma Keyer [CKY]**

The Chroma Keyer node creates an alpha channel (matte) for an image by removing selected colors from the scene. Unlike the Ultrakeyer, which has specific optimizations for keying from blue and green colors, the chroma keyer works equally well with any color.

**Chroma Key Tab**
**Key Type**
This determines the type of selection to be used for the matte creation.

**Chroma**
Chroma causes a matte to be created based on the RGB values of the selected color range.

**Color**
This causes a matte to be created based on the hue of the selected color range.

**Color Range**
These range controls update automatically to represent the current color selection. Colors are selected by selecting the Chroma Keyer node in the node tree, then dragging in the Viewer to select the colors to be used to create the matte. These range controls can be used to tweak the selection slightly, although generally selecting colors in the displays is all that is required.

**Lock Color Picking**
When this checkbox is selected, Fusion will prevent accidental growing of the selected range by selecting more colors from the view. It is a good idea to select this checkbox once the color selection has been made for the matte. All other controls in the node remain editable.

**Soft Range**
This control softens the selected color range to include additional colors into the matte.

**Reset Color Ranges**
Clicking on this button resets the Chroma Keyer’s range controls, discarding all color selections. All other sliders and controls maintain their values.

**Image Tab**

![Chroma Keyer node](image)

**Spill Color**
Use these buttons to select the color used as the base for all spill suppression techniques.

**Spill Suppression**
Spill is generally caused by the transmission of the color of the background through the semitransparent areas of the alpha channel. In the case of blue or green screen keying, this usually causes the color of the background to become apparent in the fringe of the foreground element.
Spill suppression attempts to remove color from the fringe. The process used is optimized for either blue or green screens; you select which color is used as the base from the control above. When this slider is set to 0 no spill suppression is applied to the image.

**Spill Method**
This selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color, the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue. Use this mode only for very troublesome shots. Most likely you will have to add strong color correction after the key to get, for example, your skin tones back.

**Fringe Gamma**
This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.

**Fringe Size**
This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**
Fringe Shape forces the fringe to be pressed toward the external edge of the image or pulled toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size sliders value is large.

**Cyan/Red, Magenta/Green and Yellow/Blue**
Use these three controls to color correct the fringe of the image. This is useful for correcting semi-transparent pixels that still contain color from the original background to match the new background.

**Matte Tab**

![Matte Tab Interface](image-url)
**Matte Blur**
Matte Blur blurs the edge of the matte using a standard constant speed Gaussian blur. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur applied to the matte.

**Matte Contract/Expand**
This slider shrinks or grows the semi-transparent areas of the matte. Values above 0.0 expand the matte, while values below 0.0 contract it.

This control is usually used in conjunction with the Matte Blur to take the hard edge of a matte and reduce fringing. Since this control only affects semi-transparent areas, it will have no effect on a hard edge’s matte.

**Matte Gamma**
Matte Gamma raises or lowers the values of the matte in the semi-transparent areas. Higher values cause the gray areas to become more opaque, and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

Since this control only affects semi-transparent areas, it will have no effect on a hard edge’s matte.

**Matte Threshold**
Any value below the lower threshold becomes black or transparent in the matte.

Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

This control is often used to reject salt and pepper noise in the matte.

**Invert Matte**
When this checkbox is selected, the alpha channel created by the keyer is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

**Garbage Matte Mode**
Garbage Mattes are Mask nodes or images connected to the Garbage Matte input on the node’s tile. The Garbage matte is applied directly to the alpha channel of the image. Generally, Garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a Garbage matte with the opposite effect of the matte applied to the keyer.

**Make Transparent**
Select this button to make the Garbage matte transparent.

**Make Solid**
Select this button to make the Garbage matte solid.

**Post Multiply Image**
Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered pre-multiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information, see the Merge node documentation.
Clean Plate

The Clean plate tool is a pre keying node used to generate an image of the green or blue color screen to smooth out the lighting differences so that later keying can key fine detail without choking or clipping the matte.

Method
Color Uses a difference method to replace the color; choose by Click-Drag clicking to the image.
Ranges uses a chroma range method to separate the background color.

Matte Threshold
Any value below the lower threshold becomes black or transparent in the matte.
Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values. This control is often used to reject salt and pepper noise in the matte.
**Erode**
Will decrease the size of the screen area.

**Crop**
Will trim in from the edges of the image.

**Grow Edges**
Will expand the color of the edges of the subject.

**Fill**
Will fill in remaining holes with color from the surrounding screen color.

**Time Mode**
- **Sequence**: will generate a new clean plate every frame.
- **Hold Frame**: will hold the clean plate at a single frame.

**Mask Tab**

**Garbage Mask**
Garbage mask can be applied to clear areas before growing edges or filling remaining holes.

**Invert**
Invert will use the transparent parts of the mask to clear the image.

**Delta Keyer**

The Delta Keyer is a classic color difference keyer, with many features and controls for tuning the matte and separating the subject from blue or green screen.

It contains several keying systems; the Key tab is the master difference keyer, Pre Matte is a pre clean plate to smooth out screen color. Tuning, Fringe, and Matte finish the key process.
How to Key

Use the Pick button on the background color to select the blue or green screen color from the image. Hold Option (Alt) while click dragging the pick and it will pick the color from the upstream image, making the key not flicker.

The Pre Matte is a clean plate generator that smooths out the color of the screen and is instigated by box selecting areas of the screen color. Tweaking the Erode will expand the pre matte so it does not clip into the subject of the image.

Inputs

- Delta keyer has the image input.
- Garbage Matte
- Clean Plate
- Effect mask
- Solid Matte

View Mode

At the top of the controls is View Mode, the default is to show the final result. This can be changed to see the output of the various intermediate stages of the Key process.

- **Pre Matte**: Will display the output of the Pre Matte key.
- **Matte**: Will display the alpha of the key before being combined with Solid and Garbage masks.
- **Tuning Ranges**: Will display the Shadow Midtone and Highlight range of the image. Shadows are in the red channel, Midtones in the green channel and Highlights in the blue channel.
- **Status**: Displays information to indicate areas that are solid, transparent or in-between. It also displays areas that have been affected by matte adjustments, such as thresholding or erode/dilate, and areas affected by the solid mask.
- **Intermediate Result**: Is the original source image color channels combined with the final matte. This can be combined with further DeltaKeyer tools.
- **Final Result**: Is the final keyed image with spill suppression, ready to merge onto a scene.
Key Tab

Background Color
This is the color of the blue or green screen, the keying color. This will be turned black with no alpha. Use the Pick button on the background color to select the blue or green screen color from the image. Hold Option (Alt) while click dragging the pick and it will pick the color from the upstream image, making the key not flicker.

Pre-Blur
Applies a blur before generating the alpha. This can help with certain types of noise and edge enhancements and artifacts in the source image.

Gain
Increases the influence of the background color. This will cause areas of background color to become more transparent.

Balance
The key is performed by comparing the differences between the dominant channel determined by the background color and the other two channels, with balance determining the proportions of the other two channels. A value of 0 will use the minimum of the other two channels, where a value of 1 will use the maximum. A value of 0.5 will use half of each.
Lock Alpha/Spill Removal Color Balance Reference
Unlocking this allows a different color references to be used when generating the alpha and when determining how much of the background color to subtract from the image.

Color Balance Reference
Can be used to adjust for lighting or white balance that might be reducing background color purity and saturation. A correction can be applied based on the reference of a neutral colored object when generating the key alpha and determining the amount of background color subtraction, without altering the background color that is subtracted.

Pre Matte

Soft Range
The soft range will extend the range of selected color and roll off the screen color.

Erode
Erode will contract the edge of the pre matte, so the edge detail will not be clipped.

Blur
This will soften the edges of the pre matte.

PreMatte Range
These range controls update automatically to represent the current color selection. Generally, the Reveal control does not have to be opened to display these controls. Colors are selected by selecting the Ultra Keyer node’s tile in the flow and dragging in the Viewer to select the colors to be used to create the matte. These range controls can be used to tweak the selection slightly, although generally selecting colors in the displays is all that is required.

Lock Color Picking
When this checkbox is selected, Fusion will prevent accidental growing of the selected range by selecting more colors from the view. It is a good idea to select this checkbox once the color selection is made for the matte. All other controls in the node remain editable.
Reset Pre Matte Ranges
This discards all color selection by resetting the ranges but maintains all other slider and control values.

Matte Tab

Threshold
Any value below the lower threshold becomes black or transparent in the matte.
Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

Restore Fringe
This restores the edge of the matte around the keyed subject. Often to get a key, the edge of the subject where you have hair will get clipped out, Restore Fringe will bring back that edge while keeping the matte solid.

Erode/Dilate
Expands or contracts the matte.

Blur
Softens the matte.

Clean Foreground
Fills slightly transparent areas of the matte.

Clean Background
Clips the bottom dark range of the matte.
**Replace Mode**
Determines how matte adjustments will cause color to be restored to the image.

- **None**: Is no color replacement. Matte processing will not affect the color.
- **Source**: Is the original color from the unkeyed image.
- **Hard Color**: Is solid color.
- **Soft Color**: Is solid color weighted by how much background color was originally removed.

**Replace Color**
The color used with the Hard Color and Soft Color replace modes.

**Fringe Tab**

![Fringe Tab](image)

**Spill Suppression**
Spill is generally caused by the transmission of the color of the background through the semi transparent areas of the alpha channel. In the case of blue or green screen keying, this usually causes the color of the background to become apparent in the fringe of the foreground element.

Spill suppression attempts to remove color from the fringe. The process used is optimized for either blue or green screens; you select which color is used as the base from the control above.

When this slider is set to 0, no spill suppression is applied to the image.

**Spill Method**
This selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color, the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue. Use this mode only for very troublesome shots.
**Fringe Gamma**
This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.

**Fringe Size**
This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**
Fringe Shape forces the fringe to be pressed toward the external edge of the image or pulled toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size value is large.

**Cyan/Red, Magenta/Green and Yellow/Blue**
Use these three controls to color correct the fringe of the image.
This is useful for correcting semi-transparent pixels that still contain color from the original background to match the new background.

**Tuning Tab**

![Tuning Tab Image]

**Range controls**
This defines how much color range is in the Dark Shadows, Midtones, and Highlight bright areas of the image. This spline controls allow for easy adjusting of the tonal ranges of each Shadow and Highlight tonal map.

Preset Simple will set the range to be linear. Preset Smooth sets a smooth tonal gradient for the ranges.

**Lock Alpha/Spill Removal Tuning**
Unlocking this allows a different tuning to be used when generating the alpha and when determining how much of the background color to subtract from the image.

- **Shadows**: Adjusts the strength of the key in darker areas of the background.
- **Midtones**: Adjusts the strength of the key in midtone areas of the background.
- **Highlights**: Adjusts the strength of the key in brighter areas of the background.
Mask Tab

Solid Mask

Solid Source Alpha
Used to combine the existing alpha from the source image into the solid mask.

- **Ignore**: Does not combine the alpha from the source image.
- **Add**: Solid areas of the source image alpha will be made solid in the solid mask.
- **Subtract**: Transparent areas of the source image alpha will be made transparent in the solid mask.

Solid Replace Mode
This determines how the solid mask will cause color to be restored to the image.

- **None**: Is no color replacement. The solid mask will not affect the color.
- **Source**: Is the original color from the unkeyed image.
- **Hard Color**: Is solid color.
- **Soft Color**: Is solid color weighted by how much background color was originally removed.

Solid Replace Color
The color used with the Hard Color and Soft Color replace modes.

- **Invert**: will invert the solid mask, before it is combined with the source alpha.

Garbage Mask

- **Invert**: Normally solid areas of the Garbage mask will clear the image. When inverted it’s the transparent areas of the mask that will clear the image.
Difference Keyer [DfK]

Difference keying is a process that produces a matte based on the differences between two images. A Difference key uses two input images, one containing the subject with the background and another containing the background without the subject.

The Difference Keyer node is very sensitive and, although the process sounds reasonable at first glance, subtle variations in the position of the camera from shot to shot usually make it difficult to pull a highly-detailed alpha channel using this method. Think of the futile attempt of trying to key smoke in front of a brick wall and using a clean plate of the brick wall as your difference input. Part of the wall’s structure will always be visible in this keying method. Instead, a Difference keyer is often used to produce a rough matte that is combined with other nodes to produce a more detailed matte.

Controls

Threshold High and Low
This slider works by defining a range of difference values between the images to create a matte. A difference below the lower threshold becomes black in the matte. Any difference above the upper threshold becomes white (solid) in the matte. The difference values in the range in between create a gray scale matte.

Matte Blur
This blurs the edge of the matte using a standard constant speed Gaussian blur. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur.
**Matte Contrast**
The Matte Contrast slider changes the Look up Table curve of the matte’s luminance values. This creates a soft cropping of the matte at the low end of the slider and a hard edge expansion of the matte at higher slider values.

**Matte Gamma**
Matte Gamma raises or lowers the values of the matte in the semi-transparent areas. Higher values cause the gray areas to be more opaque and lower values cause the gray areas to be more transparent. Completely black or white regions of the matte remain unaffected.

**Invert**
Selecting this checkbox inverts the matte, causing all transparent areas to be opaque and all opaque areas to be transparent.

**Garbage Matte Mode**
Garbage Mattes are Mask nodes or images connected to the Garbage Matte input on the node’s tile. The Garbage matte is applied directly to the alpha channel of the image. Generally, Garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single node. A Matte Control node is often used after a Keyer node to add a Garbage matte with the opposite effect of the matte applied to the keyer.

**Make Transparent**
Select this button to make the Garbage matte transparent.

**Make Solid**
Select this button to make the Garbage matte solid.

**Post Multiply Image**
Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered pre-multiplied for purposes of merging it with other images. Use the Subtractive option of the Merge tool instead of the Additive option.

For more information, see the Merge Nodes documentation.
Luma Keyer [LKY]

The Luma Keyer node uses the overall luminance of an image to create an alpha channel. When this node was first created it was used exclusively on the luminance channel of the image, but it has since grown to allow pulling mattes from virtually any channel Fusion understands. In some respects, it would now be more accurate to call this node a Channel Keyer.

**Controls**

**Channel**
Use this drop-down list to select the color channel used for creating the matte. Select from the Red, Green, Blue, Alpha, Hue, Luminance, Saturation, and Depth (Z-buffer) channels.

**Threshold High and Low**
This slider works by defining a range of luminance values in the image to create a matte. Any value below the lower threshold becomes black in the matte. Any value above the upper threshold becomes white (solid) in the matte. All values within the range create the gray scale matte.

**Matte Blur**
Matte Blur blurs the edge of the matte using a standard constant speed Gaussian blur. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur applied to the matte.
Matte Contrast
The Contrast slider changes the Look up Table curve of the matte’s luminance values. This creates a soft cropping of the matte at the low end of the slider and a hard edge expansion of the matte at higher slider values.

Matte Gamma
Matte Gamma raises or lowers the values of the matte in the semi-transparent areas. Higher values cause the gray areas to be more opaque and lower values cause the gray areas to be more transparent. Completely black or white regions of the matte remain unaffected.

- **Invert**: When toggled on, the matte is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

Garbage Matte Mode
Garbage Mattes are Mask nodes or images connected to the Garbage Matte input on the node’s tile. The Garbage matte is applied directly to the alpha channel of the image. Generally, Garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single node. A Matte Control tool is often used after a Keyer node to add a Garbage matte with the opposite effect of the matte applied to the keyer.

Make Transparent
Select this button to make the Garbage matte transparent.

Make Solid
Select this button to make the Garbage matte solid.

Post Multiply Image
Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered pre-multiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information, see the Merge Nodes documentation.

Matte Control [MAT]
Keyer nodes are generally used to create an alpha channel on an image that does not already have one. The Matte Control node is used to manipulate an existing alpha channel or to create one by hand via rotoscoping.

The Matte Control node also has a Foreground Image input. Use this node to copy a color channel or alpha channel from the foreground to the background, or to combine alpha channels from the two images.
Controls

Matte Combine

The Matte Control node can combine alpha or color channels from an image in the foreground input with the background image. Use this menu to select which operation is applied. The default is set to None for no operation.

- **None**: This causes the foreground image to be ignored.
- **Combine Red**: This combines the foreground red channel to the background alpha channel.
- **Combine Green**: This combines the foreground green channel to the background alpha channel.
- **Combine Blue**: This combines the foreground blue channel with the background alpha channel.
- **Combine Alpha**: This combines the foreground alpha channel with the background alpha channel.
- **Solid**: This causes the background alpha channel to become completely opaque.
- **Clear**: This causes the background alpha channel to become completely transparent.

Combine Operation

Use this menu to select the method used to combine the foreground channel with the background.

- **Copy**: This copies the foreground source over the background alpha, overwriting any existing alpha in the background.
- **Add**: This adds the foreground source to the background alpha.
- **Subtract**: This subtracts foreground source from the background alpha.
• **Inverse Subtract:** This subtracts the background alpha from the foreground source.

• **Maximum:** This compares the foreground source and the background alpha and takes the value from the pixel with the highest value.

• **Minimum:** This compares the foreground source and the background alpha and takes the value from the pixel with the lowest value.

• **And:** This performs a logical AND on the two values.

• **Or:** This performs a logical OR on the values.

• **Merge Over:** This merges the foreground source channel over the background alpha channel.

• **Merge Under:** This merges the foreground source channel under the background alpha channel.

**Filter**
Selection of the Filter that is used when blurring the matte.

• **Box Blur:** This option applies a Box Blur effect to the whole image. This method is faster than the Gaussian blur but produces a lower quality result.

• **Bartlett:** Bartlett applies a more subtle, anti-aliased blur filter.

• **Multi-box:** Multi-Box uses a box filter layered in multiple passes to approximate a Gaussian shape. With a moderate number of passes (e.g., four), a high quality blur can be obtained, often faster than the Gaussian filter and without any ringing.

• **Gaussian:** Gaussian applies a smooth, symmetrical blur filter, using a sophisticated constant-time Gaussian approximation algorithm. In extreme cases, this algorithm may exhibit ringing; see below for a discussion of this. This mode is the default filter method.

**Matte Blur**
This blurs the edge of the matte using a standard constant speed Gaussian blur. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur applied to the matte.

**Matte Contract/Expand**
This shrinks or grows the matte to exclude some of the keyed image or include some of its surrounding area. Values above 0.0 expand the matte and values below 0.0 contract it.

**Matte Gamma**
This raises or lowers the values of the matte in the semi-transparent areas. Higher values cause the gray areas to become more opaque and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

**Matte Threshold**
Any value below the lower threshold becomes black or transparent in the matte. Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

• **Invert Matte:** When this checkbox is selected, the alpha channel of the image is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.
Garbage Matte

Garbage Mattes are Mask nodes or images connected to the Garbage Matte input on the node’s tile. The Garbage matte is applied directly to the alpha channel of the image. Generally, Garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single node. A Matte Control node is often used after a Keyer node to add a Garbage matte with the opposite effect of the matte applied to the keyer.

- **Make Transparent**: Select this button to make the Garbage matte transparent.
- **Make Solid**: Select this button to make the Garbage matte solid.
- **Post Multiply Image**: Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.
  
  Deselect this checkbox and the image can no longer be considered pre-multiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.
- **Multiply Garbage Matte**: When selected, the values of the image's Red, Green, and Blue channels will be multiplied against the Garbage Matte input.

For more information, see the Merge nodes documentation.

Spill Tab

![Spill Tab Image]

Spill Color

Use these buttons to select the color used as the base for all spill suppression techniques.

Spill Suppression

Spill is generally caused by the transmission of the color of the background through the semi-transparent areas of the alpha channel. In the case of blue or green screen keying, this usually causes the color of the background to become apparent in the fringe of the foreground element.

Spill suppression attempts to remove color from the fringe. The process used is optimized for either blue or green screens; you select which color is used as the base from the control above.

When this slider is set to 0, no spill suppression is applied to the image.
Spill Method
This selects the strength of the algorithm used to apply spill suppression to the image.

- **None**: None is selected when no spill suppression is required.
- **Rare**: This removes very little of the spill color, the lightest of all methods.
- **Medium**: This works best for green screens.
- **Well Done**: This works best for blue screens.
- **Burnt**: This works best for blue. Use this mode only for very troublesome shots.

Fringe Gamma
This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.

Cyan/Red, Magenta/Green and Yellow/Blue
Use these three controls to color correct the fringe of the image. This is useful for correcting semi-transparent pixels that still contain color from the original background to match the new background.

Fringe Size
This expands and contracts the size of the fringe or halo surrounding the keyed image.

Fringe Shape
Fringe Shape forces the fringe to be pressed toward the external edge of the image or pulled toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size sliders value is large.

**Ultra Keyer [UKY]**

The Ultra Keyer node has 2 keyers built in to it, a Prematte keyer acts as garbage matte creator and the color difference keyer that will extract fine detail and transparency. This optimized to extract mattes from images using blue screen or green screen backgrounds.

How to Key
Use the Pick Button on the Background Color to select the blue or green screen color from the image. Hold Option (Alt) while click dragging the pick and it will pick the color from the up stream image, making the key not flicker.

The Pre Matte garbage keyer is instigated by box selecting areas of the screen color, and tweaking the Pre Matte Size will expand the Garbage matte so it does not clip into the subject of the image.
**Pre Matte Tab**

**Background Color**

This is used to select the color of the blue or green screen of the images. It is good practice to select the screen color close to the subject to be separated from the screen background.

**Red Level, Green Level, Blue Level**

These tune the level of the difference channels, to help separate the color. When the background color is green, Red and Blue level options are provided. When the background color is blue, Red and Green level options are provided.

**Background Correction**

Depending on the background color selected above, the keyer will iteratively merge the pre-keyed image over either a blue or green background before processing it further.

In certain cases this leads to better, more subtle edges.
Matte Separation
Matte Separation performs a pre-process on the image to help separate the foreground from the background before color selection. Generally, increase this control while viewing the alpha to eliminate the bulk of the background, but stop just before it starts cutting holes in the subject or eroding fine detail on the edges of the matte.

- **PreMatte Range:** These range controls update automatically to represent the current color selection. Generally, the Reveal control does not have to be opened to display these controls. Colors are selected by selecting the Ultra Keyer node’s tile in the node tree and dragging in the Viewer to select the colors to be used to create the matte. These range controls can be used to tweak the selection slightly, although generally selecting colors in the displays is all that is required.
- **Lock Color Picking:** When this checkbox is selected, Fusion will prevent accidental growing of the selected range by selecting more colors from the view. It is a good idea to select this checkbox once the color selection is made for the matte. All other controls in the node remain editable.

Pre Matte Size
The Pre Matte Size control can be used to soften the general area around the keyed image. This is used to close holes in the matte often caused by spill in semi-transparent areas of the subject. This generally will also cause a small halo around the subject, which can be removed using the Matte Contract tools found later in the tool.

Reset Pre Matte Ranges
This discards all color selection by resetting the ranges but maintains all other slider and control values.

Image Tab

Spill Suppression
Spill is generally caused by the transmission of the color of the background through the semitransparent areas of the alpha channel. In the case of blue or green screen keying, this usually causes the color of the background to become apparent in the fringe of the foreground element.

Spill suppression attempts to remove color from the fringe. The process used is optimized for either blue or green screens; you select which color is used as the base from the control above.

When this slider is set to 0, no spill suppression is applied to the image.
**Spill Method**
This selects the strength of the algorithm used to apply spill suppression to the image.

- **None:** None is selected when no spill suppression is required.
- **Rare:** This removes very little of the spill color, the lightest of all methods.
- **Medium:** This works best for green screens.
- **Well Done:** This works best for blue screens.
- **Burnt:** This works best for blue. Use this mode only for very troublesome shots.

**Fringe Gamma**
This control can be used to adjust the brightness of the fringe or halo that surrounds the keyed image.

**Fringe Size**
This expands and contracts the size of the fringe or halo surrounding the keyed image.

**Fringe Shape**
Fringe Shape forces the fringe to be pressed toward the external edge of the image or pulled toward the inner edge of the fringe. Its effect is most noticeable while the Fringe Size sliders value is large.

**Cyan/Red, Magenta/Green and Yellow/Blue**
Use these three controls to color correct the fringe of the image. This is useful for correcting semi-transparent pixels that still contain color from the original background to match the new background.

**Matte Tab**

**Matte Blur**
Matte Blur blurs the edge of the matte using a standard constant speed Gaussian blur. A value of zero results in a sharp, cutout-like hard edge. The higher the value, the more blur applied to the matte.
Matte Contract/Expand
This slider shrinks or grows the semi-transparent areas of the matte. Values above 0.0 expand the matte while values below 0.0 contract it.

This control is usually used in conjunction with the Matte Blur to take the hard edge of a matte and reduce fringing. Since this control only affects semi-transparent areas, it will have no effect on a hard edge’s matte.

Matte Gamma
Matte Gamma raises or lowers the values of the matte in the semi-transparent areas. Higher values cause the gray areas to become more opaque and lower values cause the gray areas to become more transparent. Completely black or white regions of the matte remain unaffected.

Since this control only affects semi-transparent areas, it will have no effect on a hard edge’s matte.

Matte Threshold
Any value below the lower threshold becomes black or transparent in the matte. Any value above the upper threshold becomes white or opaque in the matte. All values within the range maintain their relative transparency values.

This control is often used to reject salt and pepper noise in the matte.

Restore Fringe
This restores the edge of the matte around the keyed subject. Often to get a key, the edge of the subject where you have hair will get clipped out, Restore Fringe will bring back that edge while keeping the matte solid.

Invert Matte
When this checkbox is selected, the alpha channel created by the keyer is inverted, causing all transparent areas to be opaque and all opaque areas to be transparent.

Make Solid
Select this button to make the Garbage matte solid.

Make Transparent
Select this button to make the Garbage matte transparent.

Garbage Matte
Garbage Mattes are Mask nodes or images connected to the Garbage Matte input on the node’s tile. The Garbage matte is applied directly to the alpha channel of the image. Generally, Garbage mattes are used to remove unwanted elements that cannot be keyed, such as microphones and booms. They are also used to fill in areas that contain the color being keyed but that you wish to maintain.

Garbage mattes of different modes cannot be mixed within a single tool. A Matte Control node is often used after a Keyer node to add a Garbage matte with the opposite effect of the matte applied to the keyer.

Post Multiply Image
Select this option to cause the keyer to multiply the color channels of the image against the alpha channel it creates for the image. This option is usually enabled and is on by default.

Deselect this checkbox and the image can no longer be considered pre-multiplied for purposes of merging it with other images. Use the Subtractive option of the Merge node instead of the Additive option.

For more information, see the Merge nodes documentation.
Chapter 93

Metadata Nodes

This chapter details the Metadata nodes available in the Fusion page.
Contents

Copy Metadata [META] 1760
Set Metadata [SMETA] 1761
Set Timecode [TCMETA] 1762
Copy Metadata [META]

Copy Metadata combines, replaces or clears the metadata in your image.

Controls

**Operation**
The drop-down defines how the metadata of foreground and background input are treated.

Imagine having metadata in the background image looking like this:

- **FrameRate** = 24
- **Record** = Scratched
- **TimeCode** = 00:00:08:15
- **Hovercraft_Filing** = Eeb

and the foreground's metadata looking like this:

- **Hovercraft_Filing** = Oysters

**Merge (Replace Duplicates)**
All values will be merged, but values with duplicate names will be taken from the foreground input.

The output looks like this:

- **FrameRate** = 24
- **Record** = Scratched
- **TimeCode** = 00:00:08:15
- **Hovercraft_Filing** = Oysters
**Merge (Preserve Duplicates)**
All values will be merged, but values with duplicate names will be taken from the background input.

The output looks like this:

```
FrameRate = 24
Record = Scratched
TimeCode = 00:00:00:01:15
Hovercraft_Filling = Oysters
```

**Replace**

```
Hovercraft_Filling = Oysters
```

The entire metadata in the background will be replaced by the ones in the foreground. The output looks like this:

**Clear**

All metadata will be discarded.

---

**Set Metadata [SMETA]**

Set Metadata allows the user to create new Name = Value pairs in the metadata.

**Controls**

**Field Name**
The name of the Metadata Value. Do not use spaces.

**Field Value**
The value assigned to the name above.
Set Timecode [TCMETA]

Set Timecode inserts dynamic timecode values into the metadata table based on the FPS settings.

**Controls**

**FPS**
You can choose from a variety of Frame Per Second settings here. Since this is a Fuse, you can easily adapt the settings to your needs by editing the appropriate piece of code for the buttons:

```plaintext
MBTNC_ShrinkToFit = true,
    { MBTNC_AddButton = "24" },
    { MBTNC_AddButton = "25" },
    { MBTNC_AddButton = "30" },
    { MBTNC_AddButton = "48" },
    { MBTNC_AddButton = "50" },
    { MBTNC_AddButton = "60" },
    }
```

as well as for the actual values:

```plaintext
local rates = { 24, 25, 30, 48, 50, 60 }
```

**Hours/Minutes/Seconds/Frames sliders**
Define an offset from the starting frame of the current comp.

**Print to Console**
Verbose output of the Timecode/Frame value in the Console.

The Timecode/Frames conversion is done according to the FPS settings. The result can look like this:

```
TimeCode: 00:00:08:15
Frames: 207
```
Chapter 94

Miscellaneous Nodes

This chapter details miscellaneous nodes within the Fusion page.
Contents

Auto Domain [ADOD] 1765
Change Depth [CD] 1766
Custom [CT] 1767
Fields [FLD] 1776
Run Command [RUN] 1778
Set Domain [DOD] 1781
Time Speed [TSPD] 1783
Time Stretcher [TST] 1784
Auto Domain [ADOD]

The Auto Domain node automatically sets the image's domain of definition based on bounds of the input image's background Canvas color. It does not change the image's physical dimensions. This node can be used to speed up compositions by optimizing the DoD of images based on their content rather than their dimensions.

For example, a CG character rarely takes up the entire frame of an image. The Auto Domain node would set the DoD to a rectangular region encompassing the portion of the scene actually containing the character. The DoD is updated on each frame to accommodate changes, such as a character walking closer to the camera.

See the Set Canvas Color node for more information about the Canvas color.

Controls

**Left**
Defines the left border of the search area of the ADoD. Higher values on this slider move the left border toward the right, excluding more data from the left margin.

1 represents the right border of the image, 0 represents the left border. The slider defaults to 0 (Left Border).

**Bottom**
Defines the bottom border of the search area of the ADoD. Higher values on this slider move the bottom border toward the top, excluding more data from the bottom margin.

1 represents the top border of the image, 0 represents the bottom border. The slider defaults to 0 (Bottom Border).

**Right**
Defines the right border of the search area of the ADoD. Higher values on this slider move the right border toward the left, excluding more data from the right margin.

1 represents the right border of the image, 0 represents the left border. The slider defaults to 1 (Right Border).
**Top**
Defines the top border of the search area of the ADoD. Higher values on this slider move the top border toward the bottom, excluding more data from the top margin.
1 represents the top border of the image, 0 represents the bottom border. The slider defaults to 1 (Top Border).

**Change Depth [CD]**

The Change Depth node has one simple use, to change the bits per color channel used to process a node. The single control for this node is Depth, which contains five buttons. Select Keep to leave the color depth as is, or either 8-bit, 16-bit or Float to change to the selected color depth.

This node is often used after color correcting Cineon files, converting from Float processing to 16-bit per channel to preserve memory and performance.

It can also be useful if, from a certain point in your node tree, you feel the need to process your images in a higher bit depth than their original one or to reduce the bit depth to save memory.

**Controls**

**Depth**
Keep doesn't do anything to the image but rather keeps the input depth. The other options change the bit depth of the image to the respective value.

**Dither**
When down converting from higher bit depth it might be useful to add Error Diffusion or Additive Noise to camouflage artifacts that result from problematic (high contrast) areas.
Custom [CT]

The Custom node is quite likely the most complex, and the most powerful, node in Fusion. Any user moderately experienced with scripting, or C++ programming, should find the structure and terminology used by the Custom node to be familiar.

The Custom node is used to create custom expressions and filters to modify an image. In addition to providing three image inputs, the Custom node will allow for the connection of up to eight numeric inputs and as many as four XY position values from other controls and parameters in the node tree.

Per-pixel calculations can be performed on the Red, Green, Blue, Alpha, Z, Z-Coverage, UV texture coords, XYZ Normals, RGBA background color, and XY motion vector channels of the images.

Controls

Point in 1-4, X and Y
These four controls are 2D X and Y center controls that are available to expressions entered in the Setup, Intermediate, and Channels tabs as variables p1x, p1y, ..., p4x, p4y. They are normal positional controls and can be animated or connected to modifiers as any other node might.

Number in 1-8
The values of these controls are available to expressions entered in the Setup, Intermediate, and Channels tabs as variables n1, n2, n3, ..., n8. They are normal slider controls and can be animated or connected to modifiers exactly as any other node might.
**LUT in 1-4**

The Custom node provides 4 LUT splines. The values of these controls are available to expressions entered in the Setup, Intermediate, and Channels tabs using the getlut# function. For example, setting the R, G, B, and A expressions to getlut1(r1), getlut2(g1), getlut3(b1), and getlut4(a1) respectively would cause the Custom node to mimic the Color Curves node.

These controls can be renamed using the options in the Config tab to make their meanings more apparent, but expressions will still see the values as n1, n2, ..., n8.

**Custom Setup Tab**

![Custom Setup Tab Image]

**Setup 1-4**

Up to four separate expressions can be calculated in the Setup tab of the Custom node. The Setup expressions are evaluated once per frame, before any other calculations are performed. The results are then made available to the other expressions in the Custom node as variables s1, s2, s3 and s4.

**NOTE:** Because these expressions are evaluated once per frame only and not for each pixel, it makes no sense to use per-pixel variables like X and Y or channel variables like r1,g1,b1, and so on. Allowable values include constants, variables like n1..n8, time, W and H, and so on, and functions like sin() or getr1d().
Custom Inter Tab

Intermediate 1-4
An additional four expressions can be calculated in the Inter tab. The Inter expressions are evaluated once per pixel, after the Setup expressions are evaluated but before the Channel expressions are evaluated. Per-pixel channel variables like r1, g1, b1, and a1 are allowable. Results are available as variables i1, i2, i3, and i4.

Custom Config Tab
Random Seed
Use this to set the seed for the rand() and rands() functions. Click the Randomize button to set the seed to a random value. This control may be needed if multiple Custom nodes are required with different random results for each.

Number Controls
There are eight sets of Number controls, corresponding to the eight Number In sliders in the Controls tab. Untick the Show Number checkbox to hide the corresponding Number In slider, or edit the Name for Number text field to change its name.

Point Controls
There are four sets of Point controls, corresponding to the four Point In controls in the Controls tab. Untick the Show Point checkbox to hide the corresponding Point In control and its crosshair in the Viewer. Similarly, edit the Name for Point text field to change the control’s name.

Channels Tab
RGB, Z, UV Expressions and XYZ Normal Expressions
The Channel tab is used to set up one expression per each available channel of the image. Each expression is evaluated once per pixel, and the result is used to create the value for that pixel in the output of the image.

Color Channel expressions (RGBA) should generally return floating-point values between 0.0 and 1.0. Values beyond this will be clipped if the destination image is an integer. Other expression fields should produce values appropriate to their channel (e.g., between -1.0 and 1.0 for Vector and Normal fields, 0.0 to 1.0 for Coverage, or any value for Depth). The Channel expressions may use the results from both the Setup expressions (as variables s1–s4) and Inter expressions (as variables i1–i4).

<td>vy1..vy3</td>
<td>Y Vector (for image1..image3)</td>
</tr>
<tr>
<td>nz1..nz3</td>
<td>Z Normal (for image1..image3)</td>
</tr>
</tbody>
</table>

**NOTE:** Use c1, c2, c3 to refer to the value of a pixel in the current channel. This makes copy/pasting expressions easier. For example, if c1/2 is typed as the red expression, the result would be half the value of the red pixel from image 1, but if the expression is copied to the blue channel, now it would have the value of the pixel from the blue channel.
To refer to the red value of the current pixel in input 1, type r1. For the image in input 2, it would be r2.

- \textit{get[ch][#]b}(x, y) Read pixel at \(x,y\) or 0 if out of bounds, e.g., \textit{getr1b}(0,0)
- \textit{get[ch][#]d}(x, y) Read pixel at \(x,y\) or edge pixel if out of bounds, e.g., \textit{getr1d}(0,0)
- \textit{get[ch][#]w}(x, y) Read pixel at \(x,y\) or wrap if out of bounds, e.g., \textit{getr1w}(0,0)

\textbf{NOTE:} There are a variety of methods used to refer to pixels from other locations than the current one in an image.

In the above description, [ch] is a letter representing the channel to access, and [#] is a number representing the input image. So to get the red component of the current pixel (equivalent to ‘r’), you would use \textit{getr1b}(x,y). To get the alpha component of the pixel at the center of image 2 you would use \textit{geta2b}(0.5, 0.5).

- \textit{getr1b}(x,y) Output the red value of the pixel at position \(x,y\), if there were a valid pixel present. It would output 0.0, if the position were beyond the boundaries of the image (all channels).
- \textit{getr1d}(x,y) Output the red value of the pixel at position \(x,y\). If the position specified were outside of the boundaries of the image, the result would be from the outer edge of the image (RGBA only).
- \textit{getr1w}(x,y) Output the red value of the pixel at position \(x,y\). If the position specified were outside of the boundaries of the image, the \(x\) and \(y\) coordinates would wrap around to the other side of the image and continue from there (RGBA only).

To access other channel values with these functions, substitute the \(r\) in the above examples with the correct channel variable (r, g, b, a and, for the \textit{getr1b()} functions only, z, and so on), as shown above. Substitute the \(1\) with either 2 or 3 in the above examples to access the images from the other image inputs.

</table>
Example

The following examples are intended to help you understand the various components of the Custom node.

Rotation

To rotate an image, we need the standard equations for 2D rotation:

\[ x' = x \cdot \cos(\theta) - y \cdot \sin(\theta) \]
\[ y' = x \cdot \sin(\theta) + y \cdot \cos(\theta) \]

Using the n1 slider for the angle theta, and a sample function, we get (for the red channel):

\[ \text{getr1b}(x \cdot \cos(n1) - y \cdot \sin(n1), x \cdot \sin(n1) + y \cdot \cos(n1)) \]

This will calculate the current pixel’s (x,y) position rotated around the origin at (0,0) (the bottom-left corner), and then fetch the red component from the source pixel at this rotated position. For centered rotation, we need to subtract 0.5 from our x and y coordinates before we rotate them, and add 0.5 back to them afterwards:

\[ \text{getr1b}((x-.5) \cdot \cos(n1) - (y-.5) \cdot \sin(n1) + .5, (x-.5) \cdot \sin(n1) + (y-.5) \cdot \cos(n1) + .5) \]

Which brings us to the next lesson: Setup and Intermediate Expressions. These are useful for speeding things up by minimizing the work that gets done in the channel expressions. The Setup expressions are executed only once, and their results don’t change for any pixel, so you can use these for s1 and s2 respectively

\[ \cos(n1), \sin(n1) \]

Intermediate expressions are executed once for each pixel, so you can use these for i1 and i2:

\[ (x-.5) \cdot s1 - (y-.5) \cdot s2 + .5 \]
\[ (x-.5) \cdot s2 + (y-.5) \cdot s1 + .5 \]

These are the x and y parameters for the getr1b() function, from above, but with the Setup results, s1 and s2, substituted so that the trig functions are executed only once per frame, not every pixel. Now you can use these intermediate results in your channel expressions:

\[ \text{getr1b}(i1, i2) \]
\[ \text{getg1b}(i1, i2) \]
\[ \text{getb1b}(i1, i2) \]
\[ \text{geta1b}(i1, i2) \]

With the Intermediate expressions substituted in, we only have to do all the adds, subtractions and multiplies once per pixel, instead of four times per pixel. As a rule of thumb, if it doesn’t change, do it only once.

This is a simple rotation that doesn’t take into account image aspect at all. It is left as an exercise to the reader to include this (sorry). Another improvement could be to allow rotation around different points than the center.
Filtering

Our second example duplicates the functionality of a 3x3 Custom Filter node set to averages the current pixel together with the eight pixels surrounding it. To duplicate it with a Custom node, add a Custom node to the node tree, and enter the following expressions into the Setup tab.

(Leave the node disconnected to prevent it from updating until we are ready.)

S1
1.0/w1
S2
1.0/h1

These two expressions will be evaluated at the beginning of each frame. S1 divides 1.0 by the current width of the frame, and S2 divides 1.0 by the height. This provides a floating-point value between 0.0 and 1.0 that represents the distance from the current pixel to the next pixel along each axis.

Now enter the following expression into the first text control of the Channel tab (r).

\[(\text{getr1w}(x-s1, y-s2) + \text{getr1w}(x, y-s2) + \text{getr1w}(x+s1, y-s2) + \text{getr1w}(x+s1, y) + \text{getr1w}(x-s1, y) + r1 + \text{getr1w}(x-s1, y+s2) + \text{getr1w}(x, y+s2) + \text{getr1w}(x+s1, y+s2)) / 9\]

This expression adds the nine pixels above the current pixel together by calling the getr1w() function nine times and providing it with values relative to the current position. Note that we referred to the pixels by using \(x+s1, y+s2\), rather than using \(x+1, y+1\). Fusion refers to pixels as floating-point values between 0.0 and 1.0, which is why we created the expressions we used in the Setup tab. If we had used \(x+1, y+1\) instead, the expression would have sampled the exact same pixel over and over again. (The function we used wraps the pixel position around the image if the offset values are out of range.)

That took care of the red channel; now use the following expressions for the green, blue and alpha channels.

\[(\text{getg1w}(x-s1, y-s2) + \text{getg1w}(x, y-s2) + \text{getg1w}(x+s1, y-s2) + \text{getg1w}(x+s1, y) + \text{getg1w}(x-s1, y) + g1 + \text{getg1w}(x-s1, y+s2) + \text{getg1w}(x, y+s2) + \text{getg1w}(x+s1, y+s2)) / 9\]

\[(\text{getb1w}(x-s1, y-s2) + \text{getb1w}(x, y-s2) + \text{getb1w}(x+s1, y-s2) + \text{getb1w}(x+s1, y) + \text{getb1w}(x-s1, y) + b1 + \text{getb1w}(x-s1, y+s2) + \text{getb1w}(x, y+s2) + \text{getb1w}(x+s1, y+s2)) / 9\]

\[(\text{geta1w}(x-s1, y-s2) + \text{geta1w}(x, y-s2) + \text{geta1w}(x+s1, y-s2) + \text{geta1w}(x+s1, y) + \text{geta1w}(x-s1, y) + a1 + \text{geta1w}(x-s1, y+s2) + \text{geta1w}(x, y+s2) + \text{geta1w}(x+s1, y+s2)) / 9\]

It is time to view the results. Add a Background node set to solid color and change the color to a pure red. Add a hard-edged Rectangular Effects mask and connect it to the expression just created.

For comparison, add a Custom Filter node and duplicate the settings from the image above. Connect a pipe to this node from the background to the node and view the results. Alternate between viewing the Custom node and the Custom Filter while zoomed in close to the top corners of the Effects mask.
Of course, the Custom Filter node renders a lot faster than the Custom node we created, but the flexibility of the Custom node is its primary advantage. For example, you could use an image connected to input 2 to control the median applied to input one by changing all instances of getr1w, getg1w, and getb1w in the expression to getr2w, getg2w, and getb2w, but leaving the r1, g1, and b1s as they are. This is just one example; the possibilities of the Custom node are limitless.

Fields [FLD]

The Fields node is a robust multi-purpose utility offering several functions related to interlaced video frames. It interpolates separate video fields into video frames, or separates video frames into individual fields. It can be used to assist in the standards conversion of PAL to NTSC and provides the ability to process fields and frames for specific portions of a node tree.

Controls

**Operation**
This control is used to select the type of operation the node will perform. See below for a detailed explanation.

**Process Mode**
This control is used to select the field’s format used for the output image. See below for a detailed explanation.
Operation

**Do Nothing**
This causes the images to be affected by the Process Mode selection exclusively.

**Strip Field 2**
This removes field 2 from the input image stream, which shortens the image to half of the original height.

**Strip Field 1**
This removes field 1 from the input image stream, which shortens the image to half of the original height.

**Strip Field 2 and Interpolate**
This removes field 2 from the input image stream and inserts a field interpolated from field 1 so that image height is maintained. Should be supplied with frames, not fields.

**Strip Field 1 and Interpolate**
This removes field 1 from the input image stream and inserts a field interpolated from field 2 so that image height is maintained. Should be supplied with frames, not fields.

**Interlace**
This combines fields from the input image stream(s). If supplied with one image stream, each pair of frames will be combined to form half of the amount of double height frames. If supplied with two image streams, single frames from each stream will be combined to form double height images.

**De-Interlace**
This separates fields from one input image stream. This will produce double the amount of half height frames.

**Reverse Field Dominance**
When selected, the Field Order or Dominance of the image will be swapped.
Process

Full Frames
This forces Frame Processing. Useful for processing frames in a part of a node tree that is otherwise field processing.

NTSC Fields
This forces NTSC Field Processing. Useful for processing fields in a part of a node tree that is otherwise frame processing.

PAL Fields
This forces PAL Field Processing. Useful for processing fields in a part of a node tree that is otherwise frame processing.

PAL Fields (Reversed)
This forces PAL swapped Field Processing.

NTSC Fields (Reversed)
This forces NTSC swapped Field Processing.

Auto
This attempts to match the mode of its input images. Fields is used if the input types are mixed.

Run Command [RUN]

The RunCommand node is used to execute an external command or batch file at certain points during a render. Choose to run a command once at the start, or at the end of a render, or have the command execute once for each frame.

An image input is not required for this node to operate. However, if RunCommand is connected to a node's output, the command will only be launched after that node has finished rendering. This is often useful when connected to a Saver, to ensure that the output frame has been fully saved to disk first. If the application launched returns a non-0 result, the node will also fail.
RunCommand can be used to net render other command line applications using the Fusion render manager, as well as a host of other useful functions.

**Controls**

### Frame Command
The first file browser in the node is used to specify the path and parameters for the command to be run after each frame is rendered. Select the Hide checkbox to prevent the application or script from displaying a window when it is executed.

#### Hide
Select this checkbox to suppress the display of any window or dialog started by the command.

#### Wait
Enable this checkbox to cause the node to Wait for the remote application or tool to exit before continuing. If this checkbox is cleared, the system will continue rendering without waiting for the external application.

#### Number A (%a) And Number B (%b)
Various wildcards can be used with the frame commands; these wildcards will be substituted at render time with the correct values.

- `%a`: Outputs the number from the Number A thumbwheel control
- `%b`: Outputs the number from the Number B thumbwheel control
- `%t`: Outputs the current frame number (without zero padding)
- `%s`: Substituted with the text from the large text entry field

If you want to add zero padding to the numbers generated by %t, refer to the wildcard with %0x where x is the number of characters with which to pad the value. This also works for %a and %b.
For example, test%04f.tga would return the following values at render time:

- test0000.tga
- test0001.tga
- test0009.tga
- test0010.tga

You may also pad a value with spaces by calling the wildcard as %x, where x is the number of spaces with which you would like to pad the value.

**Process Priority**

The Process Priority buttons provide options for selecting the priority at which the launched process runs. This determines how much processor time the launched process receives compared to other applications.

**Interactive**

This checkbox determines whether the launched application should run interactively, allowing user input.

**RunCommand Start and End Tabs**

The Start and End tabs contain a file browser for a command to be run when the composition starts to render and when the composition is done rendering.

**Example**

To copy the saved files from a render to another directory as each frame is rendered, save the following text in a file called copyfile.bat to your C\ directory (the root folder).

```batch
@echo off
set parm=%1 %2
copy %1 %2 set parm=
```

Create or load any node tree that contains a Saver. The following example assumes a Saver is set to output D\ test0000.tga, test0001.tga, etc. You may have to modify the example to match.

Add a RunCommand node after the Saver, to ensure the Saver has finished saving first. Now enter the following text into the RunCommand node's Frame Command text box:

`C\copytest.bat D\test%04f.tga C\`
Select the Hide Frame command checkbox to prevent the command prompt window from appearing briefly after every frame.

When this node tree is rendered, each file will be immediately copied to the C\ directory as it is rendered.

The RunCommand node could be used to FTP the files to a remote drive or Abekas device on the network, to print out each frame as it is rendered, or to execute a custom image-processing tool.

The RunCommand node is not restricted to executing simple batch files. FusionScript, VBScript, Jscript, CGI, and Perl files could also be used, as just a few examples.

Set Domain [DOD]

Set Domain is used to adjust or set the active area of an image, or in other words the area of the image considered to have valid data.

It does not change the image's physical dimensions. Anything outside the DoD will not be processed by downstream nodes, thus speeding up rendering of computational intensive nodes.

This node provides an absolute mode, for setting the Domain of Definition manually, and a relative mode for adjusting the existing Domain of Definition.

Controls/Set Mode

Left
Defines the left border of the DoD. Higher values on this slider move the left border toward the right, excluding more data from the left margin.
1 represents the right border of the image, 0 represents the left border. The slider defaults to 0 (Left Border).
**Bottom**
Defines the bottom border of the DoD. Higher values on this slider move the bottom border toward the top, excluding more data from the bottom margin.
1 represents the top border of the image, 0 represents the bottom border. The slider defaults to 0 (Bottom Border).

**Right**
Defines the right border of the DoD. Higher values on this slider move the right border toward the left, excluding more data from the right margin.
1 represents the right border of the image, 0 represents the left border. The slider defaults to 1 (Right Border).

**Top**
Defines the top border of the DoD. Higher values on this slider move the top border toward the bottom, excluding more data from the top margin.
1 represents the top border of the image, 0 represents the bottom border. The slider defaults to 1 (Top Border).

**External Inputs**
- **SetDomain.Input**: [orange, required] This input must be connected to the output of a node that produces a 2D image.
- **SetDomain.Foreground**: [green, optional] This input expects a 2D image as its input. When the foreground input is connected, the Set Domain node will replace the Background input’s Domain of Definition with the foreground’s DoD.

Set Mode defaults to the full extent of the visible image.

**Controls/Adjust Mode**

In Adjust mode, basically the same operations can be carried out like in Set Mode. All Sliders default to 0, though, marking their respective full extent of the image. Positive values shrink the DoD while negative values expand the DoD to include more data.
Time Speed [TSPD]

Time Speed allows image sequences to be sped up, slowed down, reversed or delayed. Image Interpolation offers smooth, high quality results. Time Speed should be used for static speed changes or to introduce delays in the footage. To apply animated changes in time, such as accelerating or decelerating time, use a Time Stretcher instead.

When operating in Flow mode, Optical Flow data is required.

This node does not generate optical flow directly. You have to create it manually upstream using an OpticalFlow node or by loading the forward/reverse vector channels from disk.

TimeSpeed does not interpolate the aux channels, but rather destroys them. In particular, the Vector/BackVector channels are consumed and destroyed after computation.

Add an OpticalFlow after the FlowSpeed if you want to generate flow vectors for the retimed footage.

Controls

**Speed**
This control is used to adjust the Speed, in percentage values, of the outgoing image sequence. Negative values reverse the image sequence. 200% Speed is represented by a value of 2.0, 100% is 1.0, 50% is 0.5 and 10% is 0.1.

The Speed control cannot be animated.

**Delay**
Use this control to Delay the outgoing image sequence by the specified number of frames. Negative numbers will offset time back and positive numbers will advance.

Interpolate Between Frames

When checked, frames before and after the current frame will be interpolated to create new frames. This usually offers smoother and cleaner results. When cleared, no interpolation will take place.

**Sample Spread**
This slider controls the strength of the interpolated frames on the current frame. A value of 0.5 causes 50% of the frame before and 50% of the frame ahead of the current frame to be blended with 0% of the current frame.
**Depth Ordering**

The Depth Ordering is used to determine which parts of the image should be rendered on top. This is best explained by example.

In a locked off camera shot where a car is moving through the frame, the background does not move, so it will produce small or slow vectors. The car will produce larger or faster vectors. The Depth Ordering in this case is Fastest Ontop, since the car will draw over the background.

In a shot where the camera pans to follow the car, the background will have faster vectors, and the car will have slower vectors, so the Depth ordering method would be Slowest Ontop.

**Clamp Edges**

Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to only use clamp edges to correct small gaps around the edges of an interpolated frame.

**Softness**

Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you'll want to keep the softness rather small at around 0.01. If you only have one checkbox enabled, you can use a larger softness at around 0.03.

**Source Frame and Warp Direction**

This control set allows for the choosing of which frames and which vectors are used to create the in-between frames. Each method ticked on will be blended into the result.

- **Prev Forward**: Will take the previous frame and use the Forward vector to interpolate the new frame.
- **Next Forward**: Will take the next frame in the sequence and use the Forward vector to interpolate the new frame.
- **Prev Backward**: Will take the previous frame and use the Back Forward vector to interpolate the new frame.
- **Next Backward**: Will take the next frame in the sequence and use the Back vector to interpolate the new frame.

**Time Stretcher [TST]**

The Time Stretcher node is similar to the Time Speed node, but it permits the speed of the clip to be animated over the course of the effect. Full spline control of the effect is provided, including smoothing. As a result, the Time Stretcher can be used to animate a single clip to 200, back to normal speed, pause for a second, and then play backward (like a VCR rewinding).
Image interpolation offers smooth, high quality results, all using a spline curve to adjust time non-linearly. To apply steady time changes such as frame rate changes, use a TimeSpeed instead. When operating in Flow mode, Optical Flow data is required.

This node does not generate optical flow directly; you have to create it manually upstream using an OpticalFlow node or by loading the forward/reverse vector channels from disk.

FlowStretcher does not interpolate the aux channels but rather destroys them. In particular, the Vector/BackVector channels are consumed/destroyed. Add an OpticalFlow after the FlowStretcher if you want to generate flow vectors for the retimed footage.

**Controls**

**Source Time**
This control designates from which frame in the original sequence to begin sampling.

When a Time Stretcher node is added to the node, the Source Time control already contains a Bezier spline with a single keyframe set to 0.0. The position of the keyframe is determined by the current time when the node is added to the node tree.

(The Source Time spline may not be immediately visible until Edit is selected from the Source Time’s contextual menu, or Display all Splines from the Spline Window’s contextual menu.)

**Interpolate Between Frames**
This toggles whether the Time Stretcher will interpolate between the next and previous frames.

**Sample Spread**
This determines the strength of the interpolated frames on the current frame. A value of 0.5 causes 50% of the frame before and 50% of the frame ahead of the current frame to be blended with 0% of the current frame. A value of 0.25 would blend 25% of the previous and next frames with 50% of the current frame. Set this control over 0.25 only in extreme cases.

**Clamp Edges**
Under certain circumstances this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to only use clamp edges to correct small gaps around the edges of an interpolated frame.

**Softness**
Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you only have one checkbox enabled, you can use a larger softness at around 0.03.
**Source Frame and Warp Direction**
This control set allows for the choosing of which frames and which vectors are used to create the in between frames. Each method ticked on will be blended into the result.

- **Prev Forward**: Will take the previous frame and use the Forward vector to interpolate the new frame.
- **Next Forward**: Will take the next frame in sequence and use the Forward vector to interpolate the new frame.
- **Prev Backward**: Will take the previous frame and use the Back Forward vector to interpolate the new frame.
- **Next Backward**: Will take the next frame in sequence and use the Back vector to interpolate the new frame.

**Depth Ordering**
The Depth ordering is used to determine which parts of the image should be rendered on top. This is best explained by example.

In a locked off camera shot where a car is moving through the frame, the background does not move, so it will produce small or slow vectors. The car will produce larger or faster vectors. The Depth ordering in this case is Fastest Ontop, since the car will draw over the background.

In a shot where the camera pans to follow the car, the background will have faster vectors, and the car will have slower vectors, so the Depth ordering method would be Slowest Ontop.

**Example**

Make certain that the current time is either the first or last frame of the clip to be affected in the project. Add the Time Stretcher node to the node tree. This will create a single point on the Source Time spline at the current frame. The value of the Source Time will be set to zero for the entire Global Range.

Set the value of the Source Time to the frame number to be displayed from the original source, at the frame in time it is to be displayed in during the project.

To shrink a 100-frame sequence to 25 frames, follow these steps:

- Change the Current Time to frame 0.
- Change the Source Time control to 0.0.
- Advance to frame 24.
- Change the Source Time to 99.
- Check that the spline result is linear.
- Fusion will render 25 frames by interpolating down the 100 frames to a length of 25.
- Hold the last frame for 30 frames, then play the clip backward at regular speed.
- Continue the example from above and follow the steps below.
- Advance to frame 129.
- Right-click on the Source Time control and select Set Key from the menu.
- Advance to frame 229 (129 + 100).
- Set the Source time to 0.0.
Chapter 95

Optical Flow

This chapter details the Optical Flow nodes available in the Fusion page.
Contents

Optical Flow [OF] 1789
Repair Frame [REP] 1791
Smooth Motion [SM] 1793
Tween [TW] 1794
Optical Flow [OF]

This node computes the Optical Flow between the frames of the input sequence. The optical flow can be thought of as a per pixel displacement vector which matches up features between two frames.

The computed optical flow is stored within the Vector and BackVector aux channels of the output image. At its highest quality settings, the Optical Flow node can be slow to process. If you find optical flow is too slow, you should consider tweaking the quality settings, using a disk cache, or pre-rendering it out into OpenEXR files.

There are quite a few quality settings to tweak, many with small or diminishing returns; depending on the settings, there is easily a variation of 10x in rendering time. As a hint to those interested in reducing process time, try experimenting with the Proxy, Number of Iterations, and Number of Warps sliders and changing the filtering to Bilinear.

OpticalFlow can only work with the frames you allow. If you trim an upstream Loader to a subframe range, OpticalFlow cannot see beyond the subframe range, even if there are additional frames on disk that it could use.

If the footage input flickers on a frame-by-frame basis, it is a good idea to deflicker the footage beforehand.

Currently, OpticalFlow will have to render twice for a downstream Time Stretcher or Time Speed to evaluate. This is because Time Speed needs A. FwdVec and B. BackVec to work, but OpticalFlow generates A. BackVec and A. FwdVec when it processes.

When pre-generating Optical Flow vectors, consider adding a SmoothMotion node afterward with smoothing for forward/ backward vectors enabled.

Inputs/Outputs

**Input**

This is the sequence of images for which you want to compute optical flow.

**Output**

This is the sequence of images with the optical flow stored in its Vector and BackVector channels.
Controls

Proxy (for tracking)
The input images are re-sized down by the proxy scale and tracked to produce the optical flow. This option is purely to speed up calculation of the optical flow. The computational time is roughly proportional to the number of pixels in the image. This means a proxy scale of 2 will give a 4x speed up and a proxy scale of 3 will give a 9x speed up.

Advanced
The Advanced Control section has parameter controls to tune the OpticalFlow vector calculations. The default settings have been chosen to be the best default values from experimentation with many different shots and should serve as a good standard. In most cases, tweaking of the advanced settings will not be needed.

Smoothness
This controls the Smoothness of the optical flow. Higher smoothness helps deal with noise, while lower smoothness brings out more detail.

Edges
This slider is another control for smoothness but applies smoothing based upon the color channel. It tends to have the effect of determining how edges in the flow follow edges in the color images. When it is set to Loose, the optical flow becomes smoother and tends to overshoot edges. When it is set Tight, details from the color images start to slip into the optical flow, which is not desirable, and edges in the flow more tightly align with the edges in the color images. As a rough guideline, if you are using the disparity to produce a Z-channel for post effects like DoF, then prefer it tight, and if you are using the disparity to do interpolation, you might want to be looser.

In general, if it is too tight, there can be problems with streaked out edges when the optical flow is used for interpolation.

Match Weight
This controls how the matching of neighborhoods in the subsequent image is done. When set to Match Color, large structural color features are matched. When set to Match Edges, small sharp variations in the color are matched. Typically, a good value for this slider is in the [0.7, 0.9] range although on some shots, values closer to 0.0 work well. Setting this option higher tends to improve the matching results in the presence of differences due to smoothly varying
shadows or local lighting variations between the left and right images. The user should still do a color match or deflickering on the initial images, if necessary, so they are as similar as possible. This option also helps with local variations like lighting differences due to light passing through a mirror rig.

**Mismatch Penalty**
This option controls how the penalty for mismatched regions grows as they become more dissimilar. The slider gives the choice between a balance of Quadratic and Linear penalties. Quadratic strongly penalizes large dissimilarities, while Linear is more robust to dissimilar matches. Moving this slider toward Quadratic tends to give a disparity with more small random variations in it, while Linear produces smoother more visually pleasing results.

**Number of Warps**
Turning this option down makes the optical flow computations faster. In particular, the computational time depends linearly upon this option. To understand what this option does, you need to understand that the optical flow algorithm progressively warps one image until it matches with the other image. After some point, convergence is reached and additional warps are just a waste of computational time. The default value in Fusion is set high enough that convergence should always be reached. You can tweak this value to speed up the computations, but it is good to watch what the optical flow is doing at the same time.

**Number of Iterations**
Turning this option down makes the computations faster. In particular, the computational time depends linearly upon this option. Just like adjusting Number of Warps, at some point adjusting this option higher will give diminishing returns and not produce significantly better results. By default, this value is set to something that should converge for all possible shots and can be tweaked lower fairly often without reducing the disparity’s quality.

**Filtering**
This controls filtering operations used during flow generation. Catmull-Rom filtering will produce better results, but at the same time, turning on Catmull-Rom will increase the computation time steeply.

**Repair Frame [REP]**

RepairFrame is used for replacing damaged or missing frames or portions of frames with scratches or other temporally transient artifacts.

You can use the Mask input to limit the repairs to certain areas. If your footage varies in color from frame to frame, sometimes the repair can be noticeable because, to fill in the hole, RepairFrame needs to pull color values from adjacent frames. Consider some kind of deflickering, color correction, and/or using a soft edged mask to help reduce these kinds of artifacts.

RepairFrame replaces parts of a frame by examining its two neighboring frames and thus requires three sequential frames as opposed to TimeStretcher/TimeSpeed, which work between two sequential frames to create a new in-between frame.
Unlike TimeStretcher and TimeSpeed, RepairFrame does not require, nor need, input Vector/BackVectors in order to work. An upstream OpticalFlow is not required.

RepairFrame internally will compute the optical flow it needs. This can make it slow to process.

RepairFrame will not pass through, but rather destroy, any aux channels after the computation is done.

See the Optical Flow node for control and setting information.

**Controls**

![Controls panel](image)

**Depth Ordering**

The Depth Ordering is used to determine which parts of the image should be rendered on top. This is best explained by an example.

In a locked off camera shot where a car is moving through the frame, the background does not move, so it will produce small or slow vectors, while the car will produce larger or faster vectors.

The depth ordering in this case is Fastest On Top since the car will draw over the background.

In a shot where the camera pans to follow the car, the background will have faster vectors and the car will have slower vectors, so the Depth ordering method would be Slowest Ontop.

**Clamp Edges**

Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to only use clamp edges to correct small gaps around the edges of an interpolated frame.

**Softness**

Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case you’ll want to keep the softness rather small at around 0.01. If you only have one checkbox enabled you can use a larger softness at around 0.03.
Source Frame and Warp Direction
This control set allows for the choosing of which frames and which vectors are used to create the in-between frames. Each method ticked on will be blended into the result.

- **Prev Forward**: Will take the previous frame and use the Forward vector to interpolate the new frame.
- **Next Forward**: Will take the next frame in the sequence and use the Forward vector to interpolate the new frame.
- **Prev Backward**: Will take the previous frame and use the Back Forward vector to interpolate the new frame.
- **Next Backward**: Will take the next frame in the sequence and use the Back vector to interpolate the new frame.
- **Advanced**: Please see the Advanced Controls chapter of Optical flow.

Smooth Motion [SM]

This node takes an image sequence and smooths it using optical flow to look at neighboring frames.

It is important that the input sequence has pre-computed Vector and BackVector channels contained in it, otherwise this tool will print error messages.

Check on the channels you want to temporally smooth. If a channel selected for smoothing is not present, SmoothMotion will not fail nor will it print any error messages.

SmoothMotion was initially designed for smoothing of the Disparity channel, where it helps reduce temporal edge/fringing artifacts.

It can also be used to smooth the Vector and BackVector channels, however do be aware that in various situations this can make the interpolated results worse, especially if there are conflicting motions or objects in the shot that move around erratically, jitter or bounce rapidly.

One thing you can try is using two or more SmoothMotion nodes in sequence to get additional smoothing. With one SmoothMotion node, the previous, current and next frames are examined for a total of 3; with 2 SmoothMotion nodes, 5 frames are examined, and with 3 SmoothMotion nodes, 7 frames are examined.

Another thing you can try is using 2 SmoothMotion nodes, but in the first node enable the smoothing of the Vector and BackVector channels, and in the second SmoothMotion enable the channels you want to smooth (e.g., Disparity). This way you use the smoothed vector channels to smooth Disparity.

You can also try using the smoothed motion channels to smooth the motion channels.
Controls

Channel
SmoothMotion can be applied to more than just the RGBA channels. It can also do all of the other aux channel groups in Fusion.

Tween [TW]

Tween constructs an in-between frame by interpolating between two frames using the optical flow. Tween is nearly identical in functionality to TimeSpeed and TimeStretcher. The major difference is that it works on two images that are not serial members of a sequence. As a consequence, it cannot use the Vector or BackVector aux channels stored in the images, and it must manually generate the optical flow. There is no need to add an upstream OpticalFlow node. The generated optical flow is thrown away and not stored back into the output frames.

Since optical flow is based upon color matching, it is a good idea to color correct your images to match ahead of time. Also, if you are having trouble with noisy images, it may also help to remove some of the noise ahead of time.

Tween will destroy any input aux channels. See the Optical Flow node for control and setting information.

Inputs/Outputs

InputA
This is an image to interpolate from.

InputB
This is an image to interpolate to.

Output
This is the interpolated image.
Controls

**Interpolation Parameter**
This option determines where the frame we are interpolating is, relative to the two source frames A and B. An Interpolation Parameter of 0.0 will give frame A back, a parameter of 1.0 will give frame B back, and a parameter of 0.5 will give a result that is halfway between A and B.

**Depth Ordering**
The Depth ordering is used to determine which parts of the image should be rendered on top. This is best explained by an example.

In a locked-off camera shot where a car is moving through the frame, the background does not move, so will produce small or slow vectors. The car will produce larger or faster vectors.

The Depth Ordering in this case is Fastest Ontop since the car will draw over the background.

In a shot where the camera pans to follow the car, the background will have faster vectors and the car will have slower vectors, so the Depth Ordering method would be Slowest Ontop.

**Clamp Edges**
Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to only use clamp edges to correct small gaps around the edges of an interpolated frame.

**Softness**
Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case, you’ll want to keep the softness rather small at around 0.01. If you only have one checkbox enabled you can use a larger softness at around 0.03.
Source Frame and Warp Direction

This control set allows for the choosing of which frames and which vectors are used to create the in between frames. Each method ticked on will be blended into the result.

- **Prev Forward**: Will take the previous frame and use the Forward vector to interpolate the new frame.
- **Next Forward**: Will take the next frame in the sequence and use the Forward vector to interpolate the new frame.
- **Prev Backward**: Will take the previous frame and use the Back Forward vector to interpolate the new frame.
- **Next Backward**: Will take the next frame in the sequence and use the Back vector to interpolate the new frame.
Chapter 96

Paint Node

This chapter details the Paint node available in the Fusion page.
Contents

Paint 1799
Hot Keys 1803
Modifiers 1804
Circle 1804
Clone Multistroke 1805
Copy Ellipse 1808
Copy Polyline 1809
Copy Rectangle 1811
Fill 1812
Multistroke 1813
Paint Group 1817
Polyline Stroke 1818
Stroke 1821
Paint

Paint is an extremely flexible, stroke-based system for making changes directly to a series of images. Use the Paint node for wire and rig removal, image cloning, or to rapidly create custom masks and mattes.

Fusion’s paint can even be used to create new images and artistic elements from scratch.

Each Paint node is made up of a series of brush strokes. These strokes are vector shapes created directly on a view. The type of brush used, the size of the stroke and the effect of the stroke on the image are all user-controllable. A wide range of apply modes and brush types are available.

Brush strokes can be made into editable polylines for fine control. They can be animated to change shape, length and size over time. The opacity and size of a stroke can be affected by velocity and pressure (when used with a supported tablet).

Unlimited undo and redo of paint provides the ability to experiment before committing changes to an image sequence. Paint strokes can be re-ordered, deleted and modified with virtually infinite flexibility.

Controls
Not all of the controls described here appear in all modes. Certain controls are only useful in a specific Paint mode and are hidden when they are not applicable. Additionally, several of the controls are considered to be self-explanatory; the purpose of a Center control, Angle or Size control should be relatively straightforward to determine.

To reduce complexity, these controls are not all described.

**Color Space**
The Color Space array of buttons is only visible when the current mode is set to Fill. These are used to select the color space when sampling colors around the fill center for inclusion in the fill range.

**R, G, B and Alpha**
When selected, these checkboxes reflect which color channel is being painted. For example, with R, G, and B off, and Alpha on, painting will occur on the Alpha channel.

**Brush Controls**

**Brush Shape**
- **Soft Brush**: The Soft Brush type is a circular brush with soft edges. Modify the size of the brush in the Viewer by holding the Command or Ctrl key down while dragging the mouse.
- **Circular Brush**: A Circular Brush is a brush shape with hard edges. Resize this brush interactively.
- **Image Brush**: The Image Brush allows images from any node in the node tree, or from a file system, to be used as a brush. See “Creating Custom Brushes” later in this chapter.
- **Single Pixel Brush**: The Single Pixel Brush is perfect for fine detail work, creating a brush exactly one pixel in size. No anti-aliasing is applied to the single pixel brush.
- **Square Brush**: A Square Brush is a brush shape with hard edges.

**Vary Size**
- **Constant**: The brush will be a constant size over the stroke.
- **With Pressure**: The stroke size will vary with the actual applied pressure.
- **With Velocity**: The stroke size will vary with the speed of painting. The faster the stroke, the thinner it is.

**Vary Opacity**
- **Constant**: The Constant brush will be a constant transparency over the entire stroke.
- **With Pressure**: The stroke transparency will vary with the applied pressure.
- **With Velocity**: The stroke transparency will vary with the speed of painting. The faster the stroke, the more transparent it is.

**Softness**
Use this control to increase or decrease the Softness of a soft brush.

**Image Source**
When using the Image Source brush type, select between three possible sources brush images.

**Node**
The image source is derived from the output of a node on the node tree. Drag the node into the Source node input to set the source.
Clip
The image source is derived from an image or sequence on disk. Any file supported by Fusion’s Loader can be used. Locate the file using the filename Clip browser that appears to set the clip used as a source.

Brush
Images stored in the Fusion > Brushes directory are used as a brush for the Paint node. Select the brush from the menu that appears.

Apply Controls

Apply Mode
- **Color**: The Color Apply Mode paints simple colored strokes on the screen. When used in conjunction with an image brush, it can also be used to tint the brush.
- **Clone**: The Clone Apply Mode copies portions of one image into another image, or to clones from the same image using adjustable positions and time offsets. Any image from the node tree can be used as the source image.
- **Emboss**: The Emboss Apply Mode embosses the portions of the image covered by the brush stroke.
- **Erase**: Erase reveals the underlying image through all other strokes, effectively erasing portions of the strokes beneath it without actually destroying the strokes.
- **Merge**: This Apply Mode effectively Merges the brush onto the image. This mode behaves in much the same way as the Color Apply Mode but has no color controls. It is best suited for use with the image brush type.
- **Smear**: Smear the image using the direction and strength of the brush stroke as a guide.
- **Stamp**: Stamp the brush onto the image, completely ignoring any alpha channel or transparency information. This mode is best suited for applying decals to the target image.
- **Wire**: This Wire Removal Mode is used to remove wires, rigging and other small elements in the frame by sampling adjacent pixels and drawing them in toward the stroke.

Stroke Controls
Size: This control adjusts the Size of the brush when the brush type is set to either soft brush or circle. The diameter of the brush is drawn in the Viewer as a small circle surrounding the mouse pointer. The size can also be adjusted interactively in the Viewer by holding the Command or Ctrl key while dragging the mouse pointer.

Spacing:
The Spacing slider determines the distance between dabs (samples used to draw a straight line along the underlying vector shape that composes a stroke or polyline stroke). Increasing the value of this slider increases the density of the stroke, whereas decreasing the value is likely to cause the stroke to assume the appearance of a dotted line.
**Stroke Animation:**
The Stroke Animation menu control provides several pre-built animation effects that can be applied to a paint stroke. This menu only appears for Vector strokes.

- **All Frames:** This default displays the stroke for All Frames of the project where a valid target image is available to the Paint node.
- **Limited Duration:** This exists on the number of frames specified by the Duration slider.
- **Write On:** When Write On is selected, an animation spline will be added to the paint stroke that precisely duplicates the timing of the paint stroke’s creation. The stroke will be written on the image exactly as it was drawn. To adjust the timing of the Write On effect, switch to the Spline Editor and use the Time Stretcher mode to adjust the overall length of the animation spline. To smooth or manually adjust the motion, try reducing the points in the animation spline.
- **Write Off:** Write Off will perform the reverse of Write On, drawing the stroke starting from the end and working backward to the start of the stroke.
- **Write On Then Off:** This mode will apply a Write On and then a Write Off animation mode to the stroke. Trail: Selecting the Trail mode will cause both the start and end points of the stroke to be animated simultaneously, offset from each other by the amount specified in the duration control. This has the effect of creating a segment of the stroke that follows the stroke as if it were a path. As with the Write On and Off effects, this will start at the frame that is current when the animation mode is selected. The timing of the animation can be adjusted manually using the Spline or Timeline Editors.
- **Duration:** Duration sets the duration of each stroke in frames. This control is only present for Multistrokes or when the stroke animation mode is set to Limited Duration. It is most commonly employed for frame-by-frame rotoscoping through a scene.
- **Each Vector stroke applied to a scene will have a duration in the Timeline that can be trimmed independently from one stroke to the next. The duration can be set to 0.5, which will allow each stroke to last for a single field only when the node tree is processing in Fields mode.
- **Write On and Write Off:** This range slider appears when the Stroke Animation is set to one of the Write On and Write Off methods. The range represents the beginning and end points of the stroke. Drag the low value upward to give the impression that the stroke is being erased, or drag the high value from 0.0 to 1.0 to give the impression that the stroke is being drawn on the screen. This control can be animated to good effect. It works most effectively when automatically animated through the use of the Write On, Write Off modes of the Stroke Animation menu.
- **Make Editable:** This button only appears for Vector strokes. Clicking on ‘Make Editable’ turns the current stroke into a polyline spline so that the shape can be adjusted or animated.

**Working with Paint Strokes**

- **Strokes Menu:** To create a new paint stroke, you can select the type of stroke you want from the menu that is displayed in the view. When a paint stroke is selected or edited, a menu is displayed in the view to select different editing options.
Types of Paint Strokes

- **Circle**: Creates a circular shape with animatable control over radius and center.
- **Clone Multistroke**: Like the Multistroke described further below, but specifically meant to clone elements from one image to the other.
- **Copy Polyline**: A Polyline area with animatable offset to clone elements from one image to the other.
- **Copy Rectangle**: A rectangular shape area with animatable offset to clone elements from one image to the other.
- **Fill**: Fills an area of the image based on adjustable color values.
- **Multistroke**: Perfect for those 100-strokes-per-frame retouching paint jobs like removing tracking markers. Much faster than the Stroke, but not editable later on.
- **Paint Group**: Allows easy grouping of multiple strokes with full control over center and size.
- **Polyline Stroke**: A fully editable stroke based on animatable polylines. Can be connected to existing polylines like Masks or Animation Paths.
- **Rectangle**: Creates a rectangular area.
- **Stroke**: The “standard” Stroke. Fully animatable and editable. Might become slow if hundreds of strokes are used in an image; for huge amounts of strokes it is better to use MultiStroke.

**Hot Keys**

Hot key control over Paint makes it interactive to adjust painting styles and color without having to navigate menus.

**While painting:**
- Hold Ctrl while left-dragging to change brush size.
- Hold Alt while clicking to pick color.

**While cloning:**
- Alt+click to set the clone source position. Strokes start cloning from here.
- Hold O to temporarily enable a 50% transparent overlay of the clone source (% can be changed with pref Tweak.CloneOverlayBlend).
- Press P to toggle an opaque overlay of the clone source.

**While overlay is showing:**
- Painting will “rub through” pixels onto the destination.
- Arrow keys will change the clone source position; you can also drag crosshair and angle control or Size slider.
- Alt+left or right will change the clone source angle.
- Alt+up or down will change the clone source size.
- Shift + Ctrl can be used with the above for greater or lesser adjustments [ & ] (Left and right square brackets) will change the clone source Time Offset (this requires a specific Clone Source node to be set in the Source Node field).
Copy Rect/Ellipse:
Hold Shift while dragging out the source to constrain the shape.

With single stroke selected (not multi or polyline strokes):
Press X or Y to flip the stroke.

Paint Groups:
Ctrl+drag to change the position of a group’s crosshair, without changing the position of the group.

Modifiers

Circle
The Circle only works on Paint nodes. Creates a circular shape with animatable control over radius and center. It can be applied by clicking on Circle in the Paint node’s Stroke menu.

Circle Controls

Center
The Center of the circle.

Radius
The Radius of the circle.

Apply Mode
For details see the Apply Controls of the Paint node.

Color
The Color of the circle.
**Opacity**
The Opacity of the circle.

**CloneMultistroke**
The CloneMultistroke is pretty much like the normal Multistroke, but specifically meant to clone areas from one image to the other. In addition to the Multistroke, it has a Source Node input, described later in this manual.

- Perfect for those 100-strokes-per-frame retouching paint jobs like removing tracking markers.
- Much faster than the Stroke, but not editable later on.
- It can be applied by clicking on the CloneMultistroke button in the Paint node’s Stroke menu.

**CloneMultistroke Controls**
Not all of the controls described here appear in all modes. Certain controls are only useful in a specific paint mode and are hidden when they are not applicable. Additionally, several of the controls are considered to be self-explanatory; the purpose of a Center control, Angle or Size control should be relatively straightforward to determine.

To reduce complexity, these controls are not all described.
**Brush Shape**
- **Soft Brush:** The Soft Brush type is a circular brush with soft edges. Modify the size of the brush in the Viewer by holding the Command or Ctrl key down while dragging the mouse.
- **Circular Brush:** A Circular Brush is a brush shape with hard edges. Resize this brush interactively.
- **Image Brush:** The Image Brush allows images from any node in the node tree, or from a file system, to be used as a brush. See Creating Custom Brushes later in this chapter.
- **Single Pixel Brush:** The Single Pixel Brush is perfect for fine detail work, creating a brush exactly one pixel in size. No anti-aliasing is applied to the single pixel brush.
- **Square Brush:** A Square Brush is a brush shape with hard edges.

**Vary Size**
- **Constant:** The brush will be a constant size over the stroke.
- **With Pressure:** The stroke size will vary with the actual applied pressure.
- **With Velocity:** The stroke size will vary with the speed of painting. The faster the stroke, the thinner it is.

**Vary Opacity**
- **Constant:** The Constant brush will be a constant transparency over the entire stroke.
- **With Pressure:** The stroke transparency will vary with the applied pressure.
- **With Velocity:** The stroke transparency will vary with the speed of painting. The faster the stroke, the more transparent it is.

**Softness**
Use this control to increase or decrease the Softness of a soft brush.

**Image Source**
When using the Image Source brush type, select between three possible sources brush images.
- **Node:** The image source is derived from the output of a node on the node tree. Drag the node into the Source Node input to set the source.
- **Clip:** The image source is derived from an image or sequence on disk. Any file supported by Fusion’s Loader can be used. Locate the file using the filename Clip browser that appears to set the clip used as a source.
- **Brush:** Images stored in the Fusion > Brushes directory are used as a brush for the Paint node. Select the brush from the menu that appears.

**Apply Controls**

**Apply Mode**
- **Color:** The Color apply mode paints simple colored strokes on the screen. When used in conjunction with an image brush, it can also be used to tint the brush.
- **Clone:** The Clone apply mode copies portions of one image into another image, or clones from the same image using adjustable positions and time offsets. Any image from the node tree can be used as the source image.
- **Emboss:** The Emboss apply mode embosses the portions of the image covered by the brush stroke.
- **Erase**: Erase reveals the underlying image through all other strokes, effectively erasing portions of the strokes beneath it without actually destroying the strokes.

- **Merge**: This apply mode effectively Merges the brush onto the image. This mode behaves in much the same way as the Color apply mode but has no color controls. It is best suited for use with the image brush type.

- **Smear**: Smear the image using the direction and strength of the brush stroke as a guide.

- **Stamp**: Stamp the brush onto the image, completely ignoring any alpha channel or transparency information. This mode is best suited for applying decals to the target image.

- **Wire**: This Wire Removal mode is used to remove wires, rigging and other small elements in the frame by sampling adjacent pixels and drawing them in toward the stroke.

- **Source Node**: Shows which node’s image output is used to clone from.

**Stroke Controls**

**Size**
This control adjusts the Size of the brush when the brush type is set to either Soft Brush or Circle. The diameter of the brush is drawn in the Viewer as a small circle surrounding the mouse pointer. The size can also be adjusted interactively in the Viewer by holding the Command or Ctrl key while click-dragging the mouse pointer.

**Spacing**
The Spacing slider determines the distance between dabs (samples used to draw a straight line along the underlying vector shape that composes a stroke or polyline stroke). Increasing the value of this slider increases the density of the stroke, whereas decreasing the value is likely to cause the stroke to assume the appearance of a dotted line.

**Stroke Animation**
The Stroke Animation menu control provides several pre-built animation effects that can be applied to a paint stroke. This menu only appears for Vector strokes.

- **All Frames**: This default displays the stroke for All Frames of the project where a valid target image is available to the Paint node.

- **Limited Duration**: This exists on the number of frames specified by the Duration slider.

- **Write On**: When Write On is selected, an animation spline will be added to the paint stroke that precisely duplicates the timing of the paint stroke’s creation. The stroke will be written on the image exactly as it was drawn. To adjust the timing of the Write On effect, switch to the Spline Editor and use the Time Stretcher mode to adjust the overall length of the animation spline. To smooth or manually adjust the motion, try reducing the points in the animation spline.

- **Write Off**: Write Off will perform the reverse of Write On, drawing the stroke starting from the end and working backward to the start of the stroke.

- **Write On Then Off**: This mode will apply a Write On and then a Write Off animation mode to the stroke.
• **Trail**: Selecting the Trail mode will cause both the start and end points of the stroke to be animated simultaneously, offset from each other by the amount specified in the duration control. This has the effect of creating a segment of the stroke that follows the stroke as if it were a path. As with the Write On and Off effects, this will start at the frame that is current when the animation mode is selected. The timing of the animation can be adjusted manually using the Spline or Timeline Editors.

**Duration**

Duration sets the duration of each stroke in frames. This control is only present for Multistrokes or when the stroke animation mode is set to Limited Duration. It is most commonly employed for frame-by-frame rotoscoping through a scene.

**NOTE**: Each Vector stroke applied to a scene will have a duration in the Timeline that can be trimmed independently from one stroke to the next. The duration can be set to 0.5, which will allow each stroke to last for a single field only when the node tree is processing in Fields mode.

**Write On and Write Off**

This range slider appears when the Stroke Animation is set to one of the Write On and Write Off methods. The range represents the beginning and end points of the stroke. Drag the low value upward to give the impression that the stroke is being erased, or drag the high value upward to give the impression that the stroke is being drawn on the screen. This control can be animated to good effect. It works most effectively when automatically animated through the use of the Write On, Write Off modes of the stroke animation menu.

**Make Editable**

This button only appears for Vector strokes. Clicking on ‘Make Editable’ turns the current stroke into a polyline spline so that the shape can be adjusted or animated.

**Copy Ellipse**

The Copy Ellipse only works on Paint nodes. It creates an elliptical shape to clone elements from one area of the image to the other. It can be applied by clicking on the Copy Ellipse button in the Paint node’s Stroke menu.

**Copy Ellipse Controls**
**Center X Y**
The Center of the Ellipse. Move this control to determine where the content will be copied to.

**Image**
The Source will be used to copy content to the destination.

**Fill**
The Fill color will be used to create a plain fill on the destination.

**Source Center X Y**
The Center of the Source Ellipse. Move this control to determine where the content will be copied from. Activate Show Source to see the onscreen controls.

**Width/Height Sliders**
The Width and Height of the ellipse. This can also be modified with the onscreen controls.

**Angle**
The Rotation of the ellipse. This can also be modified with the onscreen controls.

**Size**
The overall Size of the ellipse. This is a multiplier to the Width and Height settings.

**Softness**
The Softness of the edge of the ellipse.

**Opacity**
The overall opacity of the output.

**Flip Horiz/Flip Vert**
The area inside the ellipse will be flipped horizontally and/or vertically.

**Show Source**
Show the onscreen controls to adjust the position of the Source Ellipse.

**Apply Mode**
For more details see the Apply Controls of the Paint node section.

**Copy Polyline**
The Copy Polyline only works on Paint nodes. It creates a user-definable Polyline to clone elements from one area of the image to the other. See the Polylines and Rotoscoping section of this manual. It can be applied by clicking on the Copy Polyline button in the Paint node’s Stroke menu.
Copy Polyline Controls

**Center X Y**
The Center of the Polyline. Move this control to determine where the content will be copied to.

**Image**
The Source will be used to copy content to the Destination.

**Fill**
The Fill color will be used to create a plain fill on the Destination.

**Source Center X Y**
The Center of the Source Polyline. Move this control to determine where the content will be copied from. Activate Show Source to see the onscreen controls.

**Width/Height Sliders**
The Width and Height of the Polyline. This can also be modified with the onscreen controls.

**Angle**
The Rotation of the Polyline. This can also be modified with the onscreen controls.

**Size**
The overall Size of the Polyline. This is a multiplier to the Width and Height settings.

**Softness**
The Softness of the edge of the Polyline.

**Opacity**
The overall Opacity of the output.

**Flip Horiz/Flip Vert**
The area inside the Polyline will be flipped horizontally and/or vertically.

**Show Source**
Show the onscreen controls to adjust the position of the source Polyline.
**Apply Mode**
For more details see the Apply Controls of the Paint node section.

**Copy Rectangle**
The Copy Rectangle only works on Paint nodes. It creates a user-definable Rectangle to clone elements from one area of the image to the other. It can be applied by clicking on the Copy Rectangle button in the Paint node's Stroke menu.

**Copy Rectangle Controls**

![Copy Rectangle Controls](image)

**Center X Y**
The Center of the Rectangle. Move this control to determine where the content will be copied to.

**Image**
The Source will be used to copy content to the Destination.

**Fill**
The Fill color will be used to create a plain fill on the Destination.

**Source Center X Y**
The Center of the Source Rectangle. Move this control to determine where the content will be copied from. Activate Show Source to see the onscreen controls.

**Width/Height Sliders**
The Width and Height of the Rectangle. This can also be modified with the onscreen controls.

**Angle**
The Rotation of the Rectangle. This can also be modified with the onscreen controls.
Size
The overall Size of the Rectangle. This is a multiplier to the Width and Height settings.

Softness
The Softness of the edge of the Rectangle.

Opacity
The overall Opacity of the output.

Flip Horiz/Flip Vert
The area inside the Rectangle will be flipped horizontally and/or vertically.

Show Source
Show the onscreen controls to adjust the position of the source Rectangle.

Apply Mode
For more details see the Apply Controls of the Paint node section.

Fill
The Fill only works on Paint nodes. It fills an area of the image with a user-definable color. From the way it works, it can be compared with the Wand mask. It can be applied by clicking on the Fill button in the Paint node’s Stroke menu.

Fill Controls

Selection Point
The Selection Point is a pair of X and Y coordinates that determine from where in the source image the fill derives its initial color sample. This control is also seen as a crosshair in the Viewers. The selection point can be positioned manually, connected to a Tracker, Path, or other expressions.

Color Space
The Color Space button group determines the color space used when selecting the source color for the mask. The fill can operate in RGB, YUV, HLS, or LAB color spaces.
Channel
The Channel button group is used to select whether the color that is masked comes from all three color channels of the image, the alpha channel, or from an individual channel only. The exact labels of the buttons will depend on the Color Space selected for the fill operation. If the color space is RGB, the options will be R, G, or B. If YUV is the color space, the options will be Y, U, or V.

Range
The Range slider controls the range of colors around the source color that will be included in the fill. If the value is left at 0.0, only pixels of exactly the same color as the source will be considered part of the fill. The higher the value, the more similar colors in the source will be considered to be wholly part of the fill.

Range Soft Edge
The Range Soft Edge determines the falloff range of the colors selected. Any pixel within the range defined above will be treated as 100% for the fill. If the soft range is set to 0.0, no other pixels will be considered for the fill. Increasing the soft range will increase the number of colors close to, but not quite within, the range that will be included in the fill. These pixels will be semi-transparent in the fill.

Apply Mode
For more details see the Apply Controls of the Paint node section.

Multistroke
The Multistroke is the standard stroke in the Paint node. Perfect for those 100-strokes-per-frame retouching paint jobs like removing tracking-markers. Much faster than the Stroke, but not editable later on.

While Multistrokes aren’t directly editable, they can be grouped with the PaintGroup modifier, then tracked, moved and rotated by animating the PaintGroup instead. Alternatively, the Edit Multistrokes and Combine Strokes node scripts can be used to convert multistrokes into ordinary, editable strokes, and vice versa.

It can be applied by clicking on the Multi Stroke button in the Paint node’s Stroke menu.

Multistroke Controls
Not all of the controls described here appear in all modes. Certain controls are only useful in a specific paint mode and are hidden when they are not applicable. Additionally, several of the controls are considered to be self-explanatory the purpose of a Center control, Angle or Size control should be relatively straightforward to determine.

To reduce complexity, these controls are not all described.
Brush Controls

**Brush Shape**
- **Soft Brush**: The Soft Brush type is a circular brush with soft edges. Modify the size of the brush in the Viewer by holding Command or Ctrl down while dragging the mouse.
- **Circular Brush**: A Circular Brush is a brush shape with hard edges. Resize this brush interactively.
- **Image Brush**: The Image Brush allows images from any node in the node tree, or from a file system, to be used as a brush. See “Creating Custom Brushes” later in this chapter.
- **Single Pixel Brush**: The Single Pixel Brush is perfect for fine detail work, creating a brush exactly one pixel in size. No anti-aliasing is applied to the single pixel brush.
- **Square Brush**: A Square Brush is a brush shape with hard edges.

**Vary Size**
- **Constant**: The brush will be a constant size over the stroke.
- **With Pressure**: The stroke size will vary with the actual applied pressure.
- **With Velocity**: The stroke size will vary with the speed of painting. The faster the stroke, the thinner it is.
**Vary Opacity**
- **Constant**: The Constant brush will be a constant transparency over the entire stroke.
- **With Pressure**: The stroke transparency will vary with the applied pressure.
- **With Velocity**: The stroke transparency will vary with the speed of painting. The faster the stroke, the more transparent it is.

**Softness**
Use this control to increase or decrease the Softness of a soft brush.

**Image Source**
When using the Image Source brush type, select between three possible sources brush images.
- **Node**: The image source is derived from the output of a node on the node tree. Drag the node into the Source Node input to set the source.
- **Clip**: The image source is derived from an image or sequence on disk. Any file supported by Fusion’s Loader can be used. Locate the file using the filename Clip browser that appears to set the clip used as a source.
- **Brush**: Images stored in the Fusion > Brushes directory are used as a brush for the Paint node. Select the brush from the menu that appears.

**Apply Controls**

**Apply Mode**
- **Color**: The Color apply mode paints simple colored strokes on the screen. When used in conjunction with an Image brush, it can also be used to tint the brush.
- **Clone**: The Clone apply mode copies portions of one image into another image, or to clones from the same image using adjustable positions and time offsets. Any image from the node tree can be used as the source image.
- **Emboss**: The Emboss apply mode embosses the portions of the image covered by the brush stroke.
- **Erase**: Erase reveals the underlying image through all other strokes, effectively erasing portions of the strokes beneath it with out actually destroying the strokes.
- **Merge**: This apply mode effectively Merges the brush onto the image. This mode behaves in much the same way as the Color apply mode but has no color controls. It is best suited for use with the image brush type.
- **Smear**: Smear the image using the direction and strength of the brush stroke as a guide.
- **Stamp**: Stamp the brush onto the image, completely ignoring any alpha channel or transparency information. This mode is best suited for applying decals to the target image.
- **Wire**: This Wire Removal mode is used to remove wires, rigging and other small elements in the frame by sampling adjacent pixels and drawing them in toward the stroke.
Stroke Controls

Size
This control adjusts the Size of the brush when the brush type is set to either soft brush or circle. The diameter of the brush is drawn in the Viewer as a small circle surrounding the mouse pointer. The size can also be adjusted interactively in the Viewer by holding the Command or Ctrl key while click-dragging the mouse pointer.

Spacing
The Spacing slider determines the distance between dabs (samples used to draw a straight line along the underlying vector shape that composes a stroke or polyline stroke). Increasing the value of this slider increases the density of the stroke, whereas decreasing the value is likely to cause the stroke to assume the appearance of a dotted line.

Stroke Animation
The Stroke Animation menu control provides several pre-built animation effects that can be applied to a paint stroke. This menu only appears for Vector strokes.

- **All Frames**: This default displays the stroke for All Frames of the project where a valid target image is available to the Paint node.
- **Limited Duration**: This exists on the number of frames specified by the Duration slider.
- **Write On**: When Write On is selected, an animation spline will be added to the paint stroke that precisely duplicates the timing of the paint stroke’s creation. The stroke will be written on the image exactly as it was drawn. To adjust the timing of the Write On effect, switch to the Spline Editor and use the Time Stretcher mode to adjust the overall length of the animation spline. To smooth or manually adjust the motion, try reducing the points in the animation spline.
- **Write Off**: Write Off will perform the reverse of Write On, drawing the stroke starting from the end and working backward to the start of the stroke.
- **Write On Then Off**: This mode will apply a Write On and then a Write Off animation mode to the stroke.
- **Trail**: Selecting the Trail mode will cause both the start and end points of the stroke to be animated simultaneously, offset from each other by the amount specified in the duration control. This has the effect of creating a segment of the stroke that follows the stroke as if it were a path. As with the Write On and Off effects, this will start at the frame that is current when the Animation mode is selected. The timing of the animation can be adjusted manually using the Spline or Timeline Editors.
- **Duration**: Duration sets the duration of each stroke in frames. This control is only present for Multistrokes or when the Stroke Animation mode is set to Limited Duration. It is most commonly employed for frame-by-frame rotoscoping through a scene.

**NOTE**: Each Vector stroke applied to a scene will have a duration in the Timeline that can be trimmed independently from one stroke to the next. The duration can be set to 0.5, which will allow each stroke to last for a single field only when the node tree is processing in Fields mode.
• **Write On and Write Off**: This range slider appears when the Stroke Animation is set to one of the Write On and Write Off methods. The range represents the beginning and end points of the stroke. Drag the low value upward to give the impression that the stroke is being erased, or drag the high value from 0.0 to 1.0 to give the impression that the stroke is being drawn on the screen. This control can be animated to good effect. It works most effectively when automatically animated through the use of the Write On/Write Off modes of the Stroke animation menu.

• **Make Editable**: This button only appears for Vector strokes. Clicking on ‘Make Editable’ turns the current stroke into a polyline spline so that the shape can be adjusted or animated.

**Paint Group**

The Paint Group only works on Paint strokes and objects. It groups all currently selected paint strokes together, making it easier to handle them all together.

Multistroke modifiers can be grouped as well, which includes all the multistrokes contained within that modifier. By animating the Paint Group, it is thus possible to move, track and rotate a collection of multistrokes.

It can be applied by clicking on the Paint Group button in the Paint node’s Stroke menu.

**Paint Group Controls**

**Center X Y**
The Center of the Group. Modify this control to move the group around.

**Angle**
The entire group can be rotated using this control.

**Size**
Scales the entire group.

**Show Subgroup Controls**
Displays the controls of the individual strokes in the group and allows the user to modify them.

**Reset Center**
Puts the Center back to the position where it was when the group was created.

**Ungroup**
Disassembles the group back into individual strokes and deletes the Group modifier.

For temporary opening of the group, use the Show Subgroup controls switch instead.
Polyline Stroke

Fusion offers a Polyline Stroke mode. This provides the ability to create and manipulate a stroke in the same way that a path or mask might be created. To add a polyline stroke to the node tree, select the Polyline button from the Paint node's Stroke toolbar and click in the view to add the first point. Continue clicking to add additional points to the polyline.

Notice that the usual Polyline toolbar buttons will appear in the Viewer toolbar. Polyline strokes are created in Click Append mode by default, but they can also be created in Draw Append mode.

Polyline Stroke Controls

Not all of the controls described here appear in all modes. Certain controls are only useful in a specific paint mode and are hidden when they are not applicable. Additionally, several of the controls are considered to be self-explanatory; the purpose of a center control, angle or size control should be relatively straightforward to determine.

To reduce complexity, these controls are not all described.
Brush Controls

Brush Shape
- **Soft Brush**: The Soft Brush type is a circular brush with soft edges. Modify the size of the brush in the Viewer by holding Command or Ctrl down while dragging the mouse.
- **Circular Brush**: A Circular Brush is a brush shape with hard edges. Resize this brush interactively.
- **Image Brush**: The Image Brush allows images from any node in the node tree, or from a file system, to be used as a brush. See “Creating Custom Brushes” later in this chapter.
- **Single Pixel Brush**: The Single Pixel Brush is perfect for fine detail work, creating a brush exactly one pixel in size. No anti-aliasing is applied to the single pixel brush.
- **Square Brush**: A Square Brush is a brush shape with hard edges.

Vary Size
- **Constant**: The brush will be a constant size over the stroke.
- **With Pressure**: The stroke size will vary with the actual applied pressure.
- **With Velocity**: The stroke size will vary with the speed of painting. The faster the stroke, the thinner it is.

Vary Opacity
- **Constant**: The Constant brush will be a constant transparency over the entire stroke.
- **With Pressure**: The stroke transparency will vary with the applied pressure.
- **With Velocity**: The stroke transparency will vary with the speed of painting. The faster the stroke, the more transparent it is.

Softness
Use this control to increase or decrease the Softness of a soft brush.

Image Source
When using the Image Source brush type, select between three possible sources brush images.
- **Node**: The image source is derived from the output of a node on the node tree. Drag the node into the Source Node input to set the source.
- **Clip**: The image source is derived from an image or sequence on disk. Any file supported by Fusion’s Loader can be used. Locate the file using the filename Clip browser that appears to set the clip used as a source.
- **Brush**: Images stored in the Fusion > Brushes directory are used as a brush for the Paint node. Select the brush from a the menu that appears.

Apply Controls

Apply Mode
- **Color**: The Color apply mode paints simple colored strokes on the screen. When used in conjunction with an image brush, it can also be used to tint the brush.
- **Clone**: The Clone apply mode copies portions of one image into another image, or to clones from the same image using adjustable positions and time offsets. Any image from the node tree can be used as the source image.
- **Emboss:** The Emboss apply mode embosses the portions of the image covered by the brush stroke.

- **Erase:** Erase reveals the underlying image through all other strokes, effectively erasing portions of the strokes beneath it without actually destroying the strokes.

- **Merge:** This apply mode effectively Merges the brush onto the image. This mode behaves in much the same way as the color apply mode but has no color controls. It is best suited for use with the image brush type.

- **Smear:** Smear the image using the direction and strength of the brush stroke as a guide.

- **Stamp:** Stamp the brush onto the image, completely ignoring any alpha channel or transparency information. This mode is best suited for applying decals to the target image.

- **Wire:** This Wire Removal mode is used to remove wires, rigging and other small elements in the frame by sampling adjacent pixels and drawing them in toward the stroke.

- **Source Node:** Shows which node's image output is used to clone from.

### Stroke Controls

#### Size
This control adjusts the size of the brush when the brush type is set to either soft brush or circle. The diameter of the brush is drawn in the Viewer as a small circle surrounding the mouse pointer. The size can also be adjusted interactively in the Viewer by holding the Command or Ctrl key while click-dragging the mouse pointer.

#### Spacing
The Spacing slider determines the distance between dabs (samples used to draw a straight line along the underlying vector shape that composes a stroke or polyline stroke). Increasing the value of this slider increases the density of the stroke, whereas decreasing the value is likely to cause the stroke to assume the appearance of a dotted line.

![Spacing](image)

### Stroke Animation
The Stroke Animation menu control provides several pre-built animation effects that can be applied to a paint stroke. This menu only appears for Vector strokes.

- **All Frames:** This default displays the stroke for all frames of the project where a valid target image is available to the Paint node.

- **Limited Duration:** This exists on the number of frames specified by the Duration slider.

- **Write On:** When Write On is selected, an Animation spline will be added to the paint stroke that precisely duplicates the timing of the paint stroke's creation. The stroke will be written on the image exactly as it was drawn. To adjust the timing of the Write On effect, switch to the Spline Editor and use the Time Stretcher mode to adjust the overall length of the Animation spline. To smooth or manually adjust the motion, try reducing the points in the Animation spline.
• **Write Off**: Write Off will perform the reverse of Write On, drawing the stroke starting from the end and working backward to the start of the stroke.

• **Write On Then Off**: This mode will apply a Write On and then a Write Off animation mode to the stroke.

• **Trail**: Selecting the Trail mode will cause both the start and end points of the stroke to be animated simultaneously, offset from each other by the amount specified in the duration control. This has the effect of creating a segment of the stroke that follows the stroke as if it were a path. As with the Write On and Off effects, this will start at the frame that is current when the Animation mode is selected. The timing of the animation can be adjusted manually using the Spline or Timeline Editors.

**Duration**

Duration sets the duration of each stroke in frames. This control is only present for Multistrokes or when the stroke animation mode is set to Limited Duration. It is most commonly employed for frame-by-frame rotoscoping through a scene.

**NOTE**: Each Vector stroke applied to a scene will have a duration in the Timeline that can be trimmed independently from one stroke to the next.

The duration can be set to 0.5, which will allow each stroke to last for a single field only when the node tree is processing in Fields mode.

**Write On and Write Off**

This range slider appears when the Stroke Animation is set to one of the Write On and Write Off methods. The range represents the beginning and end points of the stroke. Drag the low value upward to give the impression that the stroke is being erased, or drag the high value from 0.0 to 1.0 to give the impression that the stroke is being drawn on the screen. This control can be animated to good effect. It works most effectively when automatically animated through the use of the Write On/Write Off modes of the stroke animation menu.

**Right Click Here for Shape Animation**

To animate the Polyline shape like Polyline Masks, right click on this control and choose animate.

**Stroke**

When the Paint node is first added to the node tree, the brush type is set to a medium sized soft, circular brush with a white Color apply mode.

Release the mouse button to end the creation of the stroke. To draw another stroke, simply click again and continue. A new stroke will be added to the image with the same settings as the last applied stroke. When the painting is complete, choose the Select button in the Paint toolbar to avoid accidentally adding new strokes.

While in Brush or Polyline modes, the controls displayed in the Node tab affect the next stroke created, not the strokes that are already created. To adjust the settings of an existing stroke, switch to Select mode using the Paint toolbar and select the stroke.

To add a stroke to the node tree, select the Polyline Button from the Paint Node’s Stroke toolbar, place the mouse or pen over the image, click-hold the left mouse button and start drawing.
Stroke Controls

Not all of the controls described here appear in all modes. Certain controls are only useful in a specific paint mode and are hidden when they are not applicable. Additionally, several of the controls are considered to be self-explanatory; the purpose of a center control, angle or size control should be relatively straightforward to determine. To reduce complexity, these controls are not all described.

Brush Controls

Brush Shape

- **Soft Brush**: The Soft Brush type is a circular brush with soft edges. Modify the size of the brush in the Viewer by holding Command or Ctrl down while dragging the mouse.
- **Circular Brush**: A Circular Brush is a brush shape with hard edges. Resize this brush interactively.
- **Image Brush**: The Image Brush allows images from any node in the node tree, or from a file system, to be used as a brush. See “Creating Custom Brushes” later in this chapter.
- **Single Pixel Brush**: The Single Pixel Brush is perfect for fine detail work, creating a brush exactly one pixel in size. No anti-aliasing is applied to the single pixel brush.
- **Square Brush**: A Square Brush is a brush shape with hard edges.
Vary Size
- **Constant**: The brush will be a constant size over the stroke.
- **With Pressure**: The stroke size will vary with the actual applied pressure.
- **With Velocity**: The stroke size will vary with the speed of painting. The faster the stroke, the thinner it is.

Vary Opacity
- **Constant**: The Constant brush will be a constant transparency over the entire stroke.
- **With Pressure**: The stroke transparency will vary with the applied pressure.
- **With Velocity**: The stroke transparency will vary with the speed of painting. The faster the stroke, the more transparent it is.

Softness
Use this control to increase or decrease the Softness of a soft brush.

Image Source
When using the Image Source brush type, select between three possible sources brush images.
- **Node**: The image source is derived from the output of a node on the node tree. Drag the node into the Source Node input to set the source.
- **Clip**: The image source is derived from an image or sequence on disk. Any file supported by Fusion’s Loader can be used. Locate the file using the filename Clip browser that appears to set the clip used as a source.
- **Brush**: Images stored in the Fusion > Brushes directory are used as a brush for the Paint node. Select the brush from the menu that appears.

Apply Controls

Apply Mode
- **Color**: The Color apply mode paints simple colored strokes on the screen. When used in conjunction with an image brush, it can also be used to tint the brush.
- **Clone**: The Clone apply mode copies portions of one image into another image, or to clones from the same image using adjustable positions and time offsets. Any image from the node tree can be used as the source image.
- **Emboss**: The Emboss apply mode embosses the portions of the image covered by the brush stroke.
- **Erase**: Erase reveals the underlying image through all other strokes, effectively erasing portions of the strokes beneath it with out actually destroying the strokes.
- **Merge**: This apply mode effectively Merges the brush onto the image. This mode behaves in much the same way as the color apply mode but has no color controls. It is best suited for use with the image brush type.
- **Smear**: Smear the image using the direction and strength of the brush stroke as a guide.
- **Stamp**: Stamp the brush onto the image, completely ignoring any alpha channel or transparency information. This mode is best suited for applying decals to the target image.
- **Wire**: This Wire removal mode is used to remove wires, rigging and other small elements in the frame by sampling adjacent pixels and drawing them in toward the stroke.
- **Source Node**: Shows which node’s image output is used to clone from.
Stroke Controls

**Size**
This control adjusts the Size of the brush when the brush type is set to either soft brush or circle. The diameter of the brush is drawn in the Viewer as a small circle surrounding the mouse pointer. The size can also be adjusted interactively in the Viewer by holding the Command or Ctrl key while click-dragging the mouse pointer.

**Spacing**
The Spacing slider determines the distance between dabs (samples used to draw a straight line along the underlying vector shape that composes a stroke or polyline stroke). Increasing the value of this slider increases the density of the stroke, whereas decreasing the value is likely to cause the stroke to assume the appearance of a dotted line.

Stroke Animation
The Stroke Animation menu control provides several pre-built animation effects that can be applied to a paint stroke. This menu only appears for Vector strokes.

- **All Frames**: This default displays the stroke for All Frames of the project where a valid target image is available to the Paint node.
- **Limited Duration**: This exists on the number of frames specified by the Duration slider.
- **Write On**: When Write On is selected, an Animation spline will be added to the paint stroke that precisely duplicates the timing of the paint stroke’s creation. The stroke will be written on the image exactly as it was drawn. To adjust the timing of the Write On effect, switch to the Spline Editor and use the Time Stretcher mode to adjust the overall length of the Animation spline. To smooth or manually adjust the motion, try reducing the points in the Animation spline.
- **Write Off**: Write Off will perform the reverse of Write On, drawing the stroke starting from the end and working backward to the start of the stroke.
- **Write On Then Off**: This mode will apply a Write On and then a Write Off animation mode to the stroke.
- **Trail**: Selecting the Trail mode will cause both the start and end points of the stroke to be animated simultaneously, offset from each other by the amount specified in the duration control. This has the effect of creating a segment of the stroke that follows the stroke as if it were a path. As with the Write On and Off effects, this will start at the frame that is current when the Animation mode is selected. The timing of the animation can be adjusted manually using the Spline or Timeline Editors.
**Duration**

Duration sets the duration of each stroke in frames. This control is only present for Multistrokes or when the stroke Animation mode is set to Limited Duration. It is most commonly employed for frame-by-frame rotoscoping through a scene.

**NOTE:** Each Vector stroke applied to a scene will have a duration in the Timeline that can be trimmed independently from one stroke to the next. The duration can be set to 0.5, which will allow each stroke to last for a single field only when the node tree is processing in Fields mode.

**Write On and Write Off**

This range slider appears when the Stroke Animation is set to one of the Write On and Write Off methods. The range represents the beginning and end points of the stroke. Drag the low value upward to give the impression that the stroke is being erased, or drag the high value from 0.0 to 1.0 to give the impression that the stroke is being drawn on the screen. This control can be animated to good effect. It works most effectively when automatically animated through the use of the Write On, Write Off modes of the stroke animation menu.

**Right Click Here for Shape Animation**

To animate the shape, like Polyline Masks, right-click on this control and choose animate.
Chapter 97

Particle Nodes

This chapter details the Particle nodes available in the Fusion page.
Contents

pAvoid [PAV] 1828
pBounce [PBN] 1830
pChangeStyle 1832
pCustom 1834
pCustomForce 1836
pDirectionalForce 1839
pEmitter 1841
pFlock 1845
pFriction 1847
pGradientForce 1848
pImageEmitter 1850
pKill 1854
pMerge 1855
pPointForce 1855
pRender [PRN] 1857
pSpawn [PSP] 1862
pTangentForce [PTF] 1863
pTurbulence [PTR] 1865
pVortex [PVT] 1867
Particle Common Controls 1869
Conditions Tab 1869
Regions Tab 1870
Mesh Regions 1871
pStyle 1873
pAvoid [PAV]

The pAvoid node is used to create a region or area within the image that affected particles will attempt to avoid entering and/or crossing.

It has two primary controls, one that determines the distance from the region a particle should be before it begins to move away from the region, and another to determine how strongly the particle moves away from the region.

A pAvoid node creates a ‘desire’ in a particle to move away from a specific region. If the velocity of the particle is stronger than the combined distance and strength of the pAvoid region, the particle's desire to avoid the region will not overcome its momentum and the particle will cross that region anyway.

Controls

Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

Distance
Determines the distance from the region a particle should be before it begins to move away from the region.

Strength
Determines how strongly the particle moves away from the region. Negative values will make the particles move toward the region instead.
Conditions Tab

See Particle Common Controls in this chapter.

Regions Tab
pBounce [PBN]

The pBounce node is used to create a region from which affected particles will bounce away when they come into contact with the region. The pBounce node has three main controls, as described below.

**Controls**

![pBounce node](image)

**Randomize**
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result.

Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Elasticity**
Elasticity affects the strength of a bounce, or how much velocity the particle will have remaining after impacting upon the Bounce region. A value of 1.0 will cause the particle to possess the same velocity after the bounce as it had entering the bounce. A value of 0.1 will cause the particle to lose 90% of its velocity upon bouncing off of the region.

The range of this control is 0.0 to 1.0 by default, but greater values can be entered manually. This will cause the particles to gain momentum after an impact, rather than lose it. Negative values will be accepted, but do not produce a useful result.

**Variance**
By default, particles that strike the Bounce region will reflect evenly off the edge of the Bounce region, according to the vector or angle of the region. Increasing the Variance above 0.0 will introduce a degree of variation to that angle of reflection. This can be used to simulate the effect of a rougher surface.
**Spin**
By default, particles that strike the region will not have their angle or orientation affected in any way. Increasing or decreasing the Spin value will cause the Bounce region to impart a spin to the particle based on the angle of collision, or to modify any existing spin on the particle. Positive values will impart a forward spin and negative values impart a backward spin. The larger the value, the faster the spin applied to the particle will be.

**Roughness**
This slider varies the bounce off the surface to slightly randomize particle direction.

**Surface Motion**
This slider makes the bounce surface behave as if it had motion, thus affecting the particles.

**Surface Motion Direction**
This thumbwheel control sets the angle relative to the bounce surface.

Regions Tab

See Particle Common Controls in this chapter.

pChangeStyle

The pChangeStyle node provides a mechanism for changing the appearance or style of particles that interact with a defined region. The primary controls in this node perfectly mirror those found in the Style tab of the pEmitter node. Particles that intersect or enter the region defined for this node will change as described by this node.

With the possible exception of the pCustom node, this is the only node that modifies the appearance of a particle, rather than its motion. It is often used to cause the appearance of particles changing in response to some event, like striking a barrier.

When using the pChangeStyle node in this fashion, it would be natural to assume that the node should be placed after the node causing the event. As an example, consider the creation of a particle system that appears to change its style after bouncing off a pBounce using a line region. In this case, the pChangeStyle node also uses a line region, positioned identically to the one in the pBounce node. Placing the pBounce before the pChangeStyle in the node tree causes the particles to bounce off the region before the pChangeStyle gets an opportunity to calculate its effect on the particle.

The result is that the particle is no longer intersecting with the pChangeStyle node’s region, and so the style never changes.

As a rule, to create a change in style that appears to be caused by a physical event created by another modifier node in the node tree, the pChangeStyle node must be placed before that node for the effect to work properly.
**Style Tab**

![Style Tab Interface]

**Randomize**
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Change Sets**
This option allows the user to change the particle’s Set to become influenced by other forces than the original particle. See Chapter 70, “Particle Systems,” to learn more about Sets.

**Style**
This option allows the user to change the particle’s Style and thus the look. See Chapter 70, “Particle Systems,” to learn more about Styles.
Conditions Tab

Regions Tab

See Particle Common Controls in this chapter.

**pCustom**

The pCustom node is used to create custom expressions that affect the properties of particles. This node is almost identical to the Custom node, except that the calculations affect properties of the particles rather than the properties of a pixel.

Additional information on the custom class of nodes can be found in documentation for the Custom node.

All of the operators, functions and conditional statements described for that node apply to pCustom as well, including Pixel-read functions for the two image inputs (e.g., getr1w(x,y), getz2b(x,y), and so on).

**pCustomForce**

The Particle Custom Force node allows you to change the forces applied to a particle system or subset. This node is quite likely the most complex and the most powerful node in Fusion. Any user moderately experienced with scripting or C++ programming, should find the structure and terminology used by the Custom Force node to be familiar.

The forces on a particle within a system can have their positions and rotations affected by forces. The position in XYZ and the Torque, which is the spin of the particle, are controlled by independent custom equations. The Custom Force node is used to create custom expressions and filters to modify the behavior. In addition to providing three image inputs, this node will allow for the connection of up to eight numeric inputs and as many as four XY position values from other controls and parameters in the node tree.

Setup Tab

Numbers Tab
Inter Tab

Force Tab
Positions Tab

pDirectionalForce

This node applies a uni-directional force that pulls the affected particles in a specified direction. Its primary controls affect the strength of the force, and the angle of the forces pull along the X, Y, and Z axis.

As the most common use of this node is to simulate gravity, the default direction of the pull is down along the Y axis (-90 degrees) and the default behavior is to ignore regions and affect all particles.

Controls
Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to select a new seed value randomly, or adjust the slider to select a new seed value manually.

Strength
Determines the power of the force. Positive values will move the Particles in the direction set by the controls, negative values will move the Particles in the opposite direction.

Direction
Determines the direction in X/Y Space.

Direction Z
Determines the direction in Z Space.

Conditions Tab

Regions Tab
See Particle Common Controls in this chapter.
The pEmitter node is the main source of Particles (pImageEmitter is another) and will usually be the first node used in any new particle system. This node contains controls for setting the initial position, orientation and motion of the particles, as well as controls for the visual style of each particle.

Like all other Particle nodes (with the exception of the pRender node), the pEmitter produces a particle set, not a visible image, and therefore cannot be displayed directly on a viewer. To view the output of a particle system, add a pRender node after the pEmitter.

**Controls**

This tab contains settings that affect the physics of the particles emitted by the node. These settings do not directly affect the appearance of the particles. They modify behavior like velocity, spin, quantity and lifespan instead.

**Randomize and Random Seed**

The Random Seed slider is used to seed all of the variance and random number generators used by the node when creating the particle system. Two pEmitter nodes with exactly the same settings for all controls and the same random seed will generate exactly the same particle system. Changing the random seed will cause variation between the nodes. Click on the Randomize button to automatically set a randomly chosen value for the Random Seed.
Style Tab

**Number**
This control is used to set the amount of new particles generated on each frame. A value of 1 would cause one new particle to be generated each frame. By frame 10, there would be a total of 10 particles in existence (unless Particle Lifespan was set to fewer than 10 frames).

Animate this parameter to specify the number of particles generated in total. For example, if only 25 particles in total are desired, animate the control to produce five particles on frame 0–4, then set a key on frame five to generate zero particles for the remainder of the project.

**Number Variance**
This modifies the amount of particles generated for each frame, as specified by the Number control. For example, if Number is set to 10.0 and Number Variance is set to 2.0, the emitter will produce anywhere from 9-11 particles per frame. If the value of Number Variance is more than twice as large as the value of Number, it is possible that no particles will be generated for a given frame.

**Lifespan**
This control determines how long a particle will exist before it disappears or ‘dies.’ The default value of this control is 100 frames, although this can be set to any value. The timing of many other particle controls is relative to the Lifespan of the particle. For example, the size of a particle can be set to increase over the last 80% of its life, using the Size Over Life graph in the Style tab of the pEmitter.

**Lifespan Variance**
Like Number Variance, the Lifespan Variance control allows the Lifespan of particles produced to be modified. If Particle Lifespan was set to 100 frames and the Lifespan Variance to 20 frames, particles generated by the emitter would have a lifespan of 90–110 frames.
**Color Source**
This provides the ability to specify from where the color of each particle is derived. The default setting is Use Style Color, which will provide the color from each particle according to the settings in the Style tab of the pEmitter node.

The alternate setting is Use Color From Region, which overrides the color settings from the Style tab and uses the color of the underlying bitmap region.

The Use Color From Region option only makes sense when the pEmitter region is set to use a bitmap produced by another node in the composition. Particles generated in a region other than a bitmap region will be rendered as white when the Use Color From Region option is selected.

**Position Variance**
This control determines whether or not particles can be ‘born’ outside the boundaries of the pEmitter region. By default, the value is set to zero, which will restrict the creation area for new particles to the exact boundaries of the defined region. Increasing this control’s value above 0.0 will allow the particle to be born slightly outside the boundaries of that region. The higher the value, the ‘softer’ the region’s edge will become.

**Regions Tab**

![Regions Tab Image]

**Velocity and Velocity Variance**
These determine the initial speed or velocity of new particles. By default, the particle has no velocity and will not move from its point of origin unless acted upon by outside forces. A velocity setting of 10.0 would cause the particle to cross the entire width of the image in one step so a velocity of 1.0 would cause the particle to cross the width of the image over 10 frames.

Velocity Variance modifies the velocity of each particle at birth, in the same manner described in Lifespan Variance and Number Variance above.

**Angle and Angle Variance**
This determines the angle at which particles with velocity applied will be heading at their birth.
Angle Z and Angle Z Variance
This is as above, except this control determines the angle of the particles along the Z space axis (toward or away from the camera).

Rotation Mode
This menu control provides two options to help determine the orientation of the particles emitted. When the particles are spherical, the effect of this control will be unnoticeable.

Absolute Rotation
The particles will be oriented as specified by the Rotation controls, regardless of velocity and heading.

Rotation Relative To Motion
The particles will be oriented in the same direction as the particle is moving. The Rotation controls can now be used to rotate the particle’s orientation away from its heading.

Rotation XYZ and Rotation XYZ Variance
These controls allow for Rotation of the individual particles. This can be particularly useful when dealing with a bitmap particle type, as the incoming bitmap may not be oriented in the desired direction.
Rotation XYZ Variance can be used to randomly vary the rotation by a specified amount around the center of the Rotation XYZ value to avoid having every particle oriented in the exact same direction.

Spin XYZ and Spin Variance
These provide a spin to be applied to each particle at birth. The particles will rotate ‘x’ degrees each frame, as determined by the value of Spin XYZ.
The Spin XYZ variances will vary the amount of rotation applied to each frame in the manner described by Number Variance and Lifespan Variance documented above.

Sets Tab
This tab contains settings that affect the physics of the particles emitted by the node. These settings do not directly affect the appearance of the particles. They modify behavior like velocity, spin, quantity and lifespan instead.
pFlock

Flocking is a mechanism that can be used to simulate the behavior of organic systems, such as a flock of birds or a colony of ants. Its use can make an otherwise mindless particle system appear to be motivated, or acting under the direction of intelligence.

The pFlock node works through two basic principles. Each particle attempts to stay close to other particles and each particle attempts to maintain a minimum distance from other particles. The strength of these desires produces the seemingly motivated behavior perceived by the viewer.

Controls

Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.
Flock Number
The value of this control represents the number of other particles that the affected particle will attempt to follow. The higher the value, the more visible ‘clumping’ will appear to be in the particle system and the larger the groups of particles will appear to be.

Follow Strength
This value represents the strength of each particle’s desire to follow other particles. Higher values will cause the particle to appear to expend more energy and effort to follow other particles. Lower values increase the likelihood that a given particle will break away from the pack.

Attract Strength
This value represents the strength of attraction between particles. When a particle moves farther from other particles than the Maximum Space defined in the pFlock node, it will attempt to move closer to other particles. Higher values cause the particle to maintain its spacing energetically, resolving conflicts in spacing more rapidly.

Repel Strength
This value represents the force applied to particles that get closer together than the distance defined by the Minimum Space control of the pFlock node. Higher values will cause particles to move away from neighboring particles more rapidly, shooting away from the pack.

Minimum/Maximum Space
This range control represents the distance each particle attempts to maintain between it and other particles. Particles will attempt to get no closer or farther than the space defined by the Minimum/Maximum values of this range control. Smaller ranges will give the appearance of more organized motion. Larger ranges will be perceived as disorganized and chaotic.

Conditions Tab
Regions Tab

See Particle Common Controls in this chapter.

pFriction

The pFriction node applies resistance to the motion of a particle, slowing the particle’s motion through a defined region. This node produces two types of Friction. One type reduces the Velocity of any particle intersecting/crossing the defined region, and one reduces or eliminates spin and rotation.

Controls

Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

Velocity Friction
This value represents the Friction force applied to the particle’s Velocity. The larger the value, the greater the friction, thus slowing down the particle.

Spin Friction
This value represents the Friction force applied to the particle’s Rotation or Spin. The larger the value, the greater the friction, thus slowing down the rotation of the particle.
Conditions Tab

Regions Tab

See Particle Common Controls in this chapter.

pGradientForce

The Gradient Force control accepts two inputs, one from a particle system and one from a bitmap image. The particles are affected by a force generated by the gradients in the alpha values of the input image. Particles will accelerate along the gradient, moving from white to black (high values to low).

This node can be used to give particles the appearance of moving downhill, or of following the contour of a provided shape.
Controls

Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result.

Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

Strength
Gradient Force has only one specific control, it affects the strength of the force and acceleration applied to the particles. Negative values on this control will cause the Gradient Force to be applied from black to white (low values to high values).

Conditions Tab
Regions Tab

See Particle Common Controls in this chapter.

pImageEmitter

The pImageEmitter node takes an input image and treats each pixel of the image as if it were a particle. The main differences between the pImageEmitter and the normal pEmitter is that instead of emitting particles randomly within a given region, this node emits pixels in a regular 2D grid with colors based on the input image.

Controls

The great majority of controls in this node are identical to those found in the pEmitter, and those controls are documented there. Below are the descriptions of the controls unique to the pImageEmitter node.
**X and Y Density**
The X and Y Density sliders are used to set the mapping of particles to pixels for each axis. They control the density of the sampling grid. A value of 1.0 for either slider indicates 1 sample per pixel. Smaller values will produce a looser, more pointillistic distribution of particles, while values above 1.0 will create multiple particles per pixel in the image.

**Alpha Threshold**
The Alpha Threshold is used for limiting particle generation so that pixels with semi-transparent alpha values will not produce particles. This can be used to harden the edges of an otherwise soft alpha channel. The higher the threshold value, the more opaque a pixel has to be before it will generate a particle. Note that the default threshold of 0.0 will create particles for every pixel, regardless of alpha, though many may be transparent and invisible.

**Lock Particle Color to Initial Frame**
Select this checkbox to force the particles to keep the color with which they were born throughout the life of the particle. If this is off, and the input image changes on successive frames, the particles will also change color to match the image. This allows video playback on a grid of particles.

**Create Particles Every Frame**
Enabling this creates a whole new set of particles every frame, instead of just one set on the frame. This can lead to very large particle systems, but allows some interesting effects, for example, if the particles are given some initial velocity or if emitting from an animated source. Try a small velocity, Angle Z of -90 and a seething Fast Noise as a source, to get smoothly-varying clouds of particles that you could fly through. Note that if this checkbox is left off, only one set of particles is ever created, and thus animating any of the emitter’s other controls will have no effect.

**X/Y/Z Pivot**
These controls allow you to position the grid of emitted particles.
Use Z Channel for Particle Z

If the input image used to generate the particles has a Z depth channel, that channel can be used to determine the initial position of the particle in Z space. This can have an interesting hollow shell effect when used in conjunction with camera rotation in the pRender node.

Regions Tab

See Particle Common Controls in this chapter.
**Sets Tab**

**NOTE:** Pixels with a black (transparent) alpha channel will still generate invisible particles, unless you raise the Alpha Threshold above 0.0. This can slow down rendering significantly.

An Alpha Threshold value of 1/255 = 0.004 is good for eliminating all fully-transparent pixels.

The pixels are emitted in a fixed-size 2D grid on the XY plane, centered on the Pivot position. Changing the Region from the default of All allows you to restrict particle creation to more limited areas. If you need to change the size of this grid, use a Transform 3D node after the pRender.

Remember that the various emitter controls apply only to particles when they are emitted. That is, they set the initial state of the particle, and do not affect it for the rest of its lifespan. Since pImageEmitter (by default) emits particles only on the first frame, animating these controls will have no effect. However, if the Create Particles Every Frame checkbox is turned on, new particles will be emitted each frame, and will use the specified initial settings for that frame.
The great majority of controls in this node are identical to those found in the pEmitter, and those controls are documented there. Below are the descriptions of the controls unique to the pImageEmitter node.

The Kill node is used to destroy (kill) any particle that crosses or intersects its region. It has no specific controls, as it has only one possible affect on a particle. The controls found in the Region tab are normally used to limit this node, by restricting the effect to particles which fall within a certain region, age, set, or by reducing the probability of the node applying to a given particle.

**Conditions Tab**

**Regions Tab**

See Particle Common Controls in this chapter.
**pMerge**

This node has no controls whatsoever. It serves to combine particles from two streams. Any nodes downstream of the Particle Merge node will treat the two streams as one.

The combined particles will preserve any sets assigned to them when they were created, making it possible for nodes downstream of the pMerge to isolate specific particles when necessary.

**pPointForce**

This node applies a force to the particles that emanates from a single point in 3D space. The pPointForce can either attract or repel particles within its sphere of influence. There are four controls specific to the pPointForce node.

**Controls**

**Randomize**

The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.
**Strength**
This parameter sets the Strength of the force emitted by the node. Positive values represent attractive forces. Negative values represent repellent forces.

**Power**
This determines the degree to which the Strength of the force falls off over distance. A value of zero causes there to be no falloff of strength. Higher values will impose an ever-sharper falloff in strength of the force with distance.

**Limit Force**
The Limit Force control is used to counter-balance potential problems with temporal sub-sampling. Because the position of a particle is only sampled once a frame (unless sub-sampling is increased in the pRender node), it is possible that a particle can overshoot the Point Force’s position and end up getting thrown off in the opposite direction. Increasing the value of this control reduces the likelihood that this will happen.

**X, Y, Z Center Position**
These controls are used to represent the X, Y, and Z coordinates of the point force in 3D space.

**Conditions Tab**

**Regions Tab**

See Particle Common Controls in this chapter.
pRender [PRN]

The pRender node converts the particle system to either an image or geometry. The default is a 3D particle system, which must be connected to a Renderer 3D to produce an image. This allows the particles to be integrated with other elements in a 3D scene before they are rendered.

Controls

Output Mode (2D/3D)

While the pRender defaults to 3D output, it can be made to directly render a 2D image instead, as with DF4. This is done with the 3D and 2D buttons on the Output Mode control. If the pRender is not connected to a 3D-only or 2D-only node, you can also switch it by selecting View > 2D Viewer from the display view’s context menu.

In 3D mode, the only controls in the pRender node that have any affect at all are Restart, Pre-roll and Automatic Pre-Roll, Sub-Frame Calculation Accuracy and Pre-Generate frames. The remaining controls affect 2D particle renders only. The pRender node also has a Camera input on the node tree that allows connection of a 3D Camera 3D node. This can...
be used in both 2D and 3D modes to allow control of the viewpoint used to render an output image.

**Render and the Display Views**
When the pRender node is selected in a node tree, all of the onscreen controls from Particle nodes connected to it are presented in the display views. This provides a fast, easy-to-modify overview of the forces applied to the particle system as a whole.

**Pre-Roll Options**
Particle nodes generally need to know the position of each particle on the last frame before they can calculate the affect of the forces applied to them on the current frame. This makes changing current time manually by anything but single frame intervals likely to produce an inaccurate image.

The controls here are used to help accommodate this by providing methods of calculating the intervening frames.

**Restart**
This control also works in 3D. Clicking on the Restart button will restart the particle system at the current frame, removing any particles created up to that point and starting the particle system from scratch at the current frame.

**Pre-Roll**
This control also works in 3D. Clicking on this button will cause the particle system to recalculate, starting from the beginning of the render range up to the current frame. It will not render the image produced. It will only calculate the position of each particle. This provides a relatively quick mechanism to ensure that the particles displayed in the views are correctly positioned.

If the pRender node is displayed when the Pre-Roll button is selected, the progress of the pre-roll is shown in the display view, with each particle shown as point style only.

**Automatic Pre-Roll**
Selecting the Automatic Pre-Roll checkbox causes the particle system to automatically pre-roll the particles to the current frame whenever the current frame changes. This prevents the need to manually select the Pre-Roll button whenever advancing through time in jumps larger than a single frame. The progress of the particle system during an Automatic Pre-Roll is not displayed to the views, to prevent distracting visual disruptions.

**About Pre-Roll**
Pre-Roll is necessary because the state of a particle system is completely dependent on the last known position of the particles. If the current time were changed to a frame where the last frame particle state is unknown, the display of the particle is calculated on the last known position, producing inaccurate results.

To demonstrate, add a pEmitter and pRender node to the composition. View the pEmitter in one of the display views. Right-click in the display view and select Views > 2D Viewer from the context menu.

Set the Velocity of the particles to 0.1. Place the pEmitter on the left edge of the screen and set the Current Frame to 0. Set a Render Range from 0–100 and press the Play button. Observe how the particle system behaves.

Stop the playback and return the current time to frame 0. Make sure that the Automatic Pre-Roll option is off in the pRender node. Now try jumping from frame 0 to 10, then to frame 60 and 90. Do not pass through the frames in between. Use the current time edit control or click in the
ruler directly to jump straight to the frame.

See how the particle system only adds to the particles it has already created and does not try to create the particles that would have been emitted in the intervening frames. Try selecting the Pre-Roll button in the Pre-Render node. Now the particle system state is represented correctly.

For simple, fast rendering particle systems, it is recommended to leave the Automatic Pre-Roll option on. For slower particle systems with long time ranges, it may be desirable to only Pre-Roll manually, as required.

- **Only Render in Hi-Q**
  Selecting this checkbox causes the style of the particles to be over-ridden when the Hi-Q checkbox is de-selected, producing only fast rendering Point style particles. This is useful when working with a large quantity of slow Image-based or Blob-style particles. To see the particles as they would appear in a final render, simply enable the Hi-Q checkbox.

- **View**
  This drop-down list provides options to determine the position of the camera view in a 3D particle system. The default option of Scene (Perspective) will render the particle system from the perspective of a virtual camera, the position of which can be modified using the controls in the Scene tab. The other options provide orthographic views of the front, top and side of the particle system.

  It is important to realize that the position of the onscreen controls for Particle nodes is unaffected by this control. In 2D mode the onscreen controls are always drawn as if the display view were showing the front orthographic view. (3D mode gets the position of controls right at all times.)

  The View setting is ignored if a Camera 3D node is connected to the pRender node’s Camera input on the node tree, or if the pRender is in 3D mode.

### Output Mode

**Blur, Glow and Blur Blend**

These sliders apply a Gaussian blur, glows and blur blending to the image as it is rendered, which can be used to soften the particles and blend them together. The end result is no different than adding a Blur after the pRender node in the node tree. For 2D particles only.

**Sub Frame Calculation Accuracy**

This determines the number of sub-samples taken between frames when calculating the particle system. Higher values will increase the accuracy of the calculation but also increase the amount of time taken to render the particle system.

**Pre-Generate Frames**

This control is used to cause the particle system to pre-generate a set number of frames before its first valid frame. This is used to give a particle system an initial state from which to start.

A good example of when this might be useful is in a shot where particles are used to create the smoke rising from a chimney. Pre-Generate Frames would be set to a number high enough to ensure that the smoke is already present in the scene before the render begins, rather than having it just starting to emerge from the emitter for the first few frames.

**Kill Particles that Leave the View**

Selecting this checkbox control will automatically destroy any particles that leave the visible boundaries of the image. This can help to speed render times. Particles destroyed in this fashion will never return, regardless of any external forces acting upon them.
**Generate Z Buffer**
Selecting this checkbox will cause the pRender node to produce a Z Buffer channel in the image. The depth of each particle is represented in the Z Buffer. This channel can then be used for additional depth operations like Depth Blur, Depth Fog, and Downstream Z Merging.

Enabling this option is likely to increase the render times for the particle system dramatically.

**Depth Merge Particles**
Enabling this option will cause the particles to be merged together using Depth Merge techniques, rather than layer-based techniques.

---

**Scene Tab**

![Scene Tab Image]

**Z Clip**
The Z Clip control is used to set a clipping plane in front of the camera. Particles that cross this plane are clipped, preventing them from impacting on the virtual lens of the camera and dominating the scene.

**Grid Tab**
None of the controls in this tab have any effect on 3D particles.

The Grid is a helpful, non-rendering display guide used to orient the 2D particles in 3D space. The grid is never seen in renders, just like a center crosshair is never seen in a render. The width, depth, number of lines, and grid color can be set using the controls found in this tab.

These controls cannot be animated.
Image Tab

The controls in the Image tab of this node determine the width, height and aspect of the image. Refer to the Creator Common Controls page for details on the use of these controls.
**Motion Blur**

As with other 2D nodes in Fusion, Motion Blur is enabled from within the Fusion tab. You may set Quality, Shutter Angle, Sample Center, and Bias, and Blur will be applied to all moving particles.

**NOTE:** Motion Blur on 3D mode particles (rendered with a Renderer 3D) also requires that identical motion blur settings are applied to the Renderer 3D node.

**pSpawn [PSP]**

The pSpawn node makes each effected particle act as an emitter that can produce one or more particles of its own. The original particle continues until the end of its own lifespan, and each of the particles it emits becomes wholly independent with a lifespan and properties of its own.

As long as a particle falls under the effect of the pSpawn node, it will continue to generate particles. It is important to restrict the effect of the node with limiters like Start and End Age, Probability, Sets and Regions, and by animating the parameters of the emitter so that the node is operative only when required.

**Controls**

The pSpawn node has a large number of controls, most of which exactly duplicate those found within the pEmitter node. There are a few controls that are unique to the pSpawn node, and their effects are described below.
Affect Spawned Particles
Selecting this checkbox causes particles created by spawning to also become affected by the Spawn node on subsequent frames. This can exponentially increase the number of particles in the system, driving render times up to an unreasonable degree. Use this checkbox cautiously.

Velocity Transfer
This control determines how much velocity of the source particle is transferred to the particles it spawns. The default value of 1.0 causes each new particle to adopt 100 percent of the velocity and direction from its source particle. Lower values will transfer less of the original motion to the new particle.

Regions Tab
See Particle Common Controls in this chapter.

pTangentForce [PTF]
This node is used to apply a tangential force to the particles, a force that is applied perpendicularly to the vector between the pTangentForce’s region and the particle it is affecting.

The controls for this node are used to position the offset in 3D space and to determine the strength of the tangential force along each axis independently.

Controls
Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result.

Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

X, Y, Z Center Position
These controls are used to represent the X, Y, and Z coordinates of the Tangent force in 3D space.

X, Y, Z Center Strength
These controls are used to determine the Strength of the Tangent force in 3D space.

Conditions Tab

Regions Tab
See Particle Common Controls in this chapter.
pTurbulence [PTR]

The pTurbulence node imposes a frequency-based chaos on the position of each particle, causing the motion to become unpredictable and uneven. The controls for this node affect the strength and density of the Turbulence along each axis.

Controls

Randomize
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

X, Y and Z Strength
The Strength control affects the amount of chaotic motion imparted to particles.

Strength Over Life
This LUT control can be used to control the amount of turbulence applied to a particle according to its age. For example, a fire particle may originally have very little turbulence applied at the start of its life, and as it ages, the turbulence increases.

Density
Use this control to adjust the density of the turbulence. Higher values will produce finer variations in the turbulence produced.
Conditions Tab

Regions Tab

See Particle Common Controls in this chapter.
The pVortex node applies a rotational force to each particle, causing them to be drawn toward the source of the Vortex. In addition to the Common Particle Controls, the pVortex node also has the following controls.

**Controls**

**Randomize**
The Seed slider and Randomize button are presented whenever a Fusion node relies on a random result. Two nodes with the same seed values will produce the same random results. Click on the Randomize button to randomly select a new seed value, or adjust the slider to manually select a new seed value.

**Strength**
This control determines the Strength of the Vortex Force applied to each particle.

**Power**
This control determines the degree to which the Strength of the Vortex Force falls off with distance.

**X, Y, and Z Offset**
Use these sliders to set the amount by which the vortex Offsets the affected particles.

**Size**
Used to set the Size of the vortex force.
Angle X and Y
These sliders control the amount of rotational force applied by the Vortex along the X and Y axis.

Conditions Tab

Regions Tab

See Particle Common Controls in this chapter.
Particle Common Controls

The Common Controls can be found in every Particle node inside Fusion.

Conditions Tab

Probability
This control determines the Probability or percentage chance that the node will affect any given particle.

The default value of 1.0 will affect all particles. A setting of 0.6 would mean that each particle has a 60 percent chance of being affected by the control.

Probability is calculated for each particle on each frame. For example, a particle that is not affected by a force on one frame has the same chance of being affected on the next frame.

Start/End Age
This range control can be used to restrict the effect of the node to a specified percentage of the particle lifespan.

For example, to restrict the effect of a node to the last 20 percent of a particle’s life, set the start value to 0.8 and the end value remains at 1.0. The node on frames 80 through 100 only affect a particle with a lifespan of 100 frames.

Set Mode and Sets
This menu control determines if the Particle node’s effect will be applied to all particles, limited only to particles from a specified set(s), or applied to all particles except the selected set(s).

Sets are assigned by the nodes that create particles the pEmitter, pimage Emitter, the pChangeStyle and the pSpawn nodes.
Regions Tab

Region
Regions are used to restrict the node’s effect to a geometric region or plane, and to determine the area where particles are created in a pEmitter node. There are seven types of regions, each with its own controls.

All
In 2D, the Particles will be created anywhere within the boundaries of the image. In 3D, this region describes a cube 1.0 x 1.0 x 1.0 units in size.

Bezier
Bezier mode uses a user-created polyline to determine the region where particles are created. The Bezier mode works in both 2D and 3D modes, however the Bezier polyline region can only be created in 2D.

To animate the shape of the polyline over time or to connect this polyline to another polyline, right-click on the Polyline label at the bottom of the control and select the appropriate option from the context menu.

Bitmap
A Bitmap source from one of the other nodes in the composition will be used as the region where particles are born.

Cube
A full 3D Cube is used to determine the region within which particles are created. The height, width, depth, and XYZ positions can all be determined by the user and animated over time.

Line
A simple Line control determines where particles are created. The Line is composed of two end-points, which can be connected to Paths or Trackers, as necessary. As with Bezier, this region type works in 3D, but the line itself can only be created and adjusted in 2D.

Mesh
Any 3D Mesh can be used as a region. In Mesh mode the region can also be restricted by the Object ID using the ObjectID slider. See below for a deeper explanation of how mesh regions work.

Rectangle
The Rectangle region type is like the Cube type, except that this region has no depth in Z space. Unlike other 2D emitter regions, this region can be positioned and rotated in Z space.

Sphere (3D)
This is a spherical 3D emitter region with size and center Z controls. Sphere (3D) is the default region type for a new pEmitter node.
Start/End X,Y,Z Offset
(Line mode only) These controls define the Start and End point of the line in 3D Space.

Mesh Regions

Region Type
The Region Type control allows the artist to choose whether the region will include the inner volume, or just the surface. For example, when a mesh region is used with a pEmitter, this control would determine whether the particles are emitted from the surface or the full volume.

Winding Rule and Winding Ray Direction
The Winding Rule and Winding Ray Direction controls determine how the mesh region will handle particle creation with meshes that are not completely closed, as is common in many meshes imported from external applications. This scenario is common with imported mesh geometry, and even geometry which appears closed will frequently appear to ‘leak’ thanks to improperly welded vertices.

To determine if a particle is in the interior of an object, a ray is cast from infinity through that particle and then out to -infinity. The Winding Ray Direction determines which direction this ray is cast in. Each time a surface is pierced by the ray it is recorded and added onto a total to generate a winding number. Going against a surfaces normal counts as +1 and going with the normal counts as -1.

The Winding Rule is then used to determine what is inside/outside. For example, setting the Winding Rule to Odd means that only particles with odd values for the winding number are kept when creating the particles. The exact same approach is used to ensure that polylines that intersect themselves are closed properly.

For example, the following node tree and image shows two image planes being used as a mesh region for particle creation.
By setting the region’s Winding Ray Direction to the Z (blue) axis, this mesh can then be treated as a closed volume for purposes of particle creation, as pictured below.

Limit By ObjectID, ObjectID
Selecting this checkbox allows the artist to use the slider found below the checkbox to filter the scene geometry so that only geometry with a matching ObjectID property is used as part of the region.

This menu control determines if the Particle node’s effect will be applied to all particles, limited only to particles from a specified set(s), or applied to all particles except the selected set(s).

Sets are assigned by the nodes that actually create particles. These are the pEmitter, pImage Emitter, the pChangeStyle and the pSpawn nodes.
pStyle

The Styles tab occurs in the Particle Emitter, Particle Spawn, Particle ChangeStyle and Particle Image Emitter. In the Style tab, the type and look of the particles is determined.

Style Tab
The Style tab provides controls that affect the appearance of the particles, allowing the look and feel of the particles to be determined and animated over time.

Style Type
The Style Menu control provides access to the various types of particles supported by the Particle Suite. Each style has its own specific controls, as well as controls it will share with other styles.

Point Style
This option produces particles exactly one pixel in size. Controls that are specific to Point Style are Apply Mode and Sub Pixel Rendered.

Bitmap Style and Brush Style
Both the Bitmap and Brush Styles produce particles based on an image file. The Bitmap Style relies on the image from another node in the node tree and the Brush Style uses image files in the Brushes directory. They both have numerous controls for affecting their appearance and animation, described below.

Blob Style
This option produces large, soft spherical particles, with controls for Color, Size, Fade timing, Merge method, and Noise.

Line Style
This style produces straight line-type particles with optional ‘falloff.’ The Size to Velocity control described below (under Size Controls) is often useful with this Line type. The Fade control adjusts the amount of falloff over the length of the line.

Point Cluster Style
This style produces small clusters of single pixel particles. Point Clusters are similar to the Point style, however they are more efficient when a large quantity of particles is required. This style shares controls with the Point style. Additional controls specific to Point Cluster style are Number of Points and Number Variance.

Color
This standard Color Control selects the color and alpha values of the particles generated by the emitter.

Color Variance
These range controls provide a means of expanding the colors produced by the pEmitter. Setting the Red variance range at -0.2 to +0.2 will produce colors that vary 20% on either side of the red channel, for a total variance of 40%. If the pEmitter is set to produce R0.5, G0.5, B0.5 (pure gray), the variance shown above will produce points with a color range between R0.3, G0.5, B0.5 and R0.7, G0.5, B0.5.

To visualize color space as values between 0-256 or as 0-65535, change the values used by Fusion using the Show Color As option provided in the General tab within the Preferences dialog.
Lock Color Variance
This checkbox locks the color variance of the particles. Unlocking this allows the color variance to be applied differently to each color channel, giving rise to a wider range of colors.

Color Over Life
This standard gradient control allows for the selection of a range of color values to which the particle will adhere over its lifetime.

The left point of the gradient represents the particle color at birth. The right point shows the color of the particle at the end of its lifespan.

Additional points can be added to the gradient control to cause the particle color to shift throughout its life.

This type of control can be extremely useful for fire-type effects (for example, the flame may start out blue, turn orange and end a darker red). The gradient itself can be animated over time by right-clicking on the control and selecting Animate from the context menu. All points on the gradient will be controlled by a single Color Over Life spline, which controls the speed at which the gradient itself changes. You may also use the From Image modifier, which produces a gradient from the range of colors in an image along a line between two points.

Size Controls
The majority of the Size Controls are self-explanatory. The Size and Size Variance controls are used to determine the size and degree of size variation for each particle. It is worth noting that the Point style does not have size controls (each point is a single pixel in size and there is no additional control).

When a Bitmap Particle style is used, a value of 1.0 indicates that each particle should be exactly the same size as the input bitmap. A value of 2.0 will scale the particle up in size by 200%. For the best quality particles, always try to make the input bitmap as big, or bigger, than the largest particle produced by the system.

For the Point Cluster style, the size control adjusts the density of the cluster, or how close together each particle will get.

There are additional size controls that can be used to further adjust the size of particles based on velocity and depth.

Size to Velocity
This increases the size of each particle relative to the Velocity or speed of the particle. The velocity of the particle is added to the size, scaled by the value of this control.

1.0 on this control, such as for a particle traveling at 0.1, will add another 0.1 to the size (velocity * sizetovelocity + size = newsize). This is most useful for Line styles, but the control can be used to adjust the size of any style.

Size Z Scale
This control measures the degree to which the size of each particle is increased or decreased according to its depth (position in Z space). The effect is to exaggerate or reduce the impact of perspective. The default value is 1.0, which provides a relatively realistic perspective effect.

Objects on the focal plane (Z = 0.0) will be actual-sized. Objects farther along Z will become smaller. Objects closer along Z will get larger.

A value of 2.0 will exaggerate the effect dramatically, whereas a value of 0.0 will cancel the effects of perspective entirely.
**Size Over Life**
This LUT spline control determines the size of a particle throughout its lifespan. The vertical scale represents a percentage of the value defined by the Size control, from 0 to 200%. The horizontal scale represents a percentage of the particle’s lifespan (0 to 100%).

This graph supports all of the features available to a standard LUT editor. These features can be accessed by right-clicking on the graph. It is also possible to view and edit the graph spline in the larger Spline view.

**Fade Controls**
This simple range slider provides a mechanism for fading a particle at the start and end of its lifetime. Increasing the Fade In value will cause the particle to fade in at the start of its life. Decreasing the Fade Out value will cause the particle to fade out at the end of its life.

This control’s values represent a percentage of the particle’s overall life, therefore, setting the Fade In to 0.1 would cause the particle to fade in over the first 10% of its total lifespan. For example, a particle with a life of 100 frames would fade in from frame 0.10.

**Merge Controls**
This set of particle controls affects the way individual particles are merged together. The Subtractive/Additive slider works exactly as documented in the standard Merge node. The Burn-In control will cause the particles to overexpose, or “blow out,” when they are combined together.

None of the Merge controls will have any effect on a 3D particle system.

**Blur Controls**
This set of particle controls can be used to apply a Blur to the individual particles. Blurring can be applied globally, by age, or by Z depth position.

None of the Blur controls will have any effect on a 3D particle system.

**Blur and Blur Variance**
These controls apply Blur to each particle. Unlike the Blur in the pRender node, this is applied to each particle independently before the particles are merged together. The Blur Variance slider modifies the amount of blur applied to each particle.

**Blur Over Life**
This spline graph controls the amount of Blur that is applied to the particle over its life. The vertical scale represents a percentage of the value defined by the Blur control. The horizontal scale represents a percentage of the particle’s lifespan.

This graph supports all of the features available to a standard LUT editor. These features can be accessed by right-clicking on the graph. It is also possible to view and edit the graph spline in the larger Spline view.

**Z Blur (DoF) and DoF Focus**
This slider control applies blur to each particle based on its position along the Z axis.

The DoF Focus range control is used to determine what area of the image remains in focus. Lower values along Z are closer to the camera. Higher values are farther away. Particles within the range will remain in focus. Particles outside that range will have the blur defined by the Z Blur control applied to them.

**Apply Mode**
This control only applies to 2D particles. 3D particle systems are not affected.
Add
Overlapping particles are combined by adding the color values of each particle together.

Merge
Overlapping particles are merged together.

Style Bitmap
(Bitmap Style Only) This control appears when the Bitmap style is selected, along with an orange Style Bitmap input on the node’s icon in the Node view. Connect a 2D node to this input to provide images to be used for the particles. You can do this on the Node view, or you may drag and drop the image source node onto the Style Bitmap control from the Node Editor or Timeline, or right-click on the control and select the desired source from the Connect To menu.

Brush
(Brush Style Only) This drop-down list shows the names of any image files stored in the Brushes directory. The location of the Brushes directory is defined in the Preferences dialog, under Path Maps. The default is the Brushes subdirectory within Fusion’s install folder. If no images are in this directory, the only option in the menu will be None, and no particles will be rendered.

Animate
(Bitmap Style Only) This list determines how the animation of the bitmap source is applied to newly-created particles. It can be hard to visualize the impact of this control until it has been experimented with. A good way to experiment is to load the node tree in the Fusion > Examples directory called pTextParticleAge.comp and try out the three settings. View the Text node in the display view and the pRender node another view, then step through the frames using the [ and ] keys.

Over Time
All particles use the image produced by the Style Bitmap node at the current time, and change to each successive image together in step, as time increases. A particle created at frame 1 will contain the image at frame 1 of the Style Bitmap. At frame 2, the original particle will use the image from frame 2, and so will any new particles. All created particles will share exactly the same bitmap image from their source at all times.

Particle Age
Each particle animates through the sequence of images provided by the Style Bitmap node, independently of other particles. In other words, an individual particle’s appearance is taken from the Style Bitmap node at successive times, indexed by its age.

Particle Birth Time
New particles take the image from the Style Bitmap node at the current time and keep it unchanged until the end of the particle’s lifespan. Thus, particles generated on a given frame will all have the same appearance and will stay that way.

Time Offset
(Bitmap Style Only) This control allows the bitmap source frame to be Offset in time from the current frame.

Time Scale
(Bitmap Style Only) This control can be used to scale the time range of the source bitmap images by a specified amount. For example, a scale of 2 will cause the particle created at frame 1 to be read from the bitmap source at frame 2.
**Gain**  
(Bitmap and Brush Style Only) This control is used to apply a correction to the overall Gain of the image that is used as the bitmap. Higher values produce a brighter image, whereas lower values reduce both the brightness and the transparency of the image.

**Noise**  
(Blob Style Only) Increasing this control’s value will introduce grain-type noise to the blobby particle.

**Fade**  
(Line Style Only) The Fade control adjusts the falloff over the line particle’s length. 

The default value of 1.0 causes the line to fade out completely by the end of the length.

**Sub Pixel Rendered**  
(Point and Point Cluster Style Only) This checkbox determines if the point particles are rendered with Sub Pixel precision, which provides smoother looking motion but blurrier particles that take slightly longer to render.

**Number Of Points And Variance**  
(Point Cluster Style Only) The value of this control determines how many points are in each Point Cluster.
This chapter details the Position nodes available in the Fusion page.
Contents

Volume Fog [VLF] 1880
Volume Mask [VLM] 1886
Z to WorldPos [Z2W] 1889
WPP Concept 1890
Volume Fog [VLF]

The Volume Fog node is used to create sophisticated volumetric fog on images containing XYZ Position channels.

As opposed to 3D-rendered volumetric Fog, it works on 2D images and delivers much faster results and interactive feedback when setting up the fog. See the “WPP Concept” section for further explanation on how this technology works and to learn about the required imagery.

External Inputs

The following inputs appear on the node’s tile in the Node Editor.

- **VolumeFog.Image:** [orange, required] This input expects an image containing a World Position Pass in the XYZ Position channels.
- **VolumeFog.FogImage:** [green, optional] For creating volumetric fog with varying depth and extent; an image sequence can be connected here.
- **VolumeFog.EffectMask:** [blue, optional] The standard Effect Mask input as found on other Fusion nodes.
- **VolumeFog.SceneInput:** [pink, optional] This input expects a 3D scene containing a 3D Camera.

Shape Tab
**Shape**
Toggle between a basic spherical or rectangular volume to be placed in your image. These Volumes can then be further refined by means of the MaskImage or MaskImage sequence.

**Translation Pick**
Left-click and hold this button to pick XYZ coordinates from any 3D scene or 2D image containing XYZ values, such as a rendered World Pass, to position the center of the Volume object. When picking from a 2D image, make sure it’s rendered in 32-bit float to get full precision.

**X, Y, Z Offset**
These controls can be used to position the center of the fog volume manually or can be animated or connected to other controls in Fusion.

**Rotation Pick**
Left-click and hold this button to pick rotational values from any 3D Scene or 2D image containing those values, like an XYZ-Normal-Pass, to re-orient the volume.

When picking from a 2D image, like an XYZ-Normal-pass, make sure it’s rendered in 32-bit float to get full precision and accurate rotational values.

**X, Y, Z Rotation**
Use these controls to rotate the Volume around its center.

**X, Y, Z Scale**
Scale the Volume in any direction from its center to further refine the overall Size value specified below.

**Size**
The overall Size of the volume created.

**Soft Edge**
Controls how much the Volume is faded toward the center from its perimeter to achieve a softer look.

**Use OpenCL**
Introduced with Fusion’s OpenCL Supercomputing, this option renders the effect on the GPU rather than on the CPU. Depending on the graphics card used in the computer, this can boost the speed of the node by a factor of 30 or more.
Color Tab

Samples
Determines how many times a “ray” shot into the volume will be evaluated before the final image is created. Not unlike raytracing, higher values lead to more detail inside the volume but also increase render times.

Z Slices
The higher this value, the more images from the connected MaskImage sequence will be used to form the Depth of the Volume.

You can, for example, use a FastNoise with a high Seethe Rate to create such a sequence of images. Be careful with the resolution of the images though. Higher resolutions can require a large amount of memory. As a rule of thumb, a resolution of 256 x 256 pixels with 256 Z Slices (i.e., forming a 256 x 256 x 256 cubic volume, which will use up to 256MB for full color 32-bit float data) should give you a good starting point.

First Slice Time
Determines which frame of the Global Range is used to deliver the first slice from the connected MaskImage sequence.

Make sure that both GlobalIn and GlobalOut as well as the valid range of your source node fall within the range of FirstSliceTime + Z Slices.

Color
Allows you to modify the color of the Fog generated. This will multiply over any color provided by the connected MaskImage.

Gain
Increases or decreases intensity of the fog created. More Gain will lead to a stronger glow and less transparency in the fog. Lower values let the fog appear less dense.
**Subtractive/Additive Slider**
Similar to the Merge node, this value controls if the fog is composed onto the image in additive or subtractive mode, leading to brighter or dimmer appearance of the fog.

**Fog Only**
Outputs the generated fog on a black background which then can be composited manually, or used as a mask on a Color Corrector for further refinement.

**Camera Tab**
For a perfect evaluation of a Volume, a Camera or 3D scene can be connected to the Scene input of the node.

![Camera Tab](image)

**Camera**
If multiple Cameras are available in the connected Scene input, this drop-down allows the user to choose the correct Camera needed to evaluate the Volume. Instead of connecting a Camera, position values can be provided manually or by connecting the XYZ values to other controls.

**Translation Pick**
Left-click and hold this button to pick XYZ coordinates from any 3D scene or 2D image containing XYZ values, like a rendered World Pass, to define the center of the Camera. When picking from a 2D image, make sure it’s rendered in 32-bit float to get full precision.

**X, Y, Z Offset**
These controls can be used to define the center of the Camera manually or can be animated or connected to other controls in Fusion.

**Light Tab**
To utilize this feature you need to have actual lights in your 3D Scene. Connect that scene, including Camera and Lights, to the 3D input of the node.

**Do Lighting**
Enables or disables lighting calculations. Keep in mind that when not using OpenCL (i.e., rendering on the CPU), these calculations may become a bit slow.

**Do In-Scattering**
Enables or disables light scattering calculations. The volume will still be lit according to the state of the Do Lighting checkbox, but scattering will not be performed.

**Light Samples**
Determines how accurate the lighting is calculated. Higher values mean more accurate calculation at the expense of higher render times.
Density
This is similar to Scattering in that it makes the fog appear thicker. With a high amount of scattering, though, the light will be scattered out of the volume before it has had much chance to travel through the fog, meaning it won’t pick up a lot of the transmission color. With a high density instead, the fog still appears thicker, but the light gets a chance to be transmitted, thus picking up the transmission color before it gets scattered out. Scattering is affected by the light direction when Asymmetry is not 0.0. Density is not affected by light direction at all.

Scattering
Determines how much of the light bouncing around in the volume ends up scattering the light out of the fog. If the light scatters more, or more accurately, then there’s a higher probability of the light being scattered out of the volume, hence less light is left to continue on through the fog. This option can make the fog seem denser.

Asymmetry
Determines in what direction the light is scattered. A value of 0 produces uniform, or isotropic, scattering, meaning all directions have equal probability. A value greater than 0 causes “forward scattering,” meaning the light is scattered more into the direction of the light rays. This is similar to what happens with water droplets in clouds. A value smaller than 0 produces “back scattering,” where the light is more scattered back toward the original light source.

Transmission
Defines the color that is transmitted through the fog. Light that doesn’t get scattered out will tend toward this color. It is a multiplier, though, so if you have red light, but blue transmission, you won’t see any blue.
**Reflection**
Changes the intensity of the light that is scattered out. It can be used to modify the overall color before Emission is added. This will be combined with the color channels of the volume texture and then used to scale the values. The color options and the color channels of the volume texture are multiplied together, so if the volume texture was red, setting the Reflection color options to blue would not make the result blue. In such a case they will multiply together to produce black.

**Emission**
This adds a bit of “glowing” to the fog, or adding energy/light back into the calculation. In fact, if there are no lights in the scene, and the fog emission is set to be 1.0, the results are similar to no lighting, like turning off the Do Lighting option. Glowing can also be done while producing a different kind of look, by having a Transmission greater than 1. This, however, would never actually happen in the real world.

**Examples**
In these examples we are looking at a volume from the outside. On the right you see how the VolumeFog looks with straight accumulation. That means the “Do Lighting” option is turned off.

On the right, you see the same volume with lighting/scattering turned on and a single point light. Here we have a slightly more complex Volume.

On the left with straight accumulation, in the middle with lighting, scattering and a single point light. On the right the actual light in the scene has been moved, which also influences the look of the volume.
Volume Mask [VLM]

The Volume Mask node is used to create volumetric masks from images containing XYZ Position channels.

This can, for example, be used to isolate objects for color correction without the need to track or roto the scene. See the “WPP Concept” section for further explanation on how this technology works and to learn about the required imagery.

External Inputs

The following inputs appear on the node tile in the Node Editor.

- **VolumeFog.Image**: [orange, required] This input expects an image containing a World Position Pass in the XYZ Position channels.
- **VolumeFog.MaskImage**: [green, optional] For refining the mask, an image can be connected here.
- **VolumeFog.EffectMask**: [blue, optional] The standard Effect Mask input as found on other Fusion nodes.
- **VolumeFog.SceneInput**: [pink, optional] This input expects a 3D scene input containing a 3D Camera.

Shape Tab
**Shape**
Toggle between a basic spherical or rectangular Mask to be placed in your image. The Mask can be further refined by means of the MaskImage.

**Translation Pick**
Left-click and hold this button to pick XYZ coordinates from any 3D scene or 2D image containing XYZ values, like a rendered World Pass, to position the center of the volumetric Mask. When picking from a 2D image make sure it’s rendered in 32-bit float to get full precision.

**X, Y, Z Offset**
These controls can be used to position the center of the Mask manually or can be animated or connected to other controls in Fusion.

**Rotation Pick**
Left-click and hold this button to pick rotational values from any 3D scene or 2D image containing those values, like an XYZ-Normal-Pass, to re-orient the Mask.
When picking from a 2D image, like an XYZ-Normal-pass, make sure it’s rendered in 32-bit float and WorldSpace coordinates to get full precision and the correct rotational values.

**X, Y, Z Rotation**
Use these controls to rotate the Mask around its center.

**X, Y, Z Scale**
Scale the Mask in any direction from its center to further refine the overall Size value specified below.

**Size**
The overall Size, in X, Y and Z, of the Mask created.

**Soft Edge**
Controls how much the Volume is faded toward the center from its perimeter to achieve a softer look.

**Use OpenCL**
Introduced with Fusion’s OpenCL Supercomputing, this option renders the effect on the GPU rather than on the CPU. Depending on the graphics card used in the computer, this can boost the speed of the node by a factor of 30 or more.
Color Tab

![Color Tab Image]

**Color**
Allows user to modify the color of the Mask generated. This will add to any color provided by the connected MaskImage.

**Subtractive/Additive Slider**
Similar to the Merge node, this value controls if the Mask is composed onto the image in Additive or Subtractive mode, leading to brighter or dimmer appearance of the Mask.

**Mask Only**
Outputs the generated Mask on a black background, which then can be used as a mask on a Color Corrector for further refinement.

Camera Tab

For a perfect evaluation of a Volume, a Camera or 3D scene can be connected to the Scene input of the node.

![Camera Tab Image]
Camera
If multiple Cameras are available in the connected Scene input, this drop-down allows the user to choose the correct Camera needed to evaluate the Volume.
Instead of connecting a Camera, position values can also be provided manually or by connecting the XYZ values to other controls.

Translation Pick
Left-click and hold this button to pick XYZ coordinates from any 3D scene or 2D image containing XYZ values, like a rendered World Pass, to define the center of the Camera.
When picking from a 2D image, make sure it’s rendered in 32bit float to get full precision.

X, Y, Z Offset
These controls can be used to define the center of the Camera manually or can be animated or connected to other controls in Fusion.

Z to WorldPos [Z2W]

The Z to WorldPos node is used to either generate a World Position Pass from a Z-channel and a 3D Camera or a Z-channel from a World Position Pass and a 3D Camera.
Creating a World Position Pass from Z-depth can be useful when your 3D application is not capable of creating a WPP.
It can also be used when a 3D tracking software outputs a per-pixel Z-depth together with the 3D Camera. Thus, the VolumeMask and Volume Fog could be applied to real-world scenes. The quality of the resulting WPP depends largely on the quality of the incoming Z-channel.
See the "WPP Concept" section for further explanation on how this technology works and to learn about the required imagery.

External Inputs
The following inputs appear on the node tile in the Node Editor.

- **ZtoWorld.Image**: [orange, required] This input expects an image containing a World Position Pass or a Z-depth pass, depending on the desired operation.
- **ZtoWorld.EffectMask**: [blue, optional] The standard Effect Mask input as found on other Fusion nodes.
- **ZtoWorld.SceneInput**: [pink, required] This input expects a 3D scene input containing a 3D Camera.
Controls

Mode
Toggle between creating a Z-channel from a World Position Pass or vice versa.

Camera
If multiple Cameras are available in the connected Scene input, this drop-down allows the user to choose the correct Camera needed to evaluate the image.

WPP Concept

The Position nodes in Fusion offer a completely new way of working with Masks and Volumetrics for footage containing XYZ Position channels. ZtoWorld offers the option to create those channels out of a Z-channel and 3D Camera information. Just for the sake of this overview we will refer to the World Position Pass as WPP.

What is a WPP?
The WPP reflects each pixel’s XYZ position in the original scene as RGB color values.

So if the face the pixel was derived from in the original scene sits at 0/0/0, the resulting pixel will have an RGB value of 0/0/0 and thus will be black. If said face sits at 1/0/0 in the original scene, the resulting pixel will be fully red. Of course if the coordinates of our face are something like -60/75/123, the pixel will hold those values as well.

As you can see here, due to the huge extent 3D scenes can have, the WPP channel should always be rendered in 32-bit floating point to provide the accuracy needed. This image shows a 3D Rendering of a scene with its center sitting at 0/0/0 in 3D Space and the according WPP. For better visibility the WPP has been normalized.
Different Coordinate Spaces

WPPs can be rendered in different Coordinate Spaces. These include World Space, Eye Space and Object Space. The image below depicts how those different spaces look, though the nodes in Fusion require the WPP to be rendered in World Space.

The Scene Input

The nodes offer a Scene Input, which can either be a 3D Camera or a 3D scene containing a camera. While the camera is vital for the ZtoWorld node, Volume Mask and Volume Fog will still generate their output without any camera attached or with the camera position set to 0/0/0.

However, connecting a camera that lines up with the original camera the WPP has been rendered from, or setting the camera’s position manually, greatly improves accuracy and look of the resulting Fog or Mask.

The “Invisible Sphere”

The example scene shown so far has an empty background, meaning there is nothing in the scene apart from the ground plane and the cubes.

If applying fog to a scene like that which is larger than said ground plane, the result will look similar to the “w/o Sphere” example shown below because with no WPP information outside the ground plane, the resulting value will be 0/0/0; the fog fills that area as well.

To get around that you can add an invisible bounding sphere to your scene to create “dummy” WPP values to help the Fog node to create the correct volume as shown in “with Sphere” below.
Chapter 99

Stereo Nodes

This chapter details the Stereo nodes available in the Fusion page.
Contents

Anaglyph [ANA] 1894
Combiner [COM] 1897
Disparity [DIS] 1898
Disparity To Z [D2Z] 1901
Global Align [GA] 1904
New Eye [NE] 1905
Splitter [SPL] 1908
Stereo Align [SA] 1908
Z To Disparity [Z2D] 1912
Anaglyph [ANA]

The Anaglyph node is used to create stereoscopic images by combining separate left eye and right eye images. It is most commonly used at the end of a stereoscopic workflow to display or deliver the final result. Stereoscopic nodes are only available in Resolve Studio.

Controls

When using separate images for the left and right eye, the left eye image is connected to the orange input and the right eye image is connected to the green input of the node. When using either horizontally or vertically stacked images containing both left eye and right eye information, these only connect to the orange input. Based on one of the methods described below, the separate images are then combined to create a stereoscopic output.

Color Type Menu

The ColorType menu allows you to choose between different color encodings to fit your preferred display device. To match your stereo glasses you can choose between Red/Cyan, Red/Green, Red/Blue, Amber/Blue and Green/Magenta encoding; Red/Cyan turns out to be the most commonly used.
Method Menu

In addition to the color used for encoding the image, you can also choose five different methods: Monochrome, Half-color, Color, Optimized and Dubois.

Monochrome
The left eye contains the luminance of the left image, and the right eye contains the luminance of the right image (e.g., the luminance of the left image is placed in the output red channel, and the luminance of the right image is placed in the output green and blue channels).

Half-Color
The left eye contains the luminance of the left image, and the right eye contains the color channels from the right image that match the glasses color for that eye (e.g., the luminance of the left image is placed in the output red channel, and the green and blue channels of the right image are placed in the output green and blue channels).

Color
The left eye contains the color channels from the left image that match the glasses color for that eye, and the right eye contains the color channels from the right image that match the glasses color for that eye (e.g., the red channel of the left image is placed in the output red channel, and the green and blue channels of the right image are placed in the output green and blue channels).
Optimized
Used with red/cyan glasses, for example, the resulting brightness of what shows through the left eye will be substantially less than the brightness of the right eye. Using typical ITU-R 601 ratios for luminance as a guide, the red eye would give 0.299 brightness, while the cyan eye would give 0.587+0.114=0.701 brightness – over twice as bright. The difference in brightness between the eyes can produce what’s referred to as retinal rivalry or binocular rivalry, which can destroy the stereo effect. The Optimized method generates the right eye in the same fashion as the Color method. The left eye also uses the green and blue channels, but in a combination with increased brightness that reduces retinal rivalry. Since it uses the same two channels from each of the source images, it doesn’t reproduce the remaining one (e.g., 1.05× the green and 0.45× the blue channels of the left image are placed in the output red channel, and the green and blue channels of the right image are placed in the output green and blue channels. Red from both the left and right images is not used).

Dubois
Images with fairly saturated colors can produce retinal rivalry with Half-color, Color and Optimized methods because the color is only visible in one eye. For example, with red/cyan glasses, a saturated green object looks black in the red eye, and green in the cyan eye. The Dubois method uses the spectral characteristics of (specifically) red/cyan glasses and CRT (Trinitron) phosphors to produce a better anaglyph and in the end tends to reduce retinal rivalry caused by such color differences in each eye, and also tends to reduce ghosting produced when one eye ‘leaks’ into the other eye. The particular calculated matrix we use is designed for red/cyan glasses and isn’t available for other glasses types. Since it is also derived from CRT color primaries, it may not give the best results with a common LCD (Though it’ll still likely produce less retinal rivalry and ghosting than the other methods).

Swap Eyes
Allows the user to easily swap the left and right eye input.

Horiz Stack
Takes an image that contains both left and right eye information stacked horizontally. These images are often referred to as ‘crosseyed’ or ‘straight stereo’ images. You only need to connect that one image to the orange input of the node. It then creates an image half the width of the original input, using the left half of the original image for the left eye and the right half of the original image for the right eye. Color encoding takes place using the specified color type and method.

Vert Stack
Takes an image that contains both left and right eye information stacked vertically. You only need to connect that one image to the orange input of the node. It then creates an image half the height of the original input, using the bottom half of the original image for the left eye and the top half of the original image for the right eye. Color encoding takes place using the specified color type and method.
Combiner [COM]

The Combiner node takes two stereoscopic inputs and creates so called stacked images with the left and right eye, either side by side or on top of each other. Stereoscopic nodes are only available in Resolve Studio.

Controls

To stack the images, the left eye image is connected to the orange input and the right eye image is connected to the green input of the node.

None
No operation will take place. The output image is identical to the left eye input.

Horiz
Both images will be stacked horizontally, or side-by-side, with the image connected to the left eye input on the left. This will result in an output image double the width of the input image.

Vert
Both images will be stacked vertically, or on top of each other, with the image connected to the left eye input on the bottom. This will result in an output image double the height of the input image.

Swap Eyes
Allows the user to easily swap the left and right eye input.
Disparity [DIS]

Stereoscopic nodes are only available in Resolve Studio.

Disparity generates the left/right shift between the frames in a stereo pair. It also generates the vertical disparity between the left/right images, which is usually a lot smaller than the horizontal disparity and ideally should be 0 to minimize viewing discomfort. When viewing the output of the Disparity node in the views, the human eye can distinguish quality/detail in the Disparity map better by looking at either the grayscale X disparity or Y disparity, rather than looking at the combined XY disparity as a Red/Green color image.

The generated disparity is stored in the output image’s Disparity aux channel, where the left image contains the left > right disparity and the right image contains the right > left disparity. Because disparity works based upon matching regions in the left eye to regions in the right eye by comparing colors and gradients of colors, it is important that colors in the two eyes are as similar as possible. Thus, it is a good idea to color correct ahead of time. It is also a good idea to crop away any black borders around the frames, as this will confuse the disparity tracking (and also cause problems if you are using ColorCorrector’s histogram match ability to do the color matching).

In Stack mode, left and right outputs will output the same image. If the left and right images have a global vertical offset bigger than a few pixels from each other, it can help the disparity tracking algorithm if you approximately vertically align features in the left/right eyes ahead of time using a Transform node. Small details tend to get lost in the tracking process when you have a large vertical offset between left/right eyes.

Consider using a SmoothMotion node to smooth your Disparity channel. This can help reduce time-dependent flickering when warping an eye. Also think about whether you want to remove lens distortion before computing disparity. If you do not, your Disparity map will become a combined Disparity and Lens Distortion map. This can have advantages and disadvantages.

One disadvantage is if you then do a vertical alignment you are also removing lens distortion effects. When trying to reduce the computation time, start first with adjusting the Proxy and Number of Iterations sliders.

The Disparity node does not support RoI or DoD.

Inputs/outputs

**Left Input**
Connect either the left eye image or the stacked image.

**Right Input**
Connect the right eye image. This input is invisible unless Stack Mode is set to Separate.

**Left Output**
This holds the left eye image with a new Disparity channel, or a Stacked Mode image with a new disparity channel.

**Right Output**
This holds the right eye image with a new Disparity channel. This output is only visible if Stack Mode is set to Separate.
**Proxy (for tracking)**

The input images are re-sized down by the proxy scale, tracked to produce the disparity, and then the resulting disparities are scaled back up. This option is purely to speed up calculation of the disparity, which can be slow. The computational time is roughly proportional to the number of pixels in the image. This means a proxy scale of 2 will give a 4x speed up and a proxy scale of 3 will give a 9x speed up. In general, 1:1 proxy will give the most detailed flow, but keep in mind that this is highly dependent on the amount of noise and film grain, which if present in large quantities can completely obliterate any gains moving from 2:1 to 1:1 proxy and in some situations even make things worse (in some sense you can think of the Proxy setting as acting as a simplistic low-pass filter for removing noise/grain).

**Stack Mode**

Determines how the input images are stacked.

When set to Separate, the Right Input and Output will appear and separate left and right images need to be connected.

**Swap Eyes**

With Stacked Mode, image stereo pairs, left and right images can be swapped.

**Advanced**

The Advanced Control section has parameter controls to tune the Disparity map calculations. The default settings have been chosen to be the best default values from experimentation with many different shots and should serve as a good standard. In most cases, tweaking of the advanced settings will not be needed.

**Smoothness**

This controls the Smoothness of the disparity. Higher smoothness helps deal with noise, while lower smoothness brings out more detail.
**Edges**
This slider is another control for smoothness but applies smoothing based upon the color channel. It tends to have the effect of determining how edges in the disparity follow edges in the color images. When it is set to Loose, the disparity becomes smoother and tends to overshoot edges. When it is set to Tight, edges in the disparity align more tightly with the edges in the color images and details from the color channels start to slip into the disparity, which is not usually desirable.

As a rough guideline, if you are using the disparity to produce a Z channel for post effects like depth of field, then you can experiment with making it tighter, but if you are using the disparity to do interpolation, you might want to keep it looser.

In general, if it is too tight, there can be problems with streaked out edges when the disparity is used for interpolation.

**Match Weight**
This controls how the matching of neighborhoods in the left to neighborhoods in the right image is done. When set to Match Color, large structural color features are matched. When set to Match Edges, small sharp variations in the color are matched. Typically, a good value for this slider is in the \([0.7, 0.9]\) range, although on some shots values closer to 0.0 work well. Setting this option higher tends to improve the matching results in the presence of differences due to smoothly varying shadows or local lighting variations between the left and right images. The user should still do a color match on the initial images so they are as similar as possible; this option tends to help with local variations (e.g., lighting differences due to light passing through a mirror rig).

**Mismatch Penalty**
This controls how the penalty for mismatched regions grows as they become more dissimilar. The slider gives the choice between a balance of Quadratic and Linear penalties. Quadratic strongly penalizes large dissimilarities while Linear is more robust to dissimilar matches. Moving this slider toward Quadratic tends to give a disparity with more small random variations in it, while Linear produces smoother, more visually pleasing results.

**Number of Warps**
Turning this option down makes the disparity computations faster. In particular, the computational time depends linearly upon this option. To understand what this option does, you need to understand that the Disparity algorithm progressively warps the left image until it matches with the right image. After some point, convergence is reached and additional warps are just a waste of computational time. The default value in Fusion is set high enough that convergence should always be reached. You can tweak this value to speed up the computations, but it is good to watch how the disparity is degrading in quality at the same time.

**Number of Iterations**
Turning this option down makes the disparity computations faster. In particular, the computational time depends linearly upon on this option. Just like adjusting Number of Warps, at some point adjusting this option higher will give diminishing returns and not produce significantly better results. By default, this value is set to something that should converge for all possible shots and can be tweaked lower fairly often without reducing the disparity’s quality.

**Filtering**
This controls Filtering operations used during flow generation. Catmull-Rom filtering will produce better results, but at the same time, turning on Catmull-Rom will increase the computation time steeply.
Disparity To Z [D2Z]

Description
DisparityToZ takes a 3D camera and an image containing a Disparity channel as inputs and outputs the same image but with a newly computed Z channel. Stereoscopic nodes are only available in Resolve Studio.

Optionally, this node can output Z into the RGB channels. Ideally, either a stereo Camera3D or a tracked stereo camera is connected into DisparityToZ, however, if no camera is connected, the node provides artistic controls for determining a Z channel. The depth created by this node can be used for post effects like fogging or depth of field.

The Z values produced become more incorrect the larger (negative) they get. The reason is that disparity approaches a constant value as Z approaches -infinity. So Z = -1000 and Z = -10000 and Z = -100000 may map to D=142.4563 and D=142.4712 and D=142.4713. As you can see, there is only 0.0001 in D to distinguish between 10,000 and 100,000 in Z. The maps produced by Disparity are not accurate enough to make distinctions like this.

Inputs/outputs

Left Input
Connect either the left eye image or the stack image.

Right Input
Connect the right eye image. This input is invisible unless Stack Mode is set to Separate.

Stereocamera
An external stereo camera tool.

Left Output
Holds the left eye image with a new Z channel or a stacked mode image with a new Z channel.

Right Output
Holds the right eye image with a new Z channel. This output is only visible if Stack Mode is Separate.
Controls

In addition to outputting Z values in the Z channel, this option promotes the color channels to float32 and outputs the Z values into the color channels as \([z, z, z, 1]\). This option is useful to get a quick look to see what the Z channel looks like. Note that Dimension’s Z values are negative, getting more negative the further you are from the camera, so you will need view Normalization On to see them correctly.

**Output Z to RGB**

Rather than keeping the Z values within the associated aux-channel only, they will be copied into the RGB channels for further modification with any of Fusion’s nodes.

**Refine Z**

This option refines the depth map based upon the RGB channels. The refinement causes edges in the flow to align more closely to edges in the color channels. The downside is that unwanted details in the color channels start to show up in the flow. You may want to experiment with using this option to soften out harsh edges for Z-channel post effects like depth of field or fogging.

**HiQ Only**

This option only processes in HiQ.

**Strength**

Increasing this slider does two things. It smooths out the depth in constant color regions and moves edges in the Z channel to correlate with edges in the RGB channels.

Increasing the refinement has the undesirable effect of causing texture in the color channel to show up in the Z channel. You will want to find a balance between the two.

**Radius**

This is the radius of the smoothing algorithm.

**Camera Tab**

If you need correct real-world Z values because you are trying to match some effect to an existing scene, you should use the External Camera options to get precise Z values back. If you just want any Z-buffer and are not that particular about the exact details on how it is offset and scaled, or if there is no camera available, the Artistic option might be helpful.
**External Mode**
An input will appear on the node tree to connect an existing stereo Camera3D. This can either be a single stereo Camera3D (i.e., its eye separation is set to non-zero), or a pair of (tracked) Camera3Ds connected together via the Camera3D > Stereo > RightCamera input.

**Artistic Mode**
If you do not have a camera, you can adjust these controls to produce an “artistic” Z channel whose values will not be physically correct but still useful. To reconstruct the Disparity > Z Curve, pick (D, Z) values for a point in the foreground and a point in the background.

If artistic mode is a little too “artistic” for you and you want more physically-based parameters to adjust (e.g., convergence and eye separation), you can always create a bogus Camera3D, connect it into the DisparityToZ > Camera input, and then fiddle with the Camera3D’s controls.

**Foreground Disparity (pick from left eye)**
This is the disparity for the closest foreground object. It will get mapped to depth value specified by the Foreground Depth control. Any objects with disparity outside of the range [ForegroundDisparity, BackgroundDisparity] will have their disparity values clipped to this range leading to flat areas in the Z channel, so make sure that you pick values that enclose the actual disparity range.

**Background Disparity (pick from left eye)**
This is the disparity for the furthest background object. It will get mapped to the depth value specified by the Background Depth control. One way to think of this input is as the upper limit to disparity values for objects at -infinity. This value should be for the left eye. The corresponding value in the right eye will be the same in magnitude but negative.

**Foreground Depth**
This is the depth to which Foreground Disparity will be mapped. Think of this as the depth of the nearest object. Note that values here are positive depth.

**Background Depth**
This is the depth to which Background Disparity will be mapped. Think of this as the depth of the most distant object.

**Falloff**
Falloff controls the shape of the depth curve between the requested foreground and background depths. When set to Hyperbolic, the disparity-depth curve behaves roughly like depth = constant/disparity. When set to Linear, the curve behaves like depth = constant*disparity. Hyperbolic tends to emphasize Z features in the foreground, while linear gives foreground/background features in the Z channel equal weighting.

Unless there’s a specific reason not to, prefer Hyperbolic, as it is more physically accurate, while Linear does not correspond to nature and is purely for artistic effect.
Global Align [GA]

As opposed to Stereo Align, this node does not utilize optical flow at all. It’s meant as a fast and convenient way to do simple stereo alignment for both X and Y as well as rotation. Stereoscopic nodes are only available in Resolve Studio.

Global Align comes in handy at the beginning of the node chain to visually correct major differences between left and right eye before calculating Disparity.

Manual correction of large discrepancies between left and right, as well as applying an initial color matching, helps Disparity to generate more accurate results.

Controls

Translation X and Y
- **Balance**: Determines how the global offset is applied to the stereo footage.
- **None**: No translation is applied.
- **Left Only**: The left eye is shifted, while the right eye remains unaltered.
- **Right Only**: The right eye is shifted, while the left eye remains unaltered.
- **Split Both**: Left and right eyes are shifted in opposite directions.

Snap to Nearest Pixel
While adjusting the translation slider, this option ensures that the image is shifted in full pixel amounts only to maintain optimum quality. This avoids sub-pixel rendering of the image, which could result in subtle blurring.
Rotation
- **Balance**: Determines how the global rotation is applied to the stereo footage.
  - **None**: No rotation is applied.
  - **Left Only**: The left eye is rotated, while the right eye remains unaltered.
  - **Right Only**: The right eye is rotated, while the left eye remains unaltered.
  - **Split Both**: Left and right eyes are rotated in opposite directions.

Angle
The angle of the rotation. Keep in mind that the result depends on the Balance settings. If only rotating one eye by, for example, 10 degrees, a full 10 degree rotation will be applied to that eye.

When applying rotation in Split mode, one eye will receive a -5 degree and the other eye a +5 degree rotation.

Translation Filter Method
A drop-down to choose a filter method that delivers the best results depending on the content of your footage.

Visualization
This control allows for different color-encodings of the left and right eye to conveniently examine the results of the above controls without needing to add an extra Anaglyph or Combiner node.

Set this to None for final output.

Stack Mode
Determine how the input images are stacked.

When set to Separate, the right input and output will appear and separate left and right images need to be connected.

Swap Eyes
With Stacked Mode, image stereo pairs, left and right images can be swapped.

New Eye [NE]

This option constructs a New Eye by interpolating between two existing eyes using the embedded Disparity channels. This node can also be used to replace one view with a warped version of the other. In Stack Mode, L and R outputs will output the same image. Stereoscopic nodes are only available in Resolve Studio.

You can map the left eye onto the right eye and replace it. This can be helpful when removing errors from certain areas of the frame.

NewEye does not interpolate the aux channels, but rather destroys them. In particular, the Disparity channels are consumed/destroyed. Add another Disparity node after the NewEye if you want to generate Disparity for the realigned footage.
**Inputs/outputs**

**Left Input**
Connect either the left eye image or the stacked image.

**Right Input**
Connect the right eye image. This input is invisible unless Stack Mode is set to Separate.

**Left Output**
This holds the left eye image with a new Disparity channel, or a Stacked Mode image with a new disparity channel.

**Right Output**
This holds the right eye image with a new Disparity channel. This output is only visible if Stack Mode is set to Separate.

**Controls**

![Image of control panel for NewEye](image)

**Enable**
When an eye is enabled, NewEye will replace it with an interpolated eye. For example, if the left eye is your “master” eye and you are recreating the right eye, you would disable the left eye and enable the right eye.

**Lock XY**
Locks the X and Y interpolation parameters. When they are unlocked you can provide separate interpolation factors for using the X and Y disparity. For example, if you are working with the right eye and you have the X Interpolation slider set to 1.0 and the Y Interpolation slider set to -1.0, you will be effectively interpolating the left eye onto the right eye but vertically aligned to the left eye.
Interpolation
Interpolation determines where the frame we are interpolating is relative to the two source frames: Left and Right. An interpolation parameter of -1.0 will give frame Left back and a parameter of 1.0 will give frame Right back. A parameter of 0.0 will give a result that is halfway between Left and Right.

Depth Ordering
The Depth Ordering is used to determine which parts of the image should be rendered on top. When warping images there is often overlap. When the image overlaps itself, there are two options for which should be drawn on top.

- **Largest Disparity Ontop**: The larger disparity values will be drawn on top in the overlapping image sections.
- **Smallest Disparity Ontop**: The smaller disparity values will be drawn on top in the overlapping image sections.

Clamp Edges
Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving. Because of these artifacts, it is a good idea to only use clamp edges to correct small gaps around the edges of an interpolated frame.

Softness
Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case you’ll want to keep the softness rather small at around 0.01. If you only have one checkbox enabled you can use a larger softness at around 0.03.

Source Frame and Warp Direction
The output of this node is generated by combining up to four different warps. You can choose to use either the color values from the left or right frame in combination with the Forward (left > right) Disparity or the Backward (right > left) Disparity. Sometimes you will want to replace an existing eye. For example, if you want to regenerate the right eye, you would only use left eye warps.

It is good to experiment with various options to see which gives the best effect. Using both the left and right eyes can help fill in gaps on the left/right side of images. Using both the Forward/Backward Disparity can give a doubling up effect in places where the disparities disagree with each other.

- **Left Forward**: This will take the Left frame and use the Forward Disparity to interpolate the new frame.
- **Right Forward**: This will take the Right frame and use the Forward Disparity to interpolate the new frame.
- **Left Backward**: This will take the Left frame and use the Backward Disparity to interpolate the new frame.
- **Right Backward**: This will take the Right frame and use the Backward Disparity to interpolate the new frame.
Splitter [SPL]

The Splitter takes a stacked input image, for example created with the Combiner, and provides two output images: a left eye and a right eye. Stereoscopic nodes are only available in Resolve Studio.

Controls

None
No operation will take place. The output image on both outputs is identical to the input image.

Horiz
The tool expects a horizontally stacked image. This will result in two output images, each being half the width of the input image.

Vert
The node expects a vertically stacked image. This will result in two output images, each being half the height of the input image.

Swap Eyes
Allows the user to easily swap the left and right eye output.

Stereo Align [SA]

This extremely versatile node for fixing Stereo issues can be used for doing any of the following or combinations of:

- Vertical Alignment of one eye to the other
- Changing the convergence
- Changing the eye separation
By combining these operations in one node, you can execute them using only a single image resampling. In essence, this node can be thought of as applying scales and translation to the disparities, and then using the modified disparities to interpolate between the views.

Changing the eye separation can cause a lot of holes to appear and it may not be possible to fill them since the information needed may not be in either image. Even if the information is there, the disparity may have mismatched the holes. You may have to fill the holes in manually. For now, this node will modify just the RGBA channels.

StereoAlign does not interpolate the aux channels, but rather destroys them. In particular, the Disparity channels are consumed/destroyed. Add another Disparity node after the StereoAlign if you want to generate Disparity for the realigned footage. Stereoscopic nodes are only available in Resolve Studio.

### Controls

![StereoAlign Node](image)

**Vertical Alignment**

This option determines how the Vertical Alignment is split between two eyes. Usually the left eye is declared inviolate and the right eye is aligned to it to avoid resampling artifacts.

When doing per pixel vertical alignment, it may be helpful to roughly pre-align the images by a global Y-shift before disparity computation because the disparity generation algorithm can have problems resolving small objects that move large distances.
Also note that you have to be careful about lens distortion because, even if two cameras are perfectly vertically aligned, they will still have vertical disparities due to lens distortion. It is probably a good idea to remove the lens distortion before computing the Disparity since, by doing a vertical alignment of the right eye, you are in effect removing the Y-component of the lens distortion in the right eye and it will look wrong later when you try to redistort it.

- **Right:** Only the right eye is adjusted.
- **Left:** Only the left eye is adjusted.
- **Both:** The vertical alignment is split evenly between the left and right eyes.

**Mode**

- **Global:** The eyes are simply translated up or down by the Y-shift to match up.
- **Per Pixel:** The eyes are warped pixel-by-pixel using the Disparity to vertically align.

Keep in mind that this can introduce sampling artifacts and edge artifacts.

**Y-shift**

Y-shift is only available in Global Mode. You can either adjust the Y-shift manually to get a match or drag the pick button, which picks from the Disparity channel of the left eye. Also remember that, if you use this node to modify disparity, you can’t pick from the node’s output.

**Snap**

You can snap the global shift to whole pixels using this option. In this mode there is no resampling of the image, but rather a simple shift is done so there will be no softening or image degradation.

**Convergence**

Convergence is just a global X-translation of L/R images.

**Eyes**

This determines which eyes are affected by convergence. In most cases, this will be set to both. If you set the eyes to Both/Split, then the convergence will be shared 50-50 between both eyes. Sharing the convergence between both eyes means you get half the shift in each eye, which in turn means smaller holes and artifacts that need to be fixed later. The tradeoff is that you’ve resampled both eyes now rather than keeping one eye as a pure reference master.

**X-shift**

X-shift can be picked from the Disparity channels for easy point to feature alignment.

**Snap**

You can snap the global shift to whole pixels using this option. In this mode there is no resampling of the image, but rather a simple shift is done so there will be no softening or image degradation.

**Eye Separation**

Eye separation changes the distance between the left/right eyes, causing objects in the left/right eyes to converge/diverge further apart depending on their distance from the camera.

This has the same effect as Eye Separation option in Camera3D.
Separation
This is a scale factor for eye separation.

- When set to 0.0, this leaves the eyes unchanged.
- Setting it to 0.1 increases the shifts of all objects in the scene by a factor of 10% in each eye.
- Setting it to 0.1 will scale the shifts of all objects 10% smaller.

Unlike the Split option for vertical alignment, which splits the alignment effect 50-50 between both eyes, the Both option will apply 100-100 eye separation to both eyes. If you are changing eye separation, it can be a good idea to enable per-pixel vertical alignment or the results of interpolating from both frames can double up.

Stack Mode
In Stack Mode, L and R outputs will output the same image.

If HiQ is off, the interpolations are done using nearest neighbor sampling leading to a more “noisy” result.

Clamp Edges
Under certain circumstances, this option can remove the transparent gaps that may appear on the edges of interpolated frames. Clamp Edges will cause a stretching artifact near the edges of the frame that is especially visible with objects moving through it or when the camera is moving.

Because of these artifacts, it is a good idea to only use clamp edges to correct small gaps around the edges of an interpolated frame.

Softness
Helps to reduce the stretchy artifacts that might be introduced by Clamp Edges.

If you have more than one of the Source Frame and Warp Direction checkboxes turned on, this can lead to doubling up of the stretching effect near the edges. In this case you’ll want to keep the softness rather small at around 0.01. If you only have one checkbox enabled you can use a larger softness at around 0.03.

Example

Different settings for Eye Separation

and example settings for Convergence
Z To Disparity [Z2D]

ZToDisparity takes a stereo camera and an image containing a Z channel and outputs the same image but with Disparity channels in it. This is useful for constructing a Disparity map from CG renders, which will be more accurate than the Disparity map created from the Disparity generator node. Stereoscopic nodes are only available in Resolve Studio.

Inputs/outputs

Left
This is the left image or stack input.

Right
This is the right image.

Stereocamera
A stereo perspective camera may be either a Camera3D with eye separation or a tracked L/R Camera3D.

Left Output
This is the left image or stack output containing new Disparity channel.

Right Output
This is the right image that contains a new Disparity channel. This output will be hidden in Stack Mode.

Controls

Output Disparity To Rgb
In addition to outputting disparity values into the Disparity channel, this option causes ZToDisparity to also output the disparity values into the color channels as \([x, y, 0, 1]\).

When enabled, this option will automatically promote the RGBA color channels to float32. This option is useful for a quick look to see what the Disparity channel looks like.

Refine Disparity
This refines the Disparity map based upon the RGB channels.
**Strength**
Increasing this slider does two things. It smooths out the depth in constant color regions and moves edges in the Z channel to correlate with edges in the RGB channels. Increasing the refinement has the undesirable effect of causing texture in the color channel to show up in the Z channel. You will want to find a balance between the two.

**Radius**
This is the pixel-radius of the smoothing algorithm.

**Camera Tab**
If you need correct real-world disparity values because you are trying to match some effect to an existing scene, you should use the External Camera options to get precise disparity values back. If you just want any disparity and do not particular care about the exact details on how it is offset and scaled, or if there is no camera available, then the Artistic option might be helpful.

**External**
An input will appear on the node tree to connect an existing stereo Camera3D, and use the Camera settings to determine the Disparity settings.

**Artistic**
If you do not have a camera, you can adjust these controls to produce an “artistic” Disparity channel whose values will not be physically correct but good enough for compositing hacks. There are two controls to adjust:

**Convergence Point**
This is the Z value of the convergence plane. This corresponds to the negative of the Convergence Distance control that appears in Camera3D. At this distance, objects in the left and right eyes are at exactly the same position (i.e., have zero disparity).

Objects closer appear to pop out of the screen, and objects further appear behind the screen.

**Background Disparity (pick from left eye)**
This is the Disparity of objects in the distant background. You can think of this as the upper limit to disparity values for objects at infinity. This value should be for the left eye. The corresponding value in the right eye will be the same in magnitude but negative.
This chapter details the Tracker nodes available in the Fusion page.

Tracker [TRA]

The Tracker is used to detect and follow one or more pixel patterns across frames in moving video. The tracking data can then be used to control the position or values of other nodes in the composition (for example, the center of a Drip). Additionally, trackers can be used to stabilize an image, or to apply de-stabilization to one image based on the motion of another.

Please also refer to Chapter 57, “Using the Tracker Node” for more information.

Tracker Onscreen Controls

Each pattern in the Tracker has its own set of onscreen controls, used to select the pixels in the image to be tracked. These controls are visible in the Viewers whenever a tracker is selected in the node tree.

- The onscreen control is indicated by a red rectangle with a handle in the top left corner. This rectangle indicates the position of the pattern in the image. Every pixel within the rectangle is considered to be part of the pattern used for tracking. Resize the pattern by clicking and dragging on the rectangle’s borders.

- Whenever the mouse moves over the pattern rectangle, a second rectangle with a dashed outline appears. This represents the search area, which determines how far away from the current pattern the Tracker looks on the next frame. This should always be larger than the pattern, and it should be large enough to encompass the largest frame-to-frame movement in the scene. Faster moving objects require larger search areas and slower moving objects can get away with smaller search areas. The larger the search area, the longer it will take to track, so try not to make the search area larger than necessary.
Dragging on the handle repositions the pattern. While repositioning the pattern, a thumbnail window with an enlarged view of the pattern is displayed in the views, to assist with precise positioning of the pattern. This thumbnail disappears when the mouse button is released. The magnification ratio can be adjusted in the Options tab. If the selected Tracker has a custom name, the name of that Tracker will be displayed as a label at the bottom right of the search area rectangle.

There is no limit to the number of trackers that can be used in one Node Editor, or in the number of connections that can be made to a tracker. This chapter serves as a reference for the various controls in the Tracker, but we strongly suggest you read the more general information about using the Tracker in Chapter 57, “Using the Tracker Node.”

The Tracker can be employed in two forms: as a node in the Node Editor, or as a modifier attached to a control. When the Tracker is used as a node in the Node Editor, the image tracked comes from the input to the Tracker node. There is no limit to the number of patterns that can be tracked by a single Tracker node.

When the Tracker is used as a modifier, its controls appear in the Modifier tab for any node with a control connected to that modifier. Only one pattern can be tracked by a Tracker Modifier, but the image source can come from anywhere in the composition. This technique is generally used when tracking a quick position for a control.

**Inspector Controls – Trackers Tab**

The Trackers tab contains all of the controls you need for creating and positioning trackers, and for customizing and initiating tracking operations. As set of offset controls may be used after tracking has been accomplished to improve the alignment of an image being transformed by a track with the subject being tracked.

**Track Buttons**

There are four buttons used to initiate tracking and one in the middle used to stop a track in progress. These buttons can track the current pattern forward or backward in time. Hold the mouse pointer over each button for a moment, and a tooltip with the name of the button will appear.
The buttons operate as follows:

- **Track Reverse**: Clicking on this button will cause all Active trackers to begin tracking their patterns, starting at the end of the render range and moving backward through time until the beginning of the render range.

- **Track Reverse From Current Time**: Clicking on this button will cause all Active trackers to begin tracking their patterns, starting at the current frame and moving backward through time until the beginning of the render range.

- **Stop Tracking**: Clicking on this button will Stop the tracking process immediately. This can also be achieved by pressing ESC. This button will only be active when tracking is in process.

- **Track Forward From Current Time**: Clicking on this button will cause all Active trackers to begin tracking their patterns, starting at the current frame and moving forward through time until the end of the render range.

- **Track Forward**: Clicking on this button will cause all Active trackers to begin tracking their patterns, starting at the first frame in the render range and moving forward through time until the end of the render range.

**Tracking Behavior Controls**

The following controls all affect how trackers adapt to changing patterns, how the resulting track path is defined, and how many keyframes should be generated.

**Frames Per Path Point**

The value of this slider determines how often the Tracker sets a Keyframe on the Path. The normal default is 1, which sets a Keyframe on the tracked path at every frame.

Increasing the value of this slider will cause the tracked path to be less accurate. This may be desirable if the track is returning fluctuating results, but under normal circumstances this control should be left at its default value.

If the project is field rendered, a value of 1 sets a Keyframe on every field. Since the tracker is extremely accurate, this will result in a slight up-and-down jittering due to the position of the tracked pattern fields. For fielded footage tracked in Field mode, you will get better results setting this slider to a value of 2, which will result in one keyframe per frame of your footage.

**Adaptive Mode**

Fusion is capable of re-acquiring the tracked pattern, as needed, to help with complex tracks. This button array determines what mode of Adaptive tracking is employed.

If selected, Fusion searches only for the pattern originally selected in each single frame.

- **Every Frame**: If selected, Fusion re-acquires the pattern every frame. This helps the Tracker compensate for gradual changes in profile and lighting over time.

- **Best Match**: If selected, the Tracker will compare the pattern acquired at each frame and compare it to the original selected pattern. If the variation between the two patterns exceeds the threshold amount defined by the Match Tolerance control, Fusion will not re-acquire the pattern on that frame. This helps to avoid tracker drift caused by transient artifacts that cross the pattern’s path (such as a shadow).

**Path Center**

The two buttons in this button array determine how the Tracker behaves when re-positioning a pattern. These controls are used when switching a path from one pattern to another, which happens when a pattern leaves the frame, or changes so significantly it can no longer be tracked.
• **Pattern Center**: When Pattern Center is the Active mode, the tracked path continues from the center of the new path. This is appropriate when replacing an existing path entirely, but when trying to append to a path using a new pattern, this will cause a discontinuity.

• **Track Center (append)**: When Track Center (append) is selected, the path tracked by a new pattern will be appended to the existing path. The Path created is automatically offset by the required amount. This technique will work best if the new pattern is located close to the position of the old pattern to avoid any problems with parallax or lens distortion. This mode can also be used to virtually continue the tracking of patterns that move out of the frame or get obstructed by other objects.

**Tracker List Controls**

Each tracker you create to use is managed in the Tracker List, with its accompanying controls.

**Add/Delete Tracker**

Use these to add or delete Trackers from your Tracker List.

**Tracker List**

The Tracker List shows the names of all of the patterns created on this Tracker. It is also used to add new Trackers.

The Tracker node is capable of hosting a virtually unlimited number of Tracker patterns.

• Click on the Add button immediately above the list to add a new Tracker pattern.

• Each pattern appears in the list by name, next to a small checkbox. Clicking on the name of the pattern will select that pattern.

• The controls below the list will change to affect that pattern only. Click once on a selected pattern to rename the pattern to something more descriptive.

• Clicking on the checkbox changes the state of the Tracker.

**Tracker States**

• **Enabled (Black Checkbox)**: An Enabled pattern will re-track each time the Track is initiated. Its path data is available for use by other nodes, and the data is available for Stabilization and Corner Positioning.

• **Suspended (Gray Checkbox)**: A Suspended pattern does not re-track when the Track is initiated. The data is locked to prevent additional changes. The data from the Path is still available for other nodes, and the data is available for advanced Tracking modes like Stabilization and Corner Positioning.

• **Disabled (Clear)**: A Disabled pattern does not create a path when tracking is initialized, and its data is not available to other nodes, or for advanced Tracking operations like Stabilization and Corner Positioning.
Show
These two buttons determine what controls are displayed in the node controls. They have no effect on the operation of the Tracker; they only affect the interface.

- **Selected Tracker Details**: When Selected Tracker Details is selected, the controls displayed pertain only to the currently selected Tracker. You will have access to the Pattern Window and the Offset sliders.

- **All Trackers**: When All Trackers is selected, the pattern window for each of the Trackers is displayed simultaneously below the Tracker List.

Left Pattern Display
The Pattern Display has two image windows next to each other, and a series of status bars. The window on the left shows the pattern initially selected, while the one on the right shows a real-time display of the current pattern as tracking progresses.

As the onscreen controls are moved for a pattern, the display in the leftmost window will update to show the pattern. As the pattern is moved, the vertical bars immediately to the right of the image display indicate the clarity and contrast of the image channels.

The channel, or channels, with the best clarity are automatically selected for tracking. These channels have a white background in the vertical bar representing that channel. The automatic tracking can be allowed to stand, or you can override the automatic selection and choose the channel used for tracking by disabling the button labeled with a question mark, and selecting the button beneath the channel to track.

Under normal circumstances, the channel selected is indicated in the Pattern Display. If the selected channel is blue, then a grayscale representation of the blue channel for the pattern appears. The image is only represented in full color if all three channels are selected for tracking.
Override this behavior by selecting the Show Full Color button beneath the Pattern Display, instead of the Show Selected Channel button.

As Fusion looks for the channel with the highest contrast automatically, you might end up tracking the blue channel, especially on scanned film material. Unfortunately the blue channel on most film stock contains the most grain as well, which naturally leads to unclean tracks. Before tracking it’s always a good idea to zoom into your footage and check the RGB channels individually.

**Right Pattern Display**
The Pattern Display on the right indicates the actual pattern acquired for tracking. This display is clear until the first time the selected pattern is actually tracked. The Pattern Display becomes active during tracking, displaying the pattern that Fusion acquires from frame to frame.

As the tracking occurs, the pattern from each frame is accumulated into a Flipbook, which can be played back in the Pattern window after tracking by using the transport controls at the bottom of the window.

While the track is progressing, the vertical bar immediately to the right of the pattern shows how confident Fusion is that the current pattern matches the originally selected pattern. A green bar indicates a high degree of confidence that the current pattern matches the original. A yellow bar indicates less certainty, and a red bar indicates that Fusion has detected extreme variations in the current pattern, and is no longer certain of its accuracy.

After tracking, the pattern display will show a small Flipbook of the track for that pattern, overlaid with a frame number to help identify problem frames for the Track.

**Tracker Sizes**
Each tracker has a set of sizing parameters that let you adjust the Pattern and Search box on-screen controls.

- **Pattern Width and Height**: Use these controls to adjust the width and height of the selected Tracker pattern manually. The size of the Tracker pattern can also be adjusted in the Viewer, which is the normal method, but small adjustments are often easier to accomplish with the precision of manual controls.

- **Search Width and Height**: The search area defines how far Fusion will look in the image from frame to frame to re-acquire the pattern during tracking. As with the Pattern Width and Height, the Search Area can be adjusted in the Viewer, but you may want to make small adjustments manually using these controls.

**Tracked Center**
This positional control indicates the position of the Tracker’s center. To remove a path from a Tracker pattern, right-click on this control and select Remove Path from the contextual menu.

**X and Y Offset**
You will often need to track the position of an object in the scene, but that object does not provide for a very reliable pattern. The Offsets permit the tracking of something close to the intended object instead. Use these Offsets to adjust the reported position of the Tracker so that the data is reported for the intended pattern instead of the actual one.

The Offset can also be adjusted directly in the view by activating the positioner’s Offsets onscreen control in the Viewer toolbar.
Inspector Controls – Operation Tab

While the Trackers tab controls let you customize how the Tracker node analyzes motion to create motion paths, the Operation tab lets you use this analyzed motion data, stored within each tracker, to perform image transforms of various kinds.

The Tracker node is capable of performing a wide variety of functions, from match moving an object into a moving scene, smoothing out in a shaky camera movement, or replacing the content of a sign. Use the options and buttons in the Operation tab to select the function performed by the Tracker node.

Operation Buttons

These four buttons select the exact function performed by the Tracker. The remaining controls in this tab fine-tune the result of the Operation.

- **None:** The Tracker performs no additional operation on the image beyond simply locating and tracking the chosen pattern. This is the default mode, used to create a path that will then drive another control in Fusion.
- **Match Move:** This mode is used when stabilizing an image, or when matching the position, rotation and scaling of the layer for match moving another element into the scene. Stabilizing requires a minimum of one Tracker to determine position, and two or more to determine scaling and rotation in the sequence.
  - **Corner Positioning:** The Corner Positioning mode is used to track the four corners of a rectangular object and replace the contents with a new image. A minimum of four Trackers is required for this mode, and if there are not enough Trackers, new ones will be created until the total equals four.
  - **Perspective Positioning:** This mode is similar to the Corner Positioner, but rather than replacing the contents of the rectangle, the four tracked corners are mapped to the four corners of the image. This is generally used to remove Perspective from an image. Like the Corner Positioner, this mode requires four Trackers, which will be created if there are not already that many.

Additional Controls For Match Move, Corner Positioning, and Perspective Positioning

When you choose any operation other than None, a series of additional controls appear.

**Merge**

The Merge control determines what is done (if anything) with the image provided to the Foreground input of the Tracker. This array of buttons appears when the operation is set to anything other than None.

- **BG Only:** The Foreground input is ignored, only the Background is affected. This is used primarily when Stabilizing an image sequence.
- **FG Only:** The Foreground input is transformed to match the movement in the background, and this transformed image is passed through the Tracker’s output. This Merge technique is used when match moving one layer’s motion to another layer’s motion.
- **FG Over BG:** The Foreground image is merged over the Background image, using the Merge method described by the Apply Mode control that appears.
- **BG Over FG:** The Background is merged over the Foreground. This technique is often used when tracking a layer with an Alpha channel so that a more static background can be applied behind it.
Apply Mode and Operator Pop-Up Menus
This drop-down menu provides a variety of options to determine how the two layers should be combined. The options in this menu are explained in more detail in the reference chapter for the Merge node.

Subtractive - Additive Slider
This determines whether the Foreground layer is placed over the Background in using Additive or Subtractive merging techniques. This control is explained in more detail in the documentation for the Merge node.

Filter Method
Determines which filter to use to handle image transforms made using the Tracker node.

Edges (Match Move)
This button array only appears if the Operation mode is set to Match Move. The various options select how the revealed edges are handled when the image is moved to match position and scaling.

- **Black Edges**: Out of frame edges revealed by Stabilization are left black.
- **Wrap**: Portions of the image moved off frame to one side are used to fill edges that are revealed on the opposite side.
- **Duplicate**: The last valid pixel on an edge is repeated to the edge of the frame.
- **Mirror**: Image pixels are mirrored to fill to the edge of the frame.

Position, Rotation and Scaling Checkboxes
The Position, Rotation and Scaling checkboxes only appear when the mode is set to Match Move. They determine what components of motion that Stabilization will attempt to correct in the image. For example, if only the Position checkbox is selected, no attempt will be made to correct for Rotation and Scaling in the image.

Flatten Transformation
This checkbox only appears when the mode is set to Match Move. Like most transformations in Fusion, Stabilization is concatenated with other sequential transformations by default. Selecting this checkbox will flatten the transform, breaking any concatenation taking place and applying the transform immediately.

- **Mapping Type**: The Mapping Type control only appears in the Corner Positioning mode. There are two options in the button array.
  - **Bi_Linear**: The first method is Bi-Linear where the Foreground image is mapped into the Background without any attempt to correct for perspective distortion. This is identical to how previous versions of Fusion operated, and the Classic mode is included pretty much for compatibility reasons only.

Perspective
The preferred setting for this control is True Perspective.

Corner Selector
When the operation of the Tracker is set to either Corner or Perspective Positioner modes, these four drop-down menus appear. They are used to select which trackers map to each of the four corners of the rectangle used by these modes. This is useful when a Tracker has more than four patterns selected, and you must choose which the positioners use.
**Rotate Clockwise and Counter-Clockwise Buttons (Corner or Perspective Positioner)**
These controls only appear when the operation of the Tracker is set to either Corner or Perspective Positioner modes. They are used to rotate the Foreground image by 90 degrees before it is applied to the Background.

**Stabilize Settings**
The Tracker node automatically outputs several steady and unsteady position outputs to which other controls in the Node Editor can be connected. The Stable Position output provides X and Y coordinates to match or reverse motion in a sequence. These controls are available even when the operation is not set to Match Move, since the Stable Position output is always available for connection to other nodes.

**Axis Type (Stabilize Setting)**
Under virtually all circumstances, the Axis for any stabilization should be the average position of all Trackers on that frame, however, the rare occasion arises when the Tracker’s axis must be elsewhere.

This array of buttons allows for the selection of an axis for the Stabilization based on the position of a single Tracker, or a manual position.

**Reference (Stabilize Setting)**
The Reference controls are used to set the “snapshot frame” for Stabilization. When you stabilize an image, there must be a position that is considered correct, to which all subsequent movement is detected and corrected.

**Match Move Settings**
These settings determine how tracking data is correlated with the reference pattern for making transforms.

**Reference**
The Reference mode determines the “snapshot frame” based on the frame where the pattern is first selected. All Stabilization is intended to return the image back to that reference.

- **Select Time**: Lets you select the current frame.
- **Start**: The Snapshot Frame is determined to be the first frame in the tracked path. All Stabilization is intended to return the image back to that reference.
- **Start and End**: The Start and End Reference mode is somewhat different from all other Reference modes. Where the others are intended to take a snapshot frame to which all stabilization returns, immobilizing the image, the Start and End mode is intended to smooth existing motion, without removing it. This mode averages the motion between the Start and End of the path, drawing a straight line between those points.

When this mode is Active, it reveals the Reference Intermediate Points control.
Increasing the value of this control increases the number of points in the path used by the Reference, smoothing the motion from a straight line between Start and End without making it wholly linear.

- **End**: The Snapshot Frame is determined to be the last frame in the tracked path. All Stabilization is intended to return the image back to that reference.

**X/Y Paths**
By default the Tracker applies a Displacement Path to the tracked points. To apply an XY Path to the tracked points go to Preferences > Globals > Splines.
Options Tab
The Options tab lets you customize the look of on-screen controls in the Viewer.

Show Pattern Names in Preview
This option defines if the Tracker’s name will be displayed in the view. Switch it off to see just the Pattern Rectangle instead.

Show Enlarged Pattern on Dragging
This option defines if there is an enlarged view on positioning the Pattern Rectangle or not.

Enlargement Scale
The Zoom factor that is used on positioning the Pattern Rectangle when the above option is on. The outputs of a Tracker (seen in the Connect to... menu) can also be used by scripts. They are:

- SteadyPosition: Steady Position
- UnsteadyPosition: Unsteady Position
- SteadyAxis: Steady Axis
- SteadySize: Steady Size
- UnsteadySize: Unsteady Size
- SteadyAngle: Steady Angle
- UnsteadyAngle: Unsteady Angle
- Position1: Tracker 1 Offset position
- PositionX1: Tracker 1 Perspective Offset position
- PositionY1: Tracker 1 Offset Y position (3D Space)
- PerspectivePositionX1: Tracker 1 Perspective Offset X position (3D Space)
- PerspectivePositionY1: Tracker 1 Perspective Offset Y position (3D Space)
- SteadyPosition1: Tracker 1 Steady Position
- UnsteadyPosition1: Tracker 1 Unsteady Position (similarly for the 2nd, 3rd and so on)

Planar Tracker Node
The Planar Tracker node is designed to solve a match moving problem that commonly comes up during post-production. Live action footage containing a planar surface such as a license plate, a road sign, or a brick wall and need to replace the numbers in the license plate, a city’s name in the road sign, or place a billboard poster on the blank brick wall. The problem is that the camera is moving in the shot so the license plate, road sign, or brick wall undergo continuous changes in perspective. The artist cannot simply merge a new license plate over the existing background without accounting for the perspective distortions. A time intensive way to solve this problem would be to use Fusion’s Corner Pin node and manually keyframe the four corners to match the perspective distortions. Planar Tracker automates this keyframing process, to track the perspective distortions of a planar surface in a background plate over time and then re-apply those same perspective distortions to a different foreground.

Part of using Planar Tracker is also knowing when to give up and fall back to using Fusion’s Tracker node or to manual keyframing. Some shots are simply not trackable or the resulting track suffers from too much jitter or drift. Planar Tracker is a useful time saving node in the artist’s toolbox and, while it may track most shots, it is not a 100% solution.
What the Planar Tracker Saves

While Planar Tracker does save the final resulting track in the composition on disk, it does not save temporary tracking information such as the individual point trackers (compare with Camera Tracker which does save the individual point trackers). Some consequences of this are:

- The point trackers no longer appear in the view when a comp containing a Planar Tracker node is saved and reloaded.
- Tracking may not be resumed after a comp containing a Planar Tracker node has been saved and reloaded. In particular, this also applies to auto saves. For this reason, it is good to complete all tracking within one Fusion session.
- The size of composition files is kept reasonable (in some situations Planar Tracker can produce 100s of megabytes of temporary tracking data).
- Saving and loading of compositions is faster and more interactive.

The Planar Node’s Main Inputs

The Planar Tracker has the following inputs:

- **Background**: Contains the planar surface to be tracked.
- **Corner Pin 1**: An image to be pinned on top of the background. There may be multiple Corner Pin inputs named Corner Pin 1, Corner Pin 2, ... etc.
- **Occlusion Mask**: Used to mask out regions that do not need to be tracked. Regions where this mask is white will not be tracked. For example, a person moving in front of and occluding bits of the pattern may be confusing the tracker, and a quickly-created rough rotomask around the person can be used to tell the tracker to ignore the masked out bits.
- **Effect Mask**: Used to mask the output from node.

A Typical Planar Track Workflow

The standard tracking workflow with Planar Tracker is:

1. **Remove lens distortion**: The more lens distortion in the footage, the more the resulting track will slide and wobble.
2. **Connect footage**: Connect a MediaIn node whose footage has a planar surface that can be tracked over time and view the Planar Tracker node in a view.
3. **Select a reference frame**: Move to a frame where the planar surface to be tracked is unoccluded and set this as the reference frame.
4. **Choose the pattern**: In the Viewer, make sure the onscreen controls are visible, and draw a polygon around the planar surface you want to track. This is called the “pattern.” In most cases, this will probably be a rectangle but an arbitrary closed polygon can be used. The pixels enclosed by this region will serve as the pattern that will be searched for on other frames. Note that it is important that the pattern is drawn on the reference frame. Do not confuse the pattern with the region to corner pin (which always has four corners and is separately specified in Corner Pin mode).
5. **Adjust render range**: In the Timeline, adjust the render range to match the range of frames where the planar surface is visible.
6. **Adjust track options**: Frequently changed options are Tracker, Motion Type, and Track Channel.
7 **Mask out occluders:** If moving objects partially cover up the planar surface, you may wish to connect in an occlusion mask to Planar Tracker. When using the Hybrid tracker, providing a mask to deal with occluding objects is pretty much mandatory, while with the Point tracker it is recommended to try tracking without a mask.

8 **Track:** Go back to the reference frame. Press the Track To End button and wait for the track to complete. Go back to the reference frame. Press the Track To Start button and wait for the track to complete. Note that the tracks in the view are not selectable or deletable like in Camera Tracker.

9 **Check track quality:** Visually inspect the track to see how accurate it is. Does it stick to the surface? Switching to Steady mode can help here.

10 **Use the track:** The Steady, Corner Pin, and Stabilize operation modes use the tracking data produced in Track mode. At this point, you may also choose to export a Planar Transform node that can be used to mirror the tracked perspective distortion onto masks.

### The Controls Tab in Track Mode

The contents of the Planar Tracker.

#### Operation Mode

Lets you choose what you want to do with the PlanarTracker node. The Planar Tracker has four modes of operation:

- **Track:** Used to isolate a planar surface and track its movement over time. Then, you can create a Planar Transform node that uses this data to match move another clip in various ways.
- **Steady:** After analyzing a planar surface, this mode removes all motion and distortions from the planar surface, usually in preparation for some kind of paint or roto task, prior to “unsteadying” the clip to add the motion back.
- **Corner Pin:** After analyzing a planar surface, this mode computes and applies a matching perspective distortion to a foreground image you connect to the foreground input of the Planar Tracker node, and merges it on top of the tracked footage.
- **Stabilize:** After analyzing a planar surface, allows smoothing of a clip’s translation, rotation, and scale over time. Good for getting unwanted vibrations out of a clip while retaining the overall camera motion that was intended.

The last three modes (Steady, Corner Pin, Stabilize) use the tracking data produced in Track mode. Note that none of the operations can be combined together. For example, both corner pin and stabilize cannot be done at the same time, nor can a track be done while in corner pinning mode.

#### Reference Time

The reference time determines the frame where the pattern is taken from. It is also the time from which tracking begins. The reference time cannot be changed once it has been set without destroying all pre-existing tracking information so scrub through the footage to be tracked and choose carefully. The reference frame needs to be carefully chosen to give the best possible quality pattern to track from.

You choose a reference time by moving the playhead to an appropriate frame, and then you click the Set button to choose that frame.
Pattern Polygon

You specify which region of the image you want to track by drawing a polygon on the reference frame. Typically, when you first add a Planar Tracker node, you are immediately ready to start drawing a polygon in the Viewer, so it’s best to do this right away. When choosing where to draw a polygon, make sure the region selected belongs to a physically planar surface in the shot. In a pinch, a region that is only approximately planar can be used, but the less planar the surface, the poorer the quality of the resulting track.

As a rule of thumb, the more pixels in the pattern, the better the quality of the track. In particular, this means on the reference frame, the pattern to be tracked should:

- Be as large as possible.
- Be as much in frame as possible.
- Be as unoccluded as possible by any moving foreground objects.
- Be at its maximal size (e.g., when tracking an approaching road sign, it is good to pick a later frame where it is 400x200 pixels big rather than 80x40 pixels).
- Be relatively undistorted (e.g., when the camera orbits around a flat stop sign, it is better to pick a frame where the sign is face on parallel to the camera rather than a frame where it is at a highly oblique angle).

If the pattern contains too few pixels or not enough trackable features, this can cause problems with the resulting track such as jitter, wobble, and slippage. Sometimes dropping down to a simpler motion type can help in this situation.

After you’ve drawn a pattern, a set of Pattern parameters let you transform and invert the resulting polygon, if necessary.

Tracker

There are two available trackers to pick from:

- **Point**: Tracks points from frame to frame. Internally, this tracker does not actually track points-per-se but small patterns like Fusion’s trusty Tracker node. The point tracker possesses the ability to automatically create its own internal occlusion mask to detect and reject outlier tracks that do not belong to the dominant motion. Tracks are colored green or red in the view, depending on whether the point tracker thinks they belong to the dominant motion or they have been rejected. The user can optionally supply an external occlusion mask to further guide the Point tracker.

- **Hybrid Point/Area**: Uses an Area tracker to track all the pixels in the pattern. Unlike the Point tracker, the area tracker does not possess the ability to automatically reject parts of the pattern that do not belong to the dominant motion so you must manually provide it with an occlusion mask. Note that for performance reasons, the Hybrid tracker internally first runs the point tracker which is why the point tracks can still be seen in the view.

There is no best tracker. They each have their own advantages and disadvantages:

- **Artist Effort (occlusion masks)**: the Point tracker will automatically create its own internal occlusion mask. However, with the Hybrid tracker you need to spend more time manually creating occlusion masks.

- **Accuracy**: the Hybrid tracker is more accurate and less prone to wobble, jitter, and drift since it tracks all of the pixels in the pattern rather than a few salient feature points.

- **Speed**: the Hybrid tracker is slower than the Point tracker.

In general, it is recommended to first quickly track the shot with the Point tracker and examine the results. If the results are not good enough, then try the Hybrid tracker.
Motion Type
Determines how Planar Tracker internally models the distortion of the planar surface being tracked. The five distortion models are:

- Translation.
- Translation, Rotation (rigid motions).
- Translation, Rotation, Scale (takes squares to squares, scale is uniform in x & y).
- Affine — includes translation, rotation, scale, skew (maps squares to parallelograms).
- Perspective (maps squares to generic quadrilaterals).

Each successive model is more general and includes all previous models as a special case.

When in doubt, choose Perspective for the initial track attempt. If the footage being tracked has perspective distortions in it and Planar Tracker is forced to work with a simpler motion type, this can end up causing the track to slide and wobble.

Sometimes with troublesome shots, it can help to drop down to simpler motion model. This can happen (for example) when a lot of track points are clustered in one side of the region to be tracked or when tracking a small region where Planar Tracker does not have a lot of pixels to work with.

Output
Controls what is output from the Planar Tracker node while in the Track operation mode.

- **Background**: Outputs the input image unchanged.
- **Background - Preprocessed**: Planar Tracker does various types of preprocessing on the input image (e.g., converting it to luma) before tracking. It can be useful to see this when deciding which Track Channel to choose.
- **Mask**: Outputs the pattern as a black and white mask.
- **Mask over Background**: Outputs the pattern mask merged over the background.

Track Channel
Determines which image channel in the background image is tracked. It is good to pick a channel with high contrast, lots of trackable features, and low noise. Allowed values are red, green, blue, and luminance.

Tracking Controls
These controls are used to control the Tracker. Note that while tracking, only track to a new frame if the current frame is already tracked or it is the reference frame.

- **Track to start**: Tracks from the current frame backward in time to the start (as determined by the current render range).
- **Step tracker to previous frame**: Tracks from current frame to the previous frame.
- **Stop Tracking**: Stops any ongoing tracking operations.
- **Step tracker to next frame**: Tracks from current frame to the next frame.
- **Track to end**: Tracks from the current frame forward in time to the end (as determined by the current render range).
- **Trim to start**: Removes all tracking data before the current frame.
- **Delete**: Deletes all tracking data at all times. Use this to destroy all current results and start tracking from scratch.
- **Trim to end**: Removes all tracking data after the current frame. This can be useful, for example, to trim the end of a track which has become inaccurate when the pattern starts to move off frame.
Show Splines
This button to the right of the “Trim to end” button opens the Spline Editor and shows the splines associated with the Planar Tracker node. This can be useful for manually deleting points from the Track and Stable Track splines.

Right-click here for Track spline
While tracking, a spline containing 4x4 matrices at each keypoint is created. This is known as the “Track spline” or just “Track” for short. These matrices completely describe the distortions of the tracked pattern.

Create Planar Transform
After tracking footage, this button can be pressed to create a Planar Transform node on the Node Editor. The information currently encoded in the Track spline is shared with the Planar Transform node so that it can replicate the planar distortions tracked by the Planar Tracker node.

Steady Mode
In Steady Mode, the Planar Tracker transforms the background plate to keep the pattern as motionless as possible. Any leftover motion is because the Tracker failed to follow the pattern accurately or because the pattern did not belong to a physically planar surface. Steady mode is not very useful to do actual stabilization but is useful for checking the quality of a track. If the track is good, during playback the pattern should not move at all while the rest of the background plate distorts around it. It can be helpful to zoom in on parts of the pattern and place the mouse cursor over a feature and see how far that feature drifts away from the mouse cursor over time.

Steady Time
This is the time where the pattern’s position is snapshotted and frozen in place. It is most common to set this to the reference time.

Invert Steady Transform
Causes the Planar Tracker node to reverse the effects of the steady transform. This means two Planar Tracker nodes connected back-to-back with the 2nd set to invert the first should give back the original image. If you place an effects node in between the two, then the effect will be locked in place. This should only be used to accomplish effects that cannot be done through corner pinning, since it involves two resamplings causing degradation (softening) of the background image.

Clipping Mode
Determines what happens to the parts of the background image that get moved off frame by the steady transform:

- **Domain**: The off frame parts are kept.
- **Frame**: The off frames parts are thrown away.

Domain mode is useful when Steady Mode is being used to “lock” an effect to the pattern. As an example, consider painting on the license plate of a moving car. One way to do this is to use a Planar Tracker node to steady the license plate, then a Paint node to paint on the license plate, and then a second Planar Tracker to undo the steady transform. If the Clipping Mode is set to Domain, the off frame parts generated by the first Planar Tracker are preserved so that the second Planar Tracker can in turn map them back into frame.
Corner Pin Mode

In Corner Pin mode, one or more textures can be attached to a previously tracked planar surface and undergo the same perspective distortions as the surface.

The corner pin workflow with Planar Tracker is:

1. **Track:** select a planar surface in the shot that you wish to attach a texture to or replace the texture on. Track the shot (see the tracking workflow in the Track section).

2. **Switch the Operation Mode to Corner Pin:** When Corner Pin mode is entered from Track mode, the pattern polygon is hidden and a corner pin control is shown in the view.

3. **Connect in the texture:** In the Node Editor view, connect the output of the MediaIn node containing the texture to the Corner Pin 1 input on the Planar Tracker node.

4. **Adjust corner pin:** Drag the corners of the corner pin in the view until the texture is positioned correctly. Sometimes the Show Grid option is useful when positioning the corners. Additionally, if it helps to position it more accurately, scrub to other times and make adjustments to the corner pin.

5. **Review:** Play back the footage and make sure the texture "sticks" to the planar surface.

Merge Mode

Controls how the foreground (the corner pinned texture) is merged over the background (the tracked footage). If there are multiple corner pins, this option is shared by all of them. There are four options to pick from:

- BG only
- FG only
- FG over BG
- BG over FG

Number of Corner Pins

Use the + and - buttons to increase and decrease the number of corner pins. Each time an additional corner pin is created, a corresponding input appears on the node in the Node Editor view.

Corner Pin 1 Input Group

- Each corner pin has a group of related inputs:
- **Enable:** controls the visibility of the corner pin in the view.
- **Show Grid:** shows a grid over the corner pin. This can be useful when positioning the corners.
- **Merge Options:** control merging of corner pin texture over the background - see the documentation for the Merge node.
- **Reference Time Positions:** The positions of the four corners at the reference time. If the track was not perfect, these positions can be animated to make adjustments on top of the track.
Stabilize Mode

Stabilize mode is used to smooth out shakiness in the camera by applying a transform that partially counteracts the camera shake. This stabilizing transform (contained in the Stable Track spline) is computed by smoothing out the tracked transforms over neighboring frames. Note that Stabilize Mode only smooths out motions, while Steady Mode tries to completely “lock off” all motion.

One thing to be aware of is that Planar Tracker stabilizes based upon the motion of the pattern so it is important to choose the pattern carefully. If the motion of the pattern does not represent the motion of the camera then there may be unexpected results. For example, if a shot has a truck moving down the road and the camera is on a vehicle also moving alongside the truck, and the tracking pattern is picked to be the side of the truck, Planar Tracker will end up smoothing the combined motion of both the truck and the vehicle the camera is mounted on. In some cases, this may not be desired and it may be better to choose the pattern to be on some fixed object like the road or the side of a building, which would result in only the motion of the camera being smoothed.

One unavoidable side effect of the stabilization process is that transparent edges are introduced along the edges of the image. These edges come about because the stabilizer does not have any information about what lies off frame so it cannot fill in the missing bits. The Planar Tracker node offers the option to either crop or zoom away these edges. When filming, if the need for post-production stabilization is anticipated, it can be sometimes useful to film at a higher resolution (or lower zoom).

The stabilization workflow with Planar Tracker is:

1. **Track**: For the pattern, select a roughly planar region in the shot that represents the motion that you want to stabilize. Track the shot (see the tracking workflow in the Track section).
2. **Switch the Operation Mode to Stabilize**: Until a stabilization is computed, Planar Tracker will just output the input footage.
3. **Adjust stabilization options**: Frequently changed options are Parameters to Smooth and Smoothing Radius.
4. **Compute stabilization**: Press the Compute Stabilization button and wait for the stabilization computations to finish. Play back the output of the Planar Tracker node to see the effects of the stabilization. Notice that transparent edges have been introduced around the edges of the image by the stabilization transform.
5. **Refine**: Adjust the stabilization options and recompute the stabilization as many times as desired.
6. **Handle transparent edges (optional)**: Set the Frame Mode to either Zoom or Crop as desired and then click the Auto Zoom or Auto Crop button. Playback the footage to observe the effects. If there is too much zoom or the image has been cropped too small, try reducing the amount of smoothing.

Parameters to Smooth

Specify which of the following parameters to smooth:

- X Translation
- Y Translation
- Rotation
- Scale

Smoothing Window

When stabilizing a particular frame, this determines how the contributions of neighboring frames are weighted. Available choices are Box and Gaussian.
Smoothing Radius (frames)
Determines the number of frames whose transforms are averaged together to compute the stabilization. A larger Smoothing Radius results in more smoothing but introduces more transparent edges.

Compute Stabilization
Clicking this button runs the stabilizer, overwriting the results of any previous stabilization. As soon as the stabilization is finished, the output of the Planar Tracker node will be immediately updated with the stabilization applied.

**NOTE:** The stabilizer uses the Track spline (created by the tracker) to produce the Stable Track spline. Both of these splines keyframes contain 4x4 matrices and the keyframes are editable in the Spline Editor.

Clipping Mode
Determines what happens to the parts of the background image that get moved off frame by the stabilization:

- **Domain:** The off frame parts are kept.
- **Frame:** The off frames parts are thrown away.

Frame Mode
This controls how transparent edges are handled. The available options are:

- **Full:** Do nothing, leaves the transparent edges as is.
- **Crop:** Crops away the transparent edges. When this option is selected, the size of Planar Tracker’s output image is smaller than the input image. No image resamplings occur. In crop mode, use the Auto Crop button or manually adjust the crop window by changing the X Offset, Y Offset, and Scale sliders.
  - **Auto Crop Button:** When this button is clicked, Planar Tracker will examine all of the frames and pick the largest possible crop window that removes all the transparent edges. The computed crop window will always be centered in frame and pixel aligned. When clicked, Auto Crop updates the X/Y Offset and Scale sliders.
- **Zoom:** Scales the image bigger until the transparent edges are off frame. Choosing this option causes an image resampling to occur. The downside of this approach is that it reduces the quality (slightly softens) of the output image. In Zoom mode, use the Auto Zoom button or manually adjust the zoom window by changing the X Offset, Y Offset, and Scale sliders.
  - **Auto Zoom:** When this button is clicked, Planar Tracker will examine all of the frames and pick the smallest possible zoom factor that removes all of the transparent edges. The computed zoom window will always be centered in frame. When clicked, Auto Zoom updates the X/Y Offset and Scale sliders.

Right-click here for Stable Track spline
Provides access to a spline whose keyframes contain 4x4 matrices which in turn represent the stabilization transforms. This is mostly here for completeness and for advanced users.
Options Tab
These controls affect the look of onscreen controls in the Viewer.

Darken Image
Darkens the image while in Track mode in order to better see the in view controls and tracks. The Shift+D keyboard shortcut toggles this.

Show Track Markers
Toggles the display of the dots marking the location of trackers at the current time.

Show Trails
Toggles the display of the trails following the location of trackers.

Trail Length
Allows the changing of the length of tracker trails. If the pattern is moving very slowly, increasing the length can sometimes make the trails easier to follow in the view. If the pattern is moving very fast, the tracks can look like spaghetti in the view. Decreasing the length can help.

Inlier/Outlier Colors
When tracking, the tracker analyzes the frame and detects which of the multitudinous tracks belong to the dominant motion and which ones represent anomalous, unexplainable motion. By default, tracks belonging to the dominant motion are colored green (and are called inliers) and those that do not belong are colored red (and are called outliers). Only the inlier tracks are used when computing the final resulting track.

Planar Transform Node
The Planar Transform node applies perspective distortions computed by the analysis done by a Planar Tracker node to any input mask. The Planar Transform node can be used to reduce the amount of artist time spent rotoscoping objects. The workflow here centers around the notion that the Planar Tracker node can be used to track objects that are only roughly planar. After an object has been tracked, a Planar Transform node can then be used to warp a rotospline, making it approximately follow the object over time. Fine level cleanup work on the rotospline then needs to be done.

Depending on how well the Planar Tracker followed the object, this can result in a substantial time savings in the amount of tedious rotoscoping that needs to be done. The key to using this technique is recognizing situations where the Planar Tracker will do passably well tracking an object that needs to be rotoscoped.

A rough outline of the workflow involved is:

1. Track: Using a Planar Tracker node, select a pattern that represents the object to be rotoscoped. Track the shot (see the tracking workflow in the Track section for the Planar Tracker node).
2. Evaluate: Check the quality of the resulting track. If it does not follow the object passably well then give up and do the rotowork the old fashioned way.
3. Create a Planar Transform node: Press the Create Planar Transform button on the Planar Tracker node to do this. The newly created Planar Transform node can be freely cut and paste into another composition as desired.
4  Rotoscope the object: Move to any frame that was tracked by the Planar Tracker. When unsure if a frame was tracked, look in the Spline Editor for a tracking keyframe on the Planar Transform node. Connect a Polygon node into the Planar Transform node. While viewing the Planar Transform node rotoscope the object.

5  Refine: Scrub the timeline to see how well the polygon follows the object. Make tweaks to the polyline on frames where it is off. It is possible to add new points to further refine the polygon.

Controls Tab
The Planar Transform node has very few controls. It’s designed to apply the analyzed Planar Tracking data as a match move,

Reference Time
The reference time that the pattern was taken from in the Planar Tracker node used to produce the Planar Transform.

Right-click here for Track spline
The Track spline contains information about the perspective distortions stored in 4x4 matrices. When a Planar Transform node is exported from a Planar Tracker node, the track spline produced by the Planar Tracker is shared by connecting it with the Planar Transform node. A consequence of this sharing of the track spline is that, if the track is changed in the Planar Tracker node, the Planar Transform will be automatically updated. Note that this spline can be examined in the Spline Editor which is useful for seeing the extent of tracked frames.

Camera Tracker
Camera tracking is match moving and a vital link between 2D and 3D, allowing compositors to integrate 3D renders into live action scenes. The Camera Tracker node is used to calculate the path of a live-action camera and generate a virtual camera in 3D space. This virtual camera’s motion is intended to be identical to the motion of the actual camera that shot the scene. Using the calculated position and movement of the virtual camera provides the flexibility to add 3D elements to a live action scene. The Camera Tracker will also create a point cloud in 3D space which can be used to align objects and other 3D models to the live action scene.

For more information about how to use the Camera Tracker, see Chapter 69, “3D Camera Tracking.”
For more information on how the Camera Tracker workflow is designed to operate, see Chapter 69, “3D Camera Tracking”

**The Track Tab**

The Track tab contains the controls you need to set up an initial analysis of the scene.

**Auto Track**

Automatically detects trackable features and tracks them through the source footage. Tracks will be automatically terminated when the track error becomes too high and new tracks are created as needed. The values of the Detection Threshold and Minimum Feature Separation sliders can be used to control the number and distribution of auto tracks.

**Reset**

Deletes all the data internal to the Camera Tracker node - this includes the tracking data and the solve data (camera motion path and point cloud). To only delete the solve data, use the “Delete” button on the Solve tab.

**Preview AutoTrack Locations**

Turning this checkbox on will show where the auto tracks will be distributed within the shot. This is helpful for determining if the Detection Threshold and Minimum Feature Separation need to be adjusted to get an even spread of trackers.

**Detection Threshold**

Determines the sensitivity to detect features. Automatically generated tracks will be assigned to the shot and the detection threshold will force them to be either in locations of high contrast or low contrast.

**Minimum Feature Separation**

Determines the spacing between the automatically generated tracking points. Decreasing this slider causes more auto tracks to be generated. Keep in mind that a large number of tracking points will also result in a lengthier solve.

**Track Channel**

Used to nominate a color channel to track: red, green, blue, or luminance. When nominating a channel, choose one that has a high level of contrast and detail.
Track Range
Used to determine which frames are tracked:

- **Global**: The global range which is the full duration of the Timeline.
- **Render**: The render duration set on the Timeline.
- **Valid**: The valid range is the duration of the source media.
- **Custom**: A user determined range. When this is selected, a separate range slider appears to set the start and end of the track range.

Bidirectional Tracking
Enabling this will force the tracker to track backward after the initial forward tracking. When tracking backward, new tracks are not started but rather existing tracks are extended backward in time. It is recommended to leave this option on, as long tracks help give better solved cameras and point clouds.

Gutter Size
Trackers can become unstable when they get close to the edge of the image and either drift or jitter or completely lose their pattern. Camera Tracker will automatically terminate any tracks that enter the gutter region. Gutter size is given as a percentage of pattern size. By default, it’s 100% of pattern size, so a 0.04 pattern means a 0.04 gutter.

New Track Defaults
There are three methods in which the Camera Tracker node can analyze the scene and each has its own strengths when dealing with certain types of camera movement.

- **Tracker**: Internally, all the Trackers use the Optical Flow Tracker to follow features over time and then further refine the tracks with the trusted Fusion Tracker or Planar Tracker. The Planar Tracker method allows the pattern to warp over time by various types of transforms to find the best fit. These transforms are:
  - Translation
  - Translation and Rotation
  - Translation, Rotation, and Scale
  - Perspective
  - It is recommended to use the default TRS setting when using the Planar Tracker. The Affine and Perspective settings need large patterns in order to track accurately.

- **Close Tracks when Track Error Exceeds**: Tracks will be automatically terminated when the tracking error gets too high. When tracking a feature, a snapshot of the pixels around a feature are taken at the reference time of the track. This is called a “pattern,” and that same pattern of pixels is searched for at future times. The difference between the current time pattern and the reference time pattern is called the “track error.” Setting this option higher produces longer but increasingly less accurate tracks.

- **Solve Weight**: By default, each track is weighted evenly in the solve process. Increasing a track’s weight means it has a stronger effect on the solved camera path. This is an advanced option that should be rarely changed.

Auto Track Defaults
Set a custom prefix name and/or color for the automatically generated tracks. This custom color will be visible when Track Colors in the Options tab is set to “User Assigned.”
**Camera Tab**

The controls of the Camera tab let you specify the physical aspects of the live action camera, which will be used as a starting point when searching for solve parameters that match the real world camera. The more accurate the information provided in this section, the more accurate the camera solve.

The three top checkboxes define which parameters the solver can adjust to make the solve work.

**Refine Focal Length**
This will allow the solver to adjust the focal length of the lens to match the tracking points.

**Refine Centre Point**
Normally ticked off, Camera lenses are normally centered in the middle of the film gate but this may differ on some cameras. For example, a cine camera may be set up for Academy 1.85, which has a sound stripe on the left, and shooting super35, the lens is offset to the right.

**Refine Lens Parameters**
This will refine the lens distortion or curvature of the lens. There tends to be larger distortion on wide angle cameras.

**Camera**
The camera group has controls relating to the lens and gate aspects of the camera being solved for.

**Focal length**
Specify the known constant focal length used to shoot the scene or a guess if the Refine Focal Length option is ticked.

**Film Gate**
Choose a film gate preset from the dropdown menu or manually enter the film back size in the Aperture Width and Aperture Height inputs. Note, these values are in inches.

**Aperture Width**
In the event that the camera used to shoot the scene is not in the preset pulldown, manually enter the aperture width (inches).

**Aperture Height**
In the event that the camera used to shoot the scene is not in the preset pulldown, manually enter the aperture height (inches).

**Resolution Gate Fit**
This defines how the image fits the sensor size. Often film sensors are of a size to cover a number of formats, and only a portion of the sensor area is recorded into an image.

For example, a 16:9 image is saved out of a full aperture sized sensor.

Typically fit to Width or Height is the best setting. The other fit modes are Inside Outside or Stretched.

**Center Point**
This is where the camera lens is aligned to the camera. The default is (0.5, 0.5) which is middle of the sensor.
Use Source Pixel Aspect
This will use the squeeze Aspect of the pixels that is loaded in the image. HD is square pixels but NTSC has a pixel aspect ratio of 0.9:1, or Anamorphic cinema scope is 2:1 aspect.

Auto Camera Planes
When this is enabled, the camera’s image plane and far plane are automatically moved to enclose the point cloud whenever a solve completes. Sometimes though, the solver can anomalously fling points off really deep into the scene and consequently the image plane ends up being pushed really far out, making the resulting scene unwieldy to work with in the 3D views. In these cases, use this option to override this default behavior (or delete the offending tracks).

Lens
When solving for the camera’s motion path, Camera Tracker internally creates and then uses a simulated lens to model lens distortion in the source footage. This simulated lens model is much simpler than real world lenses but captures the lens distortion characteristics important for getting an accurate camera solve. Two types of distortion are modeled by Camera Tracker:

1 Radial Distortion: The strength of this type of distortion varies depending on the distance from the center of the lens. Examples of this include pincushion, barrel, and mustache distortion. Larger values correspond to larger lens curvatures. Modeling radial distortion is especially important for wide angle lenses and fisheye lenses (which will have a lot of distortion because they capture 180 degrees of an environment and then optically squeeze it onto a flat rectangular sensor).

2 Tangential Distortion: This kind of distortion is produced when the camera’s imaging sensor and physical lens are not parallel to each other. It tends to produce skew distortions in the footage similar to distortions that can be produced by dragging the corners of a corner pin within Fusion. This kind of distortion occurs in very cheap consumer cameras and is practically non-existent in film cameras, DSLRs, and pretty much any kind of camera used in film or broadcast. It is recommended that it be left disabled.

Enable Parameters
Determines which lens parameters will be modeled and solved for. Parameters that are not enabled will be left at their default values. The following options are available:

- **None**: Do not do any lens curvature simulations. This should be picked if there is a very low distortion lens or the lens distortion has already been removed from the source footage in a preprocessing step.
- **Radial**: Model only radial lens curvature. This causes the low and high order distortion values to be solved for.
- **Radial & Tangential**: Model and solve for both radial and tangential distortion.

Lower Order Radial Distortion
Determines the quadratic lens curvature.

Higher Order Radial Distortion
Determines the quartic lens curvature.

Tangential Distortion X/Y
Determines skew distortion.
Solve

The Solve tab is where the tracking data is used to reconstruct the camera’s motion path along with the point cloud. It is also where cleanup of bad or false tracks is done, and other operations on the tracks can be performed, such as defining which marks are exported in the Point Cloud 3D. The markers can also have their weight set to affect the solve calculations.

For example, a good camera solve may have already been generated but there are not enough locators in the point cloud in an area where an object needs to be placed so adding more tracks and setting their Solve Weight to zero will not affect the solved camera but will give more points in the point cloud.

Average Solve Error

Once the camera has been solved, the Average Solve Error will display here. This number is a good indicator whether the camera solve was successful or not. It can be thought of as the difference (measured in pixels) between tracks in the 2D image and the reconstructed 3D locators reprojected back onto the image through the reconstructed camera. Ultimately, in trying to achieve a low solve error, any value less than 1.0 pixels will generally result in a good track. A value between 0.6 and 0.8 pixels is considered excellent.

Solve Extent

Displays the frame range for which the camera’s motion will be reconstructed. The Solver will reconstruct any frames that have tracks on them.

Solve

Pressing Solve will launch the solver, which uses the tracking information and the camera specifications to generate a virtual camera path and point cloud, approximating the motion of the physical camera in the live action footage. The console will automatically open, displaying the progress of the Solver.

Delete will remove any solved information, such as the camera and the point cloud, but will keep all of the tracking data.

Auto Select Seed Frames

Seed frames are the reference images that are used to initialize the solve process. These two frames are initially solved for and a camera is reconstructed and then gradually more frames are added in and the solution is “grown” outward from the seed frames. The choice of seed frames strongly affects the entire solve and can easily cause the solve to fail. Seed frames can be found automatically or defined manually. Manual choice of seed frames is an option for advanced users. When choosing seed frames, it is important to satisfy two conflicting desires: the seed frames should have lots of tracks in common yet be far apart in perspective (the baseline distance between the two associated cameras is long).

Selected Tracks

This area displays the properties of a track point or group of points. It has options to:

- **Clear**: Deselects all tracks and clears this area.
- **Invert**: Deselects the current selected tracks and selects the other tracks.
- **Visible**: Selects all the trackers at the current frame.
- **All**: Selects all trackers on all frames.
- **Search**: Selects tracks whose names contain a substring.
NOTE: Also select tracks directly in the 2D view using the mouse or in the 3D view by selecting their corresponding locators in the point cloud.

Track Filtering

Camera Tracker can produce a large number of automatically generated tracks. Rather than spending a lot of time individually examining the quality of each track, it is useful to have some less time intensive ways to filter out large swaths of potentially bad tracks. The following input sliders are useful for selecting large amounts of tracks based on certain quality metrics and then a number of different possible operations can be made on them. For example, weaker tracks can selected and deleted, giving a stronger set of tracks to solve from. Each filter can be individually ticked on or off.

Minimum Track Length (number of markers)
Selects tracks that have a duration shorter than the slider’s value. Short tracks usually don’t get a chance to move very far and thus provide less perspective information to the Solver than a longer track, yet both short and long tracks are weighted evenly in the solve process, making long tracks more valuable to the Solver. Locators corresponding to shorter tracks are also less accurately positioned in 3D space than those corresponding to longer tracks. If the shot has a lot of long tracks, it can be helpful to delete the short tracks. For typical shots, using a value in the range of 5 to 10 is suggested. If there are not a lot of long tracks (e.g., the camera is quickly rotating, causing tracks to start and move off frame quickly), using a value closer to 3 is recommended.

Minimum Track Error
Selects tracks that have an average track error greater than the slider’s value. When tracking, tracks are automatically terminated when their track error exceeds some threshold. This auto termination controls the maximum track error, while this slider controls the average track error. For example, tracks following the foliage in a tree tend to be inaccurate and sometimes may be detected by their high average error.

Maximum Solve Error
Selects tracks that have a solve error greater than the slider’s value. One of the easiest ways to increase the accuracy of a camera solve is to select the 20% of the tracks with the highest solve error and simply delete them (although this can sometimes make things worse).

Auto Select Tracks While Dragging Sliders
When this is ticked on, dragging the above sliders (minimum track length, maximum track error, maximum solve error) will cause the corresponding tracks to be interactively selected in the view.

Select Tracks Satisfying Filters
Selects the tracks within the scene that meet the above Track Filtering values. Note that when this button is pressed, the tracks that satisfy the filter values are displayed in the Selected Tracks area of the Solve Tab and are colored in the Viewer. This button is useful when “Auto Select Tracks While Dragging Sliders” is turned off or if the selection, for example, was accidentally lost by mis-clicking in the Viewer.
Operations On Selected Tracks

Tracks selected directly in the Viewer with the mouse or selected via track filtering can have the following operations applied:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>Will remove the tracks from the set. When there are bad tracks, the simplest and easiest option is to simply delete them.</td>
</tr>
<tr>
<td>Trim Previous</td>
<td>Will cut the tracked frames from the current frame to the start of the track. Sometimes it can be more useful to trim a track than deleting it. For example, high quality long tracks that become inaccurate when the feature they are tracking starts to become occluded or when the tracked feature moves too close to the edge of the image.</td>
</tr>
<tr>
<td>Trim Next</td>
<td>Will cut the tracked frames from the current frame to the end of the track.</td>
</tr>
<tr>
<td>Rename</td>
<td>Will replace the current auto generated name with a new name.</td>
</tr>
<tr>
<td>Set Color</td>
<td>Will allow for user assigned color of the tracking points.</td>
</tr>
<tr>
<td>Export Flag</td>
<td>This controls whether the locators corresponding to the selected tracks will be exported in the point cloud. By default all locators flagged as exportable.</td>
</tr>
<tr>
<td>Solve Weight</td>
<td>By default, all the tracks are used and equally weighted when solving for the camera’s motion path. The most common use of this option is to set a track’s weight to zero so it does not influence the camera’s motion path but is still has a reconstructed 3D locator. Setting a tracks’ weight to values other than 1.0 or 0.0 should only be done by advanced users. Onscreen display of track names and values are controlled by these functions:”</td>
</tr>
<tr>
<td>None</td>
<td>Will clear/hide the selected tracks.</td>
</tr>
<tr>
<td>Toggle</td>
<td>Will swap the selected tracks and unselect sets.</td>
</tr>
<tr>
<td>All</td>
<td>Will select all tracks.</td>
</tr>
<tr>
<td>Show Names</td>
<td>Will display the track name, by default these are a number.</td>
</tr>
<tr>
<td>Show Frame Range</td>
<td>Will display the start and end frame of a track.</td>
</tr>
<tr>
<td>Show Solve Error</td>
<td>Will display the amount of solve error each selected track has.</td>
</tr>
</tbody>
</table>

Export

The Export tab lets you turn the tracked and solved data this node has generated into a form that can be actually used for compositing.

Export

Export button will create a basic setup that can be used for 3D match moving:

- A Camera 3D with animated translation and rotation that matches the motion of the live action camera and an attached image plane.
- A Point Cloud 3D containing the reconstructed 3D positions of the tracks.
- A Shape 3D set to generate a ground plane.
- A Merge 3D merging together the camera, point cloud, and ground plane. When the Merge 3D is viewed through the camera in a 3D view, the 3D locators should follow the tracked footage.
- A Renderer 3D set to match the input footage.
The export of individual nodes can be enabled/disabled in the Export Options tab.

**Update Previous Export**

When this button is clicked, the previously exported nodes are updated with any new data generated. These previously exported nodes are remembered in the Previous Export section at the bottom of this section. An example of where this is handy:

- Solve the camera and export.
- Construct a complex Node Editor based around the exported nodes for use in set extension.
- The camera is not as accurate as preferred or perhaps the Solver is rerun to add additional tracks to generate a denser point cloud. Rather than re-exporting the Camera 3D and Point Cloud 3D nodes and connecting them back in, just press this button to "overwrite" the existing nodes in place.

**Automatically Update Previous Export After Solves**

Will cause the already exported nodes (Camera 3D, Point Cloud 3D, Lens Distort, Renderer 3D, and the ground plane) to auto update on each solve.

**3D Scene Transform**

This defines the origin and alignment of the virtual camera, point cloud, and ground plane. By default, the Solver will always place the camera in Fusion's 3D virtual environment so that on the first frame it is located at the origin (0, 0, 0) and it is looking down the -Z axis. In this default orientation, the physical ground plane in the footage will often not match up with the virtual ground plane in the 3D view and the 3D Scene Transform provides a mechanism to correct that. Note that adjusting the 3D Scene Transform does not modify the camera solve but simply repositions the 3D scene to best represent the position of the live action camera. Also note that if these options need changing, it is important to manually hit "Update Previous Export" to see the results in the exported nodes.

**Unaligned, Aligned**

The Unaligned button allows the origin and ground plane settings to be adjusted, either manually or by using a selected set of locators from the point cloud. When in unaligned mode, a 3D transform control will be shown in the 3D view which can be manually manipulated to adjust the origin.

Once alignment has been complete, the section is locked by switching to the Aligned button. From the Coordinate System, either output the Raw Unaligned scene where the 3D grid runs directly through the solved camera, or an Aligned scene where the 3D grid can be adjusted to the plane of the user's choice.

**Set From Selection**

Takes selected 3D points from the point cloud and aligns the ground plane to fit those points. This can be adjusted individually for position, rotation, and scale. To set a ground plane, select a number of Point Cloud points that are on the ground. To get the best result, try to select as many points as possible belonging to the ground and having a wide separation. Under the Origin pull down, press Set from Selection. This will reposition the Ground Plane. Under the Orientation pull down, press Set from Selection. This will alter the orientation of the Ground plane to the selected points. Finally, press the Aligned button, which repositions the 3D system so the 3D grid is aligned to the Ground Plane.

When selecting points for the ground plane, it is helpful to have the Camera Tracker node viewed in side by side 2D and 3D views. It may be easier to select tracks belonging to the ground by selecting tracks from multiple frames in the 2D view rather than trying to box select locators in the 3D view.
Ground Plane Options

These controls let you adjust the ground plane for the scene, which is a crucial step in making sure the composite looks correct.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Color</td>
<td>Will set the color of the ground plane.</td>
</tr>
<tr>
<td>Size</td>
<td>Controls how big the ground plane can be set.</td>
</tr>
<tr>
<td>Subdivision Level</td>
<td>Shows how many polygons are in the ground plane.</td>
</tr>
<tr>
<td>Wireframe</td>
<td>Sets whether the ground plane is set as wireframe or solid surface when displayed in 3D.</td>
</tr>
<tr>
<td>Line Thickness</td>
<td>Adjusts how wide the lines will draw in the view.</td>
</tr>
<tr>
<td>Offset</td>
<td>By default, the center of the ground plane is placed at the origin (0, 0, 0). This can be used to shift the ground plane up and down along the y-axis.</td>
</tr>
</tbody>
</table>

Export Options

Provides a checkbox list of what will be exported as nodes when the Export button is pressed. These options are Camera, Point Cloud, Ground Plane, Renderer, Lens Distortion, and Enable Image Plane in the camera.

Previous Export

When the Update Previous Export button is clicked, the previously exported nodes listed here are updated with any new data generated (this included the camera path and attributes, the point cloud, and the renderer).

Options

The Options tab lets you customize the CameraTracker onscreen controls so you can work most effectively with the scene material you have.

Trail Length

Will display trail lines of the tracks overlaid on the view. The amount of frames forward and back from the current frame is set by length.

Location Size

In the 3D View, the point cloud locators can be sized by this control.

Track Colors, Locator Colors, and Export Colors each have options for setting their color to one of the following: User Assigned, Solve Error, Take From Image, and White.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Track Colors</td>
<td>are the onscreen tracks in the 2D view.</td>
</tr>
<tr>
<td>Locator Colors</td>
<td>are the Point Cloud locators in the 3D view.</td>
</tr>
<tr>
<td>Export Colors</td>
<td>are colors of the locators that get exported within the Point Cloud node.</td>
</tr>
</tbody>
</table>

Darken Image

Dim the brightness of the image in views to better view the overlaid tracks. This affects both the 2D and 3D view.
Visibility

Toggles which overlays will be displayed in the 2D and 3D views. The options are Tracker Markers, Trails, Tooltips in the 2D View, Tooltips in the 3D View, Reprojected Locators, and Tracker Patterns.

Colors

Sets the color of the overlays

- **Selection Color:** controls the color of selected tracks/locators.
- **Preview New Tracks Color:** controls the color of the points displayed in the view when the “Preview AutoTrack Locations” option is enabled.
- **Solve Error Gradient:** By default, tracks and locators are colored by a green-yellow-red gradient to indicate their solve error. This gradient is completely user adjustable.

Reporting

Outputs various parameters and information to the console.

Understanding Camera Tracking

On large feature films, Camera Match moving is often farmed out to experts who have a lot of experience with the process of tracking and solving these types of shots. There is rarely a shot where automatic, press a couple of buttons and the process is complete, can be done. It does take understanding of the whole process and what is important to get a good solved track.

The Camera Tracker has to solve for hundreds of thousands of unknown variables, which is a complex task. To create an accurate solve, it is important to get to a precise set of good tracks that exists for a long time. False or bad tracks will skew the result. This section explains how to clean up false tracks and other theory to get a good solve.

Workflow

Track -> Solve -> Refine Filters -> Solve -> Cleanup tracks -> Solve -> Cleanup from point cloud -> Solve -> Repeat.

The Solve is a repeated process to get a good result. Initially, there will be a lot of tracks, and not all are good, so a process of filtering and cleaning up unwanted tracks to get to the best set is a process. At the end of each clean up stage, pressing Solve will give you a result for Solve Error. This needs to be below 1 for it to be good for use, the lower the better. Refining the tracks will result in a better solve.

False Tracks

False tracks are tracks that move or are incorrect and are caused by a number of conditions, such as moving people or objects in a shot, or reflections and highlights from a car. There are other types of false tracks like parallax errors where two objects are at different depths and the intersection gets tracked. These Moire effects can cause the track to creep. Reflections in glass on buildings are warped, trees in the wind, recognizing these False tracks and eliminating them is the most important step in the Solve process.

Track lengths

Getting a good set of long tracks is important; longer makes the solve fitting better. Bi-directional tracking is used to extend the beginning of tracks in time. The longer in time a track exists and the more tracks that overlap in time of a shot, the more consistent and accurate the solve.
**Seed frames**
There are two seed frames that are used in the solve process, the algorithm chooses two frames that are as far apart in time yet share the same tracks, hence longer tracks makes the greater difference in the selection of seed frames.

The two Seed frames are used as the reference frames, which should be from different angles of the same scene. The Solve process will use these as a master starting point to fit the rest of the tracks of the sequence.

There is an option that auto detects Seed frames, which can take some time. In the workflow of solving, auto detect is a good idea. When refining the Trackers and resolving, it should be set to Manual mode and use the previous solve’s seed frames, which are displayed in the Solve dialog window.

**Refine Filters**
After the first solve, all of the Trackers will have extra data generated. These are solve errors and tracking errors.

Use the refine filters to reduce unwanted tracks, like setting minimum tracker length to eight frames. As the value for each filter is adjusted, the Solve dialog window will indicate how many tracks are affected by the filter. Solve again.

**Onscreen Culling**
Under the Options Tab, set the track to 20, this will display each track on footage with +20 frame trail. When scrubbing/playing through the footage, false tracks can be seen and selected on screen, and deleted by pressing the delete key. This process takes an experienced eye to spot tracks that go bad. Solve again.

View the 3D scene in perspective, the point cloud will be visible. Move and pan around the point cloud, select and delete points that seem to have no inline with the image and the scene space. Solve again.

Repeat process until the Solve error is below 1.0 before exporting.

**Selecting Points for Ground plane**
Selecting tracks or points in the point cloud will allow for alignment and fitting of the ground plane.
This chapter details the Transform nodes available in the Fusion page.
Contents

Camera Shake [CSH] 1949
Crop [CRP] 1952
DVE [DVE] 1954
Letterbox [LBX] 1955
Resize [RSZ] 1958
Scale [SCL] 1960
Transform [XF] 1963
Camera Shake [CSH]

This node can simulate a variety of Camera Shake style motions from organic to mechanical. It is not the same as the Shake Modifier, which generates random number values for node controls.

See the Connections and Modifiers chapter for more information about the Shake Modifier.

The Camera Shake node concatenates its result with adjacent transformation nodes.

Controls

Deviations X and Y
These controls determine the amount of shake that is applied to the image along the horizontal (X) and vertical (Y) axis. Values between 0.0 and 1.0 are permitted. A value of 1.0 generates shake positions anywhere within the boundaries of the image.

Rotation Deviation
This determines the amount of shake that is applied to the rotational axis. Values between 0.0 and 1.0 are permitted.

Randomness
Higher values in this control cause the movement of the shake to be more irregular or random. Smaller values cause the movement to be more predictable.

Overall Strength
This adjusts the general amplitude of all the parameters and blends that affect in and out. A value of 1.0 applies the effect as described by the remainder of the controls.

Speed
Speed controls the frequency, or rate, of the shake.
**Frequency Method**
This selects the overall shape of the shake. Available frequencies are Sine, Rectified Sine, and Square Wave. A Square Wave will generate a much more mechanical looking motion than a Sine.

**Edges**
This determines how the Edges of the image are treated.

**Black**
This causes the edges that are revealed by the shake to be black.

**Wrap**
This causes the edges to wrap around (the top is wrapped to the bottom, the left is wrapped to the right, and so on).

**Duplicate**
This causes the Edges to be duplicated, causing a slight smearing effect at the edges.

**Invert Transform**
Select this control to Invert any position, rotation or scaling transformation. This option might be useful to exactly removing the motion produced in an upstream Camera Shake.

**Flatten Transform**
The Flatten Transform option prevents this node from concatenating its transformation with adjacent nodes. The node may still concatenate transforms from its input, but it will not concatenate its transformation with the node at its output.

**Filter Modes**

**Nearest Neighbor**
This skips or duplicates pixels as needed. This produces the fastest but crudest results.

**Box**
This is a simple interpolation resize of the image.

**Linear**
This uses a simplistic filter, which produces relatively clean and fast results.

**Quadratic**
This filter produces a nominal result. It offers a good compromise between speed and quality.

**Cubic**
This produces better results with continuous tone images but is slower than Bi-Cubic. If the images have fine detail in them, the results may be blurrier than desired.

**Catmull-Rom**
This produces good results with continuous tone images that are resized down. Produces sharp results with finely detailed images.

**Gaussian**
This is very similar in speed and quality to Bi-Cubic.
Mitchell
This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.

Lanczos
This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.

Sinc
This is an advanced filter that produces very sharp, detailed results, however, it may produce visible “ringing” in some situations.

Bessel
This is similar to the Sinc filter but may be slightly faster.

Window Method
Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

Hanning
This is a simple tapered window.

Hamming
Hamming is a slightly tweaked version of Hanning.

Blackman
A window with a more sharply tapered falloff.

Kaiser
A more complex window, with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter, however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

Example

Different Resize Filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, Bessel
Crop [CRP]

The Crop node can be used to cut out a portion of an image or to offset the image into a larger image area. This node actually changes the resolution of the image and should not be animated under normal circumstances.

It is possible to crop an image in the view by viewing the upstream node and selecting a region with the mouse. To do so, first activate Allow Box Selection by clicking on the icon next to your view, then dragging a rectangle to perform the operation.

Controls

Offset X and Y
These controls position the top left corner of the Cropping window. Values larger than the actual resolution of the cropped image cause it to disappear off the edges of the output image. Values below 0 will push the input image toward the bottom right of the result. The values of these controls are measured in pixels.

Size X and Y
Use this control to set the vertical and horizontal resolution of the image output by the Crop node. The values of these controls are measured in pixels.

Keep Aspect
When toggled on, the Crop node maintains the aspect of the input image.

Keep Centered
When toggled on, the Crop node automatically adjusts the X and Y Offset controls to keep the image centered.

Reset Size
This resets the image dimensions to the Size of the input image.
**Reset Offset**
This resets the X and Y Offsets to their defaults.

**Change Pixel Aspect**
Enable this checkbox to reveal a Pixel Aspect control that can be used to change the pixel aspect that the image is considered to have.

**Clipping Mode**
This option sets the mode used to handle the edges of the image when performing Domain of Definition rendering. This is profoundly important for nodes like Blur, which may require samples from portions of the image outside the current domain.

**Frame**
The default option is Frame, which automatically sets the node’s Domain of Definition to use the full frame of the image, effectively ignoring the current Domain of Definition. If the upstream DoD is smaller than the frame, the remaining area in the frame will be treated as black/transparent.

**Domain**
Setting this option to Domain will respect the upstream Domain of Definition when applying the node’s effect. This can have adverse clipping effects in situations where the node employs a large filter.

**None**
Setting this option to None will not perform any source image clipping at all. This means that any data required to process the node’s effect which would normally be outside the upstream DoD will be treated as black/transparent.

**Auto Crop Tab**

![Auto Crop Tab](image)

**RGBA Color Channels**
Select which channels are examined for an Auto Crop. This is useful for auto cropping images with non-solid backgrounds in a specific color channel, like a blue color gradient. Toggling the channel off causes Auto Crop to ignore it when evaluating the image.

**Auto Crop**
This evaluates the image and attempts to determine the background color. It then crops each side of the image to the first pixel that is not this color.
**DVE [DVE]**

The DVE node is a 3D-image transformation similar to nodes found in an online edit suite. The node encompasses image rotations, perspective changes and Z moves. The axis can be defined for all transformations.

**Controls**

**Pivot X, Y and Z**
Position the axis of rotation and scaling. The default is 0.5, 0.5 for X and Y, which is in the center of the image, and 0 for Z, which is at the center of Z space.

**Rotation Order**
Use these buttons to determine in what order Rotations are applied to the image.

**XYZ Rotation**
These controls are used to rotate the image around the pivot along the X-, Y- and Z-axis.

**Center X and Y**
This positions the Center of the DVE image on screen. The default is 0.5, 0.5, which positions the DVE in the center of the image.

**Z Move**
This zooms the image in and out along the Z-axis. Visually, when this control is animated, the effect is similar to watching an object approach from a distance.

**Perspective**
This adds additional Perspective to an image rotated along the X- or Y-axis, similar to changing the Field of View and zoom of a camera.
**Masking Tab**

The DVE node allows pre-masking of its input image. This offers the ability to create transformations from the masked area of the image while leaving the remainder of the image unaffected.

Unlike regular effect masking, the masking process occurs before the transformation. To use this feature, connect a mask to the DVE node’s DVE Mask input. Alternatively, select the DVE node, right-click on the view and select DVE Mask from the contextual menu. All of the usual mask types can be applied to the DVE mask.

**Black Background**
Toggle this on to erase the area outside the mask from the transformed image.

**Fill Black**
Toggle this on to erase the area within the mask (before transformation) from the DVE’s input, effectively cutting the masked area out of the image. Enabling both Black Background and Fill Black will show only the masked, transformed area.

**Alpha Mode**
This determines how the DVE will handle the alpha channel of the image, when merging the transformed image areas over the untransformed image.

**Ignore Alpha**
This causes the input image’s alpha channel to be ignored, so all masked areas will be opaque.

**Subtractive/Additive**
These cause the internal merge of the pre-masked image over the input image to be either Subtractive or Additive. For more information on Subtractive and Additive merges, see the Merge node.

**Letterbox [LBX]**

Use the Letterbox node to adapt existing images to the frame size and aspect ratios of any other format. The most common use of this node is to adapt film resolution images to NTSC or PAL sized frames for viewing on an external television monitor. Horizontal or vertical black edges are automatically added where necessary to compensate for aspect ratio differences.
Controls

Formats Contextual Menu
Place the pointer on the Aspect X or Y control and press the right mouse button to display a menu with available frame formats. Select any one of the choices from the menu to set the Height, Width, and Aspect controls automatically, or enter the required information manually.

Width and Height
The values of these controls determine the size of the output image as measured in pixels.

Pixel Aspect X and Y
The controls determine the Pixel Aspect Ratio of the output image.

Center X and Y
This Center control repositions the image window when used in conjunction with Pan-and-Scan mode. It has no effect on the image when the node is set to Letterbox mode.

Mode
This control is used to determine the Letterbox node’s mode of operation.

Letterbox/Envelope
This corrects the aspect of the input image and resizes it to match the specified width.

Pan-And-Scan
This corrects the aspect of the input image and resizes it to match the specified height. If the resized input image is wider than the specified width, the center control can be used to animate the visible portion of the resized input.

Filter Modes

Nearest Neighbor
This skips or duplicates pixels as needed. This produces the fastest but crudest results.

Box
This is a simple interpolation resize of the image.

Linear
This uses a simplistic filter, which produces relatively clean and fast results.
**Quadratic**  
This filter produces a nominal result. It offers a good compromise between speed and quality.

**Cubic**  
This produces better results with continuous tone images but is slower than Bi-Cubic. If the images have fine detail in them, the results may be blurrier than desired.

**Catmull-Rom**  
This produces good results with continuous tone images that are resized down. Produces sharp results with finely detailed images.

**Gaussian**  
This is very similar in speed and quality to Bi-Cubic.

**Mitchell**  
This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.

**Lanczos**  
This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.

**Sinc**  
This is an advanced filter that produces very sharp, detailed results, however, it may produce visible ‘ringing’ in some situations.

**Bessel**  
This is similar to the Sinc filter but may be slightly faster.

**Window Method**

Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a Windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

**Hanning**  
This is a simple tapered window.

**Hamming**  
Hamming is a slightly tweaked version of Hanning.

**Blackman**  
A window with a more sharply tapered falloff.

**Kaiser**  
A more complex window, with results between Hamming and Blackman. Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter, however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.
Example

Different Resize Filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, Bessel

Resize [RSZ]

Use the Resize node to increase or decrease the resolution of an input image. This is useful for converting images from one format to another (for example, from film to video resolution).

Controls

Width
This controls the new resolution for the image along the X-axis.

Height
This controls the new resolution for the image along the Y-axis.

Keep Frame Aspect
When toggled on, the Resize node maintains the aspect of the original image, preserving the original ratio between width and height.

Reset Size
Reset the image dimensions to the original size of the image.
Only Use Filter in HiQ
The Resize node will normally use the fast Nearest Neighbor filter for any non-HiQ renders, where speed is more important than full accuracy. Disable this checkbox to force Resize to always use the selected filter for all renders.

Change Pixel Aspect
Enable this checkbox to reveal a Pixel Aspect control that can be used to change the pixel aspect that the image is considered to have.

Filter Method
When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called filters. More complex filters can give better results but are usually slower to calculate. The best filter for the job will often depend on the amount of scaling and on the contents of the image itself.

Nearest Neighbor
This skips or duplicates pixels as needed. This produces the fastest but crudest results.

Box
This is a simple interpolation resize of the image.

Linear
This uses a simplistic filter, which produces relatively clean and fast results.

Quadratic
This filter produces a nominal result. It offers a good compromise between speed and quality.

Cubic
This produces better results with continuous tone images but is slower than Bi-Cubic. If the images have fine detail in them, the results may be blurrier than desired.

Catmull-Rom
This produces good results with continuous tone images that are resized down. Produces sharp results with finely detailed images.

Gaussian
This is very similar in speed and quality to Bi-Cubic.

Mitchell
This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.

Lanczos
This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.

Sinc
This is an advanced filter that produces very sharp, detailed results, however, it may produce visible “ringing” in some situations.

Bessel
This is similar to the Sinc filter but may be slightly faster.
Window Method

Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a Windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

Hanning
This is a simple tapered window.

Hamming
Hamming is a slightly tweaked version of Hanning.

Blackman
A Window with a more sharply tapered falloff.

Kaiser
A more complex window, with results between Hamming and Blackman. Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter, however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

NOTE: Because this node changes the physical resolution of the image, we do not normally advise animating the controls.

Example

Different Resize Filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, Bessel

Scale [SCL]

The Scale node is almost identical to the Resize node, except that Resize uses exact dimensions where the Scale node uses relative dimensions to describe the change to the source image’s resolution.
Controls

**Lock X/Y**
When selected, only a Size control is shown and changes to the image's scale are applied to both axes equally. If the checkbox is cleared, individual size controls appear for both X and Y Size.

**Size X/Y**
The Size control is used to set the scale used to adjust the resolution of the source image. A value of 1.0 would have no affect on the image, while 2.0 would scale the image to twice its current resolution. A value of 0.5 would halve the image's resolution.

**Change Pixel Aspect**
Enable this checkbox to reveal a Pixel Aspect control that can be used to change the Pixel Aspect that the image is considered to have.

**Only Use Filter in HiQ**
The Scale node will normally use the fast Nearest Neighbor filter for any non-HiQ renders, where speed is more important than full accuracy. Disable this checkbox to force Scale to always use the selected filter for all renders.

**Filter Method**
When rescaling a pixel, surrounding pixels are often used to give a more realistic result. There are various algorithms for combining these pixels, called Filters. More complex filters can give better results, but are usually slower to calculate. The best filter for the job will often depend on the amount of scaling and on the contents of the image itself.

**Nearest Neighbor**
This skips or duplicates pixels as needed. This produces the fastest but crudest results.

**Box**
This is a simple interpolation resize of the image.

**Linear**
This uses a simplistic filter, which produces relatively clean and fast results.

**Quadratic**
This filter produces a nominal result. It offers a good compromise between speed and quality.
**Cubic**
This produces better results with continuous tone images but is slower than Bi-Cubic. If the images have fine detail in them, the results may be blurrier than desired.

**Catmull-Rom**
This produces good results with continuous tone images that are resized down. Produces sharp results with finely detailed images.

**Gaussian**
This is very similar in speed and quality to Bi-Cubic.

**Mitchell**
This is similar to Catmull-Rom but produces better results with finely detailed images. It is slower than Catmull-Rom.

**Lanczos**
This is very similar to Mitchell and Catmull-Rom but is a little cleaner and also slower.

**Sinc**
This is an advanced filter that produces very sharp, detailed results, however, it may produce visible “ringing” in some situations.

**Bessel**
This is similar to the Sinc filter but may be slightly faster.

**Window Method**
Some filters, such as Sinc and Bessel, require an infinite number of pixels to calculate exactly. To speed up this operation, a Windowing function is used to approximate the filter and limit the number of pixels required. This control appears when a filter that requires windowing is selected.

**Hanning**
This is a simple tapered window.

**Hamming**
Hamming is a slightly tweaked version of Hanning.

**Blackman**
A window with a more sharply tapered falloff.

**Kaiser**
A more complex window, with results between Hamming and Blackman.

Most of these filters are useful only when making an image larger. When shrinking images, it is common to use the Bi-Linear filter, however, the Catmull-Rom filter will apply some sharpening to the results and may be useful for preserving detail when scaling down an image.

**NOTE:** Because this node changes the physical resolution of the image, we do not normally advise animating the controls.
Example

Different Resize Filters. From left to right: Nearest Neighbor, Box, Linear, Quadratic, Cubic, Catmull-Rom, Gaussian, Mitchell, Lanczos, Sinc, Besse

Transform [XF]

The Transform node can be used for simple 2D Transformations of the image, such as moving, rotating and scaling. The image’s aspect can also be modified using the Transform node.

The Transform node concatenates its result with adjacent Transformation nodes. For more information on concatenation, consult the Transformations chapter.

Controls

Flip Horizontally and Vertically
Toggle this control on to flip the image along the X- or Y-axis.
Edges
Edges determines how the edges of the image will be treated.

Canvas
This causes the edges of the image that are revealed to show the current Canvas Color. This defaults to black with no Alpha and can be set using the Set Canvas Color node.

Wrap
This wraps the edges of the image around the borders of the image. This is useful for seamless images to be panned, creating an endless moving background image.

Duplicate
This causes the edges of the image to be duplicated as best as possible, continuing the image beyond its original size.

Center X and Y
This sets the position of the image on the screen. The default is 0.5, 0.5, which places the image in the center of the screen. The value shown is always the actual position multiplied by the reference size. See below for a description of the reference size.

Pivot X and Y
This positions the axis of rotation and scaling. The default is 0.5, 0.5, which is the center of the image.

Use Size and Aspect
This checkbox determines whether the Transform node provides independent Size controls for the X and Y scale, or if Size and Aspect controls are used instead.

Size
This modifies the Size, or scale, of the image. Values range from 0 to 5, but any value greater than zero can be entered into the edit box. If the Use Size and Aspect checkbox is selected, this control will scale the image equally along both axes. If the Use Size and Aspect option is off, independent control is provided for X and Y.

Aspect
This control changes the Aspect Ratio of an image. Setting the value above 1.0 stretches the image along the X-axis. Values between 0.0 and 1.0 stretch the image along the Y-axis. This control is available only when the Use Size And Aspect checkbox is enabled.

Angle
This control rotates the image around the axis. Increasing the Angle rotates the image in a counter-clockwise direction. Decreasing the Angle rotates the image in a clockwise direction.

Invert Transform
Select this control to Invert any position, rotation or scaling transformation. This option is useful when connecting the Transform to the position of a tracker for the purpose of re-introducing motion back into a stabilized image.

Flatten Transform
The Flatten Transform option prevents this node from concatenating its transformation with adjacent nodes. The node may still concatenate transforms from its input but it will not concatenate its transformation with the node at its output. See the Transformations chapter earlier in this manual for details on concatenated transformation.
**Reference Size**

The controls under the Reference Size reveal do not directly affect the image. Instead they allow you to control how Fusion represents the position of the Transform node’s center.

Normally, coordinates are represented as values between 0 and 1, where 1 is a distance equal to the full width or height of the image. This allows for resolution independence, because you can change the size of the image without having to change the value of the center.

One disadvantage to this approach is that it complicates making pixel accurate adjustments to an image. To demonstrate, imagine an image that is 100 by 100 pixels in size. To move the center of the image to the right by 5 pixels, we would change the X value of the transform center from 0.5, 0.5 to 0.55, 0.5. We know the change must be 0.05 because 5/100 = 0.05.

The Reference Size controls allow you to specify the dimensions of the image. This changes the way the control values are displayed, so that the Center shows the actual pixel positions in the X and Y fields of the Center control. Extending our example, if you set the Width and Height to 100 each, the Center would now be shown as 50, 50, and we would move it 5 pixels toward the right by entering 55, 50.

Internally, the Transform node still stores this value as a number between 0 to 1, and if you were to query the Center controls value via scripting, or publish the Center control for use by other nodes, then you would retrieve the original normalized value. The change is only visible in the value shown for Transform Center in the node control.

**Use Frame Format Settings**

Select this to force the Merge to use the composition’s current frame format settings to set the Reference Width and Reference Height values.

**Reference Width and Height Sliders**

Set these to the width and height of the image to change the way that Fusion displays the values of the Transform node’s Center control.

**Filter Method**

**Nearest Neighbor**

This skips or duplicates pixels as needed. This produces the fastest but crudest results.

**Box**

This is a simple interpolation resize of the image.

**Linear**

This uses a simplistic filter, which produces relatively clean results.
Chapter 102

Warp Nodes

This chapter details the Warp nodes available in the Fusion page.
Contents

Coordinate Space [CDS] 1968
Corner Positioner [CPN] 1969
Dent [DNT] 1970
Displace [DSP] 1971
Drip [DRP] 1972
Grid Warp [GRD] 1974
Lens Distort [LENS] 1979
Perspective Positioner [PPN] 1981
Vector Distortion [DST] 1982
Vortex [VTX] 1983
Coordinate Space [CDS]

The Coordinate Space node changes the coordinate space of the image at its input from Rectangular to Polar or from Polar to Rectangular.

Controls

Select between Rectangular to Polar and Polar to Rectangular. Consider the following example to demonstrate the two coordinate spaces.

Example

To demonstrate a basic tunnel effect that can be achieved with this node:

- Create some text and animate it to move along a path from the top of the frame to the bottom.
- Connect the output of the Text+ node to a Coordinate Space node.
- Select Polar to Rectangular from the Shape menu.

As the text moves from top to bottom along the original path, it will appear to move from an infinite distance in the Coordinate Space node. It may be necessary to flip the text using the Transform (Xf) node to make it appear the correct way in the Coordinate Space node. Another common use for the Coordinate Space node is to use it in pairs; two of them set to different Shape settings with a Drip or Transform node in between. When used in this way, the effect gets modified while the image remains the same.
Corner Positioner [CPN]

The Corner Positioner can be used to interactively position the four corners of an image. This would typically be used to replace a sign or other rectangular portion of a scene. Connect all corners to Paths or Trackers for animation purposes.

Controls

Mapping Type
This determines the method used to project the image caused by the Corner Positioner. In Bi-Linear mode, a straight 2D warping takes place. In Perspective mode, the image is calculated with the offsets in 2D space and then mapped into a 3D perspective.

Corners X and Y
There are four points in the Corner Positioner. Drag these around to position each corner of the image interactively. Attach these control points to any of the usual modifiers.

The image input will be deformed and perspective corrected to match the position of the four corners.

Offset X and Y
These controls can be used to offset the position of the corners slightly. Useful when the corners are attached to Trackers with patterns that may not be positioned exactly where they are needed.
Dent [DNT]

The Dent function creates a circular deformation of an image similar to a Fish Eye Lens effect, with the choice of six different Dent filters.

Controls

Type
Select the type of Dent filter to use from this menu. All parameters for Dent are animatable.

Dent 1
This creates a bulge dent.

Kaleidoscope
This creates a dent, mirrors, and inverts it.

Dent 2
This creates a displacement dent.

Dent 3
This creates a deform dent.

Cosine Dent
This creates a fracture to a center point.

Sine Dent
This creates a smooth rounded dent.

Center X and Y
This positions the Center of the Dent effect on the image. The default values are 0.5, 0.5, which center the effect in the image.

Size
This changes the Size of the area affected by the dent. Animate this slider to make the Dent grow.

Strength
This changes the overall Strength of the Dent.
Displace [DSP]

This node uses a map image to displace or refract another image. This is useful for creating a vast range of effects from bevels and heat distortion to glass and water effects.

Controls

Type
The Type buttons can choose in what mode the Displace node operates. The Radial mode uses the map image that refracts each pixel out from the center, while X/Y mode provides control over the amount of displacement along each axis individually.

NOTE: There is one set of Refraction controls while in Radial mode, and two sets in XY mode, one for each of the X and Y channels.

Center (Radial Only)
The Center control defines the point from which pixels are displaced toward or away from.

Refraction Channel
This array of buttons controls which Channel from the foreground image is used to displace the image. Select from Red, Green, Blue, Alpha, or Luminance channels. In XY mode, this control appears twice, once for the X displacement and once for the Y displacement.

Refraction Strength (Radial)
Controls the strength of the refraction. Higher values cause stronger or more pronounced refraction.
**X and Y Refraction (X/Y)**
Two separate sliders appear to control the Refraction strength along the X- and Y-axis separately. Otherwise, this is exactly like Refraction Strength.

**Light Power**
This controls the intensity, or strength, of the simulated light, causing bright and dim areas to form according to the contour of the refraction image. Higher values cause the bright and dim areas to be more pronounced.

**Light Angle**
This sets the angle of the simulated light source.

**Spread**
This widens the Displacement effect and takes the edge off the Refraction map. Higher values cause the ridges or edges spread out.

**Light Channel**
Select the channel from the refraction image that will be used as the simulated light source. Select from Color, Red, Green, Blue, Alpha, or Luminance channels.

**NOTE:** The Radial mode pushes pixels inwards or outwards from a center point, based on pixel values from the Displacement map. The XY mode uses two different channels from the map to displace pixels horizontally and vertically, allowing more precise results. Using the XY mode, the Displace node can even accomplish simple morphing effects. The Light controls allow directional highlighting of refracted pixels for simulating a beveled look.

**Drip [DRP]**
The Drip function creates a ripple effect over the entire image, which has the potential to animate outward from a central source. There are a variety of different Drip effects from which to choose.

**Controls**
**Shape**
Use this control to select the shape of the Drip.

**Circular**
This creates circular ripples. This is the default Drip mode.

**Square**
This creates even-sided quadrilateral drips.

**Random**
This creates randomly dispersed noise that distorts your image. Similar to a particle effect.

**Horizontal**
This creates horizontal waves that move in one direction.

**Vertical**
This creates vertical waves that move in one direction.

**Exponential**
This creates a Drip effect that looks like a diamond shape with inverted, curved sides (an exponential curve flipped and mirrored).

**Star**
This creates an eight-way symmetrical star-shaped ripple that acts like a kaleidoscope when the phase is animated.

**Radial**
This creates a star-shaped ripple that emits from a fixed pattern.

**Center X and Y**
Use this control to position the Center of the Drip effect in the image. The default is 0.5, 0.5, which centers the effect in the image.

**Aspect**
Control the Aspect Ratio of the various drip shapes. A value of 1.0 causes the shapes to be symmetrical. Smaller values cause the shape to be taller and narrower, while larger values cause shorter and wider shapes.

**Amplitude**
The Amplitude of the Drip effect refers to the peak height of each ripple. Use the slider to change the amount of distortion the Drip applies to the image. A value of 0.0 gives all ripples no height and, therefore, makes the effect transparent. A maximum amplitude of 10 makes each ripple extremely visible and completely distorts the image. Higher numbers can be entered via the text entry boxes.

**Dampening**
Controls the Dampening, or falloff, of the Amplitude as it moves away from the center of the effect. It can be used to limit the size or area affected by Drip.

**Frequency**
This changes the number of ripples emanating from the center of the Drip effect. A value of 0.0 indicates that there will be no ripples. Move the slider up to a value of 100, to correspond with the density of desired ripples.

**Phase**
This controls the offset of the frequencies from the center. Animate the Phase value to make the ripple emanate from the center of the effect.
Grid Warp [GRD]

The Grid Warp node is a simple 2D deformation grid with flexible vertices. The image will be deformed so that the Source grid matches the Destination grid.

Controls

Source and Destination
The Source and Destination buttons determine whether the Source grid or Destination grid is currently active. Only one grid can be displayed or manipulated at a time. The selected button will be highlighted to indicate that is the active grid at the moment.

All of the other controls in this tab affect the grid selected by this control.

Selection Type
These three buttons determine the selection types used for manipulating the points. There are three options available.

Selected
When in Selected mode, adjustments to the grid will be applied only to the currently selected points. This mode is identical to normal polyline operation.

Region
In Region mode, all points within the area around the mouse pointer, when the left mouse button is clicked, will move. New points that enter the region during the move will be ignored. Choosing this option will expose Magnet Distance and Magnet Strength controls to determine the size and falloff of the area.
**Magnetic**
In Magnetic mode, all points within the area around the mouse pointer when the left mouse button is clicked will move. New points that enter the region during the move will be affected as well. Choosing this option will expose Magnet Distance and Magnet Strength controls to determine the size and falloff of the area.

**Magnet Distance**
The default node for selecting and manipulating the grid is a Magnet node. The magnet is represented in the Viewer by a circle around the mouse pointer. The Magnet Distance slider controls how large the region of affect for the magnet is, as in the size of the circle. Drag on the grid and any vertex within the range of the slider will move.

To increase the size of the magnet, increase the value of this slider. Alternately, adjust the size of the magnet by holding down the D key while dragging the mouse.

**Magnet Strength**
The Magnet Strength slider will increase or decrease the falloff of the magnet cursor’s effect. At a setting of 0.0, the magnetic cursor has no effect, and vertices will not move at all. As the values increase, the magnet causes a greater range of motion in the selected vertices. Use smaller values for a more sensitive adjustment and larger values for broad-sweeping changes to the grid.

**X and Y Grid Size**
The X and Y Grid Size sliders control the number of divisions in the grid. Where the X and Y divisions intersect, a control vertex is created.

Be aware that changing either of these controls after applying changes in the grid will reset the entire grid. Set the X and Y grid sizes to the appropriate resolution before making serious detailed adjustments to the grid.

**Subdivision Level**
The Subdivision Level determines how many subdivisions there are between each set of divisions. Subdivisions do not generate vertices at intersections. The more subdivisions there are, the smoother the deformation is likely to be (and the slower it will be to render the deformation).

**Center**
The Center coordinates determine the exact center of the grid. The onscreen Center control is invisible while editing the grid. Select the Edit Rect mode and the grid center becomes visible and available for editing.

Use the Center control to move the grid through a scene without affecting the animation applied to the individual vertices. For example, while deforming lips on a face, track the motion of the face with a Tracker and connect the grid center to the Tracker. This matches the grid with slight movements of the head while focusing on the deformation of the lips.

**Angle**
This Angle control rotates the entire grid.

**Size**
The Size control increases or decreases the scale of the grid.

**Edit Buttons**
There are four edit modes available, each of which can be selected by clicking on the appropriate button.
**Edit None**
Set the grid to Edit None mode to disable the display of all onscreen controls.

**Edit Grid**
The Edit Grid mode is the default mode. While this mode is enabled, the grid is drawn in the Viewer and the control vertices of the grid can be manipulated directly.

**Edit Rectangle**
When the grid is in Edit Rectangle mode, the onscreen controls display a rectangle that determines the dimensions of the grid. The sides of the rectangle can be adjusted to increase or decrease the grid’s dimension. This mode also reveals the onscreen Center control for the grid.

**Edit Line**
The Edit Line mode is extremely useful for creating grids around organic shapes. When this mode is enabled, all onscreen controls will disappear and a spline can be drawn around the shape or object to be deformed. While drawing the spline, a grid is automatically created that best represents that object. Additional controls for Tolerance, Over Size and Snap Distance appear when this mode is enabled. These controls are documented below.

**Set Mesh to Entire Image**
The Set Mesh to Entire Image button automatically resets the size of the grid to the exact dimensions of the image. Any adjustments to vertices within the grid will be reset.

**Copy Buttons**
These two buttons provide a technique for copying the exact shape and dimensions of the Source grid to the Destination, or the Destination grid to the Source. This is particularly useful after setting the Source grid to ensure that the Destination grid’s initial state matches the Source grid before beginning a deformation.

**Point Tolerance**
This control is only visible when the Edit Line mode is enabled. The Point Tolerance slider determines how much tessellation the grid will apply to closely match the density of points in the spline. The lower this value, the fewer vertices there will be in the resulting grid and the more uniform the grid will appear. Higher values will start applying denser grids with variations to account for regions in the spline that require more detail.

**Oversize Amount**
This control is only visible when the Edit Line mode is enabled. The Oversize Amount slider is used to set how large an area around the spline should be included in the grid. Higher values create a larger border, which can be useful when blending a deformation back into the source image.

**Snap Distance**
This control is only visible when the Edit Line mode is enabled. The Snap Distance slider dictates how strongly the drawn spline will attract surrounding vertices. If a vertex is close enough to a spline’s edge, the vertex will move to line up with the spline. The higher the value, the farther the reach of the spline.

**Right-Click Here for Mesh Animation**
The grids are static by default. Right-clicking on the Right-Click Here for Mesh Animation label will provide a contextual menu with options for animating the grid or connecting it to another grid in the composition.
The grid uses a Polychange spline. Any adjustment to any of the control points will add or modify the keyframe for all points to the Polychange spline.

**Right-Click Here for Shape Animation**
This label only appears in the Edit Line mode. Right-clicking on the Right-Click Here for Shape Animation label will reveal a contextual menu that can be used to animate the shaping polyline or to connect it to other polylines in the composition.

**Render Tab**

![Render Tab](image)

**Render Method**
The Render Method drop-down menu is used to select the rendering technique and quality applied to the mesh. The three settings are arranged in order of quality, with the first (Wireframe) as the fastest and lowest of quality. The default mode is Render, which produces final resolution, full quality results.

**Anti-Aliasing**
The Anti-aliasing control is a checkbox in Wireframe Render mode.

It is otherwise a drop-down menu with three levels of quality. Higher degrees of anti-aliasing improve image quality dramatically but vastly increase render times. The Low setting may be an appropriate option while setting up a large dense grid, or previewing a node tree, but almost never for a final render.

**Filter Type**
The Area Sample control is only visible when the Render Method is not set to Wireframe. Checked by default, disabling this checkbox prevents the grid from calculating area samples for each vertex in the grid. Area sampling vastly improves render quality at the cost of speed.

**Wireframe Width**
This control only appears when the Render Method is set to Wireframe. It determines the width of the lines that make up the wireframe.

**Anti-Aliased**
This control only appears when the Render Method is set to Wireframe. Use this checkbox to enable/disable antialiasing for the lines that make up the wireframe.

**Black Background**
The Black Background checkbox determines whether pixels outside of the grid in the source image will be set to black or if they will be preserved.
**Object ID and Material ID**
Enable the Object ID or Material ID checkboxes to have the grid output the proper ID channel in the final render.

**Set Image Coordinates at Subdivision Level**
Checkbox that defaults to On.

**Force Destination Render**
Checkbox that defaults to On.

**Right Click Menu**
The Grid Warp node places a submenu for both Source and Destination grids in the Viewer’s contextual menu. Both menus have the exact same name, where only the menu for the active grid is populated with options. The other menu is empty. The contextual menu options are all available from the toolbar that appears in the Viewer.

**Modify Only/Done**
These two options set the mesh to modify only and done modes, respectively. Select Modify Only to edit the mesh or Modify Done to prevent any further changes to a mesh.

**Smooth/Linear**
Use Smooth and Linear to apply or remove smoothing from selected vertices.

**Auto Smooth Points**
When Auto Smooth Points is enabled, the vertices in the grid will automatically be smoothed whenever they are moved. This is generally on by default.

**Z Under/Z Same/Z Over**
When two vertices in a grid overlap, one ends up getting clipped by the other. Z Under, Z Same and Z Over are used to select which vertices are rendered on top and which are rendered behind.
Select All
This option will Select All points in the mesh.

Show Key Points, Handles, Grid and Subdivisions
Use these four options to enable or disable the display of the grid, key points (vertices), Bezier handles and subdivisions in the Viewers.

Reset Selected Points
Reset Selected Points (vertices) to their default positions.

Reset All Points
This will Reset All Points (vertices) in the mesh to their default positions.

Stop Rendering
This option will enable Stop Rendering, which disables all rendering of the Grid Warp node until the mode is turned off. This is frequently useful when making a series of fine adjustments to a complex grid.

Screen Controls
Whenever the Grid Warp node is selected and is in Edit Grid mode, the Grid Warp toolbar is displayed in the views. This toolbar provides a variety of options for manipulating and adjusting the grid. The toolbar buttons in this toolbar are described above in the contextual menu.

Lens Distort [LENS]
This node can be used to remove or add lens distortion in an image. The amount and type of lens distortion in an image depends on a variety of factors such as the actual lens that has been used, the quality and amount of lensgroups in that lens, adjustments like shift lenses and much more.

One reason to remove lens distortion is to comp an undistorted layer as, for example, a 3D rendering, on top of a distorted layer as, for example, a real world camera shoot. When combining the layers without removing the lens distortion, unwanted effects like straight lines not matching up on foreground and background will occur. The resulting composite will not look believable.

In a typical workflow one would apply the LensDistort in Undistort mode to the original layer, add the 3D elements, do all other compositing work and finally apply LensDistort again with exactly the same settings, but this time in Distort mode to get the original look and distortion back into the image.
Controls

Mode
Undistort removes the lens distortion to create a flattened image. Distort brings the original lens distortion back into the image.

Edges
Determines how samples that fall outside the frame are treated.

- **Canvas**: Pixels outside the frame are set to the default canvas color. In most cases this is black with no alpha.
- **Duplicate**: Pixels outside the frame are duplicated. This results in “smeared” edges but is useful when, for example, applying a blur, because black pixels would in that case result in unwanted blurring between the actual image and the black canvas.

Clipping Mode
- **Domain**: Retains all pixels that might be moved out of the frame for later re-distorting.
- **Frame**: Pixels moved outside the frame will be discarded.

Output Distortion Map
Outputs the location of pixels as a warped screen-coordinate map.
**Camera Settings**
The options known from the Camera3D are duplicated here. They can either be set manually or connected to an already existing Camera3D.

**Lens Distortion Model**
Select the appropriate 3D Equalizer Lens Distortion model here: 3DE Classic Model, 3DE4 Anamorphic, 3DE4 Radial Fisheye or 3DE4 Radial. Please consult the 3D Equalizer manual for further explanation. The sliders in the 3DE Classic LD Model are most likely best suited for manually applying (un)distortion, without having imported lens data.

**Supersampling [HiQ]**
Sets the number of samples used to determine each destination pixel. As always, higher supersampling leads to higher render times. 1×1 bilinear is usually of sufficient quality, but with high lens distortion near the edges of the lens there will be noticeable differences to higher settings.

**Supersampling Mode [HiQ]**
The type of sample done for each supersample. Nearest will lead to a crisper but more aliased image. Bilinear will give a blurrier result.

**Load Distortion Data**
Allows the user to load a Lens Distortion profile created, for example, by the 3D Equalizer.

**How to Manually Determine Lens Distortion**
In the ideal world, one would have exact lens-parameters from each lens that was used during the shoot, and one could use those values to undistort the image. However, in the real world, those parameters have not been taken on set or don’t match. Another approach is to use a software like 3DEqualizer which analyzes the footage and delivers a dataset that can be imported into the LensDistort node right away.

And finally, one could try to manually eyeball the amount of lens distortion using the control sliders. To do that, one could either look out for horizontal or vertical lines in the footage that are supposed to be straight and straighten them out using the controls, or shoot a full frame checkerboard pattern on set as a reference.

**Perspective Positioner [PPN]**

The Perspective Positioner is the complementary node to the Corner Positioner node. By positioning corner points on an image and moving them, it is possible to remove the perspective from an image. This function can also be used to wobble and warp the image by animating the points over time.
Controls

Corners X and Y
There are the four control points of the Perspective Positioner. Interactively drag these in the views to position each corner of the image.

Vector Distortion [DST]

The Vector Distortion node distorts the main source image along the X- and Y-axis separately, based on the vector channel data in the source image, or a channel from a second image or reference image.

Controls

X Channel and Y Channel
Use these buttons to select which channel of the reference image will be used to distort the X and Y channels. If no Distort reference image is connected to the second (green) input of the node, then channels from the main input are used instead.
Flip X and Flip Y Channel
Use these checkboxes to flip the direction of the distortion along the specified axis.

Lock Scale X/Y
Select this checkbox to separate the Scale slider into separate Scale X and Scale Y sliders.

Scale
Use the Scale slider to apply a multiplication to the values of the distortion reference image.

Lock Bias X/Y
Select this checkbox to separate the Bias slider into separate Bias X and Bias Y sliders.

Center Bias
Use the Center Bias slider to shift or nudge the distortion along a given axis.

Edges
The Edges buttons are used to set how the node deals with pixels that reach the edge of the screen.

Glow
Use this slider to add a glow to the result of the vector distortion.

Vortex [VTX]

The Vortex effect appears as a swirling whirlpool in specified regions of the image. The Vortex can be made to move and grow by animating the various controls.

Controls

Center X and Y
This control is used to position the Center of the Vortex effect on the image. The default is 0.5, 0.5, which positions the effect in the center of the image.
Size
Change the area affected by the Vortex in the display window by dragging the circumference of the effect or by using the Size slider.

Angle
Drag the rotation handle in the Viewer or use the thumbwheel control to change the amount of rotation in the Vortex. The higher the angle value, the greater the swirling effect.

Power
Increasing the Power slider makes the Vortex smaller but tighter. It effectively concentrates it inside the given image area.
This chapter details the Modifiers available in the Fusion page.

Bezierspline

The BezierSpline is one of the animation modifiers in Fusion and normally is applied to numerical values rather than point values. It is applied by default each time you right-click on a numerical control and select Animate.

It can also be applied by right-clicking on a numerical control and selecting Modify with > BezierSpline.

Usage

Being an animation spline, this modifier has no actual Controls tab. However, its effect can be seen and influenced in the Spline Editor. The Bezier Spline offers individual control over each point’s smoothness by means of handles. The smoothness can be applied by multiple ways.

- To make the keys smooth, select them and press Shift-S. The handles can then be used to further modify the behavior of in and out.
- To make the keys linear, select them and press Shift-L. These operations can also be performed using the contextual menu.
- Select the keyframe(s), right click and select Smooth or Linear. The menu also allows the user to apply smoothing using a Savitzky-Golay filter. Select the keyframe(s), right-click and select Smooth Points -Y Dialog.

Ease In/Out Can Also Be Modified by Using the Control Slider

Select the keyframe you want to modify, right-click and select Ease In/Out... from the contextual menu. Then use the sliders to individually control the Ease In/Out numerically.
B-Spline

The B-spline is one of the animation modifiers in Fusion and normally is applied to numerical values rather than point values.

It can be applied by right-clicking on a numerical control and selecting Modify with > B-Spline.

Usage

- Being an animation spline, this modifier has no actual Controls tab. However its effect can be seen and influenced in the Spline Editor. Notice that, though the actual value of the second keyframe is 0, the value of the resulting spline is 0.33 due to the unique smoothing and weighing algorithms of a B-spline.
- The weight can be modified by left-clicking on the keyframe to select it, holding down W as well as the left mouse button, and moving the mouse to the left to lower the tension and to the right to increase the tension. This also can be done with multiple selected keyframes simultaneously.

Calculation

Calculations are used to create indirect connections between value controls. A calculation can perform a mathematical expression based on two operands, where each operand can be connected to another control or set manually by the user.

Additionally, the Calculation control can access the values of a connected control at times other than the current time, using Time offsets and Time Scale controls built into the Calculation Modifier.

The most common use for a calculation is when two controls need to be connected to each other, but the range or scope of the value’s output by one control is inappropriate for the other control.

NOTE: The Expression modifier is essentially a more flexible version of the Calculation modifier, with a single exception. It is far easier to manipulate the timing of the operands provided to a Calculation than it is to do so with an Expression.
**Calc Tab**

First and Second Operand
These sliders are either connected to published or animated controls from other nodes in the composition or manually set to the desired values for the calculation.

Operator
Select from the mathematical operations listed in this menu to determine how the two operands are combined. Clicking on the down arrow opens the menu with the following options:

**Time Tab**

First and Second Operand Time Scale
These sliders cause the frame used to read the values of the Operands specified in the Calc tab to be scaled. A value of 1 returns the value of the operand at frame x when the composition is set to frame x. For example, if the first operand is animated with a value of 1 to 10 from frame 0 to 10, then a scale of 0.5 would cause the calculation to return a value of 5 at frame 10 (effectively slowing the animation by half for the purposes of the calculation).
First Operand and Second Operand Time Offset
These sliders return the value of the Operand at the Time Offset specified. A value of 10 would return the value of the operand 10 frames forward in time and -10 would return the value of the operand 10 frames back in time. See the example below for a practical example.

Example
The following example uses a calculation to apply blur to a text in inverse proportion to the size of the text.

- Create a new composition, and set the Global Start and Render Start to 1. Set the Global End and Render End to 100.
- Add a Text Plus node to the composition.
- Enter a small amount of text in the StyledText input.
- Make sure the current frame is 0
- Set the Size parameter of the Text node to a value of 0.06 at frame 0.
- Right-click on the Size slider and animate the slider by setting a key.
- Advance to frame 100 and set the value of the Size control to 0.50.
- Add a Blur node immediately after the Text node. Connect the Blur input to the Text node’s output.
- View the Blur node in one of the Viewers.
- We want the blur to decrease in strength as the text gets bigger. The controls cannot be directly connected together because the values of the Text Size control are getting bigger instead of smaller.
  - Right-click on the Blur size and select Modify With Calculation from the contextual menu. A new set of controls will appear in the Modifiers tab while the Blur node is selected.
  - Switch to the Modifier tab (F11)
  - Right-click on the First Operand slider. Select Connect To > Text 1 > Size from the contextual menu. This connection isn’t very useful, though; the maximum value of the Blur Size control is 0.5, which is hardly noticeable as a blur.
  - Set the Operator drop-down menu to Multiply.
  - Set the Second Operand slider to 100.
  - Switch to the Time tab of the modifier and set the First Operand Time Scale to -1.0. Normally, the First Operand will get the value of the control it is connected to from the same frame as the current time. So at frame 10, the first operand will be set to the same value as the Text size at frame 10. By setting this value to -1, the value is read from one frame back in time whenever the current time of the composition advances by 1 frame.
  - However, this means that the Calculation would be reading the value of the Text size at frame -10 when we are at frame 10 in the composition. To correct for this, set the First Operand Time Offset slider to 100.
  - Return to the Nodes tab of the Node Control Area (F9). Press play (spacebar) and watch how the value of the Blur Size relates to the value of the Text Size.
Cubic Spline

The Cubic Spline is one of the animation modifiers in Fusion and normally is applied to numerical values rather than point values. It can be applied by right-clicking on a numerical control and selecting Modify with > Natural Cubic Spline.

Usage

Being an animation spline, this modifier has no actual Controls tab. However its effect can be seen and influenced in the Spline Editor.

Expression

Adding an Expression modifier to a control will add the ability to control and manipulate either position or value controls based on any number of controls, either positional or value-based. This modifier offers exceptional flexibility compared to the more limited Calculation or Offset modifiers, but it is unable to access values from frames other than the current time.

An Expression will accept up to nine value inputs and nine position inputs that are used as part of a user-defined mathematical expression to output a value.

To add an Expression to a control, right-click on the control and choose Modify With > Expression from the contextual menu. The type of value that will be returned by the Expression entirely depends on the type of control it is modifying.

When used with a value control (like a slider), the Expression in the Number Out tab will be evaluated to create the result. When used to modify a positional control (like a node’s center), the Point Out tab will control the result.

The Modifiers view contains the controls for the Expression modifier. Its controls are described below.
Controls

This tab provides nine number controls and nine point controls. The values of the number controls can be referred to in an expression as n1 through n9. The X-coordinate of each point control can be referred to as p1x through p9x, while the Y-coordinate is p1y through p9y.

These values can be set manually by the user, connected to other parameters, animated and even connected to other Expressions or Calculations.

Number Out Tab

This enables a mathematical formula to be entered, which can access the values from both the Number In and the Point In tabs and output a value used to modify the control to which the Expression was applied. See below for the syntax to use in this field.
Point Out Tab

Each one of the text boxes in this tab can contain a mathematical formula that can access the values from both the Number In and the Point In tabs and output a value used to modify the control to which the Expression was applied. The Expression in the top text box control is used to calculate the X-axis value and the bottom text box is used to calculate the Y-axis control. See below for the syntax to use in this field.

Config Tab

A good expression can be re-used over and over again. As a result, it can be useful to provide more descriptive names for each input and to hide the ones that are unused. The Config Tab of the Expressions modifier is used to customize visibility and name for each of the nine point and number inputs.

Random Seed

The Random Seed control is used to seed the Rand() function. The rand(x, y) function produces a random value between X and Y, producing a new value for every frame. As long as the setting of this Random Seed slider remains the same, the values produced at frame x will always be the same. Adjust the seed slider to a new value to get a different value for that frame.
**Show Number or Point X**
There are eighteen of these checkbox controls, one for each of the nine Number and Point inputs. Enable this checkbox to display the control for Number x or Point x in the Controls tab.

**Name for Number or Point X**
There are eighteen of these edit controls, one for each of the nine Number and Point inputs. Type a new name for the input into this edit control to assign a new name for the Input’s label in the Controls tab.

### Expression Syntax Formulas
Formulas are entered into the Number Out or Point Out tabs as part of an expression. They can be made up of the following functions:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n1..n9</td>
<td>The value of Number Input 1..9.</td>
</tr>
<tr>
<td>p1x..p9x</td>
<td>The X of Positional Control 1..9.</td>
</tr>
<tr>
<td>p1y..p9y</td>
<td>The Y of Positional Control 1..9.</td>
</tr>
<tr>
<td>time</td>
<td>The current time (frame number).</td>
</tr>
<tr>
<td>pi</td>
<td>The value of pi.</td>
</tr>
<tr>
<td>e</td>
<td>The value of e.</td>
</tr>
<tr>
<td>log(x)</td>
<td>The base-10 log of x.</td>
</tr>
<tr>
<td>ln(x)</td>
<td>The natural (base-e) log of x.</td>
</tr>
<tr>
<td>sin(x)</td>
<td>The sine of x (x is degrees).</td>
</tr>
<tr>
<td>cos(x)</td>
<td>The cosine of x (x is degrees).</td>
</tr>
<tr>
<td>tan(x)</td>
<td>The tangent of x (x is degrees).</td>
</tr>
<tr>
<td>asin(x)</td>
<td>The arcsine of x, in degrees.</td>
</tr>
<tr>
<td>acos(x)</td>
<td>The arccosine of x, in degrees.</td>
</tr>
<tr>
<td>atan(x)</td>
<td>The arctangent of x, in degrees.</td>
</tr>
<tr>
<td>atan2(x, y)</td>
<td>The arctangent of x,y, in degrees.</td>
</tr>
<tr>
<td>abs(x)</td>
<td>The absolute (positive) value of x.</td>
</tr>
<tr>
<td>int(x)</td>
<td>The integer (whole) value of x.</td>
</tr>
<tr>
<td>frac(x)</td>
<td>The fractional value of x.</td>
</tr>
<tr>
<td>sqrt(x)</td>
<td>The Square Root of x.</td>
</tr>
<tr>
<td>rand(x, y)</td>
<td>A random value between x and y.</td>
</tr>
<tr>
<td>rands(x, y, s)</td>
<td>A random value between x and y, based on seed s.</td>
</tr>
<tr>
<td>min(x, y)</td>
<td>The minimum (lowest) of x and y.</td>
</tr>
<tr>
<td>max(x, y)</td>
<td>The maximum (highest) of x and y.</td>
</tr>
<tr>
<td>dist(x1, y1, x2, y2)</td>
<td>The distance between point x1,y2 and x2,y2.</td>
</tr>
<tr>
<td>dist3d(x1,y1,z1,x2,y2,z2)</td>
<td>The distance between 3D points x1,y2,z1 and x2,y2,z2</td>
</tr>
<tr>
<td>noise(x)</td>
<td>A smoothly varying Perlin noise value based on x</td>
</tr>
<tr>
<td>noise2(x, y)</td>
<td>A smoothly varying Perlin noise value based on x and y</td>
</tr>
<tr>
<td>noise3(x, y, z)</td>
<td>A smoothly varying Perlin noise value based on x, y and z</td>
</tr>
<tr>
<td>if(c, x, y)</td>
<td>Returns x if c not 0, otherwise y.</td>
</tr>
</tbody>
</table>
**Expression Syntax Operators**

Operators are used to evaluate statements. They are combined with functions to perform logical and mathematical calculations in the Number Out and Point Out tabs.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x + y</code></td>
<td><code>x</code> plus <code>y</code>.</td>
</tr>
<tr>
<td><code>x - y</code></td>
<td><code>x</code> minus <code>y</code>.</td>
</tr>
<tr>
<td><code>x &gt;= y</code></td>
<td>1.0 if <code>x</code> is less than <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x &gt; y</code></td>
<td>1.0 if <code>x</code> is greater than <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>!x</code></td>
<td>1.0 if <code>x</code> is 0, otherwise 0.0.</td>
</tr>
<tr>
<td><code>-x</code></td>
<td><code>(0.0 - x)</code>.</td>
</tr>
<tr>
<td><code>+x</code></td>
<td><code>(0.0 + x)</code> (effectively does nothing).</td>
</tr>
<tr>
<td><code>x ^ y</code></td>
<td><code>x</code> raised to the power of <code>y</code>.</td>
</tr>
<tr>
<td><code>x * y</code></td>
<td><code>x</code> multiplied by <code>y</code>.</td>
</tr>
<tr>
<td><code>x / y</code></td>
<td><code>x</code> divided by <code>y</code>.</td>
</tr>
<tr>
<td><code>x % y</code></td>
<td><code>x</code> modulo <code>y</code>, (remainder of <code>x</code> divided by <code>y</code>).</td>
</tr>
<tr>
<td><code>x &gt;= y</code></td>
<td>1.0 if <code>x</code> is less than or equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x &gt; y</code></td>
<td>1.0 if <code>x</code> is greater than or equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x = y</code></td>
<td>1.0 if <code>x</code> is exactly equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x == y</code></td>
<td>1.0 if <code>x</code> is exactly equal to <code>y</code>, otherwise 0.0 (identical to above).</td>
</tr>
<tr>
<td><code>x &lt;&gt; y</code></td>
<td>1.0 if <code>x</code> is not equal to <code>y</code>, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x != y</code></td>
<td>1.0 if <code>x</code> is not equal to <code>y</code>, otherwise 0.0 (identical to above).</td>
</tr>
<tr>
<td><code>x &amp; y</code></td>
<td>1.0 if both <code>x</code> and <code>y</code> are not 0.0, otherwise 0.0.</td>
</tr>
<tr>
<td><code>x &amp;&amp; y</code></td>
<td>1.0 if both <code>x</code> and <code>y</code> are not 0.0, otherwise 0.0 (identical to above).</td>
</tr>
<tr>
<td>`x</td>
<td>y`</td>
</tr>
<tr>
<td>`x</td>
<td></td>
</tr>
</tbody>
</table>
Example 1
To make a numeric control equal to the Y value of a motion path, add an expression to the desired target control and connect the Path to Point In 1. Enter the formula:

\[ p1y \]
into the Number Out field.

Example 2
To make the result of the Expression’s Number Out be the largest of Number In 1 and Number In 2, multiplied by the cosine of Number In 3, plus the X coordinate of Point In 1, enter the formula:

\[ \max(n1, n2) \times \cos(n3) + p1x \]
into the Number Out field.

Example 3
Add a Background node set to solid black and a Hotspot node. Set the Hotspot size to 0.08 and set the Strength to maximum. Modify the Hotspot center with an expression. Change the current frame to 0.
Set n1 to 0.0 and add a Bezier spline. At frame 29, set the value of n1 to 1.0. Select both points and loop the spline using the Spline Editor. Now enter the following equations into the Point Out tab of the expression.

X-Axis Expression
\[ n1 \]
Y-Axis Expression
\[ 0.5 + \sin(time\times50) \]

Render out a preview and have a look at the results. (Try this one with motion blur.)

From Image
The From Image only works on gradients, like the gradient on a Background node. It takes samples of an image along a user-definable line and creates a gradient from those samples. It can be applied by right-clicking on a Gradient control and selecting From Image.

Controls
**Image to Scan**
Drop the node you want to be examined into this box.

**Start X/Y, End X/Y**
These two point controls define the Start and End points of the line along which the samples are taken from the image defined in the Image to scan box.

The points can also be moved directly in the view.

**Number of Sample Steps**
Defines how many individual color samples are taken along the line. You can also see the result of this setting when you look at the actual node's Gradient control. The more sample steps you define here, the more individual points you will see on the Gradient control. It is also possible to first create a gradient using the From Image modifier and then remove that modifier from the Gradient control again. The created gradient will stay intact and can then be fine tuned by hand.

**Edges**
Edges determines how the edges of the image will be treated when the sample line extends over the actual frame of the image to be sampled.

**Black**
This outputs black for every point on the sample line outside of the image bounds.

**Wrap**
This wraps the edges of the line around the borders of the image.

**Duplicate**
This causes the edges of the image to be duplicated as best as possible, continuing the image beyond its original size.

**Color**
Outputs a user-definable color instead of black for every point on the sample line outside of the image bounds.

**Example**

The source image on the left shows the color selection line in red. The image on the right shows the resulting gradient from that selection.
**GradientColorModifier**

The Gradient Color modifier allows the user to control the value of a parameter. A gradient with customized values is mapped into a specific time range to control the value. If both time values are set to 0, then the modifier returns the value at the starting point of the gradient. You can use the Offset control to animate the gradient manually.

It can be applied by right-clicking onto a control and selecting Modify with > GradientColorModifier.

**Controls**

![GradientColorModifier Interface](image)

**Gradient**

The Gradient control consists of a bar where it is possible to add, modify and remove points of the gradient. Each point has its own color. It is possible to animate the color as well as the position of the point. Furthermore, a From Image modifier can be applied to the gradient to evaluate it from an image.

**Gradient Interpolation Method**

The gradient is linearly interpolated from point to point in RGB color space by default. This can sometimes result in unwanted colors. Choosing another color space may provide a better result.
Repeat
Defines how the left and right borders of the gradient are treated.

<table>
<thead>
<tr>
<th>Gradient Offset control to shift the gradient, the border colors will keep their values. Shifting the default gradient to the left will result in a white border on the left, shifting it to the right will result in a black border on the right.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeat: When using the Gradient Offset control to shift the gradient, the border colors will be wrapped around. Shifting the default gradient to the left will result in a sharp jump from white to black, shifting it to the right will result in a sharp jump from black to white.</td>
</tr>
<tr>
<td>Ping Pong: When using the Gradient Offset control to shift the gradient, the border colors ping-pong back and forth. Shifting the default gradient to the left will result in the edge fading from white back to black, shifting it to the right will result in the edge fading from black back to white.</td>
</tr>
</tbody>
</table>

Gradient Offset
Allows you to pan through the gradient.

Time Controls
The Start Time and End Time thumbwheels determine the time range the gradient is mapped into. This is set in frames. The same effect can be achieved by setting the Gradient to Once and animating the offset thumbwheel.

MIDI Extractor
The MIDI Extractor Modifier provides the ability to modify the value of a control using the values stored in a MIDI file. Using the modifier relies on some knowledge of MIDI, which is outside of the scope of this manual to describe in detail.

The value produced by the modifier is extracted from the MIDI event selected in the Mode menu. Each mode can be trimmed so only specific messages for that event are processed. For example, only some notes are processed, while others are ignored. The value of the event can be further scaled or modified by additional factors, such as Scale, Velocity, Attack and Decay.

It can be applied by right-clicking on a control and selecting Modify with > Midi Extractor.
**Controls**

**MIDI File**
This browser control is used to specify the MIDI file that will be used as the input for the modifier.

**Time Scale**
Time Scale is used to specify the relationship between time as the MIDI file defines it and time as Fusion defines it. A value of 1.0 will play back the MIDI events at normal speed, 2.0 at double speed, and so on.

**Time Offset**
Time Offset adjusts the sync between the MIDI file’s timing and Fusion’s timing. If there is an unexpected delay or if the MIDI file should start part way into or before some animation in Fusion, this control can be used to offset the MIDI data as required.
**Result Offset, Result Scale**
These sliders adjust the range of values produced by the modifier. By default, values between 0 and 1 (or -1 and 1 for PitchBend mode) are generated. This will not always suit the node/parameter and scale can be used to make this range larger (such as * 0.0 - 2.0). Offset is used to provide some constant value as a base.

**Result Curve**
The Result Curve can also be used to adjust the output, however, this adjusts the curve of the result. By default, for any input MIDI data, the result will fall linearly between 0.1 and 1.0 (for example, a velocity 127 note will generate 1.0, where 63 will generate approximately 0.5).
Result curve applies a gamma-like curve so that middle values can produce higher or lower results while still maintaining the full scale.

**Mode**
This menu provides Beat, Note, Control Change, Poly AfterTouch, Channel AfterTouch or Pitch Bend, indicating from which MIDI event the values are being read. Beat mode is slightly different in that it produces regular pulses based on the tempo of the MIDI file (including any tempo maps).
The Beat mode does not actually use any specific messages. It bases its event timing on the tempo map contained in the MIDI file.

**Combine Events**
This menu selects what will happen when multiple events occur at the same time. In Notes mode, this can happen easily. For other events, this can happen if Multiple Channels are selected.
Use this to take the result from the most recent event to occur, the oldest event still happening, the highest or lowest valued event, the average, sum or the median of all events currently occurring.

**Beat (Quarters) Beat Mode Only**
This defines how often a beat will occur when in Beat mode. This is in Quarter notes so a value of 1.0 will give a beat every quarter.

**Note Range Note and Poly Aftertouch Modes Only**
This defines what range of notes will cause a value to be generated. For example, use this to pick out the kick drum from a GM drum track by setting the note range between 35–36.

**Pitch Scale Note Mode Only**
Pitch Scale defines how much the result changes with pitch. A value of 1.0 will cause the result to vary from 0.0 to 1.0 over the entire range.

**Velocity Scale Note Mode Only**
This defines how much the result changes with velocity. A value of 1.0 will cause the result to vary from 0.0 to 1.0 over the entire range. This is added to the result from pitch scale for the final result.

**Control Number Control Change Mode Only**
This specifies the MIDI controller number from which to extract events.
**Envelope Controls Note and Beat Modes Only**

These define an Envelope to follow for values before, during and after the note or beat. Pre-Attack Time defines how long before the event it will start ramping up to the pre-attack level. Attack is the Time/Level to ramp to once the event has occurred, followed by the Decay ramp and Sustain, until the event stops. This stage is for Notes only. Beats have an instantaneous duration, so it goes straight to Release. Release is the ramp down time after the event finishes. When trying to do a Beat, set Release to some value, or there likely will not be much on the beats.

These values can be used to follow actual sounds in the MIDI sequence, or just to create interesting effects. All time values used in the MIDI Extractor are in seconds.

**Channels Tab**

Channels checkboxes select which of the 16 channels in the MIDI file are actually considered for events. This is a good way to single out a specific instrument from an arrangement.

**More About MIDI**

A single MIDI interface allows 16 channels. Typically, these will be assigned to different instruments within a device or different devices.

Usually, MIDI data is 7-bits, ranging from 0..127. This is represented as a value between 0..1 to be more consistent with the way data is handled throughout the rest of Fusion.

There are quite a number of different MIDI messages and events but the ones that are particularly useful with this modifier are detailed below.

**MIDI Messages**

- **Note On:** This indicates that a note (on a specific channel) is being turned on, has a pitch (0..127, with middle C being 60) and a Velocity (0..127, how fast the key was or whatever was hit),

- **Note Off:** This indicates that a note (on a specific channel) is being turned off, has a pitch (0..127, with middle C being 60) and a Velocity (0..127, how fast the key was or whatever was released).

- **Control Change:** This message indicates that some controller has changed. There are 128 controllers (0..127), each of which has data from 0..127. Controllers are used to set things such as Volume, Pan, amount of Reverb or Chorus, and generic things like foot controllers or breath controllers.
Midi Events

- **Channel Aftertouch**: This event defines that pressure is being applied to the keys (or whatever) during a note. It is general, overall pressure for this channel so it simply uses a pressure value (0..127).
- **Poly Aftertouch**: This event defines that pressure is being applied to the keys (or strings, or whatever) during a note. It is specific to each particular note and, therefore, contains a note number as well as a pressure value (0..127).

General

**Pitch Bend**

The Pitch Bend controller generally specifies the degree of pitch bending or variation applied to the note. Because pitch bend values are transmitted as a 14-bit value, this control has a range between -1 and 1, and a correspondingly finer degree of resolution.

Natural Cubic Spline

The Natural Cubic Spline is one of the animation modifiers in Fusion and normally is applied to numerical values rather than point values. It can be applied by right-clicking on a numerical control and selecting Modify with > Natural Cubic Spline.

**NOTE**: Unlike other spline types, Cubic splines have no control handles and attempt to automatically provide a smooth curve through the keypoints.

Usage

Being an animation spline, this modifier has no actual Controls tab, however, its effect can be seen and influenced in the Spline Editor.
Offsets are useful for creating constant or animated variances between values, relating to various controls, paths and points. There are three types of offsets available in Fusion:

- Offset Distance
- Offset Angle
- Offset Position
- Offset Angle

The Offset Angle Modifier outputs a value between 0 and 360 that is based on the angle between two positional controls. The Position and Offset parameters may be static, connected to other positional parameters or connected to paths of their own. All of the offsets use the same set of controls, which behave differently depending on the offset type used. These controls are described below.

**Offset Distance**

The Offset Distance modifier outputs a value that is based on the distance between two positional controls. This modifier is the first one discussed that is capable of outputting a value based on a mathematical expression applied to a position.

**Offset Position**

The Offset Position modifier outputs a position (X and Y coordinate) that is based on the relationship between positional controls. This modifier is the equivalent of a calculation control except that it outputs X and Y coordinates instead of a value.

It can be applied by right-clicking on a control and selecting Modify with > Offset.

**Offset Tab**

![Offset Tab Image]
**Position X and Y**
The first position value is used by the Position to generate the calculation.

**Offset X and Y**
The first position value is used by the Offset to generate the calculation.

**Flip Position Horizontal and Vertical**
When these controls are selected, the Position will be mirrored along the vertical or horizontal axis of the image.

**Flip Offset Horizontal and Vertical**
When these controls are selected, the Offset position will be mirrored along the vertical or horizontal axis of the image.

**Mode**
Select an option from the Mode menu to choose the mathematical operation performed by the offset control.

Available options are:
- Offset
- Difference (Position - Offset)
- Difference (Offset - Position)
- Average
- Use Position Only
- Use Offset Only
- Maximum
- Minimum
- Invert Position
- Invert Offset
- Invert Sugar
- Random Offset

**Image Aspect**
Adjust the modifier’s output to compensate for the Image Aspect (not pixel aspect) of the project. A square image of 500 x 500 would use an Image Aspect value of 1 and a rectangular image of 500 x 1000 would use an Aspect value of 2. The default value is always based on the current frame format selected in the preferences. To calculate Image Aspect, divide the width by the height. This control can also be used to create the illusion of aspect.
Time Tab

**Position Time Scale**
This returns the value of the Position at the Time Scale specified (for example, 0.5 is the value at half the current frame time).

**Position Time Offset**
This returns the value of Position at the Time Offset specified (for example, 10 is 10 frames back).

**Offset Time Scale**
This returns the value of the Offset at the Time Scale specified.

**Offset Time Offset**
This returns the value of Offset at the Time Offset specified.

---

**Example**

- Let’s continue the Text banking example at the beginning of this chapter to illustrate one potential use of offsets.
- Select and view the Merge node in this node tree. Right-click on the Merge Size control and select Modify With > Offset Distance from the contextual menu. This will add two new crosshairs and Offset controls in the Modifier tab.
- The size of the text will now be determined by the distance or offset between the two new cross hairs. These points are animatable and can be connected to other controls.
- Connect the position value of the offset to the existing path by right-clicking on the Position control and selecting Connect To > Path on Merge 1 Center Value. Manually place the Offset crosshair at the bottom of the screen between the two path points.
- Now, the text should shrink near the ends of the path (when the distance between the offset and the path is at its minimum) and grow at its ends (where the distance between the offset and the path is at its maximum).
Path

The Path uses two splines to control the animation of Points. An onscreen motion path (spacial) and a Time spline visible in the Spline Editor (temporal). To animate a Coordinate control using a Path, right-click on the control and select Path from the contextual menu.

Controls

![Path control panel](image)

**Center**
The actual Center of the path. This can be modified and animated as well to move the entire path around.

**Size**
The Size of the path. Again this allows for later modification of the animation.

**X Y Z Rotation**
The Path can be rotated in all three dimensions to allow for sophisticated controls.

**Displacement**
Every motion path has an associated Displacement spline in the Spline Editor. The Displacement spline represents the position of the animated control along its path, represented as a value between 0.0 and 1.0. Displacement splines are used to control the speed of a control’s movement along its path.

To slow down, speed up, stop or even reverse the motion of the control along the path, adjust the values of the points for the path’s displacement in the Spline Editor.

- A Displacement value of 0.0 in the Spline Editor indicates that the control is at the very beginning of a path.
- A value of 1.0 indicates that the control is positioned at the end of the path.
- Each locked point on the motion path will have an associated point on the Displacement spline.

Unlocked points will not have a corresponding point on the Displacement spline.
**Heading Offset**
If another control, for example a mask's Angle, is connected to the path's heading, this control allows for adding or subtracting from the calculated angle.

**Right Click Here for Shape Animation**
It is possible to animate the shape of the path as well, or to connect it to other path controls like Polyline Masks or Paint Strokes.

**Switching Default Paths**
Change the Default Path type used when animating a Coordinate control to Path (if this is the preferred type of animation). Open the Global preferences and look under the Default tab for the drop-down list in the default animate section labeled Point With. Change this from the current value to Path. The next time Animate is selected from a Coordinate control's contextual menu, a Path will be used.

**Perturb**
The Perturb modifier generates smoothly varying random values for several input types, based on Perlin noise. It can be used to add jitter, shake or wobble to any animatable control, even if the control is already animated. Its results are similar to those of the Shake modifier, though it uses a different set of controls that may be more suitable to your needs. Unlike other random modifiers, the Perturb modifier can also be applied to polylines, shapes, grid meshes and even color gradients.

For example, to add camera shake to an existing path, right-click on the crosshair and choose Insert > Perturb, then adjust the Strength down to suit. Alternatively, right-click on the path's Shape Animation control, and apply the wobble to the path's polyline itself (this works best if the polyline has many points, for example, if it has been tracked, or hand-drawn with the Draw Append pencil node). A third option is to insert the modifier onto the Displacement control, which will cause the motion along the path to jitter back and forth without actually leaving the line of the path.

**NOTE:** Perturb can only add jitter it cannot smooth out existing animation curves.

**Controls**
Value
The actual contents of this control will depend on what type of control the modifier was applied to. If the Perturb modifier was added to a basic Slider control, the Value will be a slider. If it was added to a Gradient control, then a Gradient control will be displayed here. Use the control to set the default, or center value, for the Perturb modifier to work on.

Jaggedness
(Polyliners, Meshes only) This allows you to increase the amount of variation along the length of the polyline or mesh, rather than over time. Increasing this will give a squigglier polyline or more tangled mesh, independent of its movement.

Phase
(Polyliners, Meshes only) Animating this can be used to move the ripple of a polyline or mesh along itself, from end to end. The effect can be most clearly seen when Speed is set to 0.0.

Random Seed Randomize
The Random Seed is used to ‘seed’ the amount of jitter applied by the modifier. Two Perturb modifiers with identical settings, but different random seeds, will produce two completely different results. Click on the Randomize button to assign a random seed value.

Strength
Use this control to adjust the Strength of the Perturb modifier’s output, or its maximum variation from the primary value specified above.

Wobble
Use the Wobble control to determine how smooth the resulting values are. Less wobble implies a smoother transition between values, while more wobble produces less predictable results.

Speed
Increasing the Speed slider value will speed up the rate at which the value changes. This can increase the apparent wobbliness in a more predictable fashion than the Wobble control and make the jitter more frantic or languorous in nature.

Probe
The Probe Modifier is one of the most versatile modifiers in Fusion. It allows you to control any numeric parameter by the pixel color or luminosity at a certain position or rectangular region of an image. Think of driving values by the presence or absence of an image or by color values of an image, using colors to create X Y positions on other controls, or measuring graded LUTs to compare values.

It can be applied by right-clicking on a control and selecting Modify with > Probe.
**Probe Tab**

![Probe Tab Image]

**Image to Probe**
Drop the node of the image you want to probe into this field.

**Channel**
Select the Channel you want to probe. The usual options are:
- Red
- Green
- Blue
- Alpha

**Luma**
Once a Probe modifier is present somewhere in your comp you can connect other node’s values to its outputs as well. The Probe allows to connect to its values individually:
- Result
- Red
- Green
- Blue
- Alpha

**Position X Y**
The position in the image from where the probe samples the values.

**Probe Rectangle**
By default the Probe only samples the value of a single pixel at its position. By using the Probe Rectangle mode you can sample from a larger area of pixels based on the Evaluation method.

**Width Height Controls**
These determine the size of the area to be probed.

**Evaluation**
Sets how the pixels inside the rectangle are computed to generate the output value.
Options are:

- Average (all pixel values inside the rectangle are averaged).
- Minimum (The smallest value of all pixels inside the rectangle is used).
- Maximum (The highest value of all pixels inside the rectangle is used).

### Value Tab

#### Scale Input Black White

By default, the Probe generates the Black Value when the probed area results in a value of 0 (i.e., black) and it generates its White Value when the probed area results in a value of 1 (i.e., white). By using this range control you can modify the sensitivity of the Probe.

#### Black Value

The value that is generated by the Probe if the probed area delivers the result set in Scale Input Black.

#### White Value

The value that is generated by the Probe if the probed area delivers the result set in Scale Input White.

#### Out of Image Value

The value that is generated by the Probe if the probed area is outside the frame boundaries of the probed image. If probing a rectangle, this value will not be generated before the entire rectangle is outside the frame boundaries of the image to be probed.

### Publish

Only controls that are animated can be available from the Connect To menu option. A non-animated control (static) must be published before it can be connected. Animated controls are automatically published, whereas static controls have to be manually published.

To publish a control, right-click on the control and select Publish from the contextual menu.
Published Value
This is obviously dependent on which value is published from which node.

Shake

The Shake modifier is used to randomize a position or value control to create semi-random numeric inputs. The resulting shake can be entirely random. The motion can also be smoothed for a more gentle, organic feel.

To add the Shake modifier to a control, select Modify With > Shake from the Control's contextual menu. The Shake modifier uses the following controls to achieve its effect. It can be applied by right-clicking on a control and selecting Modify with > Shake.

Shake Tab

Random Seed
The Random Seed control contains the value used to seed the random number generator. Given the same seed, a random number generator will always produce the same results. Change the seed if the results from the randomizer are not satisfying.

Smoothness
This control is used to smooth the overall randomness of the shake. The higher the value is set, the smoother the motion will appear. A value of zero will generate completely random results, with no smoothing applied.

Lock X and Y
This checkbox is used to Unlock the X- and Y-axis, revealing independent slider controls for each axis.

Min and Max
This control is used to determine the overall strength of the shake. The low values represent the lowest value that can be generated by the randomizer and the high values represent the highest values. To create a shake that moves a center crosshair anywhere within the image, set the low to 0.0 and the high to 1.0. To restrict the motion to a smaller shake in the bottom right corner of the image, set the Min to 0.70 and the Max to 0.90.
Example

- Create a new comp and add a Text node.
- Type something in the Text node and view it in the large display.
- Add a shake modifier by selecting Modify With > Shake Position from the contextual menu for the Text Center control.
- Switch to the Modifier tab and set the smoothing to 5.0.
- Set the Low to 0.1 and the High to 0.9.
- Go to frame 0 and add a Bezier spline to both the Low and the High controls.
- Advance to frame 90 and set the Low to 0.45 and the High to 0.55.
- Render out a preview and view the results.
- The text should start out by flying all over the screen and then tighten in toward the center of the screen.

Track

Another technique for adding a tracker directly to a control is to apply the Tracker as a modifier. Right-click on the center of the mask and select Ellipse x Center > Modify With > Tracker Position > Steady Position or Unsteady Position. This would add a modifier with a set of controls almost identical to those found in the Tracker node itself.

Tracker Tab

For an in-depth explanation of this node, refer to the Tracker chapter in this manual.
The differences between a Tracker Modifier and a Tracker Node are as follows:

- The Tracker modifier can only track a single pattern.
- A source image must be set for the Tracker modifier.
- The Tracker modifier can only output a single value and cannot be used for complex stabilization procedures.
- The default source image for the modifier is the node immediately upstream of the node that contains the modifier (i.e., when adding a Tracker modifier to a Glow node with a Loader as its input, the Tracker Source input will default to the output of the Loader). Set a different source image for the Tracker modifier by typing in the name of the node. Alternately, drag and drop the Source node from the Node Editor into the Text Box control.

Example

Imagine that you needed to track an actor’s eyes so that an unearthly, alien glow could be applied to the eyes. Add a Glow node and then create an Ellipse mask in the shape of the eye. Right-click on the center of that mask and select modify with > Track. Track the actor’s eye.

Vector

The Vector Modifier is used to offset positional controls, such as crosshairs, by distance and angle. These can be static or animated values.

It can be applied by right-clicking on a control and selecting Modify with > Vector.

Controls

Origin
This control is used to represent the position from which the vector’s distance and angle values originate.

Distance Slider Control
This control is used to determine the Distance of the vector from the origin.

Angle Thumbwheel Control
This control is used to determine the Angle of the vector relative to the origin.
Image Aspect Slider Control
This control is used primarily to compensate for image aspect differences. A square image of 500 x 500 would use an Image Aspect value of 1, while a rectangular image of 500 x 1000 would use an Aspect value of 2. The default for this value is taken from the current Frame Format preferences using width/height. It may be required to modify this control to match the current image.

Example

- To illustrate, create a simple node tree consisting of a black background, a Text node and a Merge.
- Right-click on the center of the merge and select Modify With > Vector. This will add a Vector Control header under the small view. Expand it by clicking on the gold triangle. Drag the Distance control to distance the text from the vector origin.
- Drag the Angle thumbwheel to rotate the text around the vector origin.
- Add a path to the vector origin by right-clicking on the Origin control and selecting the Path option from the contextual menu. Verify that the current frame is set to frame 0 (zero) and drag the Vector Origin crosshair to the bottom left corner of the screen.
- Right-click on the Vector Angle thumbwheel and select Bezier Spline to animate this control.
- Set the Angle thumbwheel to a value of 10.
- Advance to frame 100 and click at the top left corner of the screen to move the vector origin crosshair.
- Set the Vector Angle thumbwheel to a value of 1000. This will cause the text to orbit around the path just created.

XY Path
The XY Path type uses a separate spline for the position along the X-axis, as it does for the position along the Y-axis.

To animate a coordinate control using an XY path, right-click on the control and select Modify With > XY Path from the contextual menu.

At first glance, XY paths work like Displacement paths. To describe the path, change frames and position the control where it should be on that frame, then change frames again and move the control to its new position. Fusion automatically interpolates between the points. The difference is that no keyframes are created on the onscreen path.

Look in the Spline Editor to find the X and Y channel splines. Changes to the controls position will be keyframed on these splines. The advantage to the XY path is that it becomes very easy to work with motion along an individual axis.
Controls

X Y Z Values
These reflect the position of the animated control.

Center
The actual Center of the path. This can be modified and animated as well to move the entire path around.

Size
The Size of the path. Again this allows for later modification of the animation.

Angle
The Angle of the path. Again this allows for later modification of the animation.

Heading Offset
If another control, for example a mask’s Angle, is connected to the path’s heading, this control allows for adding or subtracting from the calculated angle.

Plot Path In View
Toggles if or if not the actual path is displayed in the views.

Switching Default Paths
Change the Default Path type used when animating a coordinate control to XY path (if this is the preferred type of animation). Open the Global preferences and look under the default’s tab for the drop-down list in the default animate section labeled Point With. Change this from the current value to XY Path. The next time Animate is selected from a Coordinate Control’s contextual menu, an XY path will be used instead of a Displacement path.
Chapter 104

VR Nodes

This chapter details Virtual Reality (VR) nodes available in the Fusion page.
Contents

VR Nodes 2019
Spherical Stabilizer 2020
Spherical Camera 2021
LatLong Patcher 2023
PanoMap 2024
VR Nodes

360° (spherical) video, often described as Virtual Reality or VR, has been created and fixed in Fusion for over a decade. Dome productions, planetariums and other special-venue productions utilize the flexibility of Fusion and its 3D system to produce and deliver special content.

360° video is often represented with an equirectangular (lat-long) format, similar to how the globe is represented by a world map, with the poles at the top and bottom edges of the image and the forward view point at the center. Stereo VR can be created from two stacked lat-long images, one for each eye. VR video can also be created from 3D CGI scenes.

Fusion supports a number of common spherical image formats, and can easily convert between them.

- **VCross** and **HCross** are the six square faces of a cube laid out in a cross, vertically or horizontally, with the forward view in the center of the cross, in a 3:4 or 4:3 image.
- **VStrip** and **HStrip** are the six square faces of a cube laid vertically or horizontally in a line, ordered as Left, Right, Up, Down, Back, Front (+X, -X, +Y, -Y, +Z, -Z), in a 1:6 or 6:1 image.
- **LatLong** is a single 2:1 image in an equirectangular mapping.

Fusion 9 has built-in support for VR headsets like the Oculus Rift and HTC Vive. Fusion will display both spherical video and live 3D scenes from the comp directly to the headset.

Fusion’s “Fix it in Post” tools for VR make it easy to do several important tasks that are common in these types of productions.
Spherical Stabilizer

VR live action is often shot with a handheld camera, so the footage can be shaky. The Spherical Stabilizer node will automatically identify and track visible features in the footage, then analyze their movement to identify pan, tilt, and roll rotations. After tracking, it is then possible to smooth out or stabilize the rotation of the footage. The node requires images in a spherical layout, which can be any of LatLong (2:1 equirectangular), Horizontal/Vertical Cross, or Horizontal/Vertical Strip.

Controls

Reject Outliers to Dominant Motion While Tracking
With this control ticked (the default setting), features that move contrary to the majority of other features will be ignored. This helps ignore the movement of subjects in the shot, preferring stable and consistent markers from the surrounding environment.

Track Controls
These initiate tracking and analysis of the shot. Note that the reference frame used for stabilization is set to the first frame tracked.

- Track Backwards from end frame starts tracking backwards from the end of the current render range.
- Track Backwards from current time starts tracking backwards from the current frame.
- Stop ceases tracking, preserving all results so far.
- Track Forward from current time starts tracking forward from the start of the current render range.
- Track Forward from start frame starts tracking forward from the current time.

Append to Track
- Replace will cause the Track Controls to discard any previous tracking results and replace them with the newly-created track.
- Append will add the new tracking results to any earlier tracks.

Stabilization Strength
This control varies the amount of smoothing or stabilization applied, from 0.0 (no change) to 1.0 (maximum).
Still – Smooth
The Spherical Stabilizer node can eliminate all rotation from a shot, fixing the forward viewpoint (Still mode, 0.0) or gently smooth out any panning, rolling or tilting in order to increase viewer comfort (Smooth mode, 1.0). This control allows either option, or anything in between.

Offset Rotation
Often a shot is not completely level and needs the horizon to be realigned, or perhaps a desired pan should be reintroduced after fully stabilizing the shot. The Offset Rotation controls allow additional manual control of the Stabilizer’s rotation of the footage, for pitch/tilt (X), pan/yaw (Y), and roll (Z), respectively. Rotation is always performed in that order, i.e., XYZ.

Spherical Camera
The Spherical Camera allows the 3D Renderer to output an image covering all viewing angles, laid out in several different formats. This image may be used, for example, as a skybox texture or reflection map, or viewed in a VR headset. The Image Width setting in the 3D Renderer is used as the size of each square cube face, so the resulting image may be a multiple of this size horizontally and vertically.

Controls
Layout

- **VCross** and **HCross** are the six square faces of a cube laid out in a cross, vertical or horizontal, with the forward view in the center of the cross, in a 3:4 or 4:3 image.
- **VStrip** and **HStrip** are the six square faces of a cube laid vertically or horizontally in a line, ordered as Left, Right, Up, Down, Back, Front (+X, -X, +Y, -Y, +Z, -Z), in a 1:6 or 6:1 image.
- **LatLong** is a single 2:1 image in equirectangular mapping.

Near/Far Clip

The clipping plane is used to limit what geometry in a scene is rendered based on the object’s distance from the camera’s focal point. This is useful for ensuring that objects which are extremely close to the camera are not rendered and for optimizing a render to exclude objects that are too far away to be useful in the final rendering.

The default perspective camera ignores this setting unless the Adaptively Adjust Near/Far Clip checkbox control below is disabled.

The values are expressed in units, so a far clipping plane of 20 means that any object more than 20 units distant from the camera will be invisible to the camera. A near clipping plane of 0.1 means that any object closer than 0.1 units will also be invisible.

Adaptively Adjust Near/Far Clip

When selected, the Renderer will automatically adjust the camera’s near/far clipping plane to match the extents of the scene. This setting overrides the values of the Near and Far clip range control described above. This option is not available for orthographic cameras.

Viewing Volume Size

The Viewing Volume Size control only appears when the Projection Type is set to Orthographic. It determines the size of the box that makes up the camera’s field of view. The Z distance of an orthographic camera from the objects it sees does not affect the scale of those objects, only the viewing size does.

---

**NOTE:** A smaller range between the near and far clipping planes allows greater accuracy in all depth calculations. If a scene begins to render strange artifacts on distant objects, try increasing the distance for the Near Clip plane. Use the vertical aperture size to get the vertical angle of view and the horizontal aperture size to get the horizontal angle of view.

---

Plane of Focus (for Depth of Field)

This value is used by the OpenGL renderer to calculate depth of field. It defines the distance to a virtual target in front of the camera.

Stereo Method

Allows you to adjust your stereoscopic method to your preferred working model.

Toe in

Both cameras point at a single focal point. Though the result is stereoscopic, the vertical parallax introduced by this method can cause discomfort by the audience.
**Off Axis**
Often regarded as the correct way to create stereo pairs, this is the default method in Fusion. Off Axis introduces no vertical parallax, thus creating less stressful stereo images.

**Parallel**
The cameras are shifted Parallel to each other. Since this is a purely parallel shift, there is no Convergence Distance control. Parallel introduces no vertical parallax, thus creating less stressful stereo images.

**Eye Separation**
Defines the distance between both stereo cameras. If the Eye Separation is set to a value larger than 0, controls for each camera will be shown in the Viewer when this node is selected. There is no Convergence Distance control in Parallel mode.

**Convergence Distance**
This control sets the stereoscopic convergence distance, defined as a point located along the Z-axis of the camera that determines where both left and right eye cameras converge.

**Control Visibility**
Allows you to selectively activate the on screen controls that are displayed along with the camera.

- **Frustum**: Displays the actual viewing cone of the camera.
- **View Vector**: Displays a white line inside the viewing cone, which can be used to determine the shift when in Parallel mode.
- **Near Clip**: The Near clipping plane. This plane can be subdivided for better visibility.
- **Far Clip**: The Far clipping plane. This plane can be subdivided for better visibility.
- **Plane of Focus**: The Plane of Focus according to the respective slider explained above. This plane can be subdivided for better visibility.
- **Convergence Distance**: The point of convergence when using Stereo mode. This plane can be subdivided for better visibility.

---

**LatLong Patcher**

Equirectangular stitched images often need patches, paint work, or other VFX applied. The LatLong Patcher extracts and de-wraps a section of a lat-long (equirectangular) image to be treated, and can warp and merge fixes back over the original. This gives the ability to quickly pick a section of the spherical image to patch or paint, then apply it back to the original image. Note that matching rotations will be used in both Extract and Apply modes, allowing a node’s operation to be easily reversed by a copy or instance with the same rotation settings.
Controls

Mode

- **Extract** will pull a de-warped 90 degree square image from the equirectangular image.
- **Apply** will warp and merge a 90 degree square image over the equirectangular image. Because the square image’s alpha is used, this allows, for example, paint strokes or text drawn over a transparent black background to be applied to the original equirectangular image, avoiding any double-filtering from de-warping and re-warping the original.

Rotation

These will rotate the spherical image around each of the X, Y, and Z axes, offering independent control over pitch/tilt, pan/yaw, and roll, respectively.

Rotation Order

This chooses the ordering of the rotations around each axis. For example, XYZ will rotate first around the X axis (pitch/tilt), then around the Y axis (pan/yaw), then around the Z axis (roll). Any of the six possible orderings can be chosen.

PanoMap

Converts images from one spherical layout to another, such as cubemap to equirectangular formats. The node can also do rotations of the spherical images when converting.
Controls

From and To

- **Auto** will detect the incoming image layout from the metadata and image frame aspect.
- **VCross** and **HCross** are the six square faces of a cube laid out in a cross, vertical or horizontal, with the forward view in the center of the cross, in a 3:4 or 4:3 image.
- **VStrip** and **HStrip** are the six square faces of a cube laid vertically or horizontally in a line, ordered as Left, Right, Up, Down, Back, Front (+X, -X, +Y, -Y, +Z, -Z), in a 1:6 or 6:1 image.
- **LatLong** is a single 2:1 image in equirectangular mapping.

Rotation

These will rotate the spherical image around each of the X, Y, and Z axes, offering independent control over pitch/tilt, pan/yaw, and roll, respectively.

Rotation Order

This chooses the ordering of the rotations around each axis. For example, XYZ will rotate first around the X axis (pitch/tilt), then around the Y axis (pan/yaw), then around the Z axis (roll). Any of the six possible orderings can be chosen.
PART 9

Color
Chapter 105

Introduction to Color Grading

For over thirty years, DaVinci has pioneered the development of color correction hardware and software designed to enhance visual images acquired from film and video. DaVinci Resolve 14 possesses our newest and most evolved professional color correction tools yet. However, for all its technological sophistication, DaVinci Resolve is merely a tool that requires the hands of a skilled artist to realize its full potential.

Subsequent chapters of this user manual cover the DaVinci Resolve grading tools in the Color page in great detail, but before getting into the specifics of color balancing and contrast adjustment, Power Windows, and Custom Curves, it’s important to step back and consider what these tools are for, and why you’re learning to use this application in the first place.

This introduction is for those of you who are new to this process we call color correction, or color grading. If you’re a veteran colorist then you might want to skip ahead, but if you’re just starting out, the following sections are intended to describe the many goals of color correction, and how the DaVinci Resolve toolset has been designed to address them; making it fast and efficient to alter images in innumerable ways as we elevate raw footage to cinematic art.
Contents

The Goals of Color Correction 2029
Maximizing the Look of Your Media 2029
Emphasizing What’s Important 2032
Audience Expectations 2033
Balancing Scenes 2035
Adding Style 2036
Quality Control 2039
Never Stop Experimenting 2040
The Goals of Color Correction

If reality is a fire hose of visual information, then digital cinema and broadcast would be represented by a garden hose. Color correction, therefore, could be considered the process of choosing which parts of the fire hose of raw image data to fit into the garden hose of our displays in order to create a pleasing image for the viewer.

Maximizing the Look of Your Media

Clearly, the most fundamental aspect of the color correction process is that of making every clip look its best. While the job of the cinematographer is to light and expose the image with an artistic intent, your job is to realize this intent by making adjustments to the color and contrast of the image, so that the final result is as close to what the director and cinematographer had in mind as is humanly possible. In the process, you have the opportunity to overcome inconsistencies with exposure and white balance that were, for various reasons, unavoidable. Furthermore, you can make subtle adjustments to add warmth or contrast that was not available during the shoot, but that the cinematographer would have liked.

Increasingly, color correction is seen as a critical stage in the post-production process. For example, the newer generation of digital cinema cameras are capable of shooting raw colorspace image data, or RGB image data with a log exposure, in order to preserve the maximum amount of image data for manipulation during the color correction process. However, when you acquire image data this way, it must be transformed into a viewable image via color correction in the same way that film negative must first be developed and printed to positive film.

Of course, there are also situations in which you may find it necessary to attempt to fix source media with far more substantial problems in color and exposure. In these cases, the tools exist to make far more involved adjustments to the image; however, the quality of your results will depend heavily on the data quality and “latitude” of your source media.
For example, Blackmagic Ursa, ARRI ALEXA, and RED DRAGON cameras record quite a bit of image data, making extreme corrections far more possible than more heavily compressed camera formats such as the Canon 5D. However, in either case, DaVinci Resolve provides the tools to process images in many different ways to adjust the image for a better look.

Whether clips need changes large or small, the primary DaVinci Resolve toolset adjusts the characteristics of hue, saturation, and contrast in a variety of ways. In the Color Wheels palette, Color balance wheels let you adjust all three color channels at once, altering the color temperature of the scene at specific ranges of tonal detail referred to as lift, gamma, and gain. Alternately, the slider-based Primaries Bars mode lets you make the same kinds of controls via independently adjustable red, green, and blue lift, gamma, and gain controls.
All of these controls let you adjust the color tone of the shadows independently from that found in the brightest highlights of an image.

![Cool look](image1.png)

![Warm look](image2.png)

Meanwhile, Master Lift wheels work together to let you alter image contrast in different ways: deepening shadows, lightening highlights, and brightening or darkening the midtones in between to create whatever image tonality you prefer for a given scene.

![High contrast](image3.png)

![Low contrast](image4.png)

Source footage courtesy of Gianluca Bertone DP, www.bertonevisuals.com

Separate saturation controls let you increase or decrease color intensity throughout the scene, while the Sat vs. Lum and Sat vs. Sat give you the ability to fine-tune saturation very specifically.
For more information on these controls, which are essential to the color correction process, see Chapter 110, “Primary Grading Controls.”

**Emphasizing What’s Important**

Another important aspect of the color correction process is the ability to make adjustments to emphasize or de-emphasize specific elements within the frame. It’s similar in concept to equalization in audio mixing, in that you’re choosing which color values to boost or suppress using a variety of techniques.

This can be done to direct the viewer’s gaze, for example by surrounding a specific part of the image with a Power Window, which lets you restrict specific adjustments made to the inside and outside of the Window’s shape.
Specific alterations can also be made to prevent audience distraction. For example, a low-saturation monochromatic tint may be a pleasing look overall, but in the soft wash of color, the viewer might lose track of the watch that’s preoccupying the protagonist. Using tools such as the Hue curves and HSL Qualifier, you can quickly and easily tune the color of the woman’s hands and of the watch to guide the viewer’s eye, and bring some needed depth to the scene.

For more information on Power Windows, see Chapter 113, “Secondary Windows and Tracking.” For more information on Hue curves, see Chapter 111, “Curves.”

**Audience Expectations**

There is another family of tools, the HSL, RGB, and Luma Qualifiers, that provide even more specific control, and they’re useful for adjusting ranges of color to either play into or against the audience expectations for color in a scene. Substantial research into what has been termed “memory color” shows that people have finely tuned expectations for the hues of particular subjects, such as flesh tone, foliage greens, and sky blues. Deviation from these expectations can create a sense of something being not quite right, which can be either detrimental or beneficial, depending on your goals for a particular scene.

HSL Qualification is effectively a chroma keyer that lets you sample the image to create a key that’s used to define where to apply a specific correction. For example, if you’re happy with the rest of the image, but the skin tone of the actor has an unhealthy green tinge to it as a result, you can isolate the color of that actor’s skin and adjust it to a healthier hue.
Another common example is the adjustment of skies. If you're aiming for a gorgeous summer day, a washed out sky in the source media can be a bit of a bummer. However, using qualification it's easy to isolate that wedge of blue, then push and pull it into just the right amount of summertime joy.

For more information on using qualifiers, see Chapter 112, "Secondary Qualifiers."
Balancing Scenes

It’s rare when the uncorrected shots of a scene match one another perfectly. Even the most carefully exposed angles of coverage can have small variances that need to be evened out. On the other end of the spectrum, run-and-gun programs using available light often result in edited scenes with huge changes in lighting and color as each shot cuts away to the next.

Small or large, unintended variations from one shot to the next can call undue attention to the editing, and jar the audience’s attention in ways that throw them out of the program. Evening out these differences and balancing the clips in each scene to match is another of the fundamental tasks of the colorist. You know you’re finished when the color in the scene flows unnoticeably from one clip to the next.

DaVinci Resolve has a variety of tools that you can use to help you compare images with one another, the most important of which is the Gallery, in which you can save still images of clips that you can then compare to other clips using an adjustable split screen.

By using the Gallery to play stills, either split or whole (flipping back and forth between the clip you’re adjusting and the still), it becomes easier to use the extensive DaVinci Resolve toolset to match the color and exposure of every clip in a scene.
An additional set of features let you manage grades by copying them from clip to clip, or by linking similar clips, either automatically, or manually using groups.

For more information on using the Still Store, see Chapter 106, “Using the Color Page.” For more information on grade management, see Chapter 116, “Grade Management.”

Adding Style

Of course, it’s not all about subtlety and correction. It’s often appropriate, when grading music videos and commercials, for instance, to add some radical style to a piece. Here, too, DaVinci Resolve provides an abundance of features for manipulating unexpected aspects of the image; for example, by abusing the Custom Curves to create the illusion of chemical cross-processing.
DaVinci Resolve's node-based image processing makes it possible to use more exotic node structures to create effects using composite modes, such as a colored glow generated by adding two differently graded versions of the same image together using a Layer node.

You can also create complex node trees to build specific mattes, to use for isolating specific elements of the image. For example, if you wanted to isolate an actor in color against a background turned monochromatic, you can create multiple keys (pulled via HSL Qualification) and combine them using a Key Mixer node to build that effect.
Finally, DaVinci Resolve doesn’t just have tools governing color and contrast. A Blur palette provides controls over blurring, sharpening, or adding mist to all or part of the image. When combined with the other tools that are available for isolation and color adjustment, these are powerful additions to your creative arsenal.

For more information on all of these features, see Chapters 98 through 122 of this manual.
Quality Control

Lastly, it’s important to keep in mind that, for all the creative possibilities that DaVinci Resolve affords, it’s still important that the final deliverables that you give to your client has appropriate signal levels relative to their requirements. In particular, programs destined for broadcast have specific outer boundaries of luma and chroma that you must not exceed, or you’ll risk having a show rejected for QC (quality control) violations.

However, even if you’re not delivering a show for broadcast, it’s important to be aware of the mathematical limitations of a digital video signal to make sure you’re not clipping or crushing image detail through overzealous adjustments that you may, in fact, want to preserve.

For example, if you take a look at the next two images, you can see the perils of overzealous adjustments when compared to a clip that, while graded creatively, has been adjusted with respect to the mathematical boundaries of image data.

Here, too, DaVinci Resolve provides tools designed to help you exercise control over the fine-tuning of the image. A Video Scopes window provides the standard Waveform, Parade, Vectorscope, and Histograms that are used to analyze your image data. These scopes let you see the boundaries of what’s possible, and make it easy to spot subtle problems, and compare the characteristics of one image to another.
When the time comes that you want to start clipping data in the highlights and shadows, as part of a creative look, the Soft Clip controls let you introduce a subtle or large roll-off, compressing the extremes of the signal so that what clipping you do is softer and more pleasing.

For more information about the video scopes and the Soft Clip controls, see Chapter 106, “Using the Color Page,” and Chapter 111, “Curves.”

**Never Stop Experimenting**

So now that you’ve gotten an extremely brief overview of the grading process as seen through the toolset of DaVinci Resolve, we invite you to use this manual to explore DaVinci Resolve more thoroughly. You may discover that, the more you work with the different features that are available, the more unexpected uses you’ll find for different controls that you thought you knew well.

Have fun.
Chapter 106

Using the Color Page

Given the origin of DaVinci Resolve as a professional grading application, the Color page is at the heart of the DaVinci Resolve experience. Within the Color page are all of the controls available for manipulating color and contrast, reducing noise, creating limited secondary color corrections, building image effects of different kinds, adjusting clip geometry, and making many other corrective and stylistic adjustments.

In this chapter, you’ll learn how to understand the Color page interface, how to customize it, and how to work within it to play through and navigate your project’s timeline. You’ll also learn how to analyze and compare clips in preparation for grading using stills, playheads, and DaVinci Resolve’s own internal video scopes.

The Color Page Interface

The Color page is divided into seven main areas that work together to let you build a grade. This section provides an overview of what these areas are and how they function.

The Interface Toolbar

At the very top of the Color page is a toolbar with buttons that let you show and hide different parts of the user interface. These buttons are as follows, from left to right:

- **Gallery:** Opens and closes the Gallery panel.
- **Timeline:** Opens and closes the Mini-Timeline.
- **Clips:** Opens and closes the Thumbnail timeline. To the right is a pop-up menu that lets you choose a timeline filtering option for the Thumbnail timeline.
- **Nodes:** Opens and closes the Node Editor.
- **OpenFX:** Opens and closes the OpenFX panel.
- **Lightbox:** Opens and closes the Lightbox.

Showing Which Panel Has Focus

Whenever you click somewhere on the DaVinci Resolve interface using the pointer, or use a keyboard shortcut to “select” a particular panel (such as in the Edit page), you give that panel of the user interface “focus.” A panel with focus will capture specific keyboard shortcuts to do something within that panel, as opposed to doing something elsewhere in the interface. A highlight appears at the top edge to show you which panel has focus so that you can keep track of which part of the current page is taking precedence, and you can switch focus as necessary to do what you need to do.
The focus indicator shown at the top edge of the Media Pool, shown next to a Viewer that doesn’t have focus

**Viewer**

The Viewer shows the frame at the current position of the playhead in the Timeline. At the top of the Viewer is a header that displays the Project and Timeline names, as well as a Viewer Timecode display that shows the source timecode of each clip by default. The Timeline name is also a pop-up display that lets you switch to any other timeline in the project. A scrubber bar underneath the image lets you drag the playhead across the entire duration of the clip, while transport controls underneath that let you control playback. A toolbar at the top provides controls governing Image Wipes, Split-Screen controls, and Highlight display. Additional controls let you loop playback, switch Unmix mode on and off, turn audio playback on and off, and choose which onscreen controls are currently displayed. More information about using the Viewer appears later in this chapter.

You can also put the Viewer into one of three alternate modes to be able to see a larger image as you work. All three of these modes are available from the Workspace > Viewer Mode submenu.
• Enhanced Viewer (Option-F to toggle this on and off) hides everything to the left and right of the Viewer, giving you a large working area for tasks such as window positioning and rotoscoping, while keeping the palettes and their controls visible as you work.

The Color page in Enhanced Viewer mode

• Full Screen Viewer (Shift-F to toggle this on and off) is available to provide more working area for tasks such as window positioning and rotoscoping. Full Screen Viewer also lets you display the OpenFX panel at full height, and you can turn the Node Editor on and off to access different effects controls while you work.

The Color page in Full Screen Viewer mode

• Cinema Viewer (Command-F to toggle this on and off) expands the Viewer to fill your workstation’s entire monitor. This is useful if you want to play the current Timeline without any distractions. When you move the pointer over the image, transport controls and a jog bar appear to let you control playback. For DIIs, a contextual menu is available by right-clicking anywhere on the image with which you can turn on and customize a video scope overlay (which can be dragged to different locations on the Viewer).
The Color page in Cinema Viewer mode

**Gallery**

The Gallery is used for storing still frames to use as reference, and grades you might like to copy; stills and grades are stored together. A button lets you open up the Album browser, used for organizing your stills. At the bottom of the Gallery, Memories let you store grade information that you can apply using a control panel or keyboard shortcuts. The Gallery on the Color page mirrors the contents of the Gallery page. For more information on the Gallery page, see Chapter 115, “Using the Gallery.”
LUT Browser

The LUT Browser provides a centralized area for browsing and previewing all of the LUTs installed on your workstation. All LUTs appear in the sidebar, by category.

By default, all LUTs appear with a test thumbnail that give a preview of that LUT’s effect, but you can also get a live preview of how the current clip looks with that LUT by hover scrubbing with the pointer over a particular LUT’s thumbnail (this is described in more detail below).

To open the LUT Browser:

Click the LUT Browser button in the UI Toolbar at the top of the Color page.

Methods of working with the LUT Browser:

- **To see the LUTs in any category:** Click on a LUT category to select it in the sidebar, and its LUTs will appear in the browser area.

- **To make a LUT a favorite:** Hover the mouse over a LUT and click the star badge that appears at the upper right-hand corner, or right-click any LUT and choose Add to Favorites. That LUT will then appear when you select the Favorites category.

- **To search or filter for specific LUTs:** Open a bin that has the LUT you're looking for, then click the magnifying glass icon to open the search field, and type text that will identify the LUTs you're looking for.

- **To see LUTs in Column or Thumbnail view:** Click the Column or Thumbnail buttons at the top right of the LUT Browser to choose how to view LUTs in the browser area.

- **To sort LUTs in Thumbnail view:** Click the Thumbnail Sort pop-up menu and choose which criteria you want to sort LUTs by. The options are Filename, Type, Relative Path, File Path, Usage, Date Modified. There are also options for ascending and descending sort modes.

- **To sort LUTs in Column view:** Click the column header to sort by that column. Click a header repeatedly to toggle between ascending and descending modes.

- **To update the thumbnail of a LUT with an image from a clip:** Choose a clip and frame that you want to use as the new thumbnail for a particular LUT, then right-click that LUT and choose Update Thumbnail With Timeline Frame.

- **To reset the thumbnail of a LUT to use the standard thumbnail:** Right-click a LUT and choose Reset Thumbnail to go back to using the standard test image.

- **To refresh a LUT category with new LUTs that may have been installed:** Select a LUT category, then right-click anywhere within the browser area and choose Refresh to refresh the contents of that category from disk.
Methods of adding LUTs to a grade from the LUT Browser:

- **To apply a LUT to a clip:** Select a clip in the Thumbnail timeline, then right-click a LUT and choose Apply LUT to Clip from the contextual menu. That LUT is added to the source clip, not the grade.

- **To Append a LUT to the end of the node tree:** Right-click a LUT and choose Append to Node Graph. A new node will be appended to the end of the current node tree with that LUT applied to it.

- **To apply a LUT to a specific node:** Drag a LUT from the LUT Browser and drop it onto the node you want to apply a LUT to. If you drag a LUT onto a node that already has a LUT, the previous LUT will be overwritten by the new one.

**Media Pool**

The Media Pool is available in the Color page, making it easy to drag and drop clips you want to use as external mattes right into the Node Editor, for easy and fast connection to create various Color page effects. When opened, the Media Pool replaces the Gallery, fitting into the same area. In most respects, the Media Pool in the Color page works the same as the Media Pool on nearly every other page of DaVinci Resolve.

When you drag a clip from the Color page Media Pool to the Node Editor, two things happen:

- That clip is turned into an external matte in the current grade, which you can use as a matte for secondary adjustments, or as a compositing layer (in conjunction with the Layer mixer) for mixing textures or images with your grade.

- That clip is also automatically attached to the Media Pool clip that corresponds to the clip you’re grading as a clip matte, to help you keep track of which clips are using other clips as mattes.

For more information about the Media Pool, see Chapter 11, “Adding and Organizing Media with the Media Pool.”

**Node Editor**

The Node Editor is where you assemble one or more individual corrections (nodes) together into a complete multi-correction grade (node tree). This is a powerful way of assembling grades, since different types of nodes let you create different combinations of corrections and very specific adjustments by reordering operations, combining keys, or changing the layer order of different adjustments. For more information about the Node Editor, see the “Node Editor Basics” section of Chapter 109, “Node Editing Basics.”
Timeline

The Timeline provides several ways of navigating the clips in your project, as well as keeping track of what has been done to which clips. The Timeline is divided into two parts, each of which shows different information and provides differing controls, and each of which can be opened or closed separately via the Clips and Timeline buttons on the Interface toolbar.

Thumbnail Timeline

At the top is the Thumbnail timeline, in which each clip is represented by a single frame. The Thumbnail timeline (or its alter-ego, the Lightbox) provides the easiest way of selecting which clip you want to work on and of making clip selections for various grade management operations. The currently selected clip that reveals its controls in the various palettes of the Color page is highlighted in orange, while other clips that are selected but are not the current clip are highlighted in white.

Much valuable information appears above and below each thumbnail, such as each clip’s clip number, source timecode, track number, whether it’s been flagged, whether it’s automatically linked or part of a group, whether it’s been tracked, and so on.
What's displayed underneath each thumbnail can be changed by double-clicking the space underneath each thumbnail. There are several options; you can keep double-clicking to cycle among them:

- Clip format or codec (the default)
- Clip Name (clip name or file name, depending on what View > Show File Name is set to) or Multicam Angle (if you're working with multicam clips)
- Version name or number

**Mini-Timeline**

Underneath, the Mini-Timeline shows a small representation of the video tracks of the Timeline in the Edit page wherein each clip is as long as its actual duration. This provides the best representation of the structure of the current timeline, in which clip length shows duration and multiple tracks are displayed, so you can see which clips are superimposed. A Timeline Ruler lets you scrub the playhead across multiple clips and can be zoomed out enough to show every clip in your entire program.

The Mini-Timeline lets you see timeline structure, and small track header controls let you enable tracks, disable tracks, and set the playhead to ignore specific tracks.

Small track labels at the left of each track in the Mini-Timeline let you enable or disable tracks by clicking them (enabled tracks have white labels, disabled tracks have gray labels). Option-clicking one of these controls sets that track to be enabled but ignored by the playhead when you use the Next and Previous Clip commands, in the event you want to ignore clips you don’t need to grade (tracks in this mode show a red label).

Within the Mini-Timeline currently selected clip is orange, and you can click any clip to select it. A scroll bar at the bottom lets you navigate to the left and right, while using the scroll wheel of your mouse zooms in and out. The Mini-Timeline shows at most six tracks of video. If your project has more tracks than that, you can scroll up and down to reveal the hidden tracks. Any markers that were placed on clips or the Timeline in the Edit page appear here, and you can click any marker to reveal and edit its color and notes.

As seen above, a colored outline appears around the clip number of shots that have been graded, and this outline is doubled if there are additional versions applied to that clip.

For more detailed information about the Color page timeline, see Chapter 108, “Color Page Timeline and Lightbox.”

**Palette Area**

Most everyday tools and functions for grading are distributed among a series of palettes found in the palette area of the Color page. These palettes can be accessed via a series of palette buttons running along the Palette bar at the top of this area.
These buttons also give you feedback about which palettes have adjustments for the current selected node in the Node Editor. Palettes with adjustments show a small orange dot in the corresponding palette button.

An orange dot in a palette button lets you know there are adjustments in that palette

Left Palettes

A series of palettes at the bottom left of the Color page provide access to different sets of grading tools, used principally for manipulating color, contrast, and raw media format settings. Each individual palette is opened by clicking the corresponding icon at the top of the Palette panel.

The six available palettes are the Camera Raw palette (for making metadata adjustments to raw media formats), the Color Match palette (automatic grading based using test charts), the Color Wheels (graphical color balance controls and master wheels, along with a Slider mode for adjusting YRGB Lift/Gamma/Gain), the RGB Mixer (for mixing color channels into one another), and the Motion Effects palette (with controls for noise reduction and artificial motion blur). These palettes can be used individually or together depending on what you’re trying to accomplish. For more information on most of these palettes, see Chapter 110, “Primary Grading Controls.” For more information on the Motion Effects palette, see Chapter 127, “The Motion Effects and Blur Palettes.”

Center Palettes

At 1920x1080 resolution or higher, a second set of palettes is organized at the bottom center of the Color page. These palettes span a wide range of functionality, and the adjustments you make with them can be combined with those made using the Color palettes.

The eight available Center palettes include the Curves palette, the Qualifiers palette, the Power Windows palette, the Tracker palette, the Blur palette, the Key palette, and the Sizing and Stereoscopic 3D palettes.

NOTE: At lower resolutions, the Left and Center palettes are merged to fit the DaVinci Resolve interface into a smaller area.
Keyframe Editor, Video Scopes, and Information

The bottom right of the Color page can be switched between one of three things:

- **Keyframe Editor:** Provides an interface for animating Color, Sizing, and Stereo Format adjustments over time. Each node in the Node Editor corresponds to a track in the Keyframe Editor, which lets you animate each node’s adjustments independently. Furthermore, each node’s track can be opened up to reveal parameter groups, so that you can animate subsets of an individual node’s functions independently of other functions within the same node. For more information about keyframing, see Chapter 121, “Keyframing in the Color Page.”

- **Video scopes:** Provides a docked area where you can expose one video scope at a time for reference while you work. You can also “undock” the video scopes into a stand-alone window, in which you can show four different scopes at a time. More information about using the video scopes appears later in this chapter.

- **Information:** Provides a way of seeing clip and system information while you work.

Dual Monitor Layout

The Color page has a dual monitor layout that provides maximum space for the Viewer, Node Editor, and Control palettes on the primary monitor, and a simultaneously displayed Gallery, Lightbox, Keyframe Editor, Metadata Editor, and Video Scope panel on the secondary monitor.

To enter dual screen mode:

Choose Workspace > Dual Screen > On.
To switch which UI elements appear on which monitors:
Choose Workspace > Primary Display > Display 1 or Display 2, which reverses the contents of both monitors in dual screen mode.

The Info Palette and Clip Information

The Info palette is hidden by default. Clicking the Info palette button at the far right of the toolbar reveals it at the right of the Center palette. The Info palette has two tabs that display different information. There are no user-editable controls in the Info palette.
Clip Info
The first tab displays information about whichever clip is currently selected in the Timeline. This information is not editable, but is provided for reference, and includes:

- **File Name:** The name of the media file on disk. If the current clip is a Multicam clip, this shows the name of the currently selected angle.
- **Reel Name:** The reel name of that clip, if one is being read properly.
- **Start T/C:** The source timecode value of the first frame in the clip.
- **End T/C:** The source timecode value of the last frame in the clip.
- **Duration:** The duration of the clip, in timecode.
- **Frames:** The duration of the clip, in frames.
- **Version:** The name of the remote or local version used by that clip.
- **Frame Rate:** The frame rate used by that clip.
- **Source Res:** The native resolution of the source clip.
- **Codec:** The codec or format used by the source clip.

System Info
The second tab displays information about operational modes currently in use by DaVinci Resolve. It’s meant to provide the status of different DaVinci Resolve features that can be enabled, disabled, or cycled among various options. This information includes:

- **Clips:** The total number of clips in the Timeline.
- **Proxy:** The status of Proxy mode (On or Off).
- **Clip Cache:** The status of the Clip Cache mode (Off, All, Dissolves, User, User & D).
- **Ref Transform:** The status of Reference Still reposition.
- **Ref Mode:** The status of the Reference mode (Gallery, Timeline, Offline).
- **Wipe Style:** The currently selected Wipe Style for split screens (Wipe-H, Wipe-V, Wipe-M, Wipe-A).
- **Convergence:** The current Convergence setting (Linked Zoom, Opposite)
- **Stereo Grade:** The currently displayed Eye and Gang mode (Left or Right – Gang or Solo).
- **Stereo Display:** The current Stereo Display mode (Mono or Stereo).
Clip Details

You can right-click the currently selected clip in the Thumbnail Timeline and choose View Clip Details to show a small window with all of that clip's information available at a glance. You can drag this window anywhere you like, even to another display.

This information is not editable, but is provided for easy reference, and includes:

- **File Name:** The name of the media file on disk appears at top.
- **Start Timecode:** The source timecode value of the first frame in the clip.
- **End Timecode:** The source timecode value of the last frame in the clip.
- **Duration:** The duration of the clip, in timecode.
- **Frames:** The duration of the clip, in frames.
- **Reel Name:** The reel name of that clip, if one is being read properly.
- **Version:** The name of the remote or local version used by that clip.
- **Format:** The format used by the source clip, along with the frame size and bit depth.
- **Codec:** The codec used by the source clip.
- **Folder:** Which directory on disk the source media resides in.
- **Description:** The description field of the Metadata Editor.
- **Notes:** The notes field of the Metadata Editor.
- **EDL Comments:** EDL comments for that event, if any exist.

Customizing the Color Page

The various sections of the Color page can be resized, hidden, and rearranged as needed to accommodate different working styles. This section covers all of the methods that are available for Color page customization.

You can easily resize the Viewer, Gallery, and Nodes Editor relative to one another to make the Viewer larger, expand the width of the Node Editor to have more workspace, or to create more or less room for stills in the Gallery.
To resize the Viewer, Gallery, and Node Editor:

Move the pointer over the vertical divider between any two areas. When the resize icon appears, drag the divider to the left or right to make one area larger while making the other smaller.

You can also fully expand the Gallery, the Memories, the Node Editor, and the Keyframe Editor to replace completely whichever interface area is adjacent.

To expand the Keyframe Editor:

Click the Expand control at the bottom left of whichever interface area you want to expand. Once expanded, clicking the Expand control again will collapse that interface area back to its original size, revealing whatever was hidden.

In Display mode, you can completely hide the Viewer, pushing the Gallery all the way to the right side of the DaVinci Resolve window, and expanding the Node Editor to take the rest of the space.

To toggle Display mode, do one of the following:

- Right-click in the empty area of the Node Editor, and choose Toggle Display Mode from the contextual menu. Do this again to toggle Display Mode off and return the interface to the way it was.
- Press SHIFT UP and DISPLAY/CURSOR, above the fourth trackball of the Center panel of the DaVinci control panel.

To show and hide the Mini-Timeline:

Click the Timeline button at the right of the palette button bar.

To show and hide the Color page Viewer upper toolbar:

Click the Viewer option menu and choose Show Viewer Options to uncheck it.

To return all pages to their default layout:

Choose Workspace > Reset UI Layout.

### Undo and Redo in DaVinci Resolve

No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you’ve taken or commands you’ve executed, and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you’ve done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo “stacks” to help you manage your work.

- The Media, Edit, and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
- Each clip in the Fusion page has its own undo stack so that you can undo changes you make to the composition of each clip, independently.
- Each clip in the Color page has its own undo stack so that you can undo changes you make to grades in each clip, independently.
In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you’re in.

To simply undo or redo changes you’ve made one at a time:

- Choose Edit > Undo (Command-Z) to undo the previous change.
- Choose Edit > Redo (Shift-Command-Z) to redo to the next change.
- On the DaVinci control panel, press the UNDO and REDO buttons on the T-bar panel.

TIP: If you have the DaVinci control panel, there is one other control that lets you control the undo stack more directly when using the trackballs, rings, and pots. Pressing RESTORE POINT manually adds a memory of the current state of the grade to the undo stack. Since discrete undo states are difficult to predict when you’re making ongoing adjustments with the trackball and ring controls, pressing RESTORE POINT lets you set predictable states of the grade that you can fall back on.

You can also undo several steps at a time using the History submenu and window. At the time of this writing, this only works for multiple undo steps in the Media, Edit, and Fairlight pages.

To undo and redo using the History submenu:

1. Open the Edit > History submenu, which shows (up to) the last twenty things you’ve done.
2. Choose an item on the list to undo back to that point. The most recent thing you’ve done appears at the top of this list, and the change you’ve just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what’s possible. However, if you’ve undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.

Once you’ve selected a step to undo to, the menu closes and the project updates to show you its current state.
To undo and redo using the Undo window:

1. Choose Edit > History > Open History Window.

2. When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you’ve done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.

3. When you’re done, close the History window.
Chapter 107

Viewers, Monitoring, and Video Scopes

Viewers let you see what you’re working on, provide a UI for transport controls and image comparison, draw windows and drag on-screen controls, and provide a variety of warnings and information not found anywhere else. However, at the same time, professional workflows require real time monitoring via supported video I/O devices on a calibrated display. Lastly, video scopes provide a more precise analysis of the state of the video signal you’re viewing, and DaVinci Resolve has built-in scopes you can use for creative decision making and troubleshooting.

This chapter covers the Color page Viewer, external monitoring and display calibration, and video scopes in more detail.

Using the Viewer

The Viewer is your window into the Timeline. The clip and frame at the current position of the playhead appears in the Viewer. The Viewer also provides a workspace for picking colors, adjusting Power Windows, using split screen stills for reference, and many other display-oriented tasks. If you have a video out interface connected to a broadcast display or projector, then the contents of the Viewer are typically mirrored by the video output.

The Viewer Title Bar

The Viewer title bar has controls and indicators making it easy to control and keep track of what it is you’re looking at.

The Viewer title bar has the following controls:

- **Zoom and Fit menu:** Lets you zoom to a specific percentage, or choose Fit to fit the image to the total available area of the Viewer.
- **Playback frame rate indicator:** A dot shows green if playback performance matches the frame rate of the project, or red if playback performance drops below real time. To the right, the current frame rate is displayed.
- **Timeline name and selection pop-up:** The name of the currently open timeline is displayed. A pop-up to the right lets you open any other timeline in the current project to take its place.
- **Timecode viewer and pop-up:** A second timecode viewer lets you choose an alternate timecode/frame count/KeyKode value to display simultaneously to the timecode viewer next to the transport controls below. A pop-up lets you pick whether to display source (clip) or record (timeline) timecode.
- **Bypass Color and Fusion and pop-up:** Lets you disable grades and/or Fusion effects.
- **Enhanced Viewer pop-up:** Expands the Viewer to take up the full area of your workstation’s display above the palettes.
- **Option menu:** Has options that affect the Viewer’s functionality. Commands include: Gang timeline wipe with current clip, Show Viewer Options, Show Marker Overlays, and the Marker list for navigating among all timeline markers in the currently open timeline.

Turning Grades and/or Fusion Effects Off

The Bypass Color Grades and Fusion Effects button/pop-up commands in the Viewer’s title bar are also available via View > Bypass Color and Fusion menu commands. Turning off Fusion effects in the Color page is an easy way to improve playback performance on low power systems when you just need to make a quick set of grading adjustments. Toggling grades off and on is also a convenient way to quickly get a before-and-after look at a shot where the “before” goes all the way back to the source.
If you choose Toggle Bypass or click the Viewer control, you’ll turn off whatever is checked in the optional menu, which lets you choose whether or not you want to bypass both Color and Fusion, or just one or the other.

**Tip:** If you’re giving your client a before and after look at work you’re doing on a grade, a more effective technique is to select the specific nodes (one or more) that you want to toggle on and off, and press Command-D (Enable/Disable Selected Nodes.)

### Viewing Isolated Channels

Use the Viewer > Channels submenu to switch the Color page Viewer among RGB, R, G, or B channels. This can be useful when evaluating a single channel of an image for noise or other artifacts, or for doing color matching by comparing and adjusting the individual red, green, and blue channels of two different clips.

### The Viewer Toolbar

The Color page also exposes a toolbar at the top of the image (underneath the title bar) that makes it easy to enable and disable image wipe, split screen, and highlight viewing by clicking one of these three buttons, which then expose additional controls relating to each of these modes of operation (described elsewhere in this chapter). This toolbar can be shown or hidden by clicking the Viewer option menu and unchecking Show Viewer Options.

In the process, these buttons provide an easy reference for when a comparison mode is enabled. In each of these Viewer modes, the appropriate controls for customizing that view appear to the right of the Viewer toolbar.
The Onscreen Control (OSC) Menu

The Onscreen Control pop-up menu lets you choose which onscreen controls you want to display and adjust in the Viewer. Some palettes automatically enable corresponding onscreen controls when you open them. For example, opening the Window palette displays the Power Window onscreen controls, and opening the Qualifier palette displays the Qualifier onscreen controls.

There are a variety of choices, each corresponding to different adjustments you can make:

- **Off**: All onscreen controls are hidden from view, giving you an unimpeded display of the image in the Viewer.
- **Qualifier**: Turns on the Color Sample cursor, which lets you choose a color using the fourth trackball of the DaVinci control panel. For more about using Color Sample controls, see Chapter 112, “Secondary Qualifiers.”
- **Power Window**: Turns the Power Windows onscreen control on and off. For more about adjusting windows in the Viewer, see “Power Windows” in Chapter 113, “Secondary Windows and Tracking.”
- **Image Wipe**: Toggles mouse control of dragging the split screen directly on the Viewer on and off. For more about working with split screens, see “Comparing Clips in the Viewer” later in this chapter.
- **Dust Removal Tool**: Activates the interactive Dirt and Dust tool. For more information, see Chapter 128, “Dust Removal.”
- **OpenFX**: Only appears if a ResolveFX or OpenFX filter is applied to the current clip. Shows and hides whatever onscreen controls are exposed by an OpenFX plug-in in the currently selected node.
- **Color Chart**: Shows and hides the color chart overlay that lets you identify a color chart in the picture that you want to use with the Color Match palette to create an automatic grade.
TIP: As you work, you may find you want to temporarily hide or show the onscreen controls so you can get an uncluttered look at the image you’re adjusting. You can toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).

Toggling Viewer Overlays On and Off

Pressing Shift-` (Tilde) turns the current Viewer overlay on and off. The View > Viewer Overlay submenu contains commands for showing, hiding, and switching different overlays in the Color page Viewer. While most of the options in this menu are unassigned by default, they can be assigned to keys using the Keyboard Customization window.

Onscreen Controls and External Displays

DaVinci Resolve has been designed for use with calibrated external displays connected to video output interfaces, and for most colorists working on broadcast or theatrical programs, this is the recommended way to work for color critical evaluation.

Because of this, many of the onscreen controls associated with tasks such as color sampling, window adjustment, and key manipulation are mirrored to your video output, making it possible to hide the Viewer on your computer’s monitor and work with only an external display.

To choose whether onscreen controls are mirrored to video out or disabled:

Choose an option from the View > Window Outline submenu. There are three options:

- **Off**: Hides the window outline on both the external display and the Viewer.
- **On**: The default, shows the window outline on both the external display and the Viewer.
- **Only UI**: Hides the window outline on your external display, but leaves it in the Viewer.

To show or hide window onscreen controls using the DaVinci control panel:

Press SHIFT UP and then DISPLAY/CURSOR, above the fourth trackball on the Center panel. This command is a three-way toggle. The first use of this command hides the window outline on your external display, but leaves it in the Viewer. The second use of this command hides the window outline on both the external display and Viewer. The third use of this command shows the window outline on both the external display and Viewer.

Limitations When Grading With the Viewer on a Computer Display

Most computer displays do not operate at the color critical tolerances or specifications required for broadcast or theatrical delivery. An additional issue, however, is that the Viewer does not necessarily display each clip’s image data as it is displayed by the calibration that your operating system applies to your computer display, depending on which OS you’re running DaVinci Resolve on. This makes your computer display potentially unsuitable for monitoring projects destined for the sRGB standard of the web in its default state. For example, if you grade a project using the Color page Viewer on your computer display, the resulting clip may not look the same in the QuickTime player, or in other post-production applications.
You can address this in one of two ways:

- If you’re using DaVinci Resolve on macOS, you can turn on “Use Mac Display Color Profile for viewers” in the Hardware Configuration panel of the System Settings. This lets DaVinci Resolve use one of the preexisting profiles in the Color tab of the Displays panel in the macOS System Preferences, thereby taking advantage of ColorSync on macOS to let DaVinci Resolve display color the way your computer monitor does. Be aware that custom calibrated .icc profiles are not supported at this time.

- Alternately, you can apply a dedicated Color Viewer LUT for calibration, using the 1D/3D Color Viewer Lookup Table pop-up menu that’s found in the Color Management panel of the Project Settings. This lets you analyze your computer display for calibration in the same way you would calibrate an external display, using a probe and color management software, and apply the resulting calibration LUT in DaVinci Resolve. Keep in mind that monitor calibration can only make a high quality display standards compliant; it cannot make up for a display gamut that’s too small. For more information, see the “Lookup Tables” section of Chapter 3, “System and User Preferences.”

Strictly speaking, if you’re doing professional work, you should restrict your grading to a calibrated, 10- or 12-bit class A external broadcast display of some type, connected via a Blackmagic Design video interface. Assuming everything is running properly, an image that is output to video from DaVinci Resolve should match an image output to video from any other post-production application you’re using, and this should be your basis for comparison when examining the output of two different applications.

---

**Zooming into the Viewer**

When using the Viewer to sample tricky colors or draw a detailed PowerCurve, it can be advantageous to zoom into the image.

**To zoom into or out of the Viewer, do one of the following:**

- Make sure that View > Zoom > Allow Mouse Zoom is on, then move the pointer to within the Viewer, and then roll the scroll wheel to zoom in or out of the image.
- Press Command-Equal to zoom in, or Command-Minus to zoom out.

**To pan around the Viewer:**

Move the pointer to within the Viewer, then middle-click and drag to pan around the image.

**To reset the size of the Viewer image:**

- Choose View > Viewer Actual Size (Option-Shift-Z).
- Choose View > Zoom > Zoom to Fit (Shift-Z).

**To enable or disable image zoom being sent to video out:**

- Choose “Gang viewer zoom with video output” from the Option menu of the Viewer to zoom the image shown on video output identically to the zoom level of the Viewer, enabling you to evaluate a zoomed-in portion of the image on your suite’s hero display.
Using the Jog Bar and Transport Controls

One of the principal uses of the Viewer is to control playback. The jog bar, directly underneath the image in the Viewer, contains a playhead that you can drag to the left and right to navigate quickly through the currently selected clip as fast as you can move the pointer. The playhead in the jog bar is locked to the playheads found in the Timeline and Keyframe Editor. Moving one playhead moves all three.

How much of the Timeline the jog bar navigates depends on whether the Node Editor is set to Clip or Track mode. In Clip mode, the jog bar width equals the duration of the currently selected clip. In Track mode, the jog bar width equals the total duration of the entire Timeline.

A row of transport controls below the jog bar provides more specific control over timeline playback.

- **Previous clip:** Moves the playhead to the first frame of the previous clip.
- **Reverse:** Initiates 100% playback in reverse.
- **Stop:** Stops playback.
- **Play:** Initiates 100% playback.
- **Next clip:** Moves the playhead to the first frame of the next clip.
- **Loop:** Lets you restrict playback to the current clip, looping to the first frame if you’re playing forward to the end of a clip, or looping to the last frame if you’re playing in reverse to the beginning of a clip.

Two other buttons let you control audio playback and clip display in the Viewer:

- **Unmix:** Turning on Unmix disables all transitions, composited superimpositions, and effects that mix two or more clips together. Unmix allows you to judge the appearance of a clip without distraction whenever you need to make an adjustment based on how the clip looks on its own, or whenever you need to make changes based on frames that would otherwise be hidden underneath a transition such as a dissolve or fade from black. When you’re ready to see how your grades work in context with transitions and composites again, turn Unmix off.
- **Mute:** Lets you turn audio playback off and on if you’ve loaded an Audio Chase Track for the current edit.

Navigating Using the Arrow Keys

You can use the Arrow Keys of the keyboard to navigate clips and the Timeline in different ways.

- **Up/Down Arrow:** Moves the playhead to the first frame of the previous or next clip.
- **Left/Right Arrow:** Moves the playhead back or forward one frame at a time.
- **Shift-Left/Right Arrow:** Moves the playhead back or forward one second at a time.

Controlling Playback Using the Spacebar and JKL Keys

You can also use the spacebar to start and stop playback, or the JKL keyboard shortcut convention for controlling playback, where J plays in reverse, K stops playback, and L plays forward. There are many additional uses of these keyboard shortcuts; for more information see “Using JKL to Control Playback” in Chapter 20, “Preparing Clips for Editing and Viewer Playback.”
Navigating Using Timecode

You can also use absolute or relative timecode entry to move the playhead in both the Source and Timeline viewers. When entering timecode, type each pair of hour, minute, second, and frame values consecutively, with a period representing a pair of zeros for fast entry. The last pair of timecode values (or period) you enter is always assumed to be the frame number, with any untyped values assumed to be zero. It’s not necessary to enter colons or semicolons. For more information, see “Moving the Playhead Using Timecode” in Chapter 20, “Preparing Clips for Editing and Viewer Playback.”

Navigating Using the DaVinci Control Panel

It’s also possible to navigate the Timeline using the DaVinci control panel. A set of buttons on the Transport panel include:

- **PREV/NEXT SCENE:** Moves the playhead among the first frame of each clip.
- **STEP REV/FWD:** Moves the playhead from frame to frame.
- **FIRST FRAME/LAST FRAME:** Jumps the playhead to the first and last frame of any given clip.
- **RWD/FFWD:** Moves the playhead in rewind or fast forward.
- **REV/STOP/FWD:** The standard play reverse, stop, and play forward commands.

Another set of navigation controls is available by pressing the MODE button above the fourth trackball on the Center panel, and then pressing the CUE MODE soft key.

You can also use the jog wheel and shuttle control on the Transport panel. The jog wheel lets you scrub frame by frame, while the shuttle control moves among preset rewind and fast forward speeds.

**NOTE:** If a Gallery still is turned on for split screen comparison, the shuttle control will adjust the split screen center, and not the playhead position. Turning Reference Wipe off again frees up the shuttle control to affect playback again.

Finally, there are two additional methods of navigating using the DaVinci control panel that make it easy to jump to a specific clip or timecode value.

**To move the playhead to the first frame of a specifically numbered clip:**

On the Transport panel, enter a clip number using the number pad, then press TAKE ENTER.

**To move the playhead relative to its current position:**

1. Press + or – on the number pad.
2. Enter either a number of frames, or a timecode value using colons to divide each pair of digits (for example +01:00:23:12).
3. Press TAKE ENTER.

**To move the playhead to an exact timecode value:**

1. Using the number pad, enter a timecode value, using colons to divide each pair of digits (for example 01:00:23:12).
2. Press TAKE ENTER.
Viewer and Transport Timecode Displays

The Viewer has two timecode displays, each of which defaults to a different timecode setting. A timecode display at the top, the Header timecode display, shows the Source timecode by default. The timecode display at the bottom, the Transport timecode display, shows the Record timecode by default.

The bottom timecode display can be changed to show one of four different options, which are similar to those found in the Data Burn-In palette.

To change a timecode display to a different setting:
The top timecode display is a pop-up menu that can be changed to whatever timecode, frame number, or KeyKode you want to display. The bottom timecode display can also be changed by right-clicking on it and choosing the type of value to show from the contextual menu that appears.

- **Timeline Timecode**: The timecode corresponding to the playhead’s position in the overall Timeline.
- **Source Timecode**: The timecode corresponding to the playhead’s position relative to the currently selected clip.
- **Timeline Frame Number**: The frame count corresponding to the playhead’s position in the overall Timeline.
- **Source Frame Number**: The frame count corresponding to the playhead’s position relative to the currently selected clip.
- **KeyKode**: The KeyKode number corresponding to the media’s KeyKode track, if there is one.
- **Show Timecode at 30 FPS**: Displays 24 fps timecode, via 3:2 pulldown, as 29.97 fps timecode. Has no effect on video playback.

In the same way, the top timecode display can alternately be changed to show KeyKode, if it’s available, within a DPX media file’s header.

Enhanced, Full, and Cinema Viewing

You can expand the Viewer into Enhanced Viewing mode by choosing Workspace > Viewer Mode > Enhanced Viewer mode (Option-F), or by pressing CURRENT/VIEWER on the T-bar panel of the DaVinci control panel.

In Enhanced Viewing mode, the Viewer works exactly as it does at its regular size, but it expands to fill up the entire area of the screen above the palettes and Keyframe Editor. To exit Enhanced Viewing mode, click the lower left-hand corner button again.

This can be useful if you need a closer view of the image for purposes of making detailed corrections, examining noise patterns up close, making a tricky color selection, or drawing a complicated PowerCurve.
In Full Viewing mode (available by choosing Workspace > Viewer Mode > Full Screen Viewer, pressing Shift-F, or Option-clicking the Enhanced Viewing mode button), the Viewer takes up even more room by hiding the palette controls, but leaves room for the transport controls, the Onscreen Control pop-up menu, the timecode display, and the page buttons along the bottom of the DaVinci Resolve UI. This mode is useful when you need an even closer look at the image, but you still want access to a minimal set of onscreen controls.

Another option, Cinema mode, allows for full-screen viewing. Cinema mode is available by choosing Workspace > Viewer Mode > Cinema Mode (Command-F). In Cinema mode, the menu bar is hidden, and the image is presented full screen without any of the ordinary onscreen controls. Moving the pointer over the screen reveals a set of hidden onscreen controls that include a play button, jog bar, mute button, and exit button (which lets you turn off Cinema mode). You also have the option of superimposing scopes over the image, which can be valuable in on-set situations.
Cinema mode is useful for doing detailed reviews of media in on-set and digital dailies workflows when working remotely without a secondary video display.

**TIP:** If you’d like to superimpose timecode over the image in Cinema mode for reference, you can use the controls within the Data Burn-In window (Workspace > Data Burn-In) to set up whatever information you’d like to display during playback.

**Safe Area Overlays in the Viewer**

You can show or hide a series of safe area overlays in the Viewer. All safe area overlay options are found in the View > Safe Area menu. Each safe area overlay option can be individually enabled or disabled from this menu.

- **On/Off:** Turns all currently selected safe area marker options on or off at once.
- **Extents:** An outline showing the exact outer edge of the frame. Especially useful when the safe markers are set to an aspect ratio other than that currently used by the Viewer.
- **Action:** An outline showing the outer 90% action safe area of the frame.
- **Title:** An outline showing the outer 80% title safe area of the frame.
Center: A crosshairs showing the center of the frame.

Aspect: Enables use of the View > Select Aspect Ratio submenu to change the aspect ratio of the safe area markers. You can choose among the following aspect ratios: 1.33 (a.k.a. 4:3), 1.66, 1.77 (a.k.a. 16:9), 1.85, and 2.35.

You can also access these options directly using the DaVinci control panel.

To customize safe area markers using the DaVinci control panel:
1. Press MODES, above the fourth trackball on the Center panel.
2. Press the SAFE AREA soft key. The Center panel soft keys are remapped with all of the available safe area options.
3. When you’re finished, press EXIT.

Use Gray Background

Choosing View > Show Gray Backgrounds in Viewer sets the empty area of the Viewer (if there is any) to a lighter gray, making it easier to see which parts of the Viewer are black because of blanking, and which parts are simply empty because of the way the image is zoomed or panned.

Monitor Calibration

If you use Light Illusion’s LightSpace CMS or SpectraCal’s Calman for display calibration, you can now use DaVinci Resolve as a sync-able pattern generator. This means you can use DaVinci Resolve to output color patches, synchronized by LightSpace, to your display through whichever video interface is connected to your computer. These synchronized color patches will be analyzed by a monitor probe that’s also controlled by LightSpace, which stores the probe data and compares it to the original color values of the output color values in order to characterize that display.

To use this feature, you must first have a licensed copy of LightSpace CMS, which is a Windows application. Synchronization depends on a wired or wireless LAN being available to connect the LightSpace application with DaVinci Resolve.

To synchronize LightSpace CMS to DaVinci Resolve as a pattern generator client:
1. Open LightSpace on the Windows computer that’s running it.
2. When LightSpace is open, click the Network Manager button. A window appears displaying the two network IP addresses used by LightSpace. Note these, and click the Enable button.

4. When the LightSpace dialog opens, enter the second of the two network IP addresses LightSpace lists into the Remote Machine field, and make sure the Port number matches. Then click the Connect button.

If everything is working correctly, the LightSpace dialog in DaVinci Resolve should show the word “Connected,” and the Network Manager dialog in LightSpace should show that there is 1 available client/s.

You can now close the Network Manager dialog in LightSpace and follow the procedures outlined in the LightSpace CMS documentation for characterizing your display and building and exporting a display LUT (in the .cube format) that you can use as a display LUT in DaVinci Resolve. Alternately, you can export a display LUT from LightSpace that can be loaded onto an outboard video processing device.

5. When you’re finished, click Disconnect in the LightSpace dialog, and then click Cancel to close the window.
Viewing Broadcast Safe Exceptions

Choosing View > Display Broadcast Safe Exceptions sets the Color Page Viewer to show a false-color overlay that indicates in blue the regions of the picture that violate the currently selected broadcast safe level in the Color Management panel of the Project Settings.

Areas of the image that violate broadcast safe are highlighted in blue

More information about broadcast safe limiting in the Color Management panel of the Project Settings appears in Chapter 101, “Automatic Grading Commands and Imported Grades.”

Comparing Clips in the Viewer

The ability to compare different clips to one another is an important part of the color correction process. DaVinci Resolve provides three different ways of doing so. You can use the Gallery to display two clips for split screen comparison. You can also use different reference modes to see a timeline clip or reference movie directly as part of a split screen comparison. Finally, you can use the Split Screen controls to display multi-frame arrangements in the Viewer.

Saving and Wiping Stills in the Gallery and Timeline

The Gallery on the Color page provides fast access to stills that you’ve saved from various clips in the Timeline. While the dedicated Gallery page provides a more comprehensive interface for browsing presaved “looks,” as well as for importing stills from other projects, you can save, organize, and browse stills directly within the Gallery of the Color page.

Stills are saved in the DPX file format. Once you’ve saved one or more stills, you can set up split screen wipes in the Viewer, which will be mirrored to your external display.
Stills from the Gallery can be compared to the current shot making it easier to match grades.

This section provides an abbreviated summary of still store and split screen functionality to get you started quickly.

**To save a still, do one of the following:**
- Choose View > Stills > Grab Still (Option-Command-G).
- Right-click on the Viewer and choose Grab Still.
- Press GRAB STILL on the Transport panel of the DaVinci control panel.

**To wipe a still, do one of the following:**
- Select a still in the Gallery, and click the Image Wipe button on the top Viewer toolbar.
- Choose View > Stills > Play Still (Command-W), or right-click in the Viewer and choose Toggle Wipe.
- Double-click a still in the Gallery.
- Press PREV STILL or NEXT STILL on the Transport panel of the DaVinci control panel to select a still, then press PLAY STILL.

**To adjust a wipe in the Viewer, do one of the following:**
- Drag the pointer within the Viewer to move the wipe.
- Push the T-bar control up and down on the T-bar panel of the DaVinci control panel.

**To customize a wipe in the Viewer:**
- Click one of the Wipe mode buttons in the Viewer toolbar.
- Choose one of the following from either the View menu or the Viewer contextual menu:
  - **Wipe Style:** Cycles among the Horizontal, Vertical, Mix, Alpha, Difference, and Box modes.
  - **Invert Wipe:** Reverses each half of the wipe.
Hover Scrub in the Gallery
When Live Preview is enabled in the Gallery option menu, the Hover Scrub Preview submenu lets you choose how you want Live Preview to be shown by a thumbnail in the Gallery and in the Viewer when you hover the pointer over a still or LUT in the LUT Browser:

- You can choose to scrub both the thumbnail you’re hovering over and the Viewer, letting you preview the current still’s grade or a LUT over the duration of the current clip in both the thumbnail and Viewer.
- You can choose to scrub just the thumbnail, leaving the Viewer to show just the grade or LUT over the frame at the position of the playhead.
- You can disable scrubbing altogether, in which case both the thumbnail and the Viewer will only show the grade or LUT over the frame at the position of the playhead.

Copying Grades from Stills in the Gallery
Stills also store the grade from the clip they came from, and can be used to copy grades from one clip to another, or to store grades that you might want to use later.

To copy a grade from a still to a clip, do one of the following:

- Select one or more clips in the Timeline, then right-click a still in the Gallery and choose Apply Grade.
- Select one or more clips in the Timeline, then middle-click a still in the Gallery.

When you copy a still in this way, the saved grade completely overwrites the grade in the target clip, unless you’ve used the “Preserve number of nodes” option, found in the contextual menu of the Gallery. For more detailed information on using the Gallery, including options for organizing the Gallery browser, instructions for using Albums, Power Grades, and Memories, as well as other methods of copying grades and performing advanced grade management tasks, see Chapter 115, “Using the Gallery” and Chapter 116, “Grade Management.”

Different Viewer Reference Modes
While it’s common to use the Gallery to wipe against reference stills, by changing the reference mode you can also create a wipe against a clip in the Timeline, or against an Offline Reference Clip or Timeline, if one has been assigned to the current Timeline.

To change the Viewer reference mode, do one of the following:

- Choose an option from the View > Reference Wipe Mode submenu.
- Right-click the Viewer and choose an option from the Reference Mode submenu of the contextual menu.
- On the T-bar panel of the DaVinci control panel, press REF ON/OFF to toggle the reference mode immediately to Offline mode and back again, in order to split screen the current clip against an offline video.

There are three reference modes:

- **Gallery**: The default reference mode. Lets you wipe the current clip against a Gallery still.
- **Timeline**: Lets you wipe the current clip against another clip in the Timeline using the Wipe Timeline Clip command (see below).
- **Offline**: Lets you wipe the current clip against an offline video that’s been assigned to the current Timeline. For more information on assigning Offline References to a timeline for comparison, see Chapter 46, “Preparing Timelines for Import and Comparison.”
Wiping Between Clips in the Timeline

If you want to wipe the current clip against another clip in the Timeline without saving a still to the Gallery first, there’s a special procedure you can follow.

**To wipe between two clips using the Timeline reference mode:**

1. Click the thumbnail of the first clip you want to compare.
2. (Optional) A “Gang timeline wipe with current clip” option, available from the Viewer option menu, lets you maintain the offset between the current clip and a timeline clip you’re wiping against when you move the current clip selection to other clips. With this option enabled, the offset between the timeline wiped clip and the current clip is maintained when you move the clip selection. When this option is disabled, the timeline wiped clip stays where it is regardless of what clip you select.
3. Right-click the thumbnail of the second clip you want to compare against, and choose Wipe Timeline Clip from the contextual menu.
   Both clips appear split screened against one another.

**NOTE:** Wipe Timeline Clip only appears in the contextual menu if you right-click on a thumbnail in the Timeline that has not been selected.

Change a Timeline Wipe Using the Timelines Album of the Gallery

While you’re using the Wipe Timeline Clip to show a wipe of the current clip against any other clip in the Timeline, you can open the Timelines album of the Gallery and click different clips to change which timeline clip you’re wiping against (outlined in blue) without changing the current clip (outlined in orange).

Using Split Screen Modes

A set of split screen modes provides additional ways of comparing multiple images in the Viewer at the same time. These provide side-by-side and grid comparisons of multiple shots and multiple versions, all of which are output to video for monitoring on your external video display. For example, you can use the Split Screen Versions mode to display every single version that’s applied to the current clip in a grid, for easy evaluation. The currently selected clip in the Timeline is highlighted in gray, so you can keep track of what you’re doing.

**To enable a split screen mode, do one of the following:**

- Click the Split Screen button on the top Viewer toolbar, and choose a split screen method from the pop-up menu that appears in the Viewer toolbar at the right.
- Choose an option from the View > Split Screen submenu.
- Press Option-Command-W to turn Split Screen on and off, using the last selected option.
- Right-click the Viewer and choose an option from the Split Screen submenu in the contextual menu.

**NOTE:** When any of the split screen modes are selected, you cannot see any other onscreen controls in the Viewer, such as Power Window shapes, until you first disable split screen.
Viewing and Choosing the Current Selection

In any of the split screen modes, the current selection is indicated by a gray outline. This outline can be disabled for a more direct comparison by choosing View > Split Screen > Show Outline to toggle the outline off and on.

In certain modes, you can also double-click a particular frame of the split screen view to change the current clip, choose the active version, or apply a gallery grade.

Available Split Screen Modes

You can choose from among the following split screen modes:

- **Current Group**: Shows up to 16 clips that share the same group as the current clip. Double-clicking a frame does nothing in this mode.

- **Highlight Modes**: Shows a four-up display that lets you simultaneously see (clockwise) the clip’s RGB image, the gray matte, the high contrast matte, and a difference matte generated by the node’s input compared against its output. Double-clicking a frame does nothing in this mode.
• **Neighbor Clips**: Shows four clips that immediately surround the current clip. The previous two clips appear as the upper left- and right-hand clips, the current clip appears at the lower left-hand corner, and the next clip appears at the lower right. Double-clicking a frame does nothing in this mode. The “Neighboring Clips in Split Screen” parameter in the Color panel of the User Preferences lets you customize how many neighboring clips appear in this mode.

• **Selected Album**: When you choose this option, a split screen of the grades of every still in that album are shown in the Viewer as they appear applied to the current clip. Double-clicking a frame applies that gallery grade to the current clip. Up to 16 grades will be shown.

• **Selected Clips**: Shows all currently selected clips in the Timeline, up to 16 at one time. Clicking a clip moves the playhead to the first frame of that clip.

• **Selected LUTs**: Lets you simultaneously display previews of different LUTs effect on the current clip as a split screen in the Viewer by using the LUTs browser to Command-click up to 16 LUTs you want to preview.

The Selected LUTs split screen option lets you preview a bunch of LUT looks at once.

• **Selected Still Grades**: When you choose this option, the act of selecting stills in the Gallery of the Color page shows each of the grades associated with those stills as they appear applied to the current clip, in a split screen arrangement. Double-clicking a frame applies that gallery grade to the current clip.

Previewing four gallery grades using the Split Screen > Gallery Grades mode.

• **Selected Still Images**: Lets you view the current clip against a variety of other stills in the Gallery that you select. This is not a grading preview, you’re actually doing a split screen of the selected still images in the Gallery.
• **Versions**: Shows up to 16 versions for the current clip, all at once, making it easy to evaluate a series of different versions in relation to one another. If you have more than 16 versions, you deserve some manner of award. Double-clicking a version changes the active version.

• **Versions and Original**: Shows up to the first 15 versions for the current clip, along with the original ungraded clip at the upper left-hand corner. Double-clicking a version changes the active version, but you cannot double-click to select the original.

### Marker Overlays and Navigation

If you part the playhead on top of a marker in the Timeline of the Color page, that marker’s information appears in a Viewer overlay, just as in the Edit page, making it easier to read notes and see what information is available. These overlays can be easily hidden by clicking the Viewer option menu and turning off “Show marker overlays.”

### Timeline Marker List Available in Color Page Viewer Option Menu

The Option menu of the Color page Viewer has a submenu that lists all Timeline Markers in the currently open timeline. This makes it easy to run down client notes.

![Timeline markers list available for quick access in the Viewer’s Option menu](image)

### Using Video Scopes

While not directly tied to use of the Viewers, video scopes nonetheless work hand in hand to help you evaluate the images you’re working on. DaVinci Resolve has a set of five real-time video scopes that you can use to monitor the internal data levels of clips in your project as you work. Each scope provides an unambiguous graphical analysis of different characteristics of the video signal, showing you the relative strength and range of individual color components including luma, chroma, saturation, hue, gamut, white point, and the red, green, and blue channels that, together, comprise the color and contrast of the images in your program.

### Video Scope Location

By default, you can view any one of these scopes at a time at the bottom right corner of the Color page, by clicking the Video Scope button in the palette button bar.
The video scope, docked next to the other palettes at the bottom of the Color page

Optionally, you can click the Expand button at the top right of the video scope to open the video scopes into a floating window, within which you can display all four video scopes together, or individually, on any monitor connected to your workstation.

Video scopes in a floating window

Additionally, the video scopes are available in many of the dual-screen layouts available in DaVinci Resolve. The video scopes aren't just available in the Color page. They're also available in the Media and Deliver pages for whenever you need to evaluate the video signal more objectively, such as when you're setting up to capture from tape or scan from film, or when you're setting up for output.

**To open video scopes from the Media, Color, or Deliver pages, do one of the following:**

- Choose Workspace > Video Scopes > On/Off (Command-Shift-W) to open video scopes into a floating window.
- Choose Workspace > Dual Screen > On to open video scopes as part of a dual screen layout.
Video Scope Measurement

Because you're evaluating the internal state of the image data, by default the scales of the WFM and Parade scopes always reflect 10-bit full range data from 0–1023, regardless of the Video/Data Level setting you've selected in the Master Settings panel of the Project Settings. This gives you a window into how the image is being processed by DaVinci Resolve prior to being output via your computer’s video I/O interface.

If you’re working on an HDR (High Dynamic Range) grade, you can open the User Preferences and turn on Enable HDR Scopes for ST.2084 (this feature is only available in Studio version). This replaces the 10-bit scale of the Waveform, Parade, and Histogram video scopes with a scale based on nit values (or cd/m2) instead.

![Left] The Parade scope showing the data range scale, ![Right] The Parade scope showing the HDR “nit” scale

Video Scope Performance and Detail

All video scopes were updated for DaVinci Resolve 16 to show more detail with faster performance than in previous versions. While they’re GPU-accelerated, the video scopes require a certain amount of video processing power to operate. Depending on which combination of video scopes and scope options you have selected, you may notice your real time processing capabilities ever so slightly affected. Closing the video scopes frees up all processing for color correction and effects. On high-powered workstations, you probably won’t notice a difference, but on less powerful computers, closing the scopes might make a small difference.

Two global settings in the Scopes Option menu affect the performance and detail of all video scopes equally.

- On slower workstations, a quality submenu lets you choose High, Medium, or Low quality scope drawing, to trade off legibility for performance. High quality shows you the most information about the video signal, while an Auto option makes a selection based on your workstation’s capabilities.

The Quality setting in the Video Scope option menu
All video scopes have a Low Pass Filter setting in the Scopes Option menu that filters out a signal’s noise to make the scope graphs clearer to read. While this can act as an “x-ray” to better see detail in the scope graph interiors, it can make the highlight and shadow excursions on the graph seem a bit shy of where they actually are, so it’s recommended to enable the “Extents” option of whichever scope you’re using to get an unambiguous look at the maximum excursions in your scopes. Extents draws an outline highlighting all graph excursions to show you the true level of all overshoots and undershoots in the video signal, even when the Low Pass Filter is on.

Explanation of Each Video Scope

There are five available video scopes, each of which shows a different analysis of the video signal you’re adjusting.

Waveform Monitor

Overlays waveform analyses of the Y (luma/luminance), CBCR (the color difference channels of Y’CBCR), or RGB (red, green, and blue) channels over one another so that you can see how they align.

The Y option presents a true Luma scope that can have Colorize enabled to show false color, which lets you see which colors in the Viewer image are where in the video scope graph.

For the RGB scopes, the relative heights of the red, green, and blue graphs indicate is identical to the description seen for the parade scope below, and with color enabled the red, green, and blue graphs are tinted with the color they represent. This makes it easy to see where all three graphs align, by looking for where parts of the waveform monitor appear in white, which is the result of the red, green, and blue graphs lining up and adding their color together.
Parade

The Parade scope shows separate waveforms side by side that analyze the strength of individual video signal components. The Parade scope can be set to analyze RGB, YRGB, and Y’CBCR.

By showing a comparison of the intensity of the luma, red, green, and blue channels, the parade scope makes it possible to detect and compare imbalances by comparing the relative heights of the RGB graphs in the highlights (the top of the R, G, and B graphs), shadows (the bottom of the R, G, and B graphs), and midtones (the middle of the R, G, and B graphs) for the purposes of identifying color casts and performing scene-by-scene correction.

When the YRGB channels are taken altogether, the bottom of all graphs indicates the black point of the image, while the tops of all graphs indicate the white point. It then follows that the difference between the height of the bottom and top of all graphs indicates the overall contrast ratio of the image you’re evaluating. Tall parade graphs indicate a wide contrast ratio, while short parade graphs indicate a narrow contrast ratio.

Vectorscope

Measures the overall range of hue and saturation within an image. Measurements are relative to a centered graticule that you can enable that’s overlaid on the scope, which provides a frame of reference via crosshairs. DaVinci Resolve has a traditional vectorscope, the graph of which emulates a trace-drawn graph, with 75 percent color bar targets indicating the angle of each of the primary and secondary colors around the edge of the graph, and an optional skin tone reference graticule (otherwise known as the In-phase reference).

The Vectorscope can have Colorize enabled to show false color which lets you see which colors in the Viewer image are where in the video scope graph.

More saturated colors in the frame stretch those parts of the graph farther toward the edge, while less saturated colors remain closer to the center of the vectorscope, which represents 0 saturation. By judging how many parts of the vectorscope graph stick out at different angles, you can see how many hues there are in the image, with the specific angle of each part of the graph showing you which hues they are. Furthermore, by judging how well centered the middle of the vectorscope graph is relative to the crosshairs, you can get an idea of whether there’s a color imbalance in the image. If the vectorscope graph is off-centered, the direction in which it leans lets you know that there’s a color cast (tint) in the image.
Histogram (RGB/YRGB parade histogram)

Displays a statistical analysis of how many pixels of each color channel lie at each percentage of tonality, plotted along a digital scale from 0 percent (black) to 100 percent (white). Comparing the left, middle, and right parts of the Y, R, G, and B graphs (Y is optional) lets you evaluate the color balance in the shadows, midtones, and highlights of the image.

Taken altogether, the left of all graphs indicates the black point of the image, while the right of all graphs indicate the white point. It then follows that the difference between the width of the left and right of all graphs indicates the overall contrast ratio of the image you’re evaluating. Wide histogram graphs indicate a wide contrast ratio, while narrow histogram graphs indicate a narrow contrast ratio.

CIE 1931 xy Scope

DaVinci Resolve 16 introduced a CIE 1931 xy scope, which lets you see the current image analysis as a graph superimposed against a triangle that represents the tristimulus values of the color gamut you’re working within, along with an indication of the current white point. A label shows the currently selected gamut, with the specific coordinates of these Red, Green, and Blue values as well as the White point, while the overall “horseshoe” shape represents the entire range of visible light, all plotted against an xy graph.
In a way, the CIE 1931 graph is a 3D scope, but it’s drawn as if you’re looking down at the top of a 3D shape and can only perceive the outline around the widest part of it. The graph does indeed represent every single value found within a 3D plot of the image data, but the triangle only indicates the widest “slice” of the current gamut and of this 3D shape within the mid-tones.

What this means is that while the CIE 1931 graph gives you a rough idea of whether or not the current image is within gamut relative to your delivery spec, it’s not exact and it’s not foolproof, as part of the image data could fall within this wide triangle and yet overshoot the required gamut elsewhere in the highlights at the top or the shadows near the bottom of the 3D shape you’re looking down on. On the other hand, if any part of the graph does extend past the boundaries of the gamut triangle, then that definitely indicates a gamut violation.

**Customizing the Video Scopes**

Once you’ve opened the video scopes, there are a variety of ways you can customize how the scopes look, and expose additional onscreen graticule information to help you measure what you need.

**Methods of customizing the Scopes window:**

- **To change the size of the Scopes window:** Drag the lower right-hand corner to resize the Scopes window to the desired size.
- **To change how many scopes are displayed at once:** Click one of the buttons in the upper right-hand corner of the Scopes window to set 1, 2, or 4 up arrangements of the video scopes. You can also choose how many scopes are simultaneously displayed by choosing Workspace > Video Scopes > 1-Up, 2-Up, or 4-Up.
- **To change which scopes appear in which pane:** Click the Name pop-up at the upper left corner of each scope’s pane, and choose a different scope.

Once open, you can resize the Scopes window to make it as large or small as you require, positioning on a second display if you want to make it even larger.
To customize each video scope's display options:

1. Click the Option pop-up menu at the upper right-hand corner of any Scope pane, and choose Option to open that scope’s Custom Controls window.

2. Adjust any of the available controls to customize the look of that particular scope.

3. Click anywhere outside of the Custom Controls window to make it disappear.

Parade Scope Display Options

The Parade scope has the following options:

- RGB, YRGB, and YCbCr modes, allowing you to evaluate more channels than before.
- A colorize checkbox lets you view graphs in monochrome or false-color (indicating red, green, and blue).
- An Extents checkbox draws an outline highlighting all graph excursions, to unambiguously show you all overshoots and undershoots in each waveform.
- The Parade slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
- The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
- The Show Reference Levels checkbox lets you turn on adjustable Low and High reference level markers by setting the low and high sliders to something other than their defaults. This is especially useful for HDR grading where you’re working within a specific peak luminance threshold.
Waveform Scope Display Options

The Waveform scope has the following options:

- Y (luma) and CbCr (chrominance) modes to show you the true luma or chroma signals in isolation, and RGB to show you only an RGB analysis.
- In RGB mode, R, G, and B buttons that can be individually toggled on and off to see any combination of graphs.
- A colorize checkbox lets you view overlaid graphs in monochrome or false-color (indicating red, green, and blue). If you’re only enabling the Y or C scopes, the different areas of these graphs are drawn with color taken from the image being analyzed, which makes it easier to see which part of the scope graph corresponds to which part of the image.
- An Extents checkbox draws an outline highlighting all graph excursions, to unambiguously show you all overshoots and undershoots in each waveform.
- The Waveform slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
- The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
- The Show Reference Levels checkbox lets you turn on adjustable Low and High reference level markers by setting the low and high sliders to something other than their defaults. This is especially useful for HDR grading where you’re working within a specific peak luminance threshold.

Vectorscope Display Options

The Vectorscope has the following options:

- Choose ALL, HIG (highlights), MID (mid-tones), or LOW (shadows) to view the entire tonal range of the image as a Vectorscope graph analysis (ALL), or to selectively view just the shadows, mid-tones, or highlights of the image as a vectorscope graph analysis.
- Low Range and High Range sliders let you manually define the boundaries separating shadows from mid-tones and highlights. Low Range defaults to 0.30, and High Range defaults to 0.70.
- A Colorize checkbox draws the different areas of these graphs with color taken from the image being analyzed, which makes it easier to see which part of the scope graph corresponds to which part of the image. With colorize turned off, graphs only appear white.
- An Extents checkbox draws an outline highlighting all graph excursions to unambiguously show you all overshoots and undershoots.
- A Combine checkbox lets you see simultaneous overlapping extents for the highlights, mid-tones, and shadows overlaid on one another.
- The Vectorscope slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.
- The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.
- Show 2X Zoom zooms the vectorscope graph by 200%, making it easier to see fine detail and use the vectorscope with charts.
• Show Skin Tone Indicator checkbox shows a line at the traditional Inphase angle that is useful as a general guidepost for average skin tone hue.

• Show Graticule checkbox (Vectorscope Only) lets you show or hide the circular degrees indicator surrounding the outer edge and the cross hairs that indicate the center of the vectorscope.

Histogram Display Options

The Histogram has the following options:

• You can view either RGB or YRGB histograms.

• The Gain slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.

• The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.

• The Show Reference Levels checkbox lets you turn on adjustable Low and High reference level markers by setting the low and high sliders to something other than their defaults. This is especially useful for HDR grading where you’re working within a specific peak luminance threshold.

CIE 1931 xy Display Options

The CIE 1931 xy scope has the following options:

• The Vectorscope slider makes that scope’s graph brighter or dimmer. Brighter graphs make it easier to see fine detail, but harder to see which parts of the graph are stronger and weaker.

• The Graticule slider makes that scope’s scale brighter or dimmer, making it more or less visible (or distracting) relative to the graph.

• Show 2X Zoom zooms the CIE graph and graticule by 200%, making it easier to see fine detail and use the vectorscope with charts.

• Show Graticule checkbox (Vectorscope Only) lets you show or hide the circular degrees indicator surrounding the outer edge and the cross hairs that indicate the center of the vectorscope.
Chapter 108

Color Page Timeline and Lightbox

The Timeline in the Color page, consisting of the Thumbnail Timeline and the Mini-Timeline, is primarily used for navigating the current arrangement of clips, and for keeping track of clip properties such as whether they’re graded and ungraded, whether they use tracking, which version they’re using, and so on. It can also be used for quickly copying grades from one clip to another, for creating groups, and for comparing clips in the Viewer.

The Lightbox is the twin sibling of the Thumbnail Timeline, and provides an image-based method of comparing clips, managing grades, and performing a wide variety of organizational tasks.

This chapter covers the use of the Timeline and Lightbox.

Navigating Using the Color Page Timeline

The Color page Timeline consists of two parts that work together, the Thumbnail Timeline and the Mini Timeline. These work together to let you examine and navigate the Timeline of your program in different ways.

The Color page Timeline

The scroll bar for the Mini-Timeline is independent of the scroll bar for the Thumbnail Timeline, and both can be set to show different ranges of clips. Using the scroll control of your pointing device lets you zoom into or out of the Mini-Timeline. When zoomed all the way out, the Mini-Timeline displays the entire timeline within the available width of the screen, making it a fast way of navigating the entire program from the beginning to the end. However, you can zoom into a particular section when you need more information about how an intricate arrangement of superimposed clips are organized while you’re grading.

Thumbnail Timeline

Provides a concise visual representation of your project where each clip is a single numbered thumbnail, regardless of its duration. Clicking a thumbnail moves the playhead to the first frame of that clip, while using the Up/Down Arrow keys moves the selection to the previous or next clip. Whichever clip is at the current position of the playhead appears with its thumbnail outlined in orange. The scroll wheel of your pointing device lets you scroll backward and forward through the thumbnail timeline.

Mini-Timeline

Shows a miniature representation of the Timeline in the Edit page, where each clip’s width is proportional to its duration, and superimposed clips are shown on top of one another. The Mini-Timeline can show a maximum of six video tracks; if your edit uses more, a scroll bar lets you change which tracks are displayed. Clicking a clip in the Mini-Timeline selects that clip and moves the playhead to its first frame.
Scrolling, Zooming, and Navigation

A Timeline Ruler contains the top handle of the playhead, displays the record timecode of the current edit, and acts as a scrubber bar that typically spans a longer section of the Timeline. The scroll wheel of your mouse lets you zoom in and out of your edit, and if you zoom all the way out you can fit every clip in the Mini-Timeline into the available width of the ruler, letting you scrub through every clip in the Timeline quickly. Clicking anywhere within the ruler instantly jumps the playhead to that frame.

Enabling/Disabling Tracks

The far left of the Mini-Timeline shows numbers for each track, and hovering the pointer over the track number of any track in the Mini-Timeline of the Color page reveals a tooltip showing the name of that track. Clicking a track number enables/disables that track along with all clips on that track, similarly to using the Timeline > Enable/Disable Video Tracks submenu commands (Shift-Command-1 through 9). Clips on disabled tracks are not rendered in the Viewer or video output, and are hidden from the Thumbnail Timeline. If a track has been disabled in the Edit page, it will appear dimmed in the Mini-Timeline.

Option-clicking a track number in the Mini-Timeline turns that track number red, letting you hide clips from the Thumbnail Timeline without actually disabling the video in your program. This is useful in situations where you want to prevent clips in a particular track (such as motion graphics or titles rendered from another application) from intercepting the playhead when using the next/previous clip commands.

Setting In/Out Points for Looping

You can use the I and O keyboard shortcuts to set custom In and Out points in the Timeline. Once set, turning on Loop in the Viewer transport controls enables this range to be looped, whether it’s a partial range of one clip, or a range spanning multiple clips together.

Using Multiple Timeline Playheads

DaVinci Resolve supports creating up to four separate playheads in the Mini-Timeline, that you can use to jump back and forth among different parts of your timeline. Only one playhead can be selected at any given time, and the currently selected playhead corresponds to the current clip, highlighted in orange. Each playhead in the Mini-Timeline is labeled with a letter, A through D.

To add a new playhead to the Mini-Timeline:

Choose a playhead from the Color > Active Playheads submenu. That playhead will be placed at the same position as the original playhead, but it is now the one that is selected, so dragging the new playhead to a new position of the Mini-Timeline will reveal the original playhead you were using.
To select another playhead to view:

- Click on the top handle of any playhead to select it, making that the currently active playhead controlled by the transport controls. By default, no keyboard shortcuts are mapped to the four playheads that are available, but you can create a custom keyboard mapping that you can use to quickly switch among them.
- Using the DaVinci Advanced Control Panel, you can use the A, B, C, and D buttons on the jog/shuttle panel to switch to the playhead you want to control.

To eliminate all additional playheads from the Mini-Timeline:
Choose Color > Active Playheads > Reset Playheads.

Show Current Clip With Handles

If you're working on a project that's part of a round-trip workflow, and you know you'll be rendering handles for each clip, it can be useful to temporarily expose these handles for the current clip that you're grading, so you can easily apply tracking or keyframing effects to the full frame range of each clip.

To show or hide clip handles in the Mini-Timeline of the Color page:
Choose View > Show Current Clip With Handles.

(Left) The current clip in the Mini-Timeline, (Right) The same clip shown with Show Current Clip With Handles enabled

While this mode is enabled, Unmix is turned on and cannot be disabled, in order to let you view the overlapping handles of each clip clearly. The duration of handles that are exposed is defined by the Default Handles Length parameter of the Editing panel in the User Preferences. Clip Handles can be shown or hidden at any time.

Thumbnail Info

The thumbnails make it easy to find the clips you're looking for visually, and they always show the media as it's currently graded. The most obvious piece of information is the frame that's used for each clip's thumbnail. If you feel that a particular clip's thumbnail isn't representative of its content, you can change it.

To change the current thumbnail:
Move the pointer over a thumbnail, drag to the left or right to scrub through the clip, and stop when you find a frame you want to use as the new thumbnail.

Dragging a thumbnail to change the representative image
If media is replaced in the middle of a color correction timeline, or if you copy or ripple a grade to a range of clips, the thumbnails may not immediately update to accurately represent the current state of each clip. In this case, you can manually refresh the thumbnails.

**To refresh all thumbnails in the Timeline:**
- Right-click anywhere in the Thumbnail timeline and choose Update All Thumbnails.

You can also choose to display the codec used by each clip in the Timeline.

**To switch the Thumbnail timeline between showing clip names and codecs:**
- Double-click the thumbnail clip name of any clip to display each clip’s codec, and vice versa.

Additional information appears above and below each thumbnail, providing a way of keeping track of which clips have been graded, which clips are using different versions, which clips have been cached, and so on.

The following list explains each piece of information that can appear above, within, or below the thumbnails in the Timeline.

- **Clip number:** (top left) Each clip’s number appears above its thumbnail. Clips are numbered in ascending order according to the position of their first frame, from left to right, regardless of the video track in which they appear.
- **Grade indicator:** (top left) If a clip has been graded, a thin rainbow indicator surrounds the clip number.
- **Source Timecode:** (top center) The source timecode from the first frame of each clip appears above each thumbnail.
- **Cache indication:** (red timecode) Any clip that’s marked for caching, whether automatically via the Smart cache, or manually, has its timecode turn red to indicate that it will be cached. After it’s been cached, the timecode turns blue.
- **rack number:** (top left) The video track in which a clip is edited appears above the thumbnail.
- **Clip Color dot:** (upper right) If a clip has a clip color assigned to it, a colored dot appears on top of its thumbnail.
- **Flag icon:** (upper left) If a clip has been flagged, a flag icon of the appropriate color appears on top of its thumbnail. If a clip has multiple flags, as many as can be drawn appear along the top.
• **Linked media or group icon:** (bottom right) If clips are set to use remote versions, and if multiple clips share the same source media file, then by default their remote version 1 grade will be automatically linked. If the current clip is linked, a small link icon appears below the thumbnail of every clip in the Timeline that’s also linked to that clip. When you select another clip that’s not linked, the linked clip icons disappear.

• **Tracker icon:** (bottom right) If any node within a particular clip’s grade has been tracked, a small crosshairs tracker icon appears below the thumbnail.

• **3D indicator:** (bottom right) All stereo 3D clips in the Timeline appear with this icon below the thumbnail. The color indicates which eye you’re monitoring; red for the left eye, blue for the right eye.

• **Version name/Source format:** (bottom left) What text is displayed below each thumbnail can be changed by double-clicking the space underneath each thumbnail. There are several options; keep double-clicking to cycle among them:
  - **Clip format or codec:** This is what’s displayed by default.
  - **Clip Name:** Depending on what View > Show File Name is set to, the clip name or file name is displayed. If you’re working with multicam clips, the multicam angle or name is displayed.
  - **Version name or number:** Provides information about whether a clip is using a remote version, or a local version, indicated by an (L). If you’ve given the current version a name, it appears; otherwise the version will be labeled “Version” with its number.

## Thumbnail Contextual Menu Commands

Right-clicking a clip’s thumbnail in the Thumbnail Timeline reveals a contextual menu with many media and grade management commands that are available in the Color page. The available options are divided into the following rough categories:

- Commands for managing grade versions
- Commands for managing groups
- Commands for editing flags, markers, and clip colors
- A command for displaying the Node Graph of a clip’s grade
- Options for controlling the render cache
- Resolve Color Management clip assignments
- LUT Management commands
- A command to fix Black Sun artifacts
- Commands for viewing clip details, editing Clip Attributes, and finding clips in the Media Pool
- A command for updating clip thumbnails that are slow to update on their own

These capabilities are described in more detail in the other chapters of this manual, but it’s important to know that artists working on the Color page have many clip management options available to them, without needing to go to other pages.
Sorting and Filtering Clips in the Thumbnail Timeline

By default, the Thumbnail Timeline displays every clip of the currently selected edit in the Edit page, sorted in A mode (the record order of your edit). However, the sort order and contents of the Timeline can be changed and filtered to make it easier for you to find specific groups of clips for grading.

Changing Timelines

If you’re working on a project that has more than one timeline, you can switch timelines right from within the Color page.

To switch timelines in the Color page:
Choose another timeline from the Timelines pop-up menu at the top of the Viewer.

![Timeline selection at the top center of the Viewer](image)

To switch among timelines using the DaVinci control panel:
Press the MODES button above the fourth trackball on the Center panel, then press the SWITCH TIMELINE soft key. Press MODES to return to the main page of controls when you’re done.

A and C Mode Sorting

By default, the Timeline is set to Record mode sorting, otherwise known as A mode sorting. In this mode, clips appear in the Timeline according to the order in which they were edited. This lets you see the order of clips as they’ll appear in the final program.

![A Mode sorting, i.e., record order](image)

However, you can change the sort order of the clips in the Timeline to Source mode, or C mode sorting. In C mode sorting, all clips are rearranged in ascending order from left to right according to their source timecode, and their record timecode is temporarily ignored.

![C Mode sorting, i.e., source clip order](image)
Sorting by C mode makes it easy to identify a range of similar clips. For example, if you’re working on a narrative project, clips from each angle of coverage in the scene will naturally cluster together. In another example, sorting by C mode in a documentary will arrange all of a particular subject’s head shots from a specific interview contiguously, one after another, since they all come from the same range of timecode on the same source tape. In both examples, the close proximity of similar clips to one another that C mode creates makes it easy to copy grades among them, ripple changes, or group them.

When you’re finished, you can switch the Timeline back to A sort mode, and all of the clips will go back to being arranged in the order in which they were edited.

**To toggle between A and C mode sorting, do one of the following:**
- Choose an option from the View > Timeline Thumbnail Mode submenu.
- Press Command-Page Down to toggle to C mode sorting.
- Press A/C MODE on the T-bar panel of the DaVinci control panel.

While in C mode, the word “SOURCE” appears at the right in the Timeline Ruler of the Mini-Timeline.

A checkbox in the Conform Options group in the General Options panel of the Project Settings lets you change the behavior of C mode sorting. Opening the Settings window and clicking the General Options panel of the Project Settings reveals the Sort Timeline Using Reel Name and Timecode checkbox.

With this checkbox turned on (the default), all clips in the Timeline are sorted by reel number first, and then by source timecode. This way, clips with similar timecode from the same reel will appear next to one another in C mode.

If you turn this checkbox off, reel number is ignored, and all clips in the Timeline are sorted only by source timecode. This may result in clips from multiple sources being mixed together, but it is useful in specific situations.
For example, when grading dailies from a three camera shoot, you may want to see consecutive clips from all three cameras lined up one after the other on the Timeline, so that Cam1_Shot1, Cam2_Shot1, and Cam3_Shot1 appear first, followed by Cam1_Shot2, Cam2_Shot2, and Cam3_Shot2, and so on. In this situation, you don’t want clips from cameras 2 and 3 to be placed at the end of the Timeline simply because of their reel number.

Flags, Clip Colors, and Markers

You have the option of flagging or marking clips in the Color page just like you can in the Edit page, in order to keep track of specific media or frames that you may need to do something to later. For example, you could flag every closeup of a particular actor with a blemish that you want to spend some time fixing with a green flag.

Methods of flagging, changing colors, and marking clips in the Color page:

- **To add a flag to a clip:** Move the playhead to a clip in the Mini-Timeline, and choose a color from the Mark > Add Flag submenu, or Right-click any clip’s thumbnail, and choose a flag color from the Flags submenu. Flags are not frame-specific, so flagging one clip will result in flags also being placed on all other clips that share the same source media in the Media Pool.

- **To remove all of a clip’s flags:** Move the playhead to a clip in the Mini-Timeline, and choose Mark > Clear Flags, or right-click a clip’s thumbnail and choose Flags > Clear All.

- **To change the clip color:** Move the playhead to a clip in the Mini-Timeline, and choose a color from the Mark > Set Clip Color submenu, or Right-click any clip’s thumbnail, and choose a color from the Clip Color submenu. Clip Colors are clip-specific.

- **To remove a clip’s color:** Move the playhead to a clip in the Mini-Timeline, and choose Mark > Set Clip Color > Clear Color, or Right-click a clip’s thumbnail and choose Clip Color > Clear Color.

- **To mark a frame of a clip:** Right-click a clip’s thumbnail and choose a marker color from the Marker submenu.

- **To remove a single marker:** Right-click a clip’s thumbnail and choose Delete Marker from the Marker’s submenu. Alternately, you can select the marker in the Mini-Timeline, and press the Delete key.

- **To remove all of a clip’s markers:** Right-click that clip and choose Clear All from the Markers submenu.

Timeline Filtering

A pop-up button to the right of the Clips button at the top right of the Color page Interface Toolbar presents preset options for dynamically filtering which clips are shown in the Timeline. This allows you hide all the other clips in the Timeline except for the subset on which you want to focus.
For example, once you’ve added flags or markers to clips, it’s easy to hide every other clip in the Timeline that doesn’t fit the criteria; for example, hiding clips that don’t have a green flag. This does nothing to alter the original edit, and you can return the Timeline to its original state at any time.

**To filter the Timeline:**
Click the Timeline Filtering pop-up button to the right of the Clips button at the top left of the DaVinci Resolve UI, and choose an available option. While the timeline is filtered, an orange line appears underneath the Clips button in the UI toolbar at the top of the page.

**To return the Timeline to normal:**
Click the Timeline Filtering pop-up button, and choose All Clips.

You can use timeline filtering in conjunction with A or C mode sorting to arrange clips in whatever way is best for the task you’re trying to accomplish. Clip filtering can also be used in the Lightbox, and a currently selected clip filtering method will simultaneously isolate clips in the Timeline and Lightbox as you switch back and forth.

**Preset Timeline Filters**
DaVinci Resolve comes with several preset criteria by which you can filter the Timeline, which cover many common organizational workflows:

- **All Clips**: No clips are filtered, and every clip in the current edit is shown.
- **Selected Clips**: Filters all currently selected clips.
- **Graded Clips**: Filters all clips that have been graded.
- **Clips with Fusion Composition**: Clips with Fusion page effects applied to them.
- **Ungraded clips**: Filters all clips that have not yet been graded.
- **Modified clips**: Submenu, filters all clips that have been modified within a specified time.
- **Unrendered clips**: Filters all clips that have not yet been rendered.
• **Flagged Clips:** Filters all clips that have a particular flag, a submenu presents each color.
• **Marked Clips:** Filters all clips that have a particular mark, a submenu presents each color.
• **Stereoscopic:** Filters stereo 3D clips, a submenu presents options for filtering All Stereo Clips, or just Stereo clips that have been Autoaligned, those with Convergence adjustments, those with Floating Windows adjustments, or stereoscopic clips with swapped media for the left and right eyes.
• **Grouped:** Filters all clips belonging to a particular group, a submenu shows the available groups.
• **Tracked:** Filters all clips with motion tracking.
• **Noise Reduction:** Filters all clips using noise reduction.
• **OpenFX:** Filters all clips using OpenFX.
• **Different Frame Rate:** Filters all clips with frame rates that don’t match that of the project.
• **Edit Sizing:** Filters all clips that have had any Edit Sizing parameters adjusted.
• **Input Sizing:** Filters all clips that have had any Input Sizing parameters adjusted.
• **Common Media Pool Source:** Filters all clips sharing the same source in the Media Pool as the current clip.
• **Matte Nodes:** Filters all clips with an exposed Matte node in the Node Editor.
• **Mattes Available:** Filters all clips with a matte assigned to them, whether they’re used or not.
• **Collaborative Update Available:** (Only available in Collaborative Mode) Filters all clips that have been flagged as having been updated during a collaborative workflow.

**Creating and Using Smart Filters**

If none of the preset filters does what you need, you can create your own custom Smart Filter in order to sift out clips based on any of the intrinsic or user-entered metadata that’s available in the Metadata Editor, Media Pool, and Color page timeline. Smart Filters work much the same way as Smart Bins, and they’re created and edited using the same procedures. For more information on Smart Bins, see Chapter 11, “Adding and Organizing Media with the Media Pool.”

In fact, Smart Filters can be very sophisticated, allowing you to filter the contents of the Thumbnail timeline by multiple criteria, and using multiple groups of multiple criteria for situations where you need to find clips that match all of one set of criteria, but only one of a second set of criteria. In this way, you can create Smart Filters to solve a wide variety of workflow needs as you work in the Color page.

It’s important to point out, however, that as much intrinsic metadata is available to every clip in DaVinci Resolve (clip properties including frame rate, frame size, codec, file name, and so on), the more time you take entering extra metadata in the Metadata Editor to prepare your project for work for editing and grading (for example, entering scene and take information, and keywords for things like character names, day and night, interior and exterior, framing, and so on), the more powerful Smart Filters can be in helping you to sift and sort through the contents of a program you’re grading.

Imagine being able to filter out all the closeups associated with a particular person in a program, or finding all the establishing shots corresponding to a particular location. If you or an assistant can take the time to enter metadata for the source material in a project that identifies these characteristics, you’ll be able to work even more quickly to match shots together and find the clips you need for any given situation.
To create a Smart Filter:

1. Click the Timeline Filtering pop-up button to the right of the Clips button at the top right of the DaVinci Resolve UI, and choose Create Smart Filter.

2. In the Create Smart Filter dialog, enter a name for the filter, and use the following controls to create one or more filter criteria (you can have as many filter criteria as you like):

   - **Match options**: For multi-criteria filtering, choosing All ensures that every single criteria you specify is met for a clip to be filtered. Any means that if only one out of several criteria is met, that clip will be filtered.

   - **Filter criteria enable checkbox**: Lets you enable or disable any criteria without having to delete it.

   - **Metadata category pop-up**: Lets you choose which category of metadata you want to select a criteria from. Each category of metadata that’s available in the Metadata Editor is available from this pop-up menu. Additionally, Color Timeline Properties (containing many properties unique to the Color page timeline) and Media Pool Properties (containing every column in the Media Pool) provide access to additional metadata you can use for filtering.

   - **Metadata type pop-up**: For choosing which exact type of metadata to use, of the options available in the selected metadata category.

   - **Metadata criteria pop-up**: Lets you choose the criteria by which to filter, depending on the metadata you’ve selected. Options include “true/false,” integer ranges, date ranges, string searches, flag and marker colors, and so on.

   - **Add filter criteria button**: Lets you add additional criteria to create multi-criteria filters. You could use multiple criteria to, for example, find all clips from Scene 2, that also contain the keyword “Diana,” that also have the keyword “CU” in order to find all the Scene 2 close-ups of Diana. Additionally, if you Option-click this button, you can add a nested match option in order to create even more sophisticated filters, where the filter must match all of one set of criteria, and any of another set of criteria.

As you’re editing the filter criteria, the Thumbnail timeline automatically updates to show you how the Smart Filter you’re creating is working.
When you’re done editing the filter criteria, click Create Smart Filter. The resulting Smart Filter appears at the bottom of the Filter pop-up menu, and is turned on by default.

Methods of modifying existing Smart Filters:

- **To rename a Smart Filter:** Click the Timeline Filtering pop-up and choose the Smart Filter you want to rename from the Rename Smart Filter submenu, then change the name in the Smart Filter Name dialog, and click OK.
- **To edit a Smart Filter:** Click the Timeline Filtering pop-up and choose the Smart Filter you want to edit from the Edit Smart Filter submenu, then edit the filter criteria, and click OK.
- **To delete a Smart Filter:** Click the Timeline Filtering pop-up and choose the Smart Filter you want to delete from the Delete Smart Filter submenu. It’s immediately deleted.

Using the Lightbox

The Lightbox shows you all clips in the Timeline as a grid of thumbnails, arranged in rows from left to right and top to bottom. This lets you quickly evaluate, compare, and search for clips you want to use when making selections, creating groups, flagging clips, or when scanning for a particular scene or looking for an individual clip.
At the right of the Lightbox is a vertically oriented Timeline Ruler letting you know the timecode value at the beginning of each row of clips. At the top right is a Zoom slider that lets you change the size of the thumbnails.

Selecting a clip in the Lightbox is the same as selecting a clip in the Timeline, and right-clicking a clip in the Lightbox shows the same contextual menu items you’d see if you right-clicked a clip in the Timeline. Furthermore, you can also grade the current clip in the Lightbox using a control panel, or by exposing the color controls to grade the current clip using a mouse or other input device.

Methods of using the Lightbox:

- **To show or hide the Lightbox:** Click the Lightbox button in the toolbar.
- **To show color controls in the Lightbox:** Click the Show Color Controls button in the UI control bar above the Lightbox.
- **To show thumbnail info in the Lightbox:** Click the Clip Info button, which is the second control at the upper left-hand corner of the Lightbox, to turn each clip’s thumbnail Info off and on.
- **To resize clips in the Lightbox:** Drag the Zoom slider to the right to increase thumbnail size, or to the left to decrease thumbnail size.

The contents of the Lightbox can be filtered using the same options that are available for filtering the Thumbnail timeline.
To filter the Lightbox:

1. Click the Show sidebar button at the upper left-hand corner of the Lightbox. This reveals all of the filtering options that are available in the Lightbox, including custom Smart Filters you’ve created.

2. Click one of the options appearing in the sidebar. The Lightbox should immediately update to show just those clips that match the selected criteria.

3. To go back to seeing every clip in the Timeline, click All Clips.

The Lightbox can also be output to video, in order to see its contents on a broadcast display or projector.

To output the contents of the Lightbox to video:

Click the Output Lightbox to Video button at the upper right-hand corner of the Lightbox.

For more information about clip selections, groups, and grade management, see Chapter 116, “Grade Management.”
Automated Grading Commands and Imported Grades

While DaVinci Resolve has a wide variety of manual grading controls that afford you control over just about every component of digital imagery, DaVinci has spent a lot of time investigating ways of increasing colorist efficiency by creating automated grading tools. Furthermore, with integrated editing bringing professional editors into the world of editing, grading, and finishing in DaVinci Resolve, the same automated tools being developed to help colorists go home earlier can also be used to give non-colorists a hand in taking care of simple grading tasks.

Color Match Palette

If the camera and lighting departments had the foresight to shoot a color test chart for each of the major lighting setups in the project you’re grading, DaVinci Resolve lets you superimpose a sampling grid over a chart in a clip and mathematically analyze the sampled colors to generate an automatic correction. Using controls in the Color Match palette, you can specify the Source Gamma, Target Gamma, and Target Color Space to make sure that the resulting correction is correct for the camera you used, and the project you’ve set up.

The Color Match palette works with several standardized color charts:

- Datacolor SpyderCheckr 24
- DSC Labs ChromaDumonde 24+4
- DSC Labs SMPTE OneShot
- X-Rite ColorChecker Classic
- X-Rite ColorChecker Classic - Legacy
- X-Rite ColorChecker Video
- X-Rite ColorChecker Passport Video

The X-Rite ColorChecker, Datacolor SpyderCheckr, and DSC Labs SMPTE OneShot charts compared, all of which are supported by the Color Match palette.
The result is analyzed to generate an automatic color correction to use to create a neutral grade for the image, to use as a starting point for the rest of your grade.

Tips for Properly Shooting a Color Chart

The results you get using Color Match are completely dependent on how the charts were shot in the field. If the charts were properly shot, you’ll get great results. If the charts were improperly shot, the results will be unpredictable.

To get the best results using Color Match, adhere to the following guidelines:

- The chart must be lit evenly such that the lighting on each patch is the same intensity (level) and color. Any shadows or changes in lighting color across the chart will result in Color Match trying to compensate for these changes, and an inaccurate match will result. When viewing a chart being lit prior to a shoot shooting via a waveform monitor, the top of each individual patch as seen on the scope should appear as a rectangle with a “flat top.”

- No patches on the chart should be clipped in any of the RGB color channels. A clipped channel will force Color Match to use incorrect RGB values, and the resulting match will be inaccurate.

- The white patch on the recorded chart should be captured between 70–95 IRE. Correct exposure is essential to getting a good result, and while Color Match does allow for some adjustment via the White Level option, this will only give accurate results if the original chart is shot so that the white patch sits within the 70–95 IRE range when viewed on a waveform monitor. It is not recommended that a white patch be shot with
a signal level above 95 IRE, since this usually means that one of the RGB channels is close to or actually clipping which will cause an inaccurate match.

- The Source Gamma setting must be set to match the encoded OETF (opto-electrical transfer function, or gamma) of the recorded image. To be able to create an accurate adjustment, the Color Match function requires image data that is scene linear (linear to light). Most captured or recorded image data is encoded with a tone curve (gamma curve) to maximize the efficiency of the bit depth being used, and different cameras use different gamma curves to maximize the image data from different sensors. Since the Color Match algorithm converts image data into a scene linear space before creating an adjustment, it needs to undo the gamma curve created by the camera or debayering process. If the wrong Source Gamma setting is selected in the Match Color palette, then the data will not be linearized correctly and the resulting match will be inaccurate.

- Lighting in the scene with an unusual spectral response or a strong color cast can cause an inaccurate match. Scenes lit with lights that have an unusual spectral response (such as cheap fluorescent bulbs, or mercury vapor fixtures that exhibit a very narrow or spiky spectral power distribution) can cause metameric errors in both the camera’s response and the Color Match function, resulting in the creation of an inaccurate adjustment. The most accurate results are obtained when the scene uses lighting with a chromaticity that is close to the black body locus (with a highly correlated color temperature) and a relatively smooth spectral power distribution. In other words, use high-quality lighting that doesn’t have spikes in specific parts of the spectrum.

- Large differences between the color temperature of the lighting shining directly on the chart and ambient lighting elsewhere in the scene can cause perceptual errors. Often the problem is one of perception and not an incorrect color adjustment. For example, outdoor scenes being artificially lit with instruments shining extremely warm light (low color temperatures of 3200K or less) but that have cooler ambient lighting may appear overly blue if matched with a Target Color Temp of 6500K. This happens because the chart under direct lighting is lit at the lower (younger) color temperature, but areas of the scene in shadow are much cooler because of the ambient “blue” light from the sky; the result is an automatic color adjustment that’s correct for the chart, but exaggerated in the background.

### How to Use Color Match

The following procedure shows how to use the Color Match palette and overlay to create a color correction.

![The Color Match palette](image-url)
To sample a color chart to make an automatic correction:

1. Select the clip with a chart you want to sample. If necessary, you can use the View > Show Current Clip With Handles option to show additional frames at the beginning of the current clip to reveal a color chart in the leader of your media.

2. If necessary, choose an option from the Source Gamma pop-up menu that corresponds to the gamma with which the media was recorded.

3. Then, choose a target gamma and color space that corresponds to the format you want this clip to be matched to.

4. Click the Viewer tool pop-up, choose the Color Chart overlay, and use its corner-pinning controls to line the sampling boxes up with the color patches of the chart.

Aligning the Color Match target with the chart in the video

5. When you’re finished, click the Match button, and the clip will be automatically corrected.

A clip before and after automatic color matching

**TIP:** Keep in mind that not every shot needs to have a chart. If the lighting of the location used in a scene is consistent, you really only need a single chart analysis to generate a correction that you can copy to all other clips in the same scene. Of course, if you are using multiple cameras in a scene, you should have a chart analysis for each separate camera if you want to try and match them more closely together.
**Configuration Controls**

Here’s a more detailed explanation of each of the parameters found in the Color Match palette.

- **Source Gamma:** Defines the source gamma the media was recorded with. You must select the correct gamma or the results will not be as accurate.
- **Target Gamma:** Lets you select a target gamma that you want the corrected clip to use. While this will most likely be the gamma you’re outputting the finished program at, you can choose other target gamma values for specialized workflows.
- **Target Color Space:** The color space you’ll be outputting the finished program with.
- **Color Temp:** An adjustable color temperature control that lets you manually adjust the target color balance of the resulting correction to be warmer (lower values) or cooler (higher values).
- **White Level:** A checkbox that’s disabled by default, which lets you manually choose the target white point that the automatic correction should use. Raising or lowering this value will stretch or compress the contrast of the final correction.
- **Match button:** Once you’ve chosen the appropriate settings, and aligned the color match target with the chart that was recorded, click to execute the match. The default is 6500K.
- **Chart type pop-up menu:** You can choose from among the supported chart types in this pop-up. At the time of this writing, these include the Datacolor SpyderCheckr24, theChromaDuMonde 24+4, the DSC Labs SMPTE OneShot, the X-Rite ColorChecker Classic, the X-Rite ColorChecker Classic - Legacy, the X-Rite ColorChecker Video, and the X-Rite ColorChecker Passport Video.
- **Reset All button:** Resets all controls and adjustments in this palette.

**Reset Controls**

The Color Match option menu has a variety of commands you can use to reset your work in the Color Match palette.

- **Reset Match Configuration:** Resets the Configuration parameters described above.
- **Reset Match:** Resets the matching operation without resetting the Configuration controls.

**Automatic Adjustments in the Color Wheels Palette**

There are four controls found in the Color Wheels palette that can be used for automatically making different color adjustments, in order to give you a head start whenever you’re trying to neutralize a color cast in the image or choose better black and white points for exposure.

**White Balance Eyedropper**

The White Balance eyedropper, found at the bottom-left corner of the Color Wheels palette next to the Automatic Correction button, provides an automated way of neutralizing a color cast in your image that you can guide by manually selecting a feature in the image that is supposed to be white.
To auto white balance an image with an undesirable color cast or tint:

1. Click the White Balance eyedropper button. The pointer turns into the White Balance eyedropper.

   ![The White Balance eyedropper](image)

2. In the Viewer, click on any feature that is supposed to be white such as a white wall, white trim around a window, white blinds, a white shirt, and so on. As you drag the eyedropper around, the RGB values appear as a tooltip to give you a better idea of what the color is of the feature you’re about to click on. Make sure the feature you click on is (a) supposed to be white, and not off-white, and (b) that it corresponds to an image detail that’s not clipped, because that can make parts of the image seem white that aren’t really.

As a result, the white balance of the image should appear much more neutral than before. Note that this adjustment is not applied via any of the controls in the Color Wheels palette; it’s an invisible, self-contained adjustment.

Pick Black Point and Pick White Point

The Pick Black Point and Pick White Point eyedropper controls, found at the upper left-hand corner of the Lift and Gain controls of each mode of the Color Wheels palette, let you both adjust contrast by lowering the black point or raising the white point of the image, and also corrects for unwanted color casts in the shadows or highlights of the image.

Note: It’s easy, using the Pick Black and White Point controls, to inadvertently boost the highlights or lower the shadows so much that you end up clipping part of the image. To give these controls the best chance of succeeding, it’s advisable to find the absolute brightest or darkest parts of the image to sample, according to the following instructions.

To automatically adjust the black point of an image:

1. Click the Pick Black Point control. The pointer turns into the Black Point tool.

   ![The Auto Pick Black Point control](image)

2. In the Viewer, click on any feature that is supposed to be black such as the deepest part of a shadow in the background or within a fold of clothing, black fabric, or something painted black. As you drag the Black Point tool around, the RGB values appear as a tooltip to give you a better idea of what the color is of the feature you’re about to click on. Make sure the feature you click on is (a) supposed to be black, and not some very dark hue, and (b) that it corresponds to an image detail that’s not clipped, because that can make parts of the image seem black that aren’t really.

As a result, the darkest parts of the image should appear much darker than before, and any color imbalance in the shadows should be neutralized. Unlike the White Balance eyedropper, this adjustment is applied via the Lift controls in the Color Wheels palette, which should appear with some manner of adjustment as a result.
To automatically adjust the white point of an image:

1. Click the White Point control. The pointer turns into the White Point tool.

2. In the Viewer, click on any feature that is supposed to be white such as a white wall, white trim around a window, white blinds, a white shirt, and so on. As you drag the White Point tool around, the RGB values appear as a tooltip to give you a better idea of what the color is of the feature you’re about to click on. Make sure the feature you click on is (a) supposed to be white, and not off-white, and (b) that it corresponds to an image detail that’s not clipped, because that can make parts of the image seem white that aren’t really.

As a result, the lightest parts of the image should appear much lighter than before, and any color imbalance in the highlights should be neutralized. Unlike the White Balance eyedropper, this adjustment is applied via the Gain controls in the Color Wheels palette, which should appear with some manner of adjustment as a result.

Auto Color

The Auto Color command provides a quick way to automatically balance the blacks and whites of a clip based on the current frame at the position of the playhead. As of DaVinci Resolve 16, the A button in the Color Wheels palette and the Shot Match command available from the Thumbnail Timeline contextual menu both now use advanced algorithms, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. These controls have been developed to provide optimal results when working in the Rec.709 color space, and at a gamma of 2.4, so they work well in conjunction with using Resolve Color Management (RCM) to normalize media first.

- The A button performs an automatic analysis of the current frame at the playhead to give a more consistently useful neutral starting point for further adjustment.
- The Shot Match command matches one or more clips to the color and contrast of a graded or ungraded target clip. This updated version of Shot Match has been designed to be used after you’ve used the A button on each clip in the operation, the clips you’re matching and the clip you’re matching to.

If you’re in need of a fast neutral starting point for a range of clips, you can also use these commands together, grading a target clip using the A button, and then using Shot Match to match a range of clips in the same scene to the automatically graded example. Please note that these commands are intended to provide you with a reasonably neutral starting point for continued grading; they’re not meant to create creative or artistic grades.
To make an automatic correction, do one of the following:

- Open the Color Wheels palette to any mode, and click the A button in the lower left-hand corner.
- Choose Color > Auto Color (Option-A).
- Press the AUTO COLOR button on the T-bar panel.

The advantage of Auto Grade is that it gives you an immediate result for any clip without the requirement for sampling the image or having a specific test pattern to analyze, but the disadvantage is that this lack of guidance makes the usefulness of this command somewhat hit-or-miss. When it works, it can work very well to give you a neutral starting point for further grading. When it fails, you’re better off resetting the resulting adjustment and grading the old fashioned way.

Legacy Auto Color

The previous methods for doing Auto Color and Shot Match are available from the Color panel of the User Preferences, via two checkboxes named “Use Legacy Auto Color/Shot Match.” With these enabled, DaVinci Resolve looks for the darkest levels in the image to neutralize the RGB color balance in the blacks, and the brightest levels to neutralize the RGB color balance in the highlights. Furthermore, Master Lift and Master Gain are adjusted to maximize image contrast at the outer boundaries of 0 and 100 percent. Using this control with the Primaries Bars mode open makes it easier to see what’s been changed after these automatic adjustments are made.

Auto Color Using the DaVinci Control Panel

If you crave a bit more control over how the automatic color adjustment is made, and you have a DaVinci control panel, you can use the cursor to choose which color values to sample when making an automatic color balancing and contrast adjustment. It’s like a cross between the Auto Color control and the White and Black Point controls found in the GUI. This additional bit of guidance can make the results a lot more predictable.

To use Auto Grade to sample a feature using the DaVinci control panel:

1. Press the CURSOR button, on the trackball panel.
2. Use the fourth trackball to move the cursor to a feature you want to use to define the automatic correction. Whichever color you move the cursor over will be sampled to form the basis of the resulting color and contrast adjustment. Ideally, you should place the cursor over a feature that’s supposed to be neutral, such as a black shadow, gray wall, or white T-shirt. Don’t place the cursor over a feature that actually consists of saturated color, or that’s overexposed, as DaVinci Resolve will overcompensate and you’ll get poor results.
3. With the cursor placed over the desired neutral feature, press AUTO COLOR on the T-bar panel.
   DaVinci Resolve calculates an appropriate correction, which is applied to the selected node.
Shot Match

The previously available automated color correction commands, Auto Color and Color Match, are both useful for adjusting a selected clip to give it a clean, neutral starting point when you’re either in a hurry, or if you’re having trouble manually working out a solution. However, this is only the first step in grading a scene.

After you make a general adjustment to improve the color of a clip in a scene, one of the other principal tasks of the colorist is to adjust all of the clips in that scene so that they match the clip you started with, such that they all look like they were shot at the same time and in the same place. This is called scene-to-scene color correction, scene balancing, or shot matching. While there are abundant tools in DaVinci Resolve to ease the process of doing this manually, wouldn’t it be nice if you could just select a series of clips that you want to match, and have the software do the work?

That’s exactly what Shot Match has been designed to do. Whether you’re a colorist in a hurry, trying to blast through a low-budget feature with an absurd schedule, a DIT making best light dailies who just wants to make them match a little more closely before sending media off to editorial, or an editor who isn’t fast at color correction who needs to give a rough cut a quick color balance before showing the project to the client for the first time, the Shot Match feature of DaVinci Resolve has been created to quickly make different clips in a timeline match one another more closely, with a minimum of steps.

As of DaVinci Resolve 16, the Shot Match command available from the Thumbnail Timeline contextual menu uses an advanced algorithm, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. This control has been developed to provide optimal results when working in the Rec.709 color space, and at a gamma of 2.4, so they work well in conjunction with using Resolve Color Management (RCM) to normalize media first.

The updated version of Shot Match has been designed to be used after you’ve used the A button on each clip in the operation, on both the clips you’re matching and the clip you’re matching to.

(Top) Original scene, (Bottom) After using shot match to match all selected clips to clip 62

Chapter – 109 Automated Grading Commands and Imported Grades 2116
Legacy Auto Color

The previous methods for doing Auto Color and Shot Match are available from the Color panel of the User Preferences, via two checkboxes named “Use Legacy Auto Color/Shot Match.” With these enabled, DaVinci Resolve looks for the darkest levels in the image to neutralize the RGB color balance in the blacks, and the brightest levels to neutralize the RGB color balance in the highlights. Furthermore, Master Lift and Master Gain are adjusted to maximize image contrast at the outer boundaries of 0 and 100 percent. Using this control with the Primaries Bars mode open makes it easier to see what’s been changed after these automatic adjustments are made.

Shot Match Guidelines

Keep in mind that Shot Match isn’t supposed to make your clips look good, it’s supposed to make them look the same as the clip you choose to match to, or to at least get as close as possible without creating a color correction that will do harm to the image. The purpose of Shot Match is to make it easier for you to match a scene’s worth of clips together so you have a starting point for building the rest of the look you want for that scene, on top of this initial match.

The clip you choose to match to may have a correction applied to it, but for the best results, you should limit yourself to simple Lift/Gamma/Gain primary adjustments. If you make Custom curve or secondary adjustments to the image, it will be much more difficult for Shot Match to give you a good result.

Shot Match works best with normalized clips. If you’ve got a timeline edited with log-encoded clips, you may want to use DaVinci Color Management to normalize all the clips in the Timeline before you use Shot Match, to get the most accurate results. It’s certainly possible to use Shot Match with log-encoded media, but the flat color signal of log-encoded media may make it harder to get good results, depending on the scene.

Furthermore, Shot Match is not the right tool to use to try and match un-normalized log-encoded clips that use different types of log encoding, such as LogC and RedLogCine, or to try and match normalized and un-normalized clips. Because log-encoding is similar to a set of red, green, and blue curve operations, Shot Match is not equipped to achieve a successful result in this situation.

Shot Match is not designed to apply corrections to clips that already have node adjustments. The results will be unpredictable, and probably won’t match. While the clip you’re matching to may have simple primary adjustments applied to it, the other selected clips that are being matched should be completely ungraded.

Lastly, Shot Match has been designed to do no harm to the image. This means if you use Shot Match to try and match an underexposed interior shot to an exterior shot exposed at high noon on a sunlit day, the Shot Match algorithm will do its best to “split the difference” in order to make the difference between these two clips less jarring, while at the same time taking care not to stretch the color and contrast adjustments being made to the underexposed clips to the point where the image falls apart.

How to Use Shot Match

There’s no way to easily describe what Shot Match does. It’s a complex algorithm designed to try and deal with an impossibly varied number of different situations. As a result, Shot Match doesn’t apply adjustments to any of the user-editable controls in the Color page. Instead, the image adjustment created by Shot Match is applied invisibly, as the very last adjustment to the node that was selected when Shot Match was used, similar to a LUT.
The procedure for using Shot Match is deceptively simple. However, getting a good result requires some careful thought in terms of choosing which clips to match to one another.

**To match one or more selected clips to a specific clip:**

1. Following the guidelines presented in this section, Command-click or Shift-click one or more clips that you want to be matched. The clip you want to match to may or may not be part of the selection. You may select as few as one clip, or as many as you like.

   **TIP:** If you want to make it easier to notice the before and after, you can turn on Split Screen, and choose Selected Clips from the mode pop-up in the Viewer Options. This lets you see all the clips you’re about to match in a grid.

2. Next, right-click the clip you want to match all of the selected clips to, and choose Shot Match to This Clip.

If the resulting automated match looks good and plays well, then congratulations, you’ve got an excellent starting point for additional grading. However, keep in mind that even if the resulting match isn’t perfect, it may have taken care of enough inconsistencies between the clip you’re matching to and the clips that are being matched, that you need only make smaller, easier-to-spot adjustments in order to nail the final match between the shots in a scene. Either way, you can save time.
Suggestions for Using Shot Match

It’s certainly possible to select every clip in a scene and use Shot Match, and the results may be wonderful depending on what kind of visuals are in the scene. However, for other scenes, this may not always get you the best results.

Be strategic about which clips you select to match to one another. Don’t use Shot Match on shots that you know already have the same lighting, as you’ll risk having Shot Match make a minor adjustment that may actually make the shots match less well. Think of Shot Match as a tool for matching clips that look different.

It can also help to use Shot Match an angle at a time, and to do a small test before committing yourself to matching a bunch of clips. For example, suppose you have a scene consisting of angle A (an over of character 1), angle B (an over of character 2), and angle C (a master shot), and you want to match the scene entire scene to angle C since it has the best lighting. First, match one shot from angle B to your favorite shot from angle C, and see how you like the result. If it’s good, then go ahead and select every angle B clip and match them to angle C, before moving on to test one shot from angle A. This way, if there’s ever an angle that doesn’t work well using Shot Match, you can try matching it to one of the other angles in the scene that you’ve already matched to see if you get a better result.

NOTE: Keep in mind that, since each clip in the Timeline has its own undo stack, you cannot undo a shot match operation applied to multiple clips all at once.

Beware of clips with large areas of color in the background that don’t match any of the other angles in a scene, such as a shot-reverse-shot sequence that cuts between someone standing in a back yard and someone standing against a purple wall. You can try it to see what happens, but this kind of color distribution can often throw Shot Match results off.

Broadcast Safe

If you regularly deliver to restrictive QC standards, then you can enable Broadcast Safe in the Color Management panel of the Project Settings while you grade to limit both the luma and chroma of the video signal to one of three levels of acceptable overshoots and undershoots.

The Broadcast Safe parameters in the Color Management panel of the Project Settings

• **Broadcast safe IRE (mV) levels**: A pop-up menu for choosing one of three levels of aggressiveness when limiting the signal. Choose the range that corresponds to your QC requirements. The options are “–20 - 120” (permissive), “–10 - 110” (conservative), and “0 - 100” (very conservative).

• **Make Broadcast Safe**: A checkbox that turns broadcast safe limiting on and off.

NOTE: The clipping imposed by Broadcast Safe itself does not have an inherently soft roll-off. For best results, Broadcast Safe should be used in conjunction with the Soft Clip controls in the Color page, or a Soft Clip LUT (for more information see Chapter 3, “System and User Preferences”).
Black Sun Highlight Correction

If your project uses media shot with one of the Blackmagic Cinema, Production, Pocket, or Ursa cameras, and you have clips that exhibit so-called “black sun” artifacts, where bright onscreen highlights appear with a dark magenta spot, a command exists to quickly and easily remove these artifacts.

To remove black sun artifacts from Blackmagic camera footage:

Right-click the affected clip’s thumbnail in the Thumbnail timeline of the Color page, and choose Black Sun Highlight Correction from the contextual menu.

The command for removing black sun artifacts
Using CDL Grades

Only available in DaVinci Resolve Studio.

There are two instances where primary grading adjustments may be applied to a clip outside of adjustments that you make within the Node Editor of the Color page. If you import a CDL (Color Decision List), then the CDL adjustment for each clip is made available to you via a contextual menu command in the Thumbnail timeline of the Color page. For more information, see Chapter 122, “Copying and Importing Grades Using ColorTrace.”

Using ARRI Looks

Only available in DaVinci Resolve Studio.

If you’ve ingested ARRI raw media or Amira SXT QuickTime media, with embedded ARRI Look metadata (CDL + LUT), the embedded look can be copied to the currently selected node in the Color page.

To copy an ARRI look from the source media to the current node:

1. Select a node in the Node Editor to which you want to apply the look data.
2. Right-click that clip’s thumbnail and choose Apply ARRI CDL and LUT. A LUT and Color Wheels adjustment will be applied to the selected node.
This chapter focuses on the core color adjustments that you’ll be making to create “primary” corrections that alter the overall color and contrast of the image. These include clip-specific Camera Raw adjustments and the Lift/Gamma/Gain/Offset adjustments available in the Color Wheels palette, as well as more esoteric adjustments such as mixing colors between channels using the RGB Mixer.
## Contents

**Color Controls Covered in This Chapter** 2124

**Camera Raw** 2124

- Copying, Versioning, and Protecting Camera Raw Settings 2125
- Making Changes to Clip Camera Raw Settings 2125
- Clip Decoder Settings 2126
- Resetting Camera Raw Settings 2127

**Color Wheels Palette** 2127

- Opening the Color Wheels Palette Using the DaVinci Control Panel 2128
- HDR Grading Using Color Wheels Palette Controls 2128
- How to Use Color Balance Controls and Master Wheels 2129
- Understanding the Primaries Wheels Controls 2130
- Shared Adjustment Controls 2133
- The Log Mode of the Color Wheels Palette 2135
- The Primaries Bars Mode of the Color Wheels Palette 2140
- RGB Lift/Gamma/Gain Sliders 2140
- Offset Sliders, Offset Wheel, and Printer Points 2141

**RGB Mixer Palette** 2144

- Preserve Luminance 2144
- Resetting the RGB Mixer 2145
- Swap Channels Buttons 2145
- Using the RGB Mixer in Monochrome Mode 2145
- RGB Mixer Controls on the DaVinci Control Surface 2147
Color Controls Covered in This Chapter

The Left Palette panel contains four palettes that relate to color and contrast adjustments in different ways. The controls found within these palettes provide the foundation for any grade, and this chapter covers how you use the Camera Raw, Color Wheels, and RGB Mixer palettes. For more information on the Motion Effects palette, see Chapter 127, “The Motion Effects and Blur Palettes.”

NOTE: If you're using DaVinci Resolve with a computer monitor that's smaller than 1920x1080, then the Left and Center Palette panels are consolidated into a single panel, and all the buttons in the Palette toolbar appear together.

Camera Raw

When a timeline uses clips that are linked to camera raw source media recorded from cameras from Blackmagic Design, RED, ARRI, Sony, and Vision Research, all clips in raw media formats are initially debayered using the settings found in the Camera Raw panel of the Project Settings.

However, if there are individual clips that you want to apply different raw settings to, for example altering the ISO to pull more detail out of the highlights or shadows, then you can use the controls found in the Camera Raw palette to individually alter the parameters found within.

The Camera Raw palette is automatically set to the mode (seen within the Mode pop-up menu) that is appropriate to the clip that’s currently selected. If the current clip is not in a raw format, then the parameters within the Camera Raw palette are disabled.

All settings that currently populate the Camera Raw palette are also accessible from the DaVinci control panel.
To access camera raw settings on the DaVinci control panel:

1. Press the CAMERA RAW soft key on the Center panel.
2. Use the Center panel knobs to make camera raw parameter adjustments.
3. When you’re finished, press the MAIN soft key to return to the main page of controls.

This section covers general use of the Camera Raw palette. For in-depth documentation about specific camera raw parameters, see Chapter 5, “Camera Raw Settings.”

Copying, Versioning, and Protecting Camera Raw Settings

Ordinarily, a clip’s camera raw settings are copied along with its grade, or saved inside stills grabbed from that clip, when you use the various grade management techniques covered in Chapter 108, “Grade Management.”

When you create new versions, you copy the current Camera Raw settings to the new version, but any changes you make are specific to that version, so each version can have individual Camera Raw adjustments. For example, you could compare the results of two different camera raw adjustments on the same clip.

![Camera Raw master settings](image)

If you’re copying and rippling grades among multiple clips, you can also protect each clip’s camera raw settings from being overwritten using the “Copy Grade: Preserve Source Settings” option found in the contextual menu of the Gallery. For more information on the Copy Grade settings, see Chapter 116, “Grade Management.”

Making Changes to Clip Camera Raw Settings

If you want to make individual adjustments to a particular clip’s camera raw settings, choose “Clip” from the Decode Using pop-up menu in the Camera Raw palette. This makes all the parameters in the Camera Raw palette editable, and changes you make override the project-wide camera raw settings.

Changes to the parameters in the Camera Raw palette can also be rippled across multiple clips at once.
To ripple camera raw adjustments across multiple clips:

1. First, you must select a range of clips in the Color page timeline.
2. Open the Camera Raw palette, and make whatever adjustments are necessary to the current clip. The name of each parameter you adjust changes to amber, showing you which parameters have been modified, and which have not.
3. To ripple your changes, do one of the following:
   - Click the Use Changes button to ripple only the altered parameters (in amber) to the other clips you’ve selected in the Timeline. This preserves differences between clips in the parameters you haven’t adjusted (in gray).
   - Click the Use Settings button to ripple every parameter of the current clip to the other clips you’ve selected, overwriting all the camera raw settings at once.

The Use Changes and Use Settings buttons in the Camera Raw palette

Clip Decoder Settings

There’s much more information on the various format-specific Master settings, as well as the occasionally format-specific Clip Decoder settings, in Chapter 5, “Camera Raw Settings.” However, with the exception of the RED Clip Decoder settings that appear for R3D clips, most other formats share a set of DaVinci Resolve-specific controls that provide wide-latitude access to the raw image data for purposes of making different kinds of adjustments.

While specific raw formats have individual controls, the standard controls include:

- **Color Temp**: Designed to alter the “warmth” of the image. Adjustable in degrees Kelvin. Lower values correct for “warmer” lighting, while higher values correct for “cool” lighting. +6500 is unity. The range is +2000 to +50,000.
- **Tint**: Color balance correction for images with a green or magenta color cast, such as fluorescent or sodium vapor bulbs. 0 is unity. The range is –150 to +150.
- **Exposure**: Increases or lowers image lightness in units relative to f-stops. If your intended exposure adjustment lifts image data above the maximum white level, don’t worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –4 to +4.
• **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.

• **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 through +100.

• **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 through +100.

• **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 through +100.

• **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 through +100.

• **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 through +100.

• **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.

• **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

• **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

### Resetting Camera Raw Settings

If you’ve made changes to the parameters of the Camera Raw palette and you decide you need to reset them, there are two options, found in the Options menu.

- **Reset:** Resets all parameters in the Camera Raw palette to their default settings.
- **Revert:** Similar to the “Original Memory” command, Revert changes all camera raw parameters back to the state they were at when you first selected the current clip.

### Color Wheels Palette

If you’ve had any exposure to color correction tools in any application, the controls found within the Color Wheels palette should look familiar. These controls correspond to the most basic color correction functionality available in DaVinci Resolve, and are designed to let users without control panels have easy access to color balance and YRGB contrast manipulation using a mouse, tablet, or trackpad.
The Color Wheels palette has three distinct modes of operation:

- **Primaries Wheels mode** contains the traditional DaVinci Lift/Gamma/Gain/Offset controls that allow tonally specific yet widely overlapping regions of adjustment.
- **Primaries Bars mode** affects the same Lift/Gamma/Gain/Offset controls as the Primaries Wheels mode, but the bars interface lets you make vertical slider-driven adjustments to YRGB lift, YRGB gamma, and YRGB gain, as well as providing a slider-driven interface for Offset.
- **Log mode** contains Shadow/Midtone/Highlight/Offset controls that offer more restrictive yet customizable regions of adjustment intended for making adjustments to log-encoded image data.

Which mode you use depends entirely on what kinds of adjustments you need to make.

### Opening the Color Wheels Palette Using the DaVinci Control Panel

You can open any mode of the Color Wheels palette by doing one of the following:

- **To open the Primaries Bars**: Press SHIFT DOWN and then PRIMARY.
- **To open the Color Wheels**: Press SHIFT UP and then PRIMARY.
- **To open the Log controls**: Press SHIFT DOWN and then PRIMARY. Alternately, you can open any of the other Color Wheels palette modes, and then press the LOG soft key on the Center panel of the DaVinci control panel. Press the MAIN soft key to return to the more traditional Lift/Gamma/Gain mode of adjustment.

### HDR Grading Using Color Wheels Palette Controls

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR Mode of the node you're working on by right-clicking that node in the Node Editor and choosing HDR Mode from the contextual menu (only available in Resolve Studio).
Using a node’s contextual menu to put that node into HDR mode

This setting adapts that node’s controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.

How to Use Color Balance Controls and Master Wheels

Each of the modes in the Color Wheels palette use the same controls, albeit in different ways. This section explains, in a generic way, how to use these controls to make adjustments.

Color Balance controls provide a way to adjust all three color channels simultaneously with a single move of the pointer, according to the mode that’s currently selected. These controls correspond to the trackballs found on the DaVinci control panel, but there are a variety of keyboard modifiers that let you make specific adjustments via the GUI.

To make adjustments using the Color Balance controls:

- **Click and drag anywhere within the color ring:** Moves the Color Balance indicator relative to its previous position, and rebalances the three color channels in whatever range of image tonality is governed by that control. You don’t need to drag the Color Balance indicator itself. This simulates the kind of relative control you get when using a trackball to manipulate these parameters. As the Color Balance indicator moves, the RGB parameters underneath change independently to reflect the independent adjustments being made to each channel.

- **Shift-click and drag within the color ring:** Jumps the Color Balance indicator to the absolute position of the pointer, letting you make faster, more extreme adjustments to the color balance governed by that control.

- **Double-click within the color ring:** Resets the color adjustment without resetting the corresponding contrast adjustment for that control.

- **Command-click and drag within the color ring:** Adjusts YRGB contrast identically as if you were dragging that control’s master ring.

- **Click the reset control at the upper-right of a color ring:** Resets both the Color Balance control and its corresponding master ring.

The Master Wheels, located below the Color Balance controls, let you adjust the YRGB channels together to adjust Lift, Gamma, and Gain by individually adjusting the black point, the white point, and distribution of midtones that fall in-between. This has the practical effect of letting you adjust image contrast when you manipulate any two of these wheels together.
The Master Wheels correspond to the rings surrounding the trackballs on the DaVinci control panel, which let you modify image contrast via YRGB adjustment (as opposed to modifying image contrast via Y-only adjustment, covered later in this chapter).

**To adjust a Master Wheel:**

Dragging a Master Wheel to the left makes the corresponding tonal region of the image darker, and dragging it to the right makes that tonal region of the image lighter. The effect will vary according to the Color Wheels mode you’re in. As you make an adjustment, the YRGB parameters located underneath all change together to reflect the simultaneous adjustment you’re making to all channels.

**Understanding the Primaries Wheels Controls**

The Color Wheel palette’s Primaries Wheels mode lets you rebalance color and adjust contrast via the traditional DaVinci controls, which govern three overlapping tonal ranges referred to as Lift, Gamma, and Gain. The Lift/Gamma/Gain color balance and Master Wheel controls are tied to the YRGB Lift/Gamma/Gain sliders found in the Primaries palette; adjustments made to one set of controls are mirrored in the other.

Though they may look different, the Primaries Wheels and Primaries Bars actually adjust the same components, but in different ways.
These tonal ranges are defined by image lightness, on a scale where 0 is absolute black and 1023 is absolute white. The following illustration shows an approximation of how the Lift, Gamma, and Gain tonal zones broadly overlap, and how each zone’s influence falls off towards the opposing extremes of image tonality.

The Lift color balance control region of influence starts at black, and then falls off through the middle grays to diminish to no influence at white. Meanwhile, the Gamma color balance control has its greatest influence over the image in the middle grays, and its influence diminishes towards black and white. Lastly, the Gain control is the inverse of Lift, having its greatest effect on the image at white, with its influence falling off to diminish at black.

Because these tonal ranges overlap so broadly, you can make very soft, subtle, naturalistic adjustments using these controls. Furthermore, you can capitalize on their overlap by moving an adjacent color balance control toward a color that’s complementary to an adjustment you’ve just made to restrict further how much of the image is affected.

The following image shows the interaction of extreme corrections made to a grayscale image using all three Color Balance controls. Lift has been pushed toward green, Gamma has been pushed toward blue, and Gain has been pushed toward red.

Notice how, even though these corrections are extreme, the colors blend smoothly. This is the reason for the broad overlap among all three controls, and why Lift, Gamma, and Gain are so effective in making corrections to the ambient color temperature of a scene to account for inconsistencies in lighting or camera settings.

3-Way Master Wheel Adjustments

The Master Wheels located below the Color Balance controls let you precisely modify image contrast by YRGB adjustments, which individually alter the black point, the white point, and distribution of midtones that fall in-between.
These controls correspond to the rings surrounding the trackballs on the DaVinci control surface.

- **Lift:** Lets you adjust the perceived shadow density of the image by altering the black point of the image. Dragging the Lift master wheel to the left makes the darkest values in the image darker, increasing the distance between the black and white points of the image, and stretching all the midtone values in-between. Dragging the Lift master wheel to the right makes the darkest values in the image lighter, reducing contrast and squeezing all the midtone values between the black and white points.

- **Gamma:** Lets you adjust the overall perceived lightness of the image by altering the distribution of midtones that fall between the Lift and Gain master wheel settings. Dragging the Gamma master wheel to the left darkens the overall image, while dragging it to the right brightens it. Most Gamma contrast adjustments have a minimal effect on the black and white point of the image, but large adjustments may push either boundary of image lightness farther out. This interaction is described in more detail below.

- **Gain:** Lets you adjust the lightness of the highlights by altering the white point of the image. Dragging the Gain master wheel to the left makes the lightest values of the image darker, squeezing the midtones between the white and black points of the image. Dragging Gain to the right makes the lightest values even lighter, eventually clipping at maximum white.

![Waveform display showing the contrast range](Image)

These contrast adjustments are not limited by one another. For example, raising or lowering the Gamma master wheel by a large amount may push the highlights of the image higher or the shadows of the image lower, regardless of the current Lift or Gain contrast setting.

As a result, these controls are somewhat interactive, and you may find yourself going back and forth between controls as you make your final contrast adjustments. This is one of the reasons a control surface is valuable, as it allows you to adjust all three settings simultaneously.

**Offset Color and Master Controls**

The fourth set of Color Balance and Master Wheel controls is actually shared with the Log controls and with the Offset sliders in the Primaries palette. These are the Offset controls, which let you make linear adjustments to rebalance the entire tonal range of the RGB channels.
• **The Offset color balance control**: Works as a simultaneous adjustment to all three Offset sliders located in the Primaries palette; adjustments made to the Offset color balance control also alter the Offset sliders. Used subtly, this makes it easy to neutralize color imbalances in the darkest part of the image, while simultaneously rebalancing every other part of the image. Used more dramatically, this control makes it easy to add a color wash throughout the entire image.

• **The Offset master wheel**: Acts as a global adjustment to image lightness, an operation sometimes referred to as setup, raising or lowering all YRGB channels together.

When using a DaVinci control surface, the Offset color balance control is adjusted in either Lift/Gamma/Gain or Log modes via the fourth trackball, while the Offset wheel is adjusted via the ring surrounding the fourth trackball.

**Shared Adjustment Controls**

The three modes of the Color Wheels palette all share two pages of controls for making more specific adjustments to different aspects of the image such as Contrast, Saturation, Hue, Highlight retrieval, Color boost, and so on.

**Page 1 Adjustment Controls**

The shared Contrast, Pivot, Saturation, Hue, and Lum Mix controls are located in a set of “Page 1” controls found at the bottom of the Color Wheels palette.

![Page 1 adjustment controls](image)

The Page 1 adjustment controls

The Contrast parameters let you quickly narrow or widen image contrast about a user-definable pivot point. Regardless of which mode you’re in, these parameters are identical. Contrast and pivot can also be adjusted using the DaVinci control surface via the CONTRAST and PIVOT knobs on the Center panel's default page, regardless of whether you’re in Lift/Gamma/Gain or Log mode.

• **Contrast**: This one parameter lets you increase or reduce the distance between the darkest and lightest values of an image, raising or lowering image contrast. The effect is similar to using the Lift and Gain master controls to make simultaneous opposing adjustments. Bright and dark parts of the image are pushed apart or brought together about a center point defined by the Pivot parameter. The “Use S-curve for contrast” setting in the General Options panel of the Project Settings (on by default) sets the contrast control to apply an “S-curve” to the image, such that the shadows and highlights of a signal will not be clipped when you increase the value. If you would prefer for these contrast adjustments to be made linearly, and for the signal to be allowed to clip when you reach the upper and lower boundaries of the video signal, you can turn this checkbox off.

• **Pivot**: Changes the center of tonality about which dark and bright parts of the image are stretched or narrowed during a contrast adjustment. Darker images may require a lower Pivot value to avoid crushing the shadows too much when stretching image contrast, while lighter images may benefit from a higher Pivot value to increase shadow density adequately.
The Saturation, Hue, and Lum Mix parameters mirror the three knobs found at the right of the Center panel of the DaVinci control surface.

- **Saturation**: Increases or decreases overall image saturation. At higher values, colors appear more intense, while at lower values, color intensity diminishes until, at 0, all color is gone, leaving you with a grayscale image.

- **Hue**: Rotates all hues of the image around the full perimeter of the color wheel. The default setting of 50 shows the original distribution of hues. Raising or lowering this value rotates all hues forward or backward along the hue distribution as seen on a color wheel.

- **Lum Mix**: Lets you control the balance between YRGB contrast adjustments you’ve made using the Master Wheels or ganged Custom curves, and Y-only adjustments to contrast made using the Y channel Lift/Gamma/Gain controls of the Primaries palette or the unganged Luma curve. At the default of 100, YRGB and Y-only adjustments to contrast contribute equally. Reducing this value diminishes the effect of Y-only contrast adjustments until, at 0, Y-only contrast adjustments are turned off.

Additionally, you’ll notice that at a Lum Mix setting of 100, individual adjustments to R, G, or B using the RGB sliders or unganged Custom curves result in automatic adjustments being made to the other two color channels in order to maintain constant Luma levels. At a Lum Mix setting of 0, individual color channel adjustments have no effect on the other color channels.

Like most parameters in DaVinci Resolve, clicking and dragging a parameter’s name or value to the left or right lowers and raises that parameter with a virtual slider, while double-clicking that parameter’s number lets you edit it numerically, and double-clicking that parameter’s name resets the parameter to its default position.

**Page 2 Adjustments Controls**

The “Page 2” section of the Color Wheels palette has the same kind of highlight and shadow recovery, Color Boost, and Midtone Detail controls that are found on the Camera Raw palette. If you’re grading a camera raw format, then these controls on the Camera Raw palette will give you greater latitude for adjustment. However, the identically named controls in the Color Wheels palette can be used for any media format you like.

![Page 2 adjustment controls](image)

Even though you won’t have the kind of wide latitude that you do when using these controls with raw clips, you can still accomplish quite a lot, depending on the format you’re adjusting.

- **Temperature**: A specifically constrained Gain color balance adjustment that lets you adjust the image along a warm/orange to cool/blue axis corresponding to the naturalistic spectrum of color temperatures used for lighting. Raising this parameter performs a Gain color balance adjustment toward orange, while lowering this parameter to a negative value performs a Gain color balance adjustment toward a blue/cyan split. 0 is unity. The range is –4000 to +4000.

- **Tint**: A specifically constrained Gain color balance adjustment that lets you adjust the image along a magenta to green axis corresponding to the unnatural spectrum of color temperatures found in artificial lighting sources such as fluorescent and sodium vapor lighting fixtures. Raising this parameter performs a Gain color balance adjustment toward magenta (sometimes referred to as “minus green” to correct for fluorescent lighting), while lowering this parameter to a negative value performs a Gain color balance adjustment toward green (“plus green” to correct for other kinds of lighting). 0 is unity. The range is –4000 to +4000.
• **Midtone Detail (MD):** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 through +100.

• **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 through +100.

• **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 through +100.

• **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 through +100.

**Auto Correction in the Primaries Mode Controls**

The Auto Color button provides a quick way to automatically balance the blacks and whites of a clip based on the current frame at the position of the playhead. DaVinci Resolve looks for the darkest levels in the image to neutralize the RGB color balance in the blacks, and the brightest levels to neutralize the RGB color balance in the highlights. Furthermore, Master Lift and Master Gain are adjusted to maximize image contrast at the outer boundaries of 0 and 100 percent. Using this control with the Primaries Bars mode open makes it easier to see what’s been changed after these automatic adjustments are made.

**The Log Mode of the Color Wheels Palette**

The Shadow/Midtone/Highlight color balance and Master Wheel controls operate independently of the Lift/Gamma/Gain color balance and Master Wheel controls found in the Primaries mode. While the Log mode uses the same types of controls as the Primaries mode, the way each control affects the image is very different.

To switch between the Primaries and Log modes of the Color Wheels:
Choose an option from the mode pop-up, click the right mode button, or press Option-Z.

Log color wheels, with behavior that is very different from the Primaries mode color wheels

There are two ways of using the Log mode controls. The first takes advantage of the way these controls work to make fast, filmic adjustments to log-encoded media while it’s normalized by LUTs or manual adjustments added after it in the image processing pipeline.
The other way of using the Log controls is to take advantage of the more restrictive, but adjustable tonal range of the Shadow/Midtone/Highlight controls to stylize normalized clips by tinting specific regions of the image.

Whether or Not to Use Legacy Log Grading Ranges and Curve

DaVinci Resolve 12.5 introduced a modification to the Log grading controls that provides smoother, more pleasing results using the same controls. To maintain backward compatibility with older projects, a “Use legacy Log grading ranges and curve” checkbox in the General Options panel of the Project Settings lets you switch your project between the older Log control behavior and the newer one. Older projects that are opened in DaVinci Resolve have this checkbox turned on by default, while new projects have this turned off by default.

Using the Log Mode Controls to Grade Log-Encoded Media

The Log controls are so named because they’re designed to work specifically with media with Log-C or similar gamma and color encoding, derived from the Cineon Log gamma curve, developed by Kodak to digitally store flat-contrast, wide-gamut image data that preserves image detail with a wide latitude for adjustment.

You can debayer most raw formats to a log-encoded image in order to derive the maximum amount of image data and adjustable latitude from that source (for more information, see Chapter 5, “Camera Raw Settings”). However, the resulting image needs to be normalized to occupy the final range of color and contrast that you intend for the final result. You can do this one of two ways:

- You can make a very careful curves adjustment in a second node to stretch the log-encoded image out to fit the contrast profile you want. By making this adjustment in Node 2, you make room for a customizing adjustment made using the Log controls in Node 1, prior to the normalization adjustment. This is key.
• You can also apply a 1D Output or 3D LUT to the first node of a clip to normalize the image. This is a faster, if less flexible operation, but a smooth tonal range may be easier to obtain. Since a LUT applied within a node is always the last adjustment within that node’s order of operations, you can also use Node 1’s Log controls to customize the look of the footage.

In either case, it’s important that the normalizing adjustment happens after your Log control adjustments, for the Log control adjustments to work as they should. With your node tree set up in this way, you’ll be monitoring an ordinary-looking image, but taking advantage of the Log mode controls’ unique tonal ranges to manipulate the log-encoded image data with great specificity.

When using the Log mode controls, here’s a workflow to consider as you learn how they work:

• **First**, use the Offset master wheel to set the black point, and use the Contrast and Pivot parameters to stretch or compress contrast as necessary to achieve the tonal range you require.

• **Second**, use the Offset color balance control to adjust the overall color balance of the image to your liking.

• **Third**, use the Shadow/Midtone/Highlight color balance and Master Wheel controls to make specific, targeted adjustments to the color and contrast of the image in tonal ranges that match where that data is in the log-encoded image.

Working in this way, you’ll find that adjustments made with the Offset color balance and Master Wheel controls and Contrast controls control the log-encoded image very nicely to create an overall adjustment, while the Shadow, Midtone, and Highlight controls allow you to fix specific issues, such as shadow balance and density, after your main adjustment has been set.

The following illustration shows an approximation of how the default ranges of the Shadow, Midtone, and Highlight controls divide the tonal range of a log-encoded image.

As you can see, when used with a log-encoded image the color interactions between each adjustment overlap very softly, while still allowing more specific adjustments than those made by the Lift/Gamma/Gain controls.

Furthermore, the boundaries of the Shadows, Midtones, and Highlights Log controls can be customized using the Low and High Range parameters. This gives you added flexibility to apply more specific contrast and color adjustments.

Once you’ve made an adjustment using Log mode controls along with a normalizing LUT or curve adjustment, you can always apply additional nodes and use the Primaries mode of the Color Wheels palette to make further alterations to the now normalized image, working as you normally would with any of the other tools in DaVinci Resolve.
Using the Log Mode Controls to Stylize Normalized Media

You can also use the Log mode controls on normalized images. Although the results you get will be somewhat different, this can be a fast way to create interesting stylizations. Whereas the broadly overlapping tonal ranges of the Lift, Gamma, and Gain color balance controls allow subtle adjustments to be made very easily, the Log palette’s color balance controls affect much more restrictive tonal zones that overlap much less when used on normalized images.

The following illustration shows an approximation of how the Shadows, Midtones, and Highlights, by default, divide the tonal range of the image into non-overlapping thirds. As you saw in the previous section, these divisions were originally intended to map to log-encoded media. However, with normalized media these divisions provide a different, and potentially useful, set of ranges from the Primaries mode controls.

With normalized media, the Shadows really do only affect the darkest shadows, falling off at approximately the bottom third of image tonality. The Midtones affect only the middle third of grays, and the Highlights affect the brightest top third of image values. However, these default ranges of image tonality can be adjusted using the Low Range and High Range controls, which are described in more detail later.

The following image shows the default interaction of extreme corrections made to a grayscale image using the Log mode controls. The Shadows have been pushed toward green, the Midtones have been pushed toward blue, and the Highlights have been pushed toward red.

As you can see, with normalized media the color interaction between each adjustment is very subtle. The darkest shadows end up bright green, the midtone values are vivid blue, and the highlights are almost pure red. This restrictiveness is useful when you want to limit a correction to a specific tonal range within the image without needing to use a Luma qualifier. It’s also quite useful for making bold, stylistic color adjustments when creating a non-naturalistic look.

Adjusting Tone Ranges in Log Mode

Two parameters let you modify the range of Shadows and Highlights that each Color Balance control affects, in turn narrowing and widening the range of Midtones. Keep in mind that while the ranges can be customized, the amount of overlap between each range cannot.
• **Low Range:** Moves the border where the Shadows and Midtones meet. Lowering this parameter widens the range affected by the Midtones, and narrows the range affected by the Shadows. Raising this parameter narrows the Midtones and widens the Shadows.

• **High Range:** Moves the border where the Midtones and Highlights meet. Lowering the High Range parameter narrows the range affected by the Midtones, and widens the range affected by the Highlights. Raising this parameter narrows the Highlights and widens the Midtones.

There are also Saturation and Hue parameters which mimic these settings found within other palettes and modes.

**Adjusting Contrast in Log Mode**

When using the Log mode controls, your primary tools for adjusting image contrast will usually be the Offset master wheel and Contrast and Pivot parameters. Using these three controls, you can set a black point and adjust the overall contrast very quickly.

The Shadow, Midtone, and Highlight master wheels let you adjust image lightness within the same restrictive ranges of image tonality that are defined by the Low Range, High Range, and Pivot parameters. These adjustments should appear smooth, if somewhat narrower then the Lift/Gamma/Gain controls, when used with log-encoded media. However, when used with normalized images, severe adjustments made with one master wheel may not always make a smooth transition to the next adjacent range of image lightness.

**NOTE:** Because these controls are so restrictive when used with normalized images, it’s easy to create solarization effects by raising the shadows to be higher than the Midtones, or lowering the Highlights to fall below the Midtones, to give two examples.

**Log Offset Color and Master Controls**

The Log controls also share the same Offset color balance and Master Wheel controls that appear in the Lift/Gamma/Gain mode of the Color Wheels palette (which are tied to the Offset controls of the Primaries palette).

• **The Offset color balance control:** Works as a simultaneous adjustment to all three Offset sliders located in the Primaries palette; adjustments made to the Offset color balance control also alter the Offset sliders. Used subtly, this makes it easy to neutralize color imbalances in the darkest part of the image, while simultaneously rebalancing every other part of the image. Used more dramatically, this control makes it easy to add a color wash throughout the entire image.

• **The Offset wheel:** Acts as a global adjustment to image lightness, an operation sometimes referred to as setup, raising or lowering all YRGB channels together.

**Switching to Log Mode Using the DaVinci Control Surface**

You can switch to the Log grading mode of the currently selected node by doing one of the following:

• Press SHIFT DOWN and then PRIMARY.

• Press the LOG soft key on the Center panel of the DaVinci control surface. Press the MAIN soft key to return to the more traditional Lift/Gamma/Gain mode of adjustment.
The Primaries Bars Mode of the Color Wheels Palette

The Primaries Bars palette contains the original set of DaVinci Resolve color adjustment sliders. These sliders serve two uses. First, they’re highly visible indicators of the individual YRGB channel adjustments that are made using the trackballs, rings, and knobs of a control surface. Second, they provide control of individual YRGB Lift/Gamma/Gain parameters using a mouse, tablet, or trackpad.

RGB Lift/Gamma/Gain Sliders

The main controls of the Primaries Bars mode are the individual Luma (or Y), Red, Green, and Blue sliders, four each for Lift, Gamma, and Gain. These sliders correspond to a set of knobs on the POTS page of the DaVinci control surface, and provide precise Lift/Gamma/Gain style control over each of the YRGB channels of the image. When used in conjunction with a Parade Scope video analysis of the image, these controls can enable you to fix irregular color imbalances in specific channels quickly.

Additionally, the Luma (Y) Lift/Gamma/Gain sliders correspond to the three knobs arranged vertically to the left of the Center panel of the DaVinci control surface. These three controls allow easy Y-only adjustments to contrast, where an increase in contrast results in perceptually diminished color saturation.

Making Y-only adjustments to contrast is a great way to increase contrast when you’re going for muted saturation or a gritty look. This kind of adjustment is also useful in situations where you’re trying to increase shadow density without increasing image colorfulness.

Four Master Wheel controls appear underneath each group of Lift/Gamma/Gain sliders. The first three of these controls are identical to the Lift/Gamma/Gain master wheels in the Primaries mode of the Color Wheel palette, and control YRGB contrast, while the fourth is identical to the Offset master wheel found in the Log mode of the Color Wheel palette.

Finally, each group of Lift/Gamma/Gain sliders has its own reset button. To reset individual channels, double-click the single-letter label underneath that slider.
To adjust RGB Lift/Gamma/Gain using the DaVinci control surface:

1. Press the POTS soft key on the main page of the Center panel.
2. Use the variously identified LUM/RED/GREEN/BLUE and OFFSET/BLACK/GAMMA/GAIN knobs to make the required adjustments.
3. Press the MAIN soft key to return to the Center panel’s main page.

Offset Sliders, Offset Wheel, and Printer Points

These vertical sliders mirror the settings of the Offset color balance controls in the Color Wheel palette, except that they provide individual control over the Red, Green, and Blue color channels. When you drag one of the Offset sliders up or down, you raise or lower that color channel in its entirety, which can be useful for adjusting color channels that are particularly problematic, or for imposing the kind of traditional linear color adjustments that color timers of film have employed for decades. In fact, many colorists consider the simplicity of these controls a virtue, and embrace the slight shadow or highlight contamination that can result from color balancing in this linear way as a hallmark of traditional cinema color adjustment.

**NOTE:** Unlike the other Color Wheels control adjustments described in this chapter, the Offset controls do not use the Lum Mix parameter to control whether individual adjustments to the R, G, or B channels result in automatic adjustments being made to the other two color channels in order to maintain constant Luma levels. All Offset and printer points adjustments made to a specific color channel affect only that color channel.

Adjusting Printer Points in the Primaries Bars Palette

Each Offset slider also has a pair of arrow buttons, one at the top and one at the bottom. These buttons provide “Printer Point” adjustment of these values, which let you adjust each Offset channel in discrete increments. Printer Points can be useful for projects that have tight integration with a film lab, and are designed to emulate color adjustments made using optical printers.
The “plus” and “minus” red, green, and blue buttons for making printer point adjustments

The Offset wheel control underneath the Offset sliders lets you adjust all three sliders at once, performing a setup adjustment. The Offset sliders, Printer Point buttons, and Offset wheel can be adjusted using the DaVinci control surface.

Adjusting Printer Points Using the DaVinci Control Panel

The DaVinci Resolve Advanced and Mini color grading panels have support for adjusting printer points using rotary controls for the Red, Green, and Blue channels, as well as All channels together.

To adjust the Offset sliders individually using the DaVinci Resolve Advanced or Mini panels:

Use the MASTER OFFSET, RED OFFSET, GREEN OFFSET, and BLUE OFFSET knobs on the main page of the Center panel.

If you have the DaVinci Resolve Advanced panel, there are dedicated printer points buttons you can use.

To adjust Offset Printer Points using the DaVinci control surface:

1. Press the PRINTER LITES soft key on the main page of the Center panel to display the Printer Points controls page on the Transport panel.
2. Use the + and – MASTER, RED, GREEN, and BLUE buttons that appear on the Transport panel.
3. Press PRINTER LITES again to return the Transport panel controls to their previous state.

There’s also a special set of keyboard shortcuts, mapped to the numeric keypad of an extended keyboard, that lets you make Printer Point adjustments in discrete increments, adding or subtracting a point at a time.

Adjusting Printer Points Via Keyboard Shortcuts

One of the best ways of using printer points if you don’t have a color control panel that supports them is to enable the numeric keypad to use dedicated keyboard shortcuts just for printer points.

To use the Printer Lights Hotkeys:

Choose Color > Printer Lights Hotkeys, or press Option-Command-Grave Accent (‘)

When you enable Printer Lights Hotkeys, there are two sets of shortcuts you can use to manipulate printer points. First, if you want to directly manipulate RGB, there’s one set for that.
However, if you want to work in the classic way by manipulating cyan, magenta, and yellow, there’s another set of shortcuts for that, using the remaining keys on the numeric keypad.

<table>
<thead>
<tr>
<th>Cyan</th>
<th>Magenta</th>
<th>Yellow</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - Plus Cyan</td>
<td>2 - Plus Magenta</td>
<td>3 - Plus Yellow</td>
</tr>
<tr>
<td>Minus (–) - Minus Cyan</td>
<td>0 - Minus Magenta</td>
<td>Period (.) - Minus Yellow</td>
</tr>
</tbody>
</table>

The increments used by the Printer Point buttons are defined by the Printer Light Step Calibration parameters, found in the Color panel of the User Preferences. The default settings are designed to emulate traditional film printer adjustments, but these settings can be customized to align DaVinci Resolve’s printer points adjustments with those of a particular film lab’s equipment. However, if you’re not working with a lab, you can change the Step and Density settings to alter how much of an adjustment each printer point makes. For more information, see Chapter 3, “System and User Preferences.”

There are also a pair of keyboard modifiers that gives you finer control over printer points adjustments made with these special keyboard shortcuts, while retaining the coarser default adjustments that let you make bigger changes more quickly:

- Hold down Command while using these key shortcuts to adjust printer points in half-increments.
- Hold down Shift-Command while using these key shortcuts to adjust printer points in quarter increments.

**TIP:** If you’re feeling left out because all the cool kids are using printer points and you’re unfamiliar with them, making the Parade scope visible is a great way to learn how these adjustments work while seeing their specific effects on the red, green, and blue channels of the video signal.
RGB Mixer Palette

The RGB Mixer palette lets you remix different amounts of image data from one channel to another, and has a wide variety of creative and utilitarian uses. Furthermore, the RGB Mixer can be used either to remix the color channels, or to add different proportions of each color channel into a monochrome image.

By default, the RGB Mixer palette is set to mix any amount of the Red, Green, and Blue color channels into any of the other channels. Each color channel has a dedicated control group of Red, Green, and Blue sliders that you use to do the mixing, and the default values of these can be seen in the screenshot above.

Each slider has an overall range of –2.00 to +2.00. This means that you also have the option of subtracting any combination of color channel values from a particular channel. For example, you can lower the Red control group’s Green slider to –.24 to subtract 24 percent of the Green channel from the Red channel.

Preserve Luminance

With the “Preserve Luminance” checkbox turned on, any channel adjustment you make is prevented from altering the luma of the image by automatically raising or lowering the other two channels to compensate. In the following example, you can see that when “Preserve Luminance” is turned on, lowering the Green control group’s Green slider results in the Red and Blue channels being raised by the same amount (as seen in the Parade scope). Conversely, raising a color channel’s slider ends up lowering the other two channels by the same amount to keep overall image luminosity the same.
Resetting the RGB Mixer

Clicking the Reset button at the top right-hand corner of the RGB Mixer resets each slider to its default position, where Red = 1.00 for Red output, Green = 1.00 for Green output, Blue = 1.00 for Blue output, and all other sliders = 0.

Swap Channels Buttons

A set of three buttons at the bottom of the RGB Mixer lets you easily swap two channels with one another. This can be useful as part of a creative look, or corrective in instances where two channels are accidentally reversed.

- **Swap Red and Green**: Swaps these two color channels.
- **Swap Green and Blue**: Swaps these two color channels.
- **Swap Red and Blue**: Swaps these two color channels.

Using the RGB Mixer in Monochrome Mode

When you turn on the Monochrome checkbox, two of the sliders within each Output group are disabled. This leaves the Red > Red slider, the Green > Green slider, and the Blue > Blue slider as the only available controls.

Keeping in mind that each of the color channels that makes up an image is itself a grayscale channel, the RGB sliders in Monochrome mode let you add different proportions of the Red, Green, and Blue color channels together to create custom grayscale versions of a shot.

To understand why this is useful, let’s consider the default values of the Red, Green, and Blue sliders. To emulate the human eye’s sensitivity to the wavelengths of light, the Rec. 709 video standard defines an isolated Luma (Y') component as consisting of 0.2126 of the Red channel, 0.7152 of the Green channel, and 0.0722 of the Blue channels added together. This can be seen in the default values (rounded to the nearest integer percentage) of 21, 71, and 7.

This is the standard method of deriving a black and white version of a color image, and in fact produces identical results to those obtained by setting the Saturation parameter to 0.
However, there have traditionally been other ways of mixing the colors of life into different grayscale interpretations. For example, photographers often use colored filters in conjunction with black & white film stocks, such as a yellow/green filter to emphasize pleasing skin tone for lightly complexioned people. A much older example is the use of black & white film stocks with different sensitivities (old orthochromatic stocks were not sensitive to red wavelengths, recording only blue and green to create an image).

Using the RGB Mixer with Monochrome mode turned on gives you the ability to mix your own custom blends of all three color channels to emphasize the creative characteristics you require. For instance, increasing the mix of blue and decreasing red and green can give skin tones a darker, metallic sheen. The following screenshots show multiple versions of the same image with different monochrome mixes.

Like the parameters in Color mode, you can use the RGB Mixer’s Monochrome mode to subtract one color channel from the others, for even more creative effects.
RGB Mixer Controls on the DaVinci Control Surface

All of the RGB Mixer palette controls are available from the DaVinci Resolve control surface.

**To open the RGB Mixer curve controls on the DaVinci Resolve control surface:**
Press the CURVES soft key on the main page of the Center panel.

**To exit the RGB Mixer curve controls:**
Press the MAIN soft key on the Center panel.

**To adjust the principle color regions using knobs:**
- Adjust one of the four groups of knobs on the Center panel. All are labeled to identify which RED/GREEN/BLUE source channels are paired with RED/GREEN/BLUE destination channels. For example GREEN->BLUE adds or subtracts an amount of the Green color channel from the Blue color channel.
- Press the PRESERVE LUM soft key to turn on the “With luminance level preserved” checkbox.
- Press MONO to turn on the Monochrome checkbox.
- Press COLOR to turn off the Monochrome checkbox.
Chapter 111

Curves

The Color page has a powerful curves interface that provides controls for adjusting color and contrast with the Custom Curves, as well as a variety of “Hue” or “HSL” curves that let you make more targeted adjustments to hue, saturation, and luminance in a variety of ways.

Introduction to Curves

The Curves palette, selectable via one of the toolbar buttons above the Center Palette panel of the Color page, has six modes that provide different curve-based methods of manipulating the color and contrast of an image. Each curve lets you adjust a customizable region of the image based either on image tonality (zones of lightness or darkness), hue (specific colors), or saturation (intensity of color). All curves can be adjusted using either the pointer, or knobs on the DaVinci control panel.

**TIP:** All curves in DaVinci Resolve can be used to affect the overall image, or limited to affect only a specific portion of the image as a part of a secondary operation using qualifiers, windows, imported mattes, or any combination of the three.

Adjusting Curves Using the Mouse

All Color curves in DaVinci Resolve use the following controls for basic on-screen adjustment using the pointer, controlled either with your mouse, pen, or other input device of choice.

**Methods of adjusting curves using the on-screen interface:**

- **To add a control point:** Click anywhere on or around a curve. A control point is added at the position of the mouse where you clicked, and the curve is altered, if necessary, to match the new control point’s position.

- **To add a control point without altering the curve:** Hold the Shift key down, and click anywhere on or around a curve. A control point is added to the curve at the position of the pointer where you clicked, but the curve is not altered.

- **To snap a control point to the neutral diagonal of the curve:** (Custom curve only) Hold the Option key down while dragging any control point on the curve. A diagonal line appears indicating the neutral state of the image, and the control point will snap to it. When you release the Option key and then press the Option key again after releasing, the diagonal guide line disappears.

Snapping a curve’s control point back to its neutral position by holding down the Option key

- **To remove a control point:** Right-click any control point to make it disappear.

- **To reset a single color channel curve to a completely neutral setting:** Click the reset button to the right of that color channel’s intensity slider.

- **To reset all color channel curves:** Click the Reset Custom Curve button at the upper right-hand corner of the Curves palette.
By default, a control point influences the portion of each curve that falls between its neighboring two control points.

Control point adjustments affect the entire portion of a curve between adjacent control points.

In the top screenshot, you can see that the control point at the position of the pointer is affecting the larger part of the curve that falls between the lower left-hand control point (which is there by default), and a user-created control point placed up within the highlights of the curve.

In the bottom screenshot, an additional control point to the left of the one being adjusted limits the area of the curve that is adjusted. By careful placement of additional control points, you can make extremely targeted adjustments to images using the Custom curves.

This example highlights the importance of using control points to “lock off” portions of a curve at a neutral or nearly neutral position to prevent changes to specific portions of an image, even while using other control points to make changes.

NOTE: The HSL curves also have an optional adjustment mode using Bezier curves that will be covered in those sections.

Sampling Images to Place Control Points on Curves

Another way you can add control points to curves is to move the pointer to the Viewer, and click to sample a color value and place a control point at the position on the currently open curve that corresponds to that value. This works with Custom, Hue, and HSL curves.
Creating a control point on the currently open curve

Showing Picker RGB Values
While you’re dragging the pointer over the Viewer and looking for a feature to sample, you can enable a tooltip that shows you the RGB Value of the pixel under the pointer by right-clicking the Viewer and choosing Show Picker RGB Value to toggle this feature on and off. When you turn this feature on, the View > Show RGB Picker Values In submenu has options for displaying either 8- or 10-bit tristimulus values.

The color picker tooltip that appears when you turn on Show RGB Picker Values

Curves Histograms
The Custom curves and HSL curves all show a histogram that represents the input of the currently selected Correction node, which you can use to guide your adjustments. The Histograms submenu of the Curves palette’s Option menu lets you choose to disable these histograms, or to switch the histograms between showing the input or the output of the node. If you switch to Output, the histograms will update to show you the result of your adjustments, at the expense of seeing the image data that the curve is actually working upon.

The Custom curves show a YRGB histogram:

The histogram appearing underneath the Custom Curves shows a YRGB histogram analysis
Each Hue or HSL curve shows a histogram analysis of the two color channels that Curve acts upon: hue against saturation level, luminance against saturation level, or saturation level against saturation level, to give three different examples. In the case of Hue or HSL curves, these histograms make it easy to see which parts of the Curve controls will actually affect image data.

Custom Curves

DaVinci’s Custom curves provide smooth adjustment of each clip’s Y, R, G, and B channels. The Custom curve mode of the Curves palette is divided into two areas, the Curve Editor to the left, and the Curve controls to the right. The editor contains the actual Curve controls you use to adjust the image. The controls at the right let you choose which curves you’re adjusting, and adjust their intensity.

The Custom curves are useful for making more tonally specific, channel-by-channel adjustments to an image than can be accomplished using the Color Balance controls. They’re also useful for making strange and wonderful stylistic adjustments through unusual alterations to different combinations of color channels.

Although the ganged Custom curves appear to be a single curve control, starting in version 12 the Custom curve editor is presented as a series of overlaid curves, and the YRGB curves all appear within a single editor. The default, neutral position of the Custom curves is a diagonal line that runs from the lower-left black point of the image through the upper-right white point.
The neutral diagonal position of the curve at which no adjustment is made.

The horizontal axis represents the range of image tonality in the original image, from black (at the left) to white (at the right), while the vertical axis represents the range of alteration you can make. By adding control points to the surface of the curve and raising or lowering it at different regions, you are actually remapping the original horizontal “input” value of a color channel to an “output” value of your choosing.

Additional controls appear to the right of the curve editor itself. A top row of buttons let you select the curve corresponding to an individual color channel for isolated adjustment, while a vertical stack of four sliders let you adjust the intensity of each color channel’s curve.

**Editing the Top and Bottom Control Points of Curves**

You can also edit curves using the default two control points that the curve control starts out with in the Curve Editor. The Black Point control (at the lower-left) and the White Point control (at the upper-right) let you expand and compress the video signal similarly to using the Lift and Gain Master Wheel controls in the Color Wheels palette.
You can use the Black and White Point controls in the following ways:

- **Using the Black Point control**: Dragging this control up makes a lift adjustment to raise the black point of the signal. Dragging this control to the right makes a lift adjustment to lower the black point of the signal.

- **Using the White Point control**: Dragging this control down makes a gain adjustment to lower the white point of the signal. Dragging this control to the left makes a gain adjustment to raise the white point of the signal.

**HDR Grading Using Curves**

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR mode of the node you’re working on by right-clicking that node in the Node Editor and choosing HDR mode from the contextual menu (only available in Resolve Studio).

This setting adapts that node’s controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.

**Enabling Editable Splines in the Custom Curves**

When the Curve palette is in Custom mode, you can choose Editable Splines from the option menu to expose Bezier spline handles on any selected control point, which let you make more precise curve adjustments whenever necessary.
NOTE: Beware of making curve adjustments that are too sharp, or with control points that are too close together, as they can introduce unwanted contouring within the image, causing flattening or solarization in parts of the image that you may not want.

Adding Default Anchors to the Custom Curves

You can also choose Default Anchors from the option menu of the Curve palette in Custom mode to place three additional control points on the curve, dividing the curve into five segments that affect the shadows, low midtones, medium midtones, high midtones, and highlights of the image.

Ganging and Unganging Custom Curves

By default, the Custom curves are ganged, so that curve adjustments affect a clip’s YRGB channels all together, resulting in an adjustment to image contrast that’s similar to using the Master Wheels in the Color Wheels palette, or the ring controls of the DaVinci control panel. When making this type of adjustment, increasing contrast also increases image saturation, while reducing contrast also reduces image saturation. Since curves can be manipulated with greater specificity than the three Master Wheels, you can make much finer contrast adjustments using the YRGB curves than when using the Master Wheels only.

Turning ganging off lets you use the full power of Custom curves to alter the image. Unlike the Color Balance controls, each of which adjust all three color channels simultaneously, the Curve controls let you adjust each channel individually when Gang Custom Curves is turned off.

To disable Custom curve ganging:

Click the Curve Edit button that corresponds to the curve channel you want to edit. Clicking any Curve Edit button highlights that curve to make it easy for editing when curves overlap one another. Once one or more curves is offset from the others, you can freely edit any curve by dragging its control points.
Custom Curve Edit buttons are to the left, the Gang button is to the right.

**To re-enable Custom curve ganging:**
Click the Gang button to the left of the Curve Edit buttons.

Editing color channels via individual curve adjustments lets you make smooth color-channel specific corrections, or you can make radically individual adjustments to create a wide number of creative effects.

Turning off curve ganging lets you independently adjust each curve.

**TIP:** When curve ganging is disabled, the Luma curve allows you to adjust the Y channel by itself, which is similar to using the Y-only Lift/Gamma/Gain knobs of the DaVinci control panel. When making this type of adjustment, increasing luma contrast results in a perceptual decrease of image saturation.

**Copying Custom Curves From One Color Channel to Another**
Even if you’ve unganged the Custom curves, you can still mirror one curve’s adjustments to another by copying it using the "Copy to Red/Green/Blue" commands in the Curve palette’s option menu.

**Curve Intensity Sliders**
Four Curve Intensity sliders to the right of the Curve Editor, one for each channel, let you mix between the current curve’s effect on the clip, and the original state of the image before you altered the curve. The default Intensity of 100 results in that curve exerting its full effect on the image, while an intensity of 0 results in that curve having no effect on the image. The Intensity sliders provide an easy way to “split the difference” between a curve adjustment and the previous state of the image.
Lowering the Curve Mix slider reduces the effect of that curve's adjustment on the image.

YSFX Sliders

Each of the Custom curves ('Y', 'R', 'G', and 'B') has a vertical YSFX slider at the upper left-hand corner of the Curve Editor that lets you invert any or all color channels by any amount you want, to create different types of stylized effects.

As with all other adjustments in the Color page, YSFX may be combined with Power Windows or HSL qualification to limit channel inversions to specific portions of the image for creative purposes.

Adjusting Custom Curves with the DaVinci Control Panel

The controls that correspond to the Custom curves on the DaVinci control panel are available by default when you first open DaVinci Resolve (the rotary knobs on the Center panel will be labeled PRIMARIES). If these buttons are not visible, you need to switch to the Primaries controls using the soft keys.
To open the Primary Curve controls of the DaVinci Resolve control panel:

- Press the PRIMARIES soft key on the Center panel.
- If the Center panel is currently in CURVES mode, then press the MAIN soft key on the Center panel.

The rotary knobs on the Center panel update to show the CHANNEL OFFSET/CUSTOM CURVES and YSFX controls.

To make curve adjustments:

Adjust the 0% LUM, 20% LUM, 40% LUM, 60% LUM, 80% LUM, or 100% LUM rotary knobs.

By default, all adjustments you make using these controls are ganged across all four YRGB curve controls. However, if you turn Custom curve ganging off, then these controls only affect the Luminance curve.

These controls correspond to the following default control point positions on the Curve controls.

![Curve controls](image)

Each rotary curve control on the DaVinci control surface corresponds to one of these six default control point positions.

You also have the option of using the fourth trackball from the left to adjust individual control points on curves to any position you like. This works for all curves in DaVinci Resolve that have control surface mappings.

Methods of selecting and adjusting individual control points using the master trackball of the Center panel:

- **To select a control point to adjust:** Spin the fourth ring control to the left or right to select the next control point in that direction (it takes about half of a turn to select another control point).
  
  Selected control points are highlighted in cyan.

- **To move a selected control point:** Adjust the fourth trackball to move the control point up, down, left, or right. Selected control points are constrained between whichever control points are to the left and right.

Another set of rotary knobs let you adjust Curve Mix and YSFX parameters.

**To adjust the Curve Intensity sliders:**

Adjust the LUM CURVE, RED CURVE, GREEN CURVE, or BLUE CURVE rotary knobs.

**To make YSFX adjustments:**

Adjust the LUM YSFX, RED YSFX, GREEN YSFX, or BLUE YSFX rotary knobs.
Soft Clip

The Soft Clip controls consist of four sliders underneath the Curve controls of the Custom curves, and give you an interface for adjusting highlight and shadow soft clipping either overall, with Ganging enabled, or on a per-channel basis. The Soft Clip controls are intended to provide clip-by-clip adjustment, as opposed to the Generate Soft Clip LUT settings, which let you set one soft-clipping setting for the entire program. For more information on the Soft Clip LUT setting, see Chapter 3, “System and User Preferences.”

Soft clipping lets you apply a “knee” to any clipping that occurs at the upper or lower extremes of the image, and can be used to quickly ease off any unpleasantly harsh loss of detail that occurs as a result of blowing out the highlights or crushing the shadows too aggressively.

In the following example, the screenshot at top has had the highlights deliberately blown out by excessively boosting the highlight contrast. As you can see, the edges of the clipped area lack detail. The screenshot at bottom shows the same image with soft clipping increased for all three color channels. The result retrieves detail, compressing the highlights to bring the tops of each color channel back within the allowable range.
Ganging and Unganging Soft Clip Controls

Soft clipping can be simultaneously applied to all three color channels by enabling the Ganging control (on by default), or you can disable Soft Clip ganging to individually adjust each channel. For example, using soft clipping on individual channels can be useful for legalizing RGB out-of-gamut errors for channels that over- or undershoot your QC standards.

To disable Soft Clip ganging and edit soft clipping for individual color channels:
Click the channel control button corresponding to the color channel you want to edit, and then drag the sliders to create the desired adjustment.

To re-enable Soft Clip ganging:
Click the Ganging control to the left of the Soft Clip channel controls.

TIP: Applying too much soft clipping to individual color channels may add an unwanted color tint to the corresponding highlights or shadows of an image. To avoid this, use the soft clipping parameters with ganging enabled to clip all three color channels equally.

Soft Clip Controls

Whether all channels are ganged or not, soft clipping is controlled via two sliders and two additional parameters for each color channel.

High
The High Clipping Point slider lets you adjust the maximum signal level above which the signal is clipped. Any pixels above the clipping level are made equal to the clipping level.

The High Clipping Point defaults to a digital level of 1023 relative to the DaVinci Resolve internal video scopes. Dragging this slider to the left causes the highlights of the image to clip at a lower level, resulting in lower, dimmer maximum levels.

Selecting and adjusting the high clip

RGB Parade displays the clipped image
At the default position, no clipping occurs and image data that you push above 1023 on the internal scopes is preserved and passed through the image processing pipeline to subsequent nodes. For example, in the following two screenshots, the highlights in the screenshot at top are blown out raising the gain dramatically in Node 1. In the screenshot at bottom, a subsequent adjustment in Node 2 lowers the gain and retrieves all the previously clipped values.

The image is clipped using the Gain control in Node 2.

The image data that was clipped in Node 1 is retrieved in Node 3 by lowering the Gain control. This illustrates the preservation of deliberately clipped data.

However, if at any point in a node tree you drag the High Clip slider to the left, even by a single digit, all image data above the new clipping threshold is discarded from that node forward. In the following example, the High Clip slider in Node 1 is lowered. The result is that all clipped image data is discarded. As a result, when Node 2 lowers the gain, there is no image detail left to retrieve, and all three channels exhibit flattening.

Lowering the High Clip slider in Node 1 forces all image data above the new High Clip threshold to be irretrievably discarded. Clipped data cannot be brought back by subsequent nodes.
High Soft
The High Soft slider sets the threshold, below the clipping point, at which highlights begin to compress before hard clipping. At 0, no soft clipping occurs. As you raise this value, more and more of the clipped highlight values are compressed, rather than clipped, resulting in softer, more pleasant "glowing" highlights.

**IMPORTANT** Image data that was clipped "in camera" is not necessarily retrievable using the Soft Clip controls, although there may be some preserved overhead in the super-white highlights of Y’CbCr-encoded video data.

Low
The Low Soft Clipping Point slider lets you adjust the minimum signal level at which the signal clips. This defaults to a digital level of 0 relative to the DaVinci Resolve internal video scopes. Dragging this slider to the right causes the shadows of the image to clip at a higher level, resulting in lighter minimum levels, and a lower-contrast image with lighter (possibly milky) shadows.

Low Soft
The Low Soft slider sets the threshold, above the minimum clipping point, at which shadows begin to compress before hard clipping. At 0, no soft clipping occurs. As you drag this slider to the right, more and more of the clipped shadow values are compressed, rather than clipped, resulting in a softer, more pleasant rolloff in the shadows.

Using Soft Clipping Controls with the DaVinci Control Panel
The soft clipping controls can also be manipulated using the DaVinci control panel, which provides separate controls for ganged and individual color channels.

**To open the soft clipping control on the DaVinci Resolve control panel:**
Press the CLIPS soft key on the Center panel.

**To exit the soft clipping controls:**
Press the MAIN soft key on the Center panel.

**To make a ganged soft clipping adjustment:**
- Adjust the MASTER CLIP or MASTER SOFT rotary knobs of the SCENE WHITE CLIPS or SCENE BLACK CLIPS control groups (there are four individual knobs).
- These controls adjust all four corresponding YRGB High Soft, High Clip, Low Soft, or Low Clip parameters simultaneously.

**To adjust soft clipping for individual color channels:**
- Adjust the RED/GREEN/BLUE CLIP or RED/GREEN/BLUE SOFT rotary knobs of the SCENE WHITE CLIPS or SCENE BLACK CLIPS control groups (there are 12 individual knobs).
- Each control adjusts an individual YRGB color channel.
The HSL Curves

Three sets of Hue curves, and one additional Lum vs. Sat curve, let you make different types of curve-based alterations to the image. Whereas the Custom curves let you make adjustments to the color channels of an image based on tonality (for example, boosting the Red channel in the highlights while lowering it in the shadows), the Hue curves let you make adjustments to the hue, saturation, or luma of elements in an image based on their hue.

For example, you could use the Hue vs. Sat curve to selectively lower the saturation of everything that’s blue, while raising the saturation of everything that’s red.

You can use these curves to make adjustments similar to those made using HSL qualification, but with one critical difference. Curve adjustments are mathematically smoother than the matte-limited adjustments of HSL qualifiers, so it can sometimes be easier to make specific alterations that blend smoothly with the rest of the image, without the potential for artifacts at the edges of qualified keys that can sometimes defeat a seamless result.

On the other hand, it is often easier to define more distinct boundaries between separate elements using HSL qualification. Only time and experience will help you determine which tools are best for which situations.
Unlike the Custom curves, which default to a diagonal position where lower left represents the black point and upper right represents the white point, Hue and Sat curves are flat. In the case of the Hue vs. Hue/Sat/Lum curves, the horizontal range of the curve from left to right represents the overall range of possible hues, from red through green through blue and then cycling back to red.

Because the range of hues cycle smoothly from the left to the right edge, changes that affect the curve near the left boundary of these curves loop smoothly around to the right boundary, and vice versa, such that the left and right sides of the curve always move together (as you can see in the above screenshot).

**IMPORTANT** When using Hue curves, the range of hue that you isolate with control points is always relative to the RGB input connected to that node. That means if you change the hue of a shirt from blue to red using Hue vs. Hue and you then want to raise the same shirt’s saturation with the Hue vs. Sat curve within the same node, you need to add control points to the same range of blue for both curves.

**Image Sampling for Hue and Sat Curves**

There’s an additional way to use Hue curves in DaVinci Resolve. Whenever one of the Hue vs. Hue, Hue vs. Sat, Hue vs. Lum, and Lum vs. Sat curve tabs are open, clicking or clicking and dragging over any range of pixels within the Viewer area samples the hues and/or image tonality of that region of the picture, and automatically places three control points on the currently open curve that correspond to the range of color and contrast you sampled. This also works if you use the cursor from the DaVinci control panel with the fourth trackball to sample a range of color.

**Additional Controls in the Hue and Sat Curves**

While the Hue vs. Hue, Hue vs. Sat, Hue vs. Lum, and Lum vs. Sat curves can be adjusted similarly to the Custom curves, they have additional controls running underneath the curve graph.

- **Enable Bezier button:** Turning this button on forces a curve to use Bezier control handles, rather than the default DaVinci Resolve Curve Control points, to manipulate each control point on the curve. With Bezier handles enabled, click any control point to reveal its two Bezier handles. Drag either handle to alter the shape of the curve at that control point.

- **Six-Vector Color Patches:** The Hue curves each have six buttons for automatically adding control points to manipulate the red/yellow/green/cyan/blue/magenta ranges of hue. Clicking any of these buttons adds three control points; two to define the outer range of hue to be adjusted, and a middle control point that you use to make the adjustment.

- **Input and Output (Hue Rotate/Saturation/Lum) fields:** These two numeric fields correspond to the horizontal and vertical adjustment values for the currently selected control point. Click any control point on a curve to view or alter these values. The label of the second field depends on the curve that’s selected.

The following sections describe each available curve in more detail.
Hue vs. Hue

The Hue vs. Hue curve lets you change any hue to any other hue. In the following example, the image on the left is the unadjusted original. The image on the right has had the orange jacket shifted to an olive green via a set of three control points.

changing the hue of the woman’s jacket using the Hue vs. Hue curve;
left—original image, right—altered image

One excellent use of the Hue vs. Hue curve is to quickly and subtly alter elements that require only minor adjustments. For example, a sky that appears a bit too cyan can be made into a richer shade of blue with a small adjustment.

Hue vs. Hue is also useful for making more radical changes to elements that might be too noisy to key successfully using the HSL qualifier controls. For example, red autumnal foliage blowing in the wind might result in a chattery matte, but you can use the Hue vs. Hue curve to change reds to greens, without having to worry about aliased matte edges giving your correction away.

Hue vs. Sat

The Hue vs. Sat curve lets you selectively alter the saturation of any hue within the image. This is a terrific tool for creative effect, allowing you to quickly and easily boost the saturation of elements you want to catch the viewer’s eye, while reducing the saturation of elements you’d prefer the audience not dwell upon.

This can be extremely useful for legalizing over-saturated overshoots or undershoots during a QC pass. For example, desaturating reds that are off the charts while leaving everything else alone.

changing the saturation of the woman’s jacket using the Hue vs. Sat curve;
left—original image, right—altered image

The Hue vs. Sat curve can also be a powerful tool for increasing the color contrast of images that seem lackluster and flat. By boosting the saturation of colorful elements that are distinct from the dominant palette of a scene, you can add variety to an otherwise monochromatic image.
**Hue vs. Lum**

The Hue vs. Lum curve lets you increase or decrease the lightness of elements of specific colors.

![Darkening the woman’s jacket using the Hue vs. Lum curve; Left–original image, Right–altered image](image)

This is a tricky curve to use with highly compressed footage, as it can quickly reveal artifacts in the image if you aren’t careful. However, if you’re working with very high-quality footage, this can be a great tool to darken specific hues to add richness and depth, or to lighten colorful elements to which you want to draw attention.

**Lum vs. Sat**

The Lum vs. Sat curve is similar to the Custom curves in that alterations to the saturation of an image are based on user-definable ranges of image tonality, rather than hue. In the following example, the Lum vs. Sat curve is being used to decrease selectively the saturation of everything falling into the highlights and shadows of the image, while increasing the saturation of everything within the midtones.

In the following example, a vividly saturated treatment results in shadows that seem artificially colorful. Using the Lum vs. Sat curve, it’s easy to gradually desaturate everything below a certain range, with a nice smooth falloff.

This is an outstanding curve to use for creative effect, for example, slightly boosting saturation within the midtones while reducing saturation in the shadows to increase the depth of the darkest portions of the image. It’s also a great curve to use to solve QC violations. For example, if you have illegal saturation in the highlights of an image, you can use the Lum vs. Sat curve cleanly and smoothly to lower the specific values that are causing problems.
Selective desaturation in the shadows and highlights using the Lum vs. Sat curve; Right–original image, Left–altered image

**Sat vs. Sat**

The Saturation vs. Saturation curve lets you selectively manipulate image saturation within specific regions defined by the image’s original image saturation. Control points added to the left of this curve affect areas of progressively lower saturation, effectively letting you increase or decrease the saturation of lower-saturated features. Control points added to the right affect areas of progressively higher saturation, letting you increase or decrease the most saturated features of an image.

Like all curves, this operation is extremely useful for stylizing the image. You can create custom vibrance operations, where you selectively increase the saturation of low-saturated regions of the image in different ways to give the picture more “pop.” It’s also an excellent tool for taking care of over-saturated areas of the picture when adhering to conservative QC requirements. You can specifically desaturate only the most over-saturated parts of the picture, without affecting similar hues at lower levels of saturation.

In the following example, you can see that the portion of the image with the highest saturation has been desaturated, while the rest of the image has been left alone.

Desaturating only the highest saturated elements in the picture by lower control points at the right of the Sat vs. Sat curve
Using HSL Curves with the DaVinci Control Panel

Using these curves with the DaVinci control panel unlocks their speed, letting you make fast, controlled adjustments to specific elements within each scene.

To open the Hue and Sat curve controls on the DaVinci Resolve control panel:
Press the CURVES soft key on the Center panel.

To exit the Hue and Sat curve controls:
Press the MAIN soft key on the Center panel.

To adjust the principle color regions using knobs:
Adjust one of the 18 knobs in the PRIMARIES CURVE GRADE control groups corresponding to the RED/YELLOW/GREEN/CYAN/BLUE/MAGENTA colors paired with HUE/SAT/LUM.

To sample a region of a shot to place curve control points:

1 Press the soft key corresponding to the curve you want to adjust (HUE - HUE, HUE - SAT, HUE - LUM, LUM - SAT).

2 Press the CURSOR button (located above the fourth trackball).

3 Use the fourth trackball to move the onscreen cursor to the pixel you want to sample.

4 Press the first of the three buttons underneath the fourth trackball to sample the color at the position of the cursor.

Three control points appear on the currently selected curve. The outer two control points define the region of the curve you’re adjusting, and the center control point (selected by default) lets you make the actual adjustment.

5 To hide the cursor when you’re finished sampling, press the CURSOR button again.

To select and adjust control points using the fourth trackball of the Center panel:

- To select a control point to adjust: Spin the fourth ring control to the right or left to select the next control point in that direction (it takes about half of a turn to select another control point). Selected control points are highlighted in cyan.

- To move a selected control point: Adjust the fourth trackball to move the control point up, down, left, or right. Selected control points are constrained between whichever control points are to the left and right.
Secondary correction describes isolating a specific part of the image, or a specific subject, using a key. Keys in DaVinci Resolve are grayscale images that define which areas of the picture you want to alter (in white) and which parts of the picture you want to leave alone (in black). Keys can be generated either using the controls in the Qualifier palette, by using a Power Window, or by importing an external matte (for more information on how to use external mattes, see Chapter 119, “Combining Keys and Using Mattes”). This chapter focuses on how you can use qualifiers to key a range of color values (similarly to doing a green screen key) in order to create a matte with which to do this kind of isolated adjustment.

Secondary Qualifiers

This section covers the use of the Qualifier palette, which lets you pull a 3D, HSL, RGB, or Luma key, with which to isolate the correction you need. The Qualifier controls are fast and flexible when you need to isolate an irregularly shaped subject with a distinct range of color or lightness. Since you're generating a key by sampling the image, there's no need for tracking or keyframing, so in the right situation qualifiers can be your fastest solution. In the following example, the client likes the slightly cool treatment overall, but wishes that the skin tones were a little more vibrant. This is exactly the sort of situation where qualifiers can help out. Adding a second node, and using the 3D or HSL Qualifier to isolate the face makes it relatively simple to add color exactly where you want it.

Adding a second node and using HSL Qualification to isolate the skin tones

Just about every control in the Color page can be limited using of the Qualifier modes available in DaVinci Resolve. This makes the Qualifier palette a jack-of-all-trades tool with 101 uses. A few practical examples include keying a red element that’s too intense for broadcast, in order to darken it or desaturate it; keying a range of green foliage, so you can shift its hue to a more attractive color; keying an actor’s skin tone in a commercial, to apply some selective softening to it; or keying a range of sky, in which to add blue.
Adding a Secondary Operation to the Node Editor

Any node can be switched between functioning as a primary correction, where the adjustments you make affect the entire image, and a secondary correction, where you’re adjusting a specific element in the scene. The only difference is that nodes being used for secondary corrections are limited using a qualifier, Power Windows, or an external matte.

If you’re planning to add a secondary operation to the current grade, you’ll need to first add another node in the Node Editor. When pulling a key to qualify part of the image, it’s important to understand that you’ll be sampling the YRGB values being fed to that node from any previous nodes in the tree. That means that the state of the image being fed to a node you’re qualifying affects the key you’re pulling.

For example, if the image coming out of Node 1 is well saturated and has a neutral color balance with a wide range of colors, but the image coming out of Node 2 applies a low saturation, monochromatically orange color wash, you may find it more difficult to pull a detailed key from Node 2 than you would from Node 1.

This is important because you have the flexibility of determining from what image you want to try pulling a qualified key. By connecting the node that’s outputting the best YRGB image for the key you’re trying to create to the node you’re qualifying, you can control what you’re keying. For more information about choosing which node to use for setting up a qualifier, see Chapter 119, “Combining Keys and Using Mattes.”

The Qualifier Interfaces

The DaVinci Resolve Qualifier palette interface is straightforward. To the left, graphical controls above numeric parameters let you manually adjust what ranges of each color component contributes to the key you’re creating. To the right, Selection Range tools below let you define a key by sampling pixels of the image, either using the pointer, or by using the fourth trackball of a DaVinci control panel, while below a set of Matte Finesse parameters let you alter the shape of the key that’s been pulled.
The default qualification mode is the HSL Qualifier, which uses three color components, hue, saturation, and luma, to define a key. However, you can also use the RGB or LUM (Luma) qualification modes to pull keys using other combinations of color components. The LUM qualifier mode, in particular, lets you make targeted adjustments to specific ranges of image lightness. This is a technique employed by many colorists to alter color temperature within a specific range of image highlights or shadows.

Alternately, you can use the 3D qualifier introduced in DaVinci Resolve 12 to quickly and easily pull well-refined keys by drawing lines to sample colors from the image that correspond to volumes of color within a three-dimensional gamut. While the underlying technology is sophisticated, all you have to do is to draw blue lines to sample colors you want to isolate, or red lines to sample colors you want to subtract from the isolation you’re creating, all of which automatically generate a high-quality key. Each line you draw adds a sample to the selection list; you can turn each sample off and on to evaluate its contribution to the resulting key, or delete samples that don’t make a positive contribution.

No matter which qualifier mode you use, the Matte Finesse controls make it easy to refine the resulting key to be even cleaner and more usable. In some instances, you can even take a marginal key that would otherwise be unusable, and squeeze it into something useful using the Clean Black, Clean White, and Blur Radius controls.

**Which Qualifier Do I Use?**

The Qualifier palette’s four modes offer you the flexibility to use the best keyer for the job when it comes to isolating a range of color or brightness values. In some cases, keys that are difficult to pull using some modes are easier to pull using others. Here’s a brief summary:

- **3D:** The 3D keyer is a good one to start with if you’re trying to isolate a range of color such as a blue shirt, a cyan sky, a performer’s skin tone, or the orange leaves of a tree in autumn. Its interface of drawing lines over the part of the image you want to isolate, coupled with its high quality and extreme specificity, make it a fast and accurate tool to use in a variety of circumstances. However, the 3D keyer always samples every color component of the image; it’s not useful when you want to isolate specific color components, such as luma only, or hue and saturation without luma. The 3D keyer’s greatest strength, the speed with which you can sample areas of the picture to include (or exclude) from the final key, is also occasionally a weakness with images where your initial samples aren’t giving you satisfactory results, because there aren’t many ways to fine tune the key as it’s being generated (although you can manipulate the result). On the other hand, for most images you would want to qualify, two or three samples is all you need, in conjunction with using the Matte Finesse controls to adjust the resulting key. If you need to do some compositing in the Color page, the 3D keyer also does an excellent job doing blue and green screen keying to create transparency, and has a built-in Despill control as well.
HSL: In many instances, the HSL keyer is not as immediately accurate as the 3D keyer, and will include a broader portion of the image for any given sample. On the other hand, if the 3D keyer is not giving you satisfactory results for a particular shot, the HSL keyer can sometimes do a better job. Because of its interface, the HSL keyer makes it easier to "fine-tune" the range and softness of each individual color component that’s sampled, in order to improve the result. The HSL keyer also gives you the option of disabling color components that you don’t want to contribute to the final key, so that you can pull a saturation-only key, or a hue-only key, for instances where that may solve the issue at hand.

RGB: The RGB keyer shares many of the limitations and advantages of the HSL keyer, but since you’re sampling and adjusting red, green, and blue color components, the specificity with which you can fine-tune the resulting key works much differently.

LUM: The LUM keyer works specifically to isolate parts of the image based on image tonality, lightness, or darkness. This is the perfect tool when you’re trying to isolate highlights or shadows in the image, which let you solve a multitude of different creative and technical issues. The LUM keyer is identical to using the HSL keyer with the Hue and Saturation qualifier controls turned off.

The following two sections provide an overview of how to use the 3D and HSL keyer modes in DaVinci Resolve.

Basic Qualification Using the 3D Keyer

The 3D Qualifier mode offers a fast, simple way of pulling a key to isolate a range of color in the image, by drawing lines over the parts of the image you want to key. Each line you draw over the image adds to or subtracts from the cloud of values you’re carving out of a three-dimensional representation of all available colors; you don’t see this representation, but this "under the hood" functionality is what gives the 3D keyer its name.

The 3D keyer is a general-purpose keyer, letting you isolate any color you like. However, the 3D keyer is not good at pulling luma-only keys. If you’re looking to isolate a range of luma values in the image, you should use the LUM mode.

To use the 3D mode to isolate a subject in the Viewer:

1. Open the Qualifier palette, choose 3D from the mode pop-up, and click the eyedropper.

2. Click and drag across the part of the image you want to isolate to draw a line. Lines that add to the key are colored blue.

3. To see the key you’re creating as you work, click the Highlight button in the Viewer Options toolbar at the top of the Viewer.
With the Highlight turned on, the lines you draw become invisible. They’ll reappear whenever you turn the Highlight off.

4 If necessary, draw additional lines to add more of the image to the key you’re creating. Ordinarily, it’s a good idea to not to draw more than two or three lines to sample the part of the image you’re trying to isolate. Ideally, you want the key you’re pulling to have a somewhat soft edge, which makes it easier to use the Matte Finesse controls to fine-tune your result later on. If you draw too many lines to sample the image, the result can be a key with hard, jagged edges that can sometimes be more difficult to adjust later on.
5 Alternately, if there are parts of the image that are included in the key that you want to omit, hold the Option key down and draw a line over these areas. When you turn the Highlight button off, you can see that Option-drawn lines are red, and these subtract areas from the key you’re creating. Again, try not to overdo drawing subtractive red lines, as you can end up with an overly hard-edged key that’s difficult to adjust using other controls in the next few steps.

Blue lines add to the key and a red line subtracts the grass from the key, as seen with the highlight turned off.

6 If you find yourself wondering whether a particular sample in the list at left is doing any good, you can click the color patch at the left of any entry in the list to toggle that sample off and on. If you decide you don’t need a particular sample, click the trash can button at the right to delete it.

Controls for toggling samples off and on, and deleting them from the list.

7 When you’re satisfied that the key is good enough to start fine-tuning, stop drawing lines. It’s all right if there’s a bit of noise, speckling, or if there are small holes in the key you’re creating, because you can take care of these using the Matte Finesse controls.

A sampled key that’s ready for further refinement.
Nearly every key you pull will benefit from some further “post-key” refinement. What this means is that, once you’ve created the best key you can procedurally through sampling the image, you can now adjust the resulting key itself, which is just a grayscale image, to improve the isolated result. This is what the Matte Finesse controls are for.

The three most common methods of key refinement using the Matte Finesse controls are to increase Clean Black to fill in “holes” in the parts of the image you’re omitting (the background), increase Clean White to close holes in the part of the image you’re isolating (the foreground), and then use Blur Radius and In/Out Ratio controls to blur the edge of the key and push it in and out. Using these controls, you can vastly improve nearly any key without the need to endlessly readjust the Qualifier controls.

More information about using the Matte Finesse controls appears later in this chapter.

When you’re finished, click the Highlight control to turn the highlight off, and make whatever adjustment you need. In this example, the orange of the helicopter will be adjusted using the Hue control to make it blue instead.

Adjusting the orange color of the helicopter to be blue instead
Basic Qualification Using the HSL Keyer

The HSL qualifier is one of the most flexible tools in DaVinci Resolve. Using any combination of sampled hue, saturation, and luma, you can isolate different ranges of color and contrast for specific adjustment. HSL is a general-purpose keyer, meaning you can key any color you like; it’s not restricted to blue or green.

The most straightforward way to use any qualifier is to sample the image in the Viewer. A set of four controls let you sample pixels within the image in different ways. When you sample one or more pixels, the Hue, Saturation, and Luma values are analyzed, and set different ranges in each of the Hue, Saturation, and Luma qualifier controls. There are a number of different eyedropper controls available to control how you sample color in the image.

- **Sample Eyedropper**: The first control you use whenever sampling the image. It defines the initial range of the qualification; you must use this tool before any of the others. Clicking once with this tool selects a single pixel value, while clicking and dragging selects a range of image values that add together.

- **Add/Subtract Color Range**: These two controls let you add areas of the image to, or subtract them from, the currently selected inner range of values that define the core of the key. As with the eyedropper, you can click on single pixels, or drag over a range of color.

- **Add/Subtract Softness**: These two controls let you redefine the softness that transitions from the inner range of the key, falling off towards the outer edge of the key. Just like the other controls, you can click on single pixels, or drag over a range of color.

**NOTE**: When you select one of the sampling controls, it remains selected until you select another sampling control. If you select another clip in the Timeline, then click in the Viewer to sample a key and nothing happens, make sure that you select the Eyedropper control in the Qualifier palette.

If you’re working with the DaVinci Resolve onscreen interface, the easiest way to qualify a subject is to use the pointer in conjunction with the sampling controls.
To use the HSL Qualifier mode to isolate a subject in the Viewer:

1. Open the Qualifier palette, choose HSL from the mode pop-up, and click the eyedropper.

2. Either click a pixel of the part of the image you want to isolate, or click and drag across a range of pixels within that subject.

3. To see the key you’re creating as you work, click the Highlight button in the Viewer Options toolbar at the top of the Viewer.
   By default, the area of the image you’re isolating appears in color, while the area of the image being excluded appears solid gray.

4. To subtract from the inner range of the key you’re creating, click the minus Color Range control, and click or drag across the portion of the keyed image that you’d like to exclude.
5 To add softness to the outer range of the key you’re creating, click the plus Softness control and then click or drag across the portion of the image you’d like to include as a soft edge.

Once you’ve finished using the range and softness sampling controls to refine the key you’re using to isolate the subject, nearly every key you pull will benefit from some further “post-key” refinement. What this means is that, once you’ve created the best key you can procedurally through sampling the image, you can now adjust the resulting key itself, which is just a grayscale image, to improve the isolated result. This is what the Matte Finesse controls are for.

![Matte Finesse controls](image)

6 The three most common methods of key refinement using the Matte Finesse controls are to increase Clean Black to fill in “holes” in the parts of the image you’re omitting (the background), increase Clean White to close holes in the part of the image you’re isolating (the foreground), and then use Blur Radius and In/Out Ratio controls to blur the edge of the key and push it in and out. Using these controls, you can vastly improve nearly any key without the need to endlessly readjust the Qualifier controls.

More information about using the Matte Finesse controls appears later in this chapter.

7 When you’re finished, click the Highlight control to turn the highlight off, and make whatever adjustment you need. In this example, the saturation has been raised and the color balance changed to make the adjustment obvious.

![Altered color balance of the ocean and sky](image)

If you have a DaVinci control panel, you can use the fourth trackball to sample the image, referring to either the Viewer or the display connected to the video output of your DaVinci workstation.
To sample a subject using the DaVinci control panel:

1. Press VECTORS on the T-bar panel to open the Qualifier palette, which defaults to the HSL Qualifier controls.
2. Press CURSOR (the third button above the fourth trackball) on the Center panel, to display the small cursor crosshairs in both the Viewer and the video output display.
3. Use the fourth trackball to position the cursor over the subject you want to sample, and press the leftmost of the three buttons appearing underneath the fourth trackball to sample the image.
4. Press HILITE on the Transport panel to turn on the highlight so you can see the key you’re creating, and then use the knobs at the top of the Center panel to adjust the range and softness parameters to obtain the most accurate key for your purposes.

HSL Qualifier Presets

There is a set of HSL Qualifier presets, or Six Vector presets, that you can use to isolate automatically a predefined wedge of color (green, blue, red, magenta, yellow, or cyan) or chroma intensity (chroma light, chroma dark, or both). These presets are available either from the Color > Presets menu, or from the DaVinci control panel.

The Color > Presets menu

Selecting one of these presets automatically sets the HSL Qualifier to the corresponding range or color or lightness. Afterwards you can continue modifying the HSL Qualifier to suit your purpose.

To choose a Six Vector preset from the DaVinci control panel:

1. Press the PRESETS soft key on the Center panel. The Center panel’s soft keys update with all the available lightness and color presets.
2. Press the soft key corresponding to the preset you want to use. The HSL Qualifier updates with the new settings, and the Center panel goes back to the main page of soft key controls.
Using Highlight to See What You’re Isolating

The Highlight control at the top of the Viewer (revealed by turning on Viewer Options in the Viewer’s Option menu) lets you overlay a representation of the key you’re creating over the current image in the Viewer. Overlays are also mirrored to your video output, so they’ll show up on an external display as well, in the event that you’re hiding the onscreen Viewer.

There are two types of highlights with which you can evaluate a qualification you’re creating. Each is useful for different tasks.

- **Flat-Gray**: The default highlight that DaVinci Resolve uses shows the selected portion of the image with the original colors, and the unselected portion of the image with a flat gray. It is useful for seeing the subject you’re isolating even while you’re adjusting the Qualifier controls, which lets you also see the color or contrast adjustments you’re applying at the same time.

![Oranges qualified and highlighted](image1)

- **High-Contrast**: Pressing Option-Shift-H, you can show what’s called a “high-contrast” highlight, which should be familiar to you if you’ve used other color correction applications and plug-ins; it’s a more typical display wherein the selected portion of the image is white, and the unselected portion of the image is black. The high-contrast highlight is useful in situations where you need to eliminate holes in a key, or evaluate how “chattery” a key is since irregularities are easier to spot when divorced from the original image.

![High-Contrast B&W highlighting](image2)
To enable or disable a highlight, do one of the following:
- In the Viewer Options toolbar at the top of the Viewer, click the Highlight control, and choose the type of highlight you want from the buttons that appear at the right.
- Choose an option from the View > Highlight submenu; a regular Highlight is Shift-H.
- On the T-bar panel of the DaVinci control panel, press HILITE.

To enable or disable a high-contrast highlight, do one of the following:
- Choose View > Highlight > Highlight BW (Option-Shift-H).
- On the T-bar panel of the DaVinci control panel, press SHIFT DOWN and then press HILITE.

To make high-contrast black and white the default highlight:

1. Open the Settings window.
2. Open the General Options and turn on “Mattes display high contrast black and white.”
3. Click Save.

The next time you click the Highlight control in the Qualifier palette, or press HILITE on the DaVinci control panel, the high-contrast highlight will display.

Using Highlight to Solo Nodes

There’s one other use of the Highlight control, and that’s to solo individual nodes in the Viewer and video out, rather than outputting the sum of the entire node tree. For example, if you’re trying to adjust a stack of nodes attached to a Parallel or Layer Mixer node, it’s difficult to see what you’re doing while adjusting one of the stack of nodes, because only the final result is being output.

However, if you turn on Highlight while you’re selecting a node with no key, then only the currently selected node is output, making it easy to view just one node as you adjust it. Just make sure you turn Highlight off before moving on, or you may confuse yourself.

Showing Picker RGB Values

While you’re dragging the pointer over the Viewer and looking for a feature to sample, you can enable a tooltip that shows you the RGB Value of the pixel under the pointer by right-clicking the Viewer and choosing Show Picker RGB Value to toggle this feature on and off. When you turn this feature on, the View > Show RGB Picker Values submenu has options for displaying either 8- or 10-bit tristimulus values.
Qualifier Parameters

Each of the Qualifier modes, except for the 3D qualifier, has parameters that correspond to the relevant color components for that mode, with which you can identify a range and softness, similar to using the sample tools. These parameters can be edited precisely with virtual sliders using the pointer, or using the knobs of a supported grading control panel. However, mouse and tablet users can take advantage of each qualifier’s draggable white overlays, for more direct adjustment.

- Drag the left and right edges of any qualifier control overlay to adjust the Low and High values (or the Width value of the Hue control).
- Drag the center of any qualifier control to change the center or to simultaneously change the Low and High parameters together.
- Option-drag the left and right edges of any qualifier overlay to adjust softness.

These draggable controls work for the HSL, RGB, and LUMA qualifier controls (the 3D qualifier works differently).

### HSL Qualification Controls

The HSL Qualifier is by far the most versatile mode of the Qualifier palette. It’s also the qualifier that’s easiest to understand, and the easiest to adjust by hand if you don’t feel the need to sample the image. By selecting range and softness for each of three different color components, hue, saturation, and luma, you can isolate a wide variety of colorful subjects, or ranges of image lightness and saturation.

One of the HSL Qualifier’s key strengths, and one of its most underutilized features, is that you can enable or disable each of the three HSL components using the Hue, Sat, and Lum buttons, using toggle controls found at the left of each qualifier range control’s name. This lets you ignore specific color components, while focusing on others that are more important. For
example, if you’re trying to isolate the saturated parts of an image, regardless of the hue or brightness, you can turn off the Hue and Lum qualifiers so that only Sat is used to sample the image.

Qualification with saturation only to isolate the most saturated portion of the picture

**The HSL parameters include:**

- **Hue Center:** Defines the center of the range of Hue being isolated.
- **Hue Width:** Defines the width of the range of hue being isolated. Widening or narrowing this parameter widens and narrows the range of hue about the current Hue Center.
- **Hue Soft:** Widens or narrows the falloff at both sides of the currently selected range of hue.
- **Hue Symmetry:** Lets you selectively alter the angle of Hue Soft falloff at either the right or left side. Lowering this parameter makes the softness to the right of the hue range grow steeper. Raising this parameter makes the softness to the left of the hue range grow steeper.
- **Sat Low/High:** Two parameters let you define the upper and lower range of saturation being isolated.
• **Sat Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of saturation.

• **Lum Low/High**: Two parameters let you define the upper and lower range of luma being isolated.

• **Lum Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of luma.

### RGB Qualification Controls

The RGB Qualifier mode lets you isolate range and softness in the Red, Green, and Blue channels of an image. While this is not necessarily an intuitive way of manually creating a qualification from scratch, it can provide a different way of isolating potentially trickier ranges of the RGB color space.

If you start by sampling the image, then you can widen and narrow each color channel’s isolated range of values. In some cases, you may find it’s faster to isolate a specific range of continuous color by adjusting these controls.

**The RGB parameters include:**

• **Red Low/High**: Two parameters let you define the upper and lower range of the Red channel being isolated.

• **Red Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of red.

• **Blue Low/High**: Two parameters let you define the upper and lower range of the Blue channel being isolated.

• **Blue Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of blue.

• **Green Low/High**: Two parameters let you define the upper and lower range of the Green channel being isolated.

• **Green Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of green.
Luma Qualification Controls

The Luma Qualifier mode simply pulls a key from the Luma channel all by itself. It’s identical to the HSL qualifier with H and S turned off. This single-component keyer is more useful than you might think; it’s a common technique to isolate a range of highlights, midtones, or shadows throughout the image to alter the color temperature selectively.

The Luma Keyer mode automatically disables the Hue and Saturation controls.

Also, keep in mind that the luma component is the sharpest keyable component when you’re working with heavily compressed video. Keys that are noisy or chunky with HSL qualification may be sharper if you just use the Luma Qualifier, although you won’t be able to be chromatically specific.

The Luma Qualifier has four parameters:

- **Lum Low/High**: Two parameters let you define the upper and lower range of the luma component being isolated.
- **Lum Low Soft/High Soft**: Two parameters let you define the upper and lower softness falling off outside the current range of luma.

3D Keyer Controls

As discussed earlier in this chapter, the 3D Keyer works much differently than the other qualifiers in DaVinci Resolve. In this mode, drawing lines over parts of the image you want to isolate adds samples to the Sample list, some of which add to the key (when you drag with the pointer) and some of which subtract from the key (when you Option-drag with the pointer). While this functionality is very simple to use, there are other controls that are available.

The 3D Qualifier mode
The 3D parameters include:

- **Show Paths**: A checkbox that lets you turn the visibility of the lines you’re drawing to sample the image on and off. Turning lines off does not affect the key in any way.

- **Colorspace**: A pop-up menu that lets you choose whether you’re sampling colors in YUV colorspace or HSL colorspace. YUV is the default, but if you find you’re not getting satisfactory results, you can reset the Qualifier palette and switch to HSL to see if that works any better.

- **Softness**: A single parameter lets you adjust the overall softness of the key you’re creating. The default value is 50. Raising this value increases key softness, lowering it decreases key softness.

- **Despill**: If you’re using the 3D keyer to pull a blue or green screen key to create transparency in conjunction with the optional Alpha output in the Node Editor, this checkbox lets you turn on an automatic color correction that eliminates blue or green spill from the image, while retaining the image’s original color.

- **Sample list**: A list shows each line you drew as a sampled entry. A color patch at the left shows you the average color you sampled, clicking the color patch lets you temporarily turn any color sample off to evaluate its contribution to the overall key. A plus or minus icon shows you whether that patch is adding to or subtracting from the key. The average red, green, and blue color values are shown next, and a trash can icon at the right lets you delete any sample from the list.

---

**Matte Finesse Controls**

After you’ve used the sample controls and qualifier parameters to create the most useful key for your purposes, you may find that it has problems that cannot be overcome easily by the available adjustments. Issues such as chattery edges, holes, or noisy bits can sometimes be easily fixed using the Matte Finesse controls. These controls filter the output of the Qualifier controls and are adjustments that are made to the matte itself, so they may work well in some instances, and poorly in others, depending on what you’re trying to do.

**Matte Finesse Controls, Page 1**

Denoise has been re-added to the Matte Finesse controls, providing a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling “holes” in a matte.
Denoise

Denoise provides a distinct way to post-process extracted keys to selectively reduce the noise in a key, getting rid of stray areas of qualification and softly filling holes in a matte.

Clean Black

Clean Black is a specialized operation that eliminates noise (seen as white speckling when viewing a high-contrast highlight) in the black area of a key that omits the regions of the image you don’t want to isolate, and shrinks the key by making the dark parts of a key darker the higher you raise this parameter, pushing dark gray areas of the key toward black. The practical result is that raising Clean Black lets you “fill holes” in the background portion of a key and erode translucent edges.

Clean White

Clean White is another specialized operation that eliminates noise (seen as black speckling when viewing a high-contrast highlight) in the white portion of a key that include areas of the image you’re isolating, and expands the key by making light parts of a key lighter the higher you raise this parameter, pushing light gray areas of the key toward white. The practical result is that raising Clean White lets you “fill holes” in the foreground portion of a key and grow translucent edges.
Blur Radius

In small amounts, blurring a key does well to take the edge off problem edges. However, blurring a key can also feather the edges of a key past the border of the subject you’re keying, with the result being a visible “halo” around your subject depending on the adjustment you’re making. The range is 0 to 2000, with 0 being the default. With such a large maximum blur radius, combined with the capabilities that the In/Out Ratio provides in customizing the direction of spread, you can turn some pretty precarious mattes into surprisingly smooth and useful results.

**TIP:** If haloing is a problem, you can try adjusting the In/Out Ratio parameter, or you may want to consider using the Qualifier Softness parameters to feather the edges of the key, instead.

Using the blur parameters to soften the edges of a key

**In/Out Ratio**

Controls whether the “Blur Radius” is applied equally to the inside and outside of the edge of the matte (zero), applied only within the matte (negative values), or applied only outside the matte (positive values). Using In/Out Ratio can help eliminate fringing when using the Blur Radius parameter.

(Left) In/Out Ratio lowered so blurring ends at the edge of the matte and feathers inward, (Right) In/Out Ratio raised so that blurring starts at the edge of the matte and feathers outward

However, you can also use In/Out Ratio even in situations where no Blur Radius is applied at all. Raising In/Out Ratio will fill in small black holes in the matte, while lowering In/Out Ratio below 0 will eliminate speckling by pushing small white bits of the matte toward black.

(Left) In/Out Ratio controls lowered to expand holes in the matte, (Right) In/Out Ratio controls raised to fill in small black holes in the matte
Matte Finesse Controls, Page 2

The second page of Matte Finesse controls expose controls for shrink, grow, opening, and closing functionality, with control over the shape of the operation, the radius, and iterations. The previously available Black Clip and White Clip controls have also been moved into this second page.

Shrink/Grow controls in page 2 of the Matte Finesse controls

Shrink/Grow/Opening/Closing

The Mode, Shape, Radius, and Iterations controls let you refine the edges of mattes in a variety of ways, shrinking and growing a matte with problem edges, or opening and closing holes that appear within a matte.

- **Mode**: Lets you choose how you want to modify the alpha channel/key. You can choose Shrink or Grow to dilate or erode the edges of the matte with great accuracy. Or, you can choose Opening or Closing to plug or expand holes to clean up a ragged matte.
- **Shape**: Lets you choose how corners and angles in the edges of the key are handled when you grow or shrink it. Circle is the default, and results in even expansion around the surface of the key that eventually averages all angles into a circular shape if you use extreme radius settings. Square averages all angles into a more rectangular shape if you use extreme radius settings. Diamond averages all angles into a diamond shape if you use extreme radius settings.
- **Radius**: Adjusts how much to shrink, grow, open, or close the key.
- **Iterations**: Alters the effect of the Operator Radius setting to create more extreme adjustments.

(Left) A matte with small holes in the face, (Right) Mode set to Shrink, Shape set to Circle, Radius set to 3, Iterations set to 3; used to close holes in a matte
Black Clip
Raising Black Clip applies a "lift" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed towards black. The range is 0 to 100, with 0 being the default setting.

White Clip
Lowering White Clip applies a "gain" adjustment such that translucent areas of the matte (gray areas when viewing a high-contrast highlight) are pushed towards white. The range is 0 to 100, with 100 being the default setting.

The Many Ways to Invert a Key
Sometimes, you'll need to isolate a subject or range of values in an image, and then make a change to everything else. One way to do this is to add an Outside node after the node in which you've created the key. This lets you make one set of adjustments to what you've keyed, and another set of adjustments to everything outside the key.

If you just need to make a simple adjustment, you can invert the key from within the Qualifier palette. However, there are three other ways to invert a key.

- **The Qualifier Invert button**: Clicking this control simply inverts the key being generated by all of the controls within the Qualifier palette.

- **Key Palette Qualifier Invert**: The Qualifier Invert control within the Key palette provides another control with which you can invert the key that's generated by the Qualifier palette.

- **Key Palette Output Invert**: The Output Invert control within the Key palette is notable because it inverts the sum of all keys applied within that node. For example, if you're using a Qualifier in conjunction with a Window, the two invert controls mentioned previously will only invert the Qualifier key; the Window key remains unaffected. However, using the Output Invert control inverts the overall combination of the Qualifier key and the Window, all together.
Combining Qualifiers and Windows

This is covered in more detail in a subsequent section, but if you create a key using one of the Qualifier modes, and you then add a Window, the final key that’s output by that node is limited to the intersection of the Qualifier key and the Window. This makes it easy to use a Window to “garbage matte” out bits of a key that you don’t want, that can’t be eliminated by further adjustment of the Qualifier controls.

(Top) The woman’s skin tone is too close to other elements in the scene.
(Bottom) A Circular Power Window is used to further isolate the woman being isolated.

Manipulating Keys Using Additional Nodes

If you need to make more adjustments to a qualified key than the Matte Finesse controls will allow, you can use the Node Editor to feed the key output of one node to the RGB input of another, at which point you can use all of the second node’s color adjustment controls to manipulate the grayscale image that constitutes that key, to improve it.

Connecting a key output to an RGB input, and then connecting the RGB output back to the next node’s KEY input again.
You can also use the Key Mixer node to combine multiple keys in several different ways, adding keys together, or subtracting them from one another, in order to create exactly the key you need.

Adding multiple keys together using a Key Mixer

For more information about these techniques, see Chapter 119, "Combining Keys and Using Mattes."
Secondary correction describes isolating a specific part of the image, or a specific subject, using a key. Keys in DaVinci Resolve are grayscale images that define which areas of the picture you want to alter (in white) and which parts of the picture you want to leave alone (in black). Keys are generated either using the controls in the Qualifier palette, by using a Power Window, or by importing an external matte (for more information on how to use external mattes, see Chapter 119, “Combining Keys and Using Mattes”). This chapter shows you how to use Power Windows to create shapes with which you can isolate parts of the image in different ways in order to do these kinds of targeted corrections.

Power Windows

Power Windows are another way of making secondary correction, being essentially shapes you can use to isolate regions of the image. Different controls let you use oval, rectangular, polygonal, or custom curved shapes. Because you can isolate regions of the image by drawing, Power Windows produce exceptionally clean results, with edges that can be precisely positioned and feathered to achieve a variety of effects.

Power Windows (also referred to as simply “windows”) are excellent when what you need to adjust can be encompassed within a clearly defined geometrical area. For example, the oval of a person’s face, the front of a car, or a wide expanse of sky are all good candidates for windowed adjustments. A drawback of windows can be that they must be animated to follow whatever subject they’re isolating. Fortunately, this is where DaVinci Resolve’s powerful tracker comes in, making it easy to track Power Windows quickly and accurately to follow along with the subject being isolated.
DaVinci Resolve makes it easy to combine multiple Power Windows in different ways, to intersect with one another and create even more sophisticated shapes. For example, multiple windows can be added together, or one window can be used to cut out part of another window, which saves you from the need to make complicated keyframing operations to animate that window’s shape.

Multiple windows combined to isolate and mask the image

This section covers the use of Power Windows, how to create and modify them, as well as how to combine multiple windows, and combine windows and qualifiers to create highly specific isolations.

Adding Nodes with Windows

As with qualifiers, you must first add a node to a grade’s node tree before you begin windowing a correction. This is because all of the windows within a particular node work together to limit that node’s grade. As a reminder, any node can be changed from a primary operation that affects the entire image, to a more targeted secondary operation, simply by turning on a window, using a qualifier, or enabling an external matte.

Serial nodes showing the window on Node 2

If you don’t create a new node before creating a window, you’ll discover you’ve inappropriately changed a primary correction into a secondary correction. If you create a new serial node, you’ll then need to use the controls found within the Window palette to turn on a window to customize for your purposes. However, there are also a set of commands you can use to add serial nodes with a window already turned on, saving you a few clicks or button presses in the process.

To add a new node with a window already turned on:

- Choose Color > Node + CPW (Option-C), or press the button of the same name on the T-bar panel of the DaVinci control panel to create a new serial node with a circular window.
- Choose Color > Node + LPW (Option-Q), or press the button of the same name on the T-bar panel of the DaVinci control panel to create a new serial node with a linear window.
Choose Color > Node + PPW (Option-G), or press the button of the same name on the T-bar panel of the DaVinci control panel to create a new serial node with a polygonal window.

Choose Color > Node + PCW (Option-B), or press the button of the same name on the T-bar panel of the DaVinci control panel to create a new serial node with a PowerCurve window.

When you add a node with a Power Window, the Window palette automatically opens up, ready for editing.

The Window palette is divided into three sets of controls: the Window list, the Presets, and the Transform and Softness controls.

The Window Palette Interface

Once you've created a node with which to apply a Power Window correction, you need to open the Window palette if it hasn't been opened already.

To open the Window palette:

- Click the Window palette button.
- Press the WNDWS button on the T-bar panel of the DaVinci control panel.

The majority of the Window palette is occupied by the Window list, within which you can create as many windows as you need for the task at hand. There are five types of windows you can create, each of which has a different geometry. You can use these windows individually, or you can combine them to create even more complex shapes and interactions. The Window palette has four groups of controls that let you use these windows in different ways.
• **Window list:** A row of buttons at the top of this list lets you add new windows, which you can then customize as necessary. Each window in the list exposes an On/Off button that shows the shape type, a Layer Name field (blank until you add some text) that you can use to identify what each window is for, an Invert button, and a Mask button that governs how that window interacts with the other windows that are currently enabled (adding to other windows by default, or subtracting from other windows in Mask mode).

• **Transform parameters:** Controls the overall size, aspect ratio, position, and rotation of the currently selected window.

• **Softness parameters:** Controls the edge softness of the currently selected window. Different window shapes have different softness options.

• **Window Preset browser:** A browser to which you can save presets of individual or multiple windows for easy recall later.

• **Option pop-up menu:** The Option pop-up menu has commands for resetting windows, deleting windows, saving and managing window presets, and copying and pasting track data.

Using buttons along the top of the Window palette, there are five types of windows you can create:

• **Linear:** A four-point shape that can be edited into any kind of rectangle or trapezoid you might need. In addition to the center and corner controls, you can also drag any of the four sides to change the shape.

• **Circular:** An oval that can be shaped, sized, and feathered to solve an amazing number of problems.

• **Polygonal:** A four-point shape that can be expanded with additional control points to create complex sharp-cornered polygonal shapes.

• **PowerCurve:** A Bezier drawing tool that you can use to create any kind of shape, curved, polygonal, or mixed, that you require.

• **Gradient:** A simple two-handled control for dividing the screen into two halves, with options for the center, angle, and feathering of the shape. Good for fast sky adjustments.

**Managing Windows**

To manipulate a window, first you need to create the type of window you want to use, or if you’ve got a group of windows created already, you need to select the window you want to work on.

**Methods of creating and selecting windows:**

• **To create a new window:** Click the Create Window button (at the bottom of the Window list) that corresponds to the window you want.

• **To create a new window using the DaVinci control panel:** Press WINDOWS on the T-bar panel, then use the UP and DOWN buttons on the Trackball panel to select the window type you want to apply, and press ADD.

• **To select a window using the onscreen controls:** Click anywhere within a window to select it in the Viewer.

• **To select a window from the Window list:** Click the Shape icon button corresponding to the window you want to select.
To delete a window you no longer want:
Select a window, then click the Delete button.

To reset a window:
- To reset one window to its default shape: Select a window, then choose Reset Selected Window from the Option pop-up.

Showing and Hiding Onscreen Window Controls

When you open the Window palette, the Viewer goes into Power Window mode. Enabling a window makes that window’s onscreen controls appear within the Viewer, and are mirrored to video out so you can see the window controls on your external display. If you like, you can change how and where the onscreen controls appear.

To choose whether onscreen controls are mirrored to video out, or disabled, do one of the following:
Choose an option from the View > Window Outline submenu.

There are three options:
- Off: Hides the window outline on both the external display and the Viewer.
- On: The default, shows the window outline on both the external display and the Viewer.
- Only UI: Hides the window outline on your external display, but leaves it in the Viewer.

Press Option-H to toggle among all three of the above modes.

To show or hide window on-screen controls using the DaVinci control panel:
Press SHIFT UP and then DISPLAY/CURSOR, above the fourth trackball on the Center panel.

This command is a three-way toggle. The first use of this command hides the window outline on your external display, but leaves it in the Viewer. The second use of this command hides the window outline on both the external display and Viewer. The third use of this command shows the window outline on both the external display and Viewer.

TIP: If you leave the onscreen controls visible in the Viewer, you may find that as you work you want to temporarily hide or show the onscreen controls in the Viewer so you can get an uncluttered look at the image you’re adjusting. You can quickly toggle any set of onscreen controls off and on without selecting Off in the menu by pressing Shift-` (tilde).

Using the High-Visibility Power Window Outline Option

Ordinarily, Power Window outlines are white (for the center shape) and gray (for the softness shapes). However, sometimes this color scheme can be difficult to see, so the Color panel of the User Preferences has an option in the General Settings section called “High visibility Power Window outlines.” Turning this on sets Power Window outlines to be drawn as green (for the center shape) and yellow (for the softness shapes), to make these windows easier to see in certain circumstances.
Window Transform Controls

Windows have transform parameters that are similar to those found in the Sizing palette. These parameters let you alter the window, affecting all of its control points together.

- **Size**: Scales the entire window up or down. 50.00 is the default size.
- **Aspect**: Alters the aspect ratio of the window. 50.00 is the default value, larger values make the window wider, and smaller values make the window taller.
- **Pan**: Repositions the window along the X axis. 50.00 is the default position, larger values move the window to the right, smaller values move the window to the left.
- **Tilt**: Repositions the window along the Y axis. 50.00 is the default position, larger values move the window up, smaller values move the window down.
- **Rotate**: The default value is 0. Increasing this parameter rotates the shape clockwise, decreasing this parameter rotates the shape counterclockwise.
- **Opacity**: Lets you vary the transparency of an individual window’s contribution to a node’s key.
- **Convergence**: When “Apply stereoscopic convergence to windows and effects” is enabled in the General Options of the Project Settings, this additional Transform parameter appears that lets you create properly aligned convergence for a window placed onto a stereoscopic 3D clip. For more information about working with Stereoscopic 3D projects, see Chapter 164, “Stereoscopic Workflows.”
The transform parameters also correspond to onscreen controls found in the Viewer, which can be manipulated directly using the pointer.

While many of the onscreen controls correspond to parameters within the Window palette, some onscreen controls, such as the control points that govern reshaping linear, polygonal, and PowerCurve windows, are only adjustable via the pointer.

**Onscreen controls for window transforms:**

- **To select any window:** Click on one of an arrangement of many windows to select it, making that window’s controls active.

- **To reposition any window:** Drag anywhere within the window’s onscreen control. Window position corresponds to the Window palette’s Pan and Tilt parameters. For a Gradient window, drag the center control point.

- **To resize a Circular window while locking its aspect ratio:** Drag one of the four blue corner points out to enlarge, or inwards to shrink. This corresponds to the Window palette’s Size parameter.

- **To squish or stretch a Circular window, altering its aspect ratio:** Drag one of the blue top, bottom, left, or right control points. These adjustments correspond to the Window palette’s Aspect parameter.

- **To rotate a window:** Drag the top inner blue rotate handle, in the middle of the window. For a gradient, drag the bottom arrow handle.

- **To alter window softness:** Drag any one of the magenta softness handles. Different window shapes have different sets of handles, which correspond to the Softness parameters.

- **To reshape a linear window:** Drag any of the green corner handles to corner pin the window, or drag one of the green top, bottom, or side handles to move an entire side segment of the window around.

- **To reshape a polygonal window:** Turning on a polygonal window reveals a simple green rectangle with four corner control points. Click anywhere on the surface of the rectangle to add additional control points with which to reshape the polygon, and drag any green control point to alter its shape. Polygonal windows are limited to a maximum of 128 control points.

- **To change the size and aspect of a PowerCurve:** Shift-drag a bounding box around the control points you want to transform, and then adjust the corners of the box to resize the points while maintaining the aspect ratio of the shape, or adjust the top, bottom, left, or right points to squash or stretch the shape.

- **To remove control points from polygonal or PowerCurve windows:** Middle-click the control point you want to remove.
NOTE: Removing a control point from a polygonal window that’s already been animated using the Keyframe Editor results in that point abruptly popping on and off at the keyframes creating the animation.

Window Softness

Each type of window has different Softness parameters, depending on how adjustable that window is.

- **Circular:** A single parameter, Soft 1, lets you adjust the uniform softness of the oval’s edge.
- **Linear:** Four parameters, Soft 1–4, let you adjust the softness of each of the four sides of the linear window independently. Magenta softness control points on the top, bottom, left, and right let you adjust the softness of each side of the linear shape independently.
- **Polygon:** Two parameters, Inside Softness and Outside Softness, let you adjust the overall softness of a polygonal window. There are no onscreen softness control points.
- **PowerCurve:** Two parameters, Inside Softness and Outside Softness, let you adjust the overall softness of a PowerCurve. Using the onscreen controls, you can adjust the magenta inside and outside softness control points independently, creating any softness shape you need.
- **Gradient:** A single parameter, Soft 1, lets you adjust the uniform softness of the gradient window’s edge.

Drawing a PowerCurve

The PowerCurve window is the only window that doesn’t display any onscreen controls when it’s first turned on. Instead, you must click within the Viewer to add control points, drawing your own custom shape to isolate whatever region you want.

PowerCurve window to isolate a car

TIP: Turning on the Viewer’s full-screen mode can make it easier to draw detailed shapes. You can also zoom into and out of the Viewer while you’re drawing, using either the scroll wheel of a mouse or by pressing Command-Plus or Command-Minus.
To draw a PowerCurve:

1. Turn on the PowerCurve window style control.
2. Click anywhere in the Viewer to start adding control points and drawing the shape you need.
3. Click and drag to add and shape Bezier curves, or just click and release to add a hard angle.
4. To finish drawing and close the shape, click the first control point you created to create a corner, or click and drag on the first control point you created to create a Bezier curve.

Once you’ve drawn a PowerCurve, there are many ways of manipulating it.

Simple methods of modifying a PowerCurve:

- **To add points:** Click anywhere on a PowerCurve to add control points.
- **To reshape a PowerCurve:** Drag any control point to a new location.
- **To move a PowerCurve:** Drag anywhere within or just outside a PowerCurve to move it.
- **To symmetrically alter a Bezier curve:** Drag any Bezier handle. The opposite handle automatically moves in the other direction.
- **To asymmetrically alter a Bezier curve:** Option-drag any Bezier handle. The opposite handle stays in place while you drag the current handle. Once you’ve created an asymmetric pair of Bezier handles, they move together as one if you simply drag a handle. You need to Option-drag to change the angle.
- **To change a curve into a corner:** Option-double-click any Bezier curve control point to change it to a sharp-angled corner point.
- **To change a corner into a curve:** Option-click any corner point and drag to pull out a Bezier handle, changing it to a curve.

To remove points: Middle-click the control point you want to remove.

**NOTE:** Removing a control point from a Polygonal window that’s already been animated using the Keyframe Editor results in that point abruptly popping on and off at the keyframes creating the animation.

You can also Shift-drag a bounding box to select multiple control points on a PowerCurve to move, delete, or transform them all at once.
To select multiple control points on a PowerCurve:

1. Hold the Shift key down and drag a bounding box around the control points you want to manipulate or delete. All included control points will become highlighted.

2. Do one of the following:
   - To move the control points: Drag anywhere within the bounding box.
   - To transform the control points: Drag one of the outer corners to resize all control points symmetrically, drag the top, bottom, or side handles to squish or stretch the control points relative to one another, or move the pointer to one of the corners until the rotate cursor appears, and then drag to rotate the control points.
   - To delete the control points: Press the Backspace key.

3. When you’re finished, press the Escape key to deselect the control points.

Converting Linear, Circular, and Polygon Windows into Bezier PowerCurves

If you start out isolating a subject using one of the simple Linear, Circular, or Polygon shape windows and you realize that you need a more complex shape to accomplish the task at hand, you can easily convert them to a more complex Bezier PowerCurve by choosing Convert to Bezier from the Window palette Option menu.

Before and after converting a Circular window to a Bezier PowerCurve and adjusting the result, before adding softness to the edge

Once you’ve converted a simple shape to a Bezier window, you can add control points and manipulate the shape in any way you need to make it better conform to the subject, just as you would with any PowerCurve.

Resetting the Window Palette

The entire Window palette can be reset using the Option menu’s Reset command.
Combining Power Windows with the Mask Control

Adding multiple windows to a single node is an easy way to create composite keys. When combining windows, the Mask control defines whether one window adds to another window, or subtracts from that window.

In the following example, Circular and PowerCurve windows have both been created, and each window’s Mask control is also turned on (by default), resulting in both masks being added together so that the sunset look correction affects both the sky and the woman’s face.

By turning the Mask control of the Circular window off, the Circular window is subtracted from the PowerCurve.

Now, the woman’s face is being protected from the aggressive sky treatment.
Since windows can be individually tracked and keyframed, you can quickly set up complex interactions of windows to solve common problems you’ll encounter. For example, when you’re tracking a window to follow a moving subject that moves behind something in the frame, you can use a second window with Mask turned off to cover the object in front. Now, when the tracked window intersects the subtractive window, the correction will disappear along with the subject.

You can also use the Mask control to create more complex shapes than you can with a single window.

Furthermore, once you reach the limits of what shapes you can create using the four available windows, you can combine multiple nodes containing multiple shapes and qualifiers using the Key Mixer.

**Copying and Pasting Windows**

If there’s a particular window you’ve created that you want to either duplicate within the current node, or apply to another node, you can copy and paste an individual window’s shape from one item in the Window list to another.

**Methods of copying and pasting windows:**

- **To copy a window:** Click any enabled window in the Window list, then click the Window palette option menu and choose Copy Window.
- **To duplicate a window:** After copying a window, create another window of the same type that you copied, and then click the Window palette option menu and choose Paste Window.
- **To paste a window to another node:** Double-click or otherwise select another node, open the Window palette, choose the same type of window that you copied in the Window list, and then click the Window palette option menu and choose Paste Window.
Saving Window Presets

If you find there's a particular window shape or combination of windows that you use frequently, you can save one or more windows as a preset for easy recall whenever needed. For example, if you're working on a documentary within which you find you need to do a lot of face brightening, you can create preset face ovals for close-up, medium, and wide shots, to save you from having to customize a stock circular window for every single new shot. You can also save groups of windows together as a single preset, in order to reuse complicated multi-window shapes.

Window presets are available from a group of Presets controls in the upper right-hand corner of the Window palette.

Controls for saving, applying, and deleting window presets

Methods of working with Power Window presets:

- **To save a window preset:** Once you’ve created one or more windows you want to save, click the Create button, type a name into the resulting dialog, and click OK. That preset is now available in the Preset pop-up.

- **To recall a window preset:** Click to open the Shape Preset Browser, choose a preset from the list, and click Load. Loaded window presets overwrite whatever other windows were set up in that node.

- **To update an already saved preset:** Recall a preset, change the resulting window(s), then click to open the Window Preset Browser, and click the Save button overwrite the current preset with the altered window arrangement.

- **To delete a window preset:** Click to open the Shape Preset Browser, choose a preset from the list, and click the x button to the left the preset you want to delete.

Once recalled, windows created by presets can be modified and tracked just like any other window.
Using Windows and Qualifiers Together

Another use of windows is to act as a “garbage matte” when used together with a qualifier. By default, when you use a window and qualifier together, a key is only output where both the window and qualifier intersect. This makes it easy to exclude unwanted parts of a key that are too difficult to eliminate by further refinement of the qualifier controls.

For example, the following qualification is intended to isolate the woman’s face, but some of the similarly colored wood and sky in the background is also included.

Instead of driving yourself crazy trying to eliminate the unwanted parts of the key by modifying the current qualification, which is doing a great job of isolating the skin tones, you could instead use a window to isolate her face, excluding everything outside the window, and simplifying your job considerably.

A qualified image with highlight on

If she moves, then you can simply track the window to follow. Simple tracking is covered in Chapter 106, “Motion Tracking Windows.”

Now with additional Power Window isolation

Furthermore, you can use the window’s Invert control to do the reverse, excluding all qualified portions of the key inside the window, and including all qualified portions of the key outside the window.

If you need to build more complex qualifier/window combinations than this, you can add more windows, or you can use multiple qualifiers and windows with the Key Mixer node, which is discussed in Chapter 111, “Combining Keys and Using Mattes.”
Manipulating Windows Using a Control Panel

Window shape and position can also be manipulated using the DaVinci control panel. All Windows controls are located on the T-bar panel, except for the ADJ WINDOW button above the fourth trackball of the Center panel.

To enable, mask, or disable a window:
1. Press WNDWS on the T-bar panel. The Window palette should appear.
2. Press the soft key that corresponds to the type of window you want to turn on, CPW (Circular Power Window), LPW (Linear Power Window), PPW (Polygonal Power Window), or PCW (PowerCurve window). The appropriate window controls should appear with an orange highlight.
3. Press the MATTE/MASK soft key to toggle among turning the window on, turning Mask on, and turning the window off.

To reposition a window using the Pan and Tilt knobs:
1. Press the unlabeled soft key at the bottom-right of the T-bar panel to toggle between the current knob mappings on the T-bar panel, and the PAN and TILT mappings.
2. Use the Pan and Tilt knobs to adjust the window’s position.

To reposition a window using the fourth trackball:
1. If necessary, press WNDWS on the T-bar panel to open the Window palette.
2. Press ADJ WNDW, above the fourth trackball on the Center panel.
3. Use the fourth trackball to reposition the window.
4. When you’re finished, press ADJ WNDW again to exit adjust window mode.

To alter a window’s Zoom, Aspect, or Rotation:
Use the ZOOM, ASPECT, and ROTATE knobs on the T-bar panel.

To alter a window’s softness, do one of the following:
- For Circular and Linear windows: use the SOFTNESS knob on the T-bar panel.
- For Polygonal and PowerCurve windows: press the unlabeled soft key at the bottom-right of the T-bar panel to toggle between the current knob mappings, and the PAN, TILT, INSIDE SOFT, and OUTSIDE SOFT knob mappings.

To invert a window:
Press the INVERT soft key on the T-bar panel.
Chapter 114

Motion Tracking Windows

While Power Windows can be manually keyframed to follow a moving subject you want to isolate, this chapter shows how you can use the powerful cloud and point-based motion tracking controls in DaVinci Resolve to make Power Windows follow along with the motion of subjects and the camera in the fastest, easiest way possible. Then, numerous techniques are presented for dealing with complicated tracking scenarios and common problems that arise for subjects that are difficult to track.

Motion Tracking Windows

The Tracker palette has three modes, available from the Palette menu.

- In Window mode, the tracking controls let you match the motion of a window to that of a moving feature in the frame.
- In Stabilizer mode, the same underlying technology is used to smooth or stabilize the motion within the entire frame.
- In FX mode a Point Tracker can be used to animate ResolveFX or OFX plug-ins with positioning controls. For more information about the FX and Stabilizer modes, see Chapter 126, “Sizing and Image Stabilization.”

DaVinci Resolve has an incredibly simple, yet powerful, 3D cloud tracker that allows you to track quickly and accurately any Power Window (Circular, Linear, Polygonal, PowerCurve, or Gradient) to follow any moving feature. This avoids the need to use dynamic keyframes to manually animate a window’s position.

In particular, you can use the tracker to match a window’s position, size, rotation, and its pitch and yaw in 3D space to either foreground or background elements that move within the frame.

![Power Window tracking a woman's face; the motion path resulting from the track is shown as the wiggly white line](image)

Simple Tracking Using the Tracker Menu

The simplest way to track a feature using a Power Window is to use the commands found in the Playback menu. These commands include:

- **Track Forward (Command-T):** Tracks a window to a feature from the current position of the playhead forward, ending at the last frame of a clip.
- **Track Reverse (Option-T):** Tracks a window to a feature from the current position of the playhead backward, ending at the first frame of a clip.
- **Track Stop (Command-Option-T):** Interrupts any track. This is useful for letting you cancel a long track that goes wrong (the Stop button of a control panel stops tracking as well).

Most window tracks are easy to accomplish using these three commands.
To track any Power Window to match a moving feature within the frame:

1. Move the playhead to the frame of the current shot where you want to begin (you don’t have to start tracking at the first frame of a shot).

2. Turn on any window, and adjust it to surround the feature you want to track.
   Typically, you’ll have done this anyway, for example, framing someone’s moving face with a Circular window to lighten their highlights.

3. To initiate tracking, do one of the following:
   - Choose Color > Tracker > Track Forward (press Command-T).
   - Choose Color > Tracker > Track Reverse (Option-T).
   - On the T-bar panel of the DaVinci control panel, press OBJECT TRACK MODE, and then press either the TRACK FWD or TRACK REV soft keys on the Center panel.

DaVinci Resolve automatically opens the Viewer page, places a series of tracking points within the window you’ve created, and performs the track from the current frame; forward to the last frame or backward to the first frame.

DaVinci Resolve analyzes a cloud of tracking points that follow the vectors of every trackable group of pixels within the window you’ve created, and the results are fast and accurate. After tracking, the window you’ve placed automatically moves, resizes, rotates, and skews to match the motion of the feature you’re tracking.

Object tracking in progress. Tracking points are automatically placed over trackable features of the image

Once a clip has tracking data applied to one of its windows, a small tracking icon appears within that clip’s icon in the Thumbnail timeline.

A tracking icon in the top left corner of the Thumbnail timeline shows that clip has been tracked

If the track you’ve performed is unsuitable, you can reposition the window to cover a different area of the subject you’re trying to track, and initiate tracking again. New tracking data overwrites any previous tracking data applied to that window.

Once you’re satisfied with your track, you can continue to resize, reposition, or reshape the window being tracked. Tracking data is separate from the window transform parameters (which can be keyframed), so changes you make to a window offset it from the originally tracked path.
Tracking Windows When You’ll Be Exporting Media With Handles

When you track windows to match moving features in a clip, the windows are only transformed on frames with tracking data. In Round Trip workflows where you add handles to the graded clips you render for editorial flexibility in the footage you deliver, you need to make sure that you track all windows from the beginning to the end of these handles to make sure that, if an editor actually trims any of the clips you give them to use the handles, all windows are doing what they should.

An easy way to do this is to choose View > Show Current Clips With Handles to display each clip you select in the Timeline with handles defined by the “Default handles length” setting in the Editing panel of the User Preferences. Make sure that the “Default handles length” is equal to the handles you export using the “Add X Frame handles” option in the Render Settings list of the Deliver page. With each clip’s handles made visible in this way, you can easily track windows along every frame you’ll be rendering.

Simple Ways of Working With Existing Tracking Data

If there’s a portion of a shot that you haven’t tracked (for example, you started tracking at a later frame, or you ended tracking before the end of the shot), then the window you’re tracking remains wherever it was at the first or last frame that was tracked. If you want to fill in these gaps, you can always move the playhead to the first or last frame that was tracked, and then use the Track Backward or Track Forward command to track the rest of the frames in that shot.

Tips for Better Tracking

In situations where a feature changes shape in such a way as to confuse the tracker, you can try tracking a smaller part of the feature by using a smaller window. Once you’ve achieved a successful track, you can resize the window as necessary, and it will have no effect on the track that’s already been made.

Also, if you’re tracking a feature that moves behind something onscreen and disappears for the rest of the shot, there’s an easy way to avoid having an awkward window sitting in the middle of the scene. You can use dynamic keyframes to animate the Key Output Gain parameter (in the Key tab of the Color page) to fade from the correction’s full strength of 1.0 down to 0, the value at which the correction disappears, along with the window itself.

Tracking One Frame at a Time

You can click the “track one frame forward” or “track one frame backward” buttons in the Tracker palette to track a moving feature one frame at a time, making it easier to make adjustments to follow a difficult track when you’ve set tracking to Frame mode (by clicking the Frame button).

In Frame mode, you can keyframe window transformations to more faithfully conform to troublesome motion as you’re moving one frame at a time through the track; manual changes to a window’s position will be keyframed to create frame-specific transformations, rather than used to offset the entire tracked motion path as in Clip mode. When you add multiple keyframes in the Tracker graph, animation will be automatically interpolated from keyframe to keyframe.
**Copying and Pasting Tracking**

There will be plenty of times you’ll apply multiple windows to a single moving subject, such as a car, when you can use a single motion track for all the windows. Commands in the Option menu let you copy and paste track data from one window to another within the same node, saving time when you want several windows tracking together as one.

**To copy track data from one window to another:**

1. Open the Window palette, then select a window that has tracking applied to it (indicated by a tracking badge in the corner of the shape icon), and choose Copy Track Data from the Option pop-up.

2. Select another window, and choose Paste Track Data from the Option pop-up. Once you’ve copied track data from one window, you can paste it to as many other windows as you like.

You can also copy tracking from the FX mode of the Tracker palette and paste it to a window, in case you want to use the same tracking data for both an effect and a window.

**To copy track data from an FX track to a window:**

1. Open the Tracker palette, choose the FX mode that contains the tracking data you want to copy, and choose Copy Track Data from the Option pop-up.

Open the Window palette, select a window, and choose Paste Track Data from the Option pop-up. Once you’ve copied track data from one window, you can paste it to as many other windows as you like.

**Tracker Palette Controls in More Detail**

You can easily combine object tracking and keyframing to animate windows. For example, you’ll typically use object tracking to make a window follow the position and orientation of a moving feature, but you can add dynamic marks to the window track of the correction in the Color page with which to alter its size and shape to better conform to a feature’s changing form.

**Controls in the Window Tracker Palette**

Occasionally, you’ll run into a shot that doesn’t quite track well enough using the Tracker menu’s simple controls. In these cases, the Viewer page provides the complete set of object tracking controls that can be used to modify tracking operations in different situations.

The object tracking controls are divided into seven groups.
Tracker Palette Modes

The Tracker palette’s Option pop-up menu lets you choose between Window mode (for matching a window to the motion of a feature in the frame), and Stabilizer mode (for subduing unwanted camera motion. For more information on Stabilizer mode, see Chapter 126, “Sizing and Image Stabilization.”

Types of Tracking

A pop-up menu below the Tracker graph lets you choose whether to use the Cloud Tracker or the Point Tracker.

The tracker type pop-up

There are two options:

- The Cloud Tracker automatically analyzes all parts of the image for trackable points, and uses these to automatically figure out the motion in the shot that you want to use to move a Power Window or stabilize a shot. This tracker type is great for quickly tracking a window to match the movement of almost any feature, with a minimum of work.
- The Point Tracker lets you create one or more tracker crosshairs that you can manually position in order to track specific features in the shot. The more crosshairs you create and position, the more accurate the track can be. The Point Tracker is incredibly useful in situations where you need to follow the motion of a very specific feature in the frame. It can also be useful in cases where you want to stabilize a shot that has many subjects moving in different directions, and it’s difficult to obtain a good result with the Cloud Tracker.

Object Tracking

The object tracking controls provide the most basic tracking functions, some of which are mirrored within the Tracker menu.

Choose which type of transform you want to track before tracking

A series of five checkboxes let you turn on and off which transforms you’d like motion tracking to apply automatically to the window. These checkboxes must be selected before you perform a track in order to restrict the transforms that are used.

- **Pan and Tilt**: Enables tracking of horizontal and vertical position, when you want to transform a window to follow the location of a tracked subject.
- **Zoom**: Enables tracking of size, when you want to transform a window to resize to follow a tracked subject.
- **Rotate**: Enables tracking of orientation, when you want to transform a window to rotate with a tracked subject.
- **Perspective 3D**: Enables tracking of pitch and yaw in 3D space, when you want a window to skew to follow the orientation of a tracked subject within the scene. Good when you want the window to “stick” to a surface.
NOTE: Once tracking or stabilization has been done, disabling these checkboxes does nothing to alter the result. To make changes, you need to enable or disable the necessary checkboxes first, and then reanalyze the clip.

After you've defined the transforms you want to use for the track, the analyze controls let you proceed with the analysis of the subject being tracked.

- **Track One Frame Reverse button**: Motion tracks a single frame in reverse. Useful for slow tracking of difficult subjects that may require frequent correction.
- **Track Reverse button**: Initiates tracking from the current frame backward, ending at the first frame of the clip. Good for tracking backward when your best starting point is somewhere within the middle of the shot.
- **Pause button**: Stops tracking (if you're fast enough to click this button before tracking is finished).
- **Track Forward button**: Initiates tracking from the current frame forward, ending at the last frame of the clip.
- **Track One Frame Forward button**: Motion tracks a single frame forward. Useful for slow tracking of difficult subjects that may require frequent correction.

**Clip/Frame Controls**

Two buttons let you set how manual adjustments to the position of tracked windows affect the overall track.

- **Clip**: The default mode, in which changes you make to the position of a window are globally applied to the entire track. For example, if you track a feature, and then move the window, the window moves along a motion path that's consistently offset from the original track for the duration of the clip. Use this mode if you're happy with the track, but you want to modify the window's overall shape and position relative to the motion path it's following.
- **Frame**: In this mode, changes you make to the position or shape of a window create a keyframe at the frame at the position of the playhead. Multiple keyframes are interpolated to create animation with which you can manually transform a window to solve a variety of problems. This mode is useful for rotoscoping the shape and position of windows to match a subject that's tough to automatically track. Frame mode is also useful for making corrections to individual frames that were badly tracked, for animating windows to go all the way out of frame along with a subject, or for making manual, frame-by-frame adjustments to window position to cover untrackable sections.

**The Tracker Graph**

The Tracker graph provides a visual display of the tracking data that's being analyzed. Each of the transform controls that can be tracked has an individual curve, which lets you evaluate each tracked parameter on its own, and each curve is color-coded to match the corresponding label of the tracking transforms listed above.
A vertical slider to the right of the Tracker graph lets you scale the height of the curve data within to make it easier to see it all within the graph. Above the Tracker graph, a Timeline ruler contains a playhead that’s locked to the playheads in the Viewer and Keyframe Editor.

You can draw a bounding box in the Tracker graph with which to select a portion of one or more curves to delete sections of low-quality tracking data using the Clear Selected Keyframes command found in the Palette Options menu. To eliminate the current bounding box from the Tracker graph, click once anywhere within the graph.

**Interactive Mode Controls**

The Interactive controls, at the bottom-left of the Tracker palette, let you make manual changes to the automatically generated tracking point cloud that DaVinci Resolve creates when you’re tracking with the Cloud Tracker, so you can try different ways of obtaining better tracking results in challenging situations.

- **Interactive Mode checkbox:** Turns the Interactive tracking mode on and off. When you enter Interactive mode, you can manually alter the point cloud that DaVinci Resolve uses to track the feature within the current window. You’ll then make your track while in Interactive mode.
- **Insert:** Lets you add tracking points to whatever trackable features exist within a bounding box that you’ve drawn in the Viewer. Inserted tracking points are automatically placed based on trackable pixels in the image.
- **Set Point:** Lets you use the cursor (using the DaVinci Resolve control panel), to manually place individual tracking points, one by one, with which to track a feature. If there is no trackable pixel group at the coordinates where you placed the cursor, a tracking point will be placed at the nearest trackable pixel group.
  
  You must place at least two tracking points at different pixel groups to track rotation, and at least three to track zoom.
- **Delete:** Eliminates all tracking points within a bounding box that you’ve drawn in the Viewer.
Point Tracker Controls

If you’re using the Point Tracker, then the Interactive Mode controls disappear, replaced by the two controls of the Point Tracker.

- **Add Tracker**: Click to create a new tracker that’s automatically positioned in the center of the frame. Once created, you can drag it using the pointer to line up with the feature you want to track. You can create as many trackers as you like. Multiple trackers are all tracked at once.
- **Delete Tracker**: Select any tracker (selected trackers are red, deselected trackers are blue), and click this button to remove it.

Additional Commands in the Tracker Palette Options Menu

There are some additional commands located in the Palette Options pop-up menu.

- **Reset Track Data on Active Window**: Lets you delete the tracking data corresponding to the currently selected window.
- **Clear Selected Track Data**: When you drag a bounding box over parts of one or more curves in the Tracker graph, this command lets you delete that part of the graph. This is useful when you want to eliminate sections of low-quality track data. Portions of curves that are cleared in this way have linear interpolation automatically applied to them, similar to if you used the Keyframes Interpolation controls.
- **Delete Keyframe**: Deletes tracker graph keyframes at the current position of the playhead.
- **Clear All Tracking Points**: Clears the tracking points in the Power Window at the frame you are on.
- **Show Track**: Turn this checkbox on to show the motion path produced by the tracking you’ve done.
- **Copy Track Data**: Lets you copy track data from the currently selected window. Windows can be selected directly in the Viewer while the Tracker palette is open.
- **Paste Track Data**: Pastes copied track data to the currently selected window. Windows can be selected directly in the Viewer while the Tracker palette is open.

Cloud Tracker Workflows

The next few examples illustrate how to use the Tracker palette’s controls in practical situations. In many circumstances, objects passing in front of a tracked subject, known as “occlusions,” can cause problems. While the tracker in DaVinci Resolve is highly occlusion-resistant, the following sections show a variety of techniques you can use when an occlusion prevents you from getting a useful track.
Using Interactive Mode to Manually Choose Tracking Features

Interactive mode lets you manually remove or add tracking points to improve tracking performance in situations where the automatic image analysis in DaVinci Resolve provides unsatisfactory results.

For example, you can delete tracking points within a window that correspond to overlapping features you don’t want to track. Suppose a car that you’re tracking drives by a sign that partially obscures the car. Without intervention, the PowerCurve that’s isolating the car will deform improperly when the car moves along and then away from the sign.

Using Interactive mode, you can delete the tracking points that will overlap the sign you don’t want to track, improving the result.

To eliminate specific, unwanted tracking points from a track:

1. Open the Tracker palette.
2. Turn on the Interactive Mode checkbox.

3. In the Viewer, drag a box around the tracking points you want to eliminate within the window.

4. Click the Delete button.

The points within the selection area are deleted.
While Interactive mode is still on, click Track Forward or Track Reverse to track the subject using the remaining tracking points.

When you’re finished tracking, click the Exit Interactive button.

DaVinci Resolve goes back to using automatically placed tracking points.

In another interactive tracking example, you may sometimes run into situations where you want to eliminate all automatically placed tracking points altogether, placing your own in specific regions of the image.

To eliminate automatic tracking points, adding your own instead:

1. Open the Tracker palette.
2. Turn on the Interactive Mode checkbox.
3. In the Viewer, drag a box around all the tracking points in the window, and click the Delete button to eliminate all tracking points from the image.
4. Click the Delete button to eliminate all tracking points from the image.
Deleting tracking points

5 Drag a box around the specific area where you’d like to add new tracking points. In this case, you only want to track the top half of the woman’s face, since the bottom half is cut off by the fence posts.

6 Now, click the Insert Track Points button.

The Insert button of Interactive mode automatically adds tracking points within the current bounding box.

New tracking points are automatically added to whichever features are appropriate for tracking within the box you’ve drawn.

NOTE: If no appropriate tracking features can be found, no points will be added.

While in Interactive Object Tracking mode you may also choose to add tracking points one by one.
To add a single tracking point:

1. Open the Tracker palette.
2. Turn on the Interactive Mode checkbox.
3. Using the DaVinci control panel, press the CURSOR button above the fourth trackball of the Center panel, and move the onscreen cursor to the detail of the image that you want to add a tracking point to.
4. Click the Set Point button, within the Interactive mode controls of the Tracker palette. This adds a tracking point corresponding to the feature of the image that you clicked, and you’re ready to start tracking.

Dealing With Occlusions When Tracking

Sometimes you’ll find that you need to deal with a gap in the useful tracking data. For example, objects in the frame that pass in front of the feature you’re trying to track cause gaps in the tracking information for a clip.

In situations where a subject being tracked becomes totally occluded by another object in the frame, there’s an easy method of interpolating to cover holes in the available tracking data. In the following example, the woman walks behind another fence post, this time one that’s taller than she is. The window tracking her face will become completely lost at this point, but interpolation will help to salvage this shot.

Interpolating between two sets of tracking data to track past an occlusion:

1. Move the playhead to the first trackable frame of the moving feature you’re correcting, and create a Power Window that surrounds it.
2. Use Track Forward to track the feature as far as you can before it becomes obscured behind something else in the frame.
3 When the Power Window stops tracking the feature reliably, stop the track.

The Power Window is obscured by the post

4 Open the Tracker palette.

5 Click the Frame radio button to put the Tracker controls into frame-by-frame adjustment mode. This is an important step.

Selecting Frame mode

6 Move the playhead to the frame where the feature you’re tracking reappears from behind the occlusion, then drag the window so that it again overlaps the feature.

Moving the playhead and position the window

7 Use Track Forward to continue tracking the feature until the end of the clip. Alternately, you could have started from the end of the clip and used Track Reverse to track the feature as far as possible, if that’s easier.

Now that you’ve identified the gap in reliable tracking data for this clip, it’s time to set up the interpolation.

Notice the gap in the tracking data where the window was behind the post
Drag a bounding box over the portion of the curves in the Tracker graph that fall between the good tracking data at the beginning and end of the shot.

Click the Tracker palette option pop-up menu, and choose Clear Selected Track Data.

The portions of curves that you selected are deleted, and have linear interpolation automatically applied to them so that there’s no hole in the track data or the motion of the window, which now moves smoothly from the last outgoing frame of reliable tracking data to the first incoming frame of new reliable tracking data.

**Point Tracker Workflows**

As advanced as the Cloud Tracking that is the default in DaVinci Resolve is, there are times when it may be simpler to track using good old-fashioned crosshairs. The Point Tracker, introduced in DaVinci Resolve 12.5, makes it easy to track very specific features of a subject with motion you need to follow. Unlike the Cloud Tracker, which automatically looks for all trackable points within a region of the image that you identify using a window, the Point Tracker lets you create one or more crosshairs that you must manually position to overlap with whatever high-contrast features you want to track. This section covers the three main workflows you need to know to use the Point Tracker.

**Tracking a Window Using the Point Tracker**

The following procedure describes, in a general way, how to use the Point Tracker to track a moving subject and apply that motion to a Power Window.

1. Move the playhead to the frame of the current shot where you want to begin (you don’t have to start tracking at the first frame of a shot, since you can always track backward).
2. Turn on any window, and adjust it to surround the feature you want to track. Typically, you’ll have done this anyway, for example, framing someone’s moving face with a Circular window to lighten their highlights. You want to make sure that the window you want to apply the tracked motion to is selected before you begin tracking. In this example, we’ll be tracking a Circular window to follow the woman’s face.
3 Open the Tracker palette, and choose Point Tracker from the bottom right pop-up.

Choosing the Point Tracker

4 Before you start tracking, choose what types of motion you want to track and apply to the window you’re working on. You can choose from among Pan, Tilt, Zoom, Rotate or Perspective 3D. Which methods of transformation can be applied depend on how many points you add to track.

Choosing what type of motion to analyze

5 Click the Add Tracker button. A new tracker crosshairs appears in the Viewer in the center of the frame.

Clicking the Add Tracker button

6 Move the pointer directly over the tracker crosshairs, and when it turns into the move cursor, click and drag to move the crosshairs to line up on top of the feature you want to track. For the best results, this should be a high-contrast detail such as a corner, the end of a line, a small shape like a pebble, or a jagged detail. Unlike other point trackers, there is no inside or outside region to separately adjust, there’s only the one crosshairs that you need to align. In this example, this first crosshairs is placed at the inside of her stage left eyebrow (the corner of her eye would introduce too much jitter as the tracker will pick up her blinks).
7 If you want to improve the accuracy of your track, you can create more tracker crosshairs and position them on top of other details within the subject you’re tracking. For the best results, make sure that all crosshairs are placed onto details that are in the same plane of motion. In other words, don’t put some crosshairs on a person’s face in the foreground, and other crosshairs on a tree that’s far in the background, since both these features will have very different vectors of motion. In this example, trackers are placed at her inside eyebrows and at the corner of her lips.

8 When you’re done placing crosshairs, click the Track Forward or Track Backward buttons to initiate tracking. The clip will be analyzed, and the Tracker graph will update with the tracking data, and the window you had selected automatically moves to match the motion of the feature you’re tracking.
Removing Trackers

If you find that a particular tracker is causing problems, you can remove it by selecting it in the Viewer, and clicking the Delete Tracker button, before retracking the subject.

![Clicking the Delete Tracker button](image)

Using Frame Mode to Offset Track

A common issue when point tracking is how to deal with occlusions and times when the tracked feature moves off screen. In DaVinci Resolve, the solution is to use the Tracker palette’s Frame mode to move the tracker crosshairs onto another feature to track, while offsetting the resulting motion so that it continues to follow the original motion path.

1. In this example, a point tracker crosshairs has been positioned at a corner of a window of a building that’s being separately adjusted using a Power Window. The window is being used because, as the woman turns to leave, she covers up most of the other trackable outer edges of the building, which would ruin the track.

![Setting up to track a building moving off screen](image)

2. As the camera pans, the feature being tracked is about to go off frame, which is about to ruin the track. As this happens, click the Stop Track button.

![Stopping the track on the last good frame of the track, before the tracker goes off screen](image)
3 Move the playhead back to the last good frame of tracking, and then click the Frame button in the Tracker palette to go into Frame mode.

4 In Frame mode, you can now drag the tracker to another feature of the building, this time the outer edge of the roof, that will be better to follow as the building goes out of frame to the left, since the Power Window will go out of frame before the rightmost corner of the building’s roof does.

5 Now, click the Track Forward button again, and the crosshairs will begin tracking the new feature, but the motion will be offset, so the movement of the Power Window continues to follow the original motion path.

6 If you turn on the track path (in the Tracker palette Option menu), and move the playhead to the frame where you moved the tracker, you can see that the motion before you moved the tracker and the motion after continues smoothly along the same path, with no sudden breaks. When you’re finished, click the Clip button to get out of Frame mode.
Rotoscopying Window Shapes After Tracking

While the DaVinci Resolve trackers are pretty miraculous when it comes to making a window follow moving subjects, or elements within a moving scene, there will be plenty of times when the final track isn’t quite perfect. For example, if you’re trying to isolate someone’s face with a very specific window, and the person turns their head, then the resulting change of shape is almost certainly going to require you to make animated adjustments to the window in order to continue making such a specific isolation.
Fortunately, the Tracker palette’s Frame mode makes it easy to animate shape changes you make to windows in order to better follow a moving subject, a task often referred to as rotoscoping. By following the motion of a moving subject, and making a series of automatically keyframed adjustments to the window at every point the subject changes speed or direction, you can make a window isolate a moving target with surprising precision.

Furthermore, you can also use Frame mode to repair imprecise tracks where the window is veering off course because of quickly or irregularly moving features. In these cases, you have the option of manually tracking the window in Frame mode to fit the trajectory of the feature, frame by frame.

Lastly, you don’t even have to have performed a track to use the Tracker graph in Frame mode to keyframe animated changes to a window. In fact, using the Tracker graph in Frame mode can sometimes be more convenient than using the Keyframe Editor in Auto Keyframe mode, depending on what you’re doing.

**Rotoscoping Controls**

The Clip/Frame buttons determine whether or not you’re rotoscoping a shape.

- **In Clip mode:** Any changes you make to a window transform it over the entire duration of that clip. In other words, you can track a window to a moving feature, and in Clip mode any changes you make to the size, rotation, position, or shape of the window occur equally from the beginning to the end of that clip.

- **In Frame mode:** Changes you make to a window automatically create a keyframe at the bottom of the ruler in the Tracker graph. Making two or more changes to a window in Frame mode results in automatically interpolated animation from one keyframed window transformation to the next.

You can freely move back and forth between Clip to Frame modes to make changes to a window. Even if you’ve keyframed a window to change shape, you can turn on Clip mode and make an overall change to the window, enlarging it for example, that results in the window being equally enlarged at every keyframe.
**Keyframing in Frame Mode**

Once you've added keyframes to the Tracker palette, there are a number of ways you can edit them.

**Methods of working with keyframes in the Tracker graph:**

- **To add a keyframe:** Click the Add Keyframe button at the upper right-hand corner of the Tracker graph. It looks similar to the keyframe buttons found in the Edit page Inspector. This is useful for adding a keyframe to a frame where the window fits the subject well, prior to moving forward a few frames and making an alteration to the window to follow the subject that will generate another keyframe.

- **To move the playhead from one keyframe to another:** Click the Previous Keyframe and Next Keyframe buttons at the upper right-hand corner of the Tracker graph. These controls look similar to those found in the Edit page Inspector.

- **To delete a keyframe:** With the playhead on the same frame as the keyframe you want to delete, open the Tracker graph option menu, and choose Delete Keyframe.

**A Rotoscoping Workflow**

The following procedure demonstrates how to use a window to rotoscope an onscreen feature that you want to isolate. In the process, it shows how to set up a window for rotoscoping using the Tracker palette, and discusses some best practices for rotoscoping efficiently.

**To rotoscope or manually track a window using automatic keyframing:**

1. Create a window to isolate the feature you're wanting to adjust, and use the tracker to make it follow the motion of the subject. If the window doesn’t follow the contours of the subject as precisely as you require, then you can begin manually keyframing its shape on top of the tracking you've done to rotoscope the subject.

2. With the Tracker palette open, click Frame to change the tracking mode.

3. The best way to use Frame mode for tracking is to either start at the last successfully tracked frame and work your way forward, or start at the first successfully tracked frame and work your way backward. This takes the best advantage of the automatic keyframing and interpolation between keyframes to animate the window you’re transforming smoothly.

   With the playhead at either the first or last frame where the window fits the subject you’re isolating, you can either click the Add Keyframe button at the upper right-hand corner of the Tracker graph, or wiggle any control point by a pixel or two, to add a keyframe at that frame.
Clicking the Add Keyframe button in the Tracker graph

Adding a keyframe at the last frame where the window follows the subject’s motion well means that any future animated changes you make interpolate from this frame forward, rather than from previous frames where there’s no need for alterations.

Adjusting the window in Frame mode adds a keyframe

While you’re in Frame mode, the changes you make to the window automatically generate a keyframe in the Tracker palette, which appears at the bottom of the Tracker graph’s timeline.

Keyframes appear in the Tracker graph ruler

It’s frequently essential to add a keyframe at the last frame where a window conforms well to the subject you’re trying to isolate, in order to limit window animation from that frame to the next keyframed transformation, rather than accidentally animating from the beginning of the clip, or from the next or previous keyframe in the Tracker graph.

Next, move the playhead to the next frame where the window requires adjustment to better fit the moving subject, and adjust the position of the window, the control points of the window, or both to isolate the subject as necessary.

Readjusting the window in Frame mode to follow the subject’s motion
This results in a second keyframe being placed in the ruler of the Tracker graph.

5 With your first two keyframes placed, scrub the playhead back and forth between them to evaluate how well the window's animation is automatically interpolating to fit the motion of the subject you're isolating. If the window doesn't follow the motion of your subject well enough, move the playhead to the frame where the window divergence is the most pronounced and make another adjustment to correct the shape.

6 When you're finished making adjustments between your first two keyframes, move the playhead farther along and add keyframes as necessary to make the window follow the motion of your subject.

In general, look for the frames where your subject’s motion starts, stops, speeds up, slows down, or changes direction. As you work, it’s good to try and add the fewest number of keyframes you can to ensure smooth motion from one to another. Too many keyframed adjustments made too close together for a smoothly moving subject risks adding jerky motion if you’re not careful. On the other hand, if you have an erratically moving subject, you may have to add more keyframes, possibly frame by frame, to achieve the desired result.
TIP: If you’re isolating a subject with a complex shape that moves quite a lot, you might consider using multiple simple overlapping shapes to track and rotoscope it, rather than a single complicated one, to make the task easier.

When you’re finished rotoscoping the window, be sure to click the Clip button to switch back to Clip mode, so you can trim the window’s shape across every keyframe you’ve just created, if necessary. This will also prevent you from accidentally adding more keyframes if you select other shapes.

This technique requires a bit more work than simply using the Tracker, but it’ll let you quickly adjust the animation of a window to more tightly conform to a moving subject when you need an adjustment to be specific to that subject alone. You can also use this technique to reposition specific motion path points in the middle of an otherwise successful track to make them fit better, or to add keyframes to the beginning or end of a track when the subject moves offscreen but the window does not.

Viewing a Window’s Motion Path

You can turn on the motion path of the window you’re tracking by choosing Show Track from the Tracker palette’s Option menu, or by pressing the SHOW TRACK soft key on the Center panel of the DaVinci control panel when you’re in OBJECT TRACK MODE.
Chapter 115
Using the Gallery

The Gallery provides a way to save, browse, and use saved still frames from different clips in a program. Each project is saved with its own individual set of stills, and each still you save consists of a DPX image of the saved frame, and the grade metadata. You can use saved stills for reference when matching one clip to another, or you can use them to copy grades to other clips, or other timelines.

There are two ways to work with the contents of the Gallery. The Color page has a small Gallery, to the left of the Viewer, that provides quick access to saved stills and grades as you work. The Gallery window, which can be opened via a button at the top right of the Gallery, provides a dedicated interface for organizing your grades, copying grades and memories between projects, and for accessing a dedicated collection of DaVinci Resolve looks.

Using the Gallery

The Gallery in the Color page and the expanded Gallery window environment share many of the same commands for organizing stills. However, the commands for saving stills and customizing split-screen views are restricted to the Color page.

Saving Stills

One of the most common operations is to save a clip as a still (with that clip's embedded grade) for future reference and use.

To save an individual still in the Color page, do one of the following:

- Choose View > Stills > Grab Still (Option-Command-G).
- Right-click on the Viewer and choose Grab Still.
- Press GRAB STILL on the Transport panel of the DaVinci control panel.

It's also possible to save stills automatically for every clip in the entire Timeline. This can be useful if you're planning to export a set of grades to hand off to another colorist, or if you need to apply a series of grades manually from one project to another when ColorTrace™ won't work.

To save a still for every clip in the current timeline, right-click the Viewer, and choose one of the following:

- Grab All Stills > From First Frame: The first frame of each clip is saved to the Gallery.
- Grab All Stills > From Middle Frame: The middle frame of each clip is saved to the Gallery.
- Grab Missing Stills > From First Frame: Only the first frame of clips with no stills in the Gallery are saved to the Gallery.
- Grab Missing Stills > From Middle Frame: Only the middle frame of clips with no stills in the Gallery are saved to the Gallery.
By default, when you save one or more stills, they’re named “TrackNumber.ShotNumber.
VersionNumber” with dots separating each number. If you like, you can choose an option from
the General Options panel of the Project Settings to “Automatically label Gallery stills” in
different ways. This is covered in more detail later in this chapter.

Selecting Stills

To select a range of stills, do one of the following:

• Click one still, then Shift-click another to select a contiguous range of stills.
• Command-click any stills you like to make a noncontiguous selection.
• Right-click any still, and choose one of the following commands:
  – Select All: Selects every clip in the Gallery.
  – Select Current to Last: Selects every still from the one you’ve clicked through the
    last still in the Gallery.
  – Select First to Current: Selects every still from the one you’ve clicked through the
    first still in the Gallery.

Deleting Stills

If you need to remove one or more stills, this can only be done using the Gallery’s
contextual menu.

To delete one or more stills, do one of the following:

1. Select one or more stills in the Gallery.
2. Right-click one of the selected stills and choose Delete Selected.

Each still is also saved with a variety of metadata that is used by DaVinci Resolve to manage the
contents of the Gallery in different ways. This metadata can also be used for searching and
sorting, and is viewable by opening the Still Properties window.

To display a still’s properties:

Right-click a still in the Gallery and choose Properties.

A floating translucent window appears displaying the date the still was created, what clip it was
grabbed from, when it was grabbed, and the source and record timecode values of the frame it
came from.
Where Are Stills Saved?

By default, all grades/stills you save are saved in the DPX format, and are placed in the directory path defined in the “Gallery stills stored at” field in the Working Folders section of the Master Settings panel of the Project Settings. This path defaults to a hidden “.gallery” directory that’s created at the location of the first Media Storage Volume you specify in the Media Storage panel of the System Preferences window.

Changing the PowerGrade Still Directory

Optionally, you can change the location where PowerGrade stills are saved by Opening the Gallery Option menu and choosing Change PowerGrades Path. You’ll be prompted via a “Select PowerGrades Folder” dialog to choose a directory where all PowerGrades will be saved.

Live Previews of Gallery Stills

The Live Preview option, found in the Gallery option menu, lets you preview how the current clip would look with a particular Gallery Still grade applied to the currently selected clip simply by moving the pointer over the still you want to preview.

Enabling and Disabling the Gallery Live Preview:

1. Open the Gallery option menu and choose Live Preview.

   ![Image](image.png)

   The Live Preview option for the Gallery browser lets you hover over a saved grade to preview it on the current clip in the Viewer.

2. Click a node in the Node Editor you want to preview applying the grade from a still to. The live preview will display how the current clip will appear with the grade of the still you select applied to the currently selected node of current grade, which will affect the result.

3. Move the pointer over the still you want to preview.

   The Viewer image updates to show how that clip would look with that still’s grade applied to the currently selected node.
Hover Scrub in the Gallery

When Live Preview is enabled in the Gallery option menu, the Hover Scrub Preview submenu lets you choose how you want Live Preview to be shown by a thumbnail in the Gallery and in the Viewer when you hover the pointer over a still or LUT in the LUT Browser:

- You can choose to scrub both the thumbnail you’re hovering over and the Viewer, letting you preview the current still’s grade or a LUT over the duration of the current clip in both the thumbnail and Viewer.
- You can choose to scrub just the thumbnail, leaving the Viewer to show just the grade or LUT over the frame at the position of the playhead.
- You can disable scrubbing altogether, in which case both the thumbnail and the Viewer will only show the grade or LUT over the frame at the position of the playhead.

The Hover Scrub Preview options when Live Preview is enabled

Playing Stills and Setting Up Image Wipes

There are many ways to play a still in the Color page, making it visible as an image wipe in the Viewer and on the external display connected to your video interface.

To play a still, displaying it as an image wipe or full screen, do one of the following:

- Double-click a still in the Gallery.
- Select a still in the Gallery, and click the Image Wipe button on the top Viewer toolbar.
- Click a still in the Gallery, then right-click in the Viewer and choose Show Reference Wipe.
- From the View menu, choose Next Still (Option-Command-N) or Previous Still (Option-Command-B) to select a still in the Gallery, and then choose Wipe On/Off (Command-W) to play it.
- Press PREV STILL or NEXT STILL on the Transport panel of the DaVinci control panel to select a still, then press PLAY STILL. Press PLAY STILL again to dismiss the still.

Whenever you play a still, the Viewer mode’s pop-up menu changes to Split mode. Once displayed, the wipe between the current clip and the still being referenced can be moved and reoriented in different ways. If you want a full-screen view so you can flip back and forth between the still and the current clip, simply adjust the split until the still fills the entire Viewer.

To adjust a wipe in the Viewer, do one of the following:

- Drag the pointer within the Color page’s Viewer to move the wipe.
- Push the T-bar lever up and down on the T-bar panel of the DaVinci control panel.
To customize the type of image wipe that's displayed in the Viewer, do one of the following:

- Click any of the controls at the top right of the Viewer toolbar to choose Horizontal, Vertical, Mix, Alpha, Box, and Difference types of wipe.
- Choose Gallery, Timeline, or Offline from the View > Reference Wipe Mode submenu, or the Viewer contextual menu.
- Choose Horizontal, Vertical, Mix, Alpha, and Difference from either the View > Wipe Style submenu, or the Viewer contextual menu.
- Choose View > Invert Wipe, or right-click the Source Viewer and choose Invert Wipe from the contextual menu to reverse each half of the wipe.

Timeline Wipes

A timeline wipe is when you use the Wipe Timeline Clip command in the Thumbnail timeline (it's found in the contextual menu when you right-click a clip other than the current clip) to wipe the current clip against another clip in the Timeline, without needing to save a still first. When you turn a timeline wipe on, the clip in the timeline that's being wiped is outlined in blue.

Gang Timeline Wipe With Current Clip

A "Gang timeline wipe with current clip" option, available from the Viewer option menu, lets you maintain the offset between the current clip and a timeline clip you're wiping against when you move the current clip selection to other clips. With this option enabled, the offset between the timeline wiped clip and the current clip is maintained when you move the clip selection. When this option is disabled, the timeline wiped clip stays where it is regardless of what clip you select.

Change a Timeline Wipe Using the Timelines Album of the Gallery

While you're using the Wipe Timeline Clip to show a wipe of the current clip against any other clip in the Timeline, you can open the Timelines album of the Gallery and click different clips to change which Timeline clip you're wiping against (outlined in blue) without changing the current clip (outlined in orange).

Labeling and Searching for Stills and Sources

By default, all stills are identified by a three-number code. The first number is the video track the clip is on, the second number is the clip's position number in the current Timeline, and the third number is the version number of the grade.
If you’ve saved many stills, it can help to label the important ones with whatever text you find helpful. Once labeled, you can search for stills by label using the Search field, at the upper right-hand corner of the Gallery.

**Automatic Labeling**

If you like, you can choose an option from the Color group in the General Options panel of the Project Settings to “Automatically label Gallery stills” in different ways. There are many options:

- **Clip Name:** Saves the Clip Name, which defaults to the File Name unless you’ve customized it.
- **Clip Version Name:** Automatically saves the name of the current version.
- **Source timecode (HH.MM.SS.FF):** Saves the source timecode of the current frame.
- **Timeline timecode (HH.MM.SS.FF):** Saves the timecode for the playhead's position in the Timeline.
- **Timeline Name:** Saves the name of the currently open Timeline.
- **Display LUT Name:** Saves the name of the currently used Display LUT, if one is applied.
- **Custom label using tags:** Choosing this option reveals a field you can use to either type custom text into, or in which you can use metadata variables to save automatically updated information relating to the currently selected clip and timeline.

For more information about using metadata variables, see Chapter 165, "Using Variables and Keywords."

For all options, there’s also a checkbox you can toggle:

- **Append still number on export:** Turning this checkbox on lets you choose how to include the default still number when exporting stills with the “Use labels on export” option enabled, either as a prefix or suffix.

**Manual Labeling**

Sometimes the easiest thing to do is to just give a particular still a custom name that’s representative of what that still represents, such as “SeemedLikeAGoodIdea.” When naming stills manually, it’s best to avoid using the forward slash character in case you find yourself exporting these stills with file names. In fact, it’s a good idea to avoid using the forward slash character for just about any text that you add in DaVinci Resolve.

**To manually label a still:**

1. Right-click a still in the Gallery and choose Change Label.
2. Type a name into the Change Still Label dialog, and click OK.

The new label appears underneath the still number.

You can also label stills for easier identification.
Searching For Stills

Once labeled, you can search for stills you need in the Gallery.

To search for a still by label:
Click the Magnifying Glass button to open the Search field, click to place the cursor within, and then type the name or description you are searching for.

As soon as you start typing, DaVinci Resolve automatically begins to filter the results of the currently selected album in the Gallery to match what’s been typed.

Match Reference Wipe Frame

You can right-click any Gallery still and choose Match Reference Wipe Frame to automatically move the playhead to the exact frame that corresponds to that still, and select that clip in the Color page Timeline.

Gallery Options

When you right-click the gray area of the Gallery, behind the Still icons, you can open a contextual menu that provides a variety of additional options for controlling how many stills are saved, how they’re displayed, and how they’re arranged in the Gallery. There are the following options:

- **Switch Wipe Mode:** Switches the Reference mode between showing a “Gallery” still, a “Timeline” clip, or an “Offline” reference movie.
- **Trace Timeline:** When enabled, selecting a clip in the Timeline also automatically selects the first still that was saved from that clip to the Gallery.
- **One Still Per Scene:** When enabled, restricts the Gallery to save only a single still for each clip in the Timeline. If multiple stills have already been saved before turning this option on, those stills will remain in the Gallery until you save another still from the same clip, at which time all other stills from that clip will disappear.
- **Apply Display LUT:** If you have a Display LUT selected in the Lookup Tables panel of the Color Management panel of the Project Settings, it’s applied to the video output via a connected video interface, and also to the Viewer. Ordinarily, you don’t also want the Display LUT applied to stills you’re saving since it’s meant to be temporary. Accordingly, stills are saved with a LUT-free image. However, in instances where you may also want to save a reference to the currently used Display LUT, turning on “Apply Display LUT” saves the Display LUT along with the still, and applies that LUT when that still is used for split-screen reference. Keep in mind that the internally saved Display LUT is only used when playing that still in the Viewer; the DPX image that’s saved remains unaffected.
- **Sort Stills By:** Choosing an option from this submenu changes the sort order of all clips in the Gallery. The options are:
  - **Record Timecode:** Sorts all stills by their position in the program.
  - **Source Timecode:** Sorts all stills by the timecode of the source clip they came from.
  - **Create Time:** Sorts stills based on when you saved each still.
  - **Clip and Create Time:** A two-level sort; stills are sorted primarily based on the ID number of the clips they came from, and secondarily based on the time they were created.
• **Apply Grades Using:** This submenu contains three options for how to apply the keyframes that are automatically saved within each saved grade.
  - **No Keyframes:** No keyframes are copied. The state of the grade at the frame used to save the still is what is applied to the target clip or clips.
  - **Keyframes aligning Source Timecode:** Keyframes are copied aligning the source timecode of the saved grade with the source timecode of the target clip. This is the ideal setting when you’re copying a grade back to the clip it came from originally, or to a duplicate of that clip elsewhere in the Timeline, and you want the keyframes to align with the same frames as before. If there is no source timecode overlap, keyframes will be pasted aligning with the start frame of the edit, the same as the third option (below).
  - **Keyframes aligning start frame of edits:** Keyframes are copied aligning the start frame of the clip that still was saved from with the start frame of the target clip. This is the ideal setting when you’re copying a grade with keyframes from one clip to a completely different clip, with different timecode.

• **Use labels on still export:** Lets you use labels that you’ve added to stills in the file name of exported stills.

• **Show All Stills:** This command shows all available stills in the current album if any have been hidden, for example by searching or by using the Show Current Timeline Only command.

• **Show Current Timeline Only:** Choosing this option restricts the Gallery to only showing the stills that were saved from the currently selected Timeline. All other stills from other Timelines are hidden until you switch to that Timeline.

**NOTE:** There are a variety of other commands available in this contextual menu that are covered elsewhere in this chapter.

**Organizing Stills Using Albums**

All stills you save are always placed into the currently open album of the Gallery, which defaults for new projects to “Stills 1.” However, you can create additional albums with which to organize your stills into whatever categories you require. Albums can be shown, created, and removed using the Gallery in either the Color page or Gallery windows.

To show or hide the Albums list:

Click the Album button, at the top left of the Gallery.
If the Albums list was hidden, clicking the Album button will make the Albums list appear, to the left of the Gallery, containing all albums that are currently available in the project that’s open, as well as the PowerGrade album at the bottom. If the Albums list is already visible, then it becomes hidden, making more room for still thumbnails in the Gallery.

Once you’ve displayed the Albums list, there are a variety of ways you can quickly and easily work with albums.

**Methods of working with albums:**

- **To add a new album:** Right-click the Albums list, and choose Add Still Album from the contextual menu. A new album is created, numbered incrementally.
- **To add a new PowerGrade album:** Right-click the Albums list, and choose Add PowerGrade Album from the contextual menu. A new album is created, numbered incrementally.
- **To rename an album:** Double-click any album in the list, and when it is selected, type a new name and press Return.
- **To navigate albums:** Click any album to make it the current album. Using the DaVinci control panel, you can use the PG UP/GALLERY/PG DOWN button; press SHIFT UP and GALLERY to move to the next album up the list, or press SHIFT DOWN and GALLERY to move to the next album down the list.
- **To move clips from one album to another:** Drag and drop a still from the Gallery to an album.
- **To remove an album:** Right-click any album, choose Remove Current Album, and click Delete at the prompt. All clips inside that album will be deleted along with the album, so use this carefully.

**PowerGrade Albums**

PowerGrade albums are meant to be repositories for grades you want to reuse frequently, or for stills that you need to reference from multiple projects, such as when grading a series that shares common looks from episode to episode.

Unlike stills saved to the other albums in the list, which are ordinarily available only to the project in which they were saved, stills saved to a PowerGrade album are shared among all projects that have been stored within a particular database. Each database has its own unique PowerGrade album.
Creating a new database creates a new PowerGrade album, which starts out as a clean slate. However, you can always use the Gallery window to copy PowerGrade stills from other projects and databases to the current one, and you can create as many PowerGrade albums as you need to organize your grades. For more information about project management and databases, see Chapter 2, “Managing Projects and Databases.”

Functionally, PowerGrade albums are identical to any other album, and you can save, organize, and use stills in PowerGrade albums as you would with other albums. Since PowerGrade albums are special in that they're maintained by DaVinci Resolve, the last PowerGrade album cannot be deleted.

**Browse All Grades From the Current Timeline**

The Gallery has a Timelines album, available at the bottom of the Album list, that lets you browse all the grades in the current timeline, or in other timelines of the current project (using a pop-up menu that appears at the top of the Gallery browser area), making it easy to copy grades from earlier or later in your timeline, or from other timelines that share the same media.

This is particularly useful for reality shows or documentaries where the same clips can appear multiple times in different parts of a program. Being able to simply show all existing grades in the Gallery frees you from having to save a still for every grade you think you might eventually reuse.

![The Timelines grade browser in the Gallery automatically shows all grades in the current timeline](image)

**The Gallery Management Window**

While you can do quite a lot of stills management using the Gallery as it appears in the Color page, the Gallery window provides additional functionality for copying stills among different projects and databases, for organizing your stills and memories, and for accessing the DaVinci Resolve looks that accompany the application.

**To open the Gallery window:**

- Click the Open Gallery button at the upper right-hand corner of the Gallery.
The Gallery opens into a floating window, divided into four areas:

- **Stills navigator:** Lets you navigate the contents of other projects and databases that are available. Independent projects, as well as database > user > project relationships, appear in this hierarchical list. Click the disclosure triangle next to any item on this list to reveal its contents. Click any project in the list to reveal its albums and stills in the Group Stills browser.

- **Group Stills browser:** Displays the contents of the currently selected item in the Stills navigator. One or more selected stills can be copied to the current project by selecting an album in the Project Stills browser, and dragging and dropping the selected stills to the Project Stills browsing area.

- **Project Stills browser:** Contains the same Album list and Project Stills browser that’s visible in the Color page Gallery.

- **Project Memories:** Provides a larger view of the project memories that are visible in the Color page Gallery.

**To resize different areas of the Gallery window:**

Move the pointer to the border between any areas of the Gallery. When the pointer changes to the resize cursor, drag the border to resize the adjacent interface areas to whatever size you need. Dragging all the way to the edge of the screen hides that interface area completely.

**What’s Available in the Stills Navigator**

The Stills Navigator accesses a variety of content via a hierarchical list. Disclosure triangles to the left of each item in the Stills browser let you access the contents of each item, and many items have several nested levels of content within, each accessed by its own disclosure triangle.
The Gallery Stills database show all projects connected so you can import those stills

- **DaVinci Resolve looks**: A collection of predefined grades, categorized by type, that provides excellent examples of different looks available in DaVinci Resolve. These grades are installed with DaVinci Resolve and cannot be altered.

- **Databases**: Each database that’s available appears within this list. Each database has a nested series of users, projects, and timelines within, as well as one nested PowerGrade item for each user, which provides access to the saved stills within.

- **Orphans**: Stills are saved to a separate directory which is defined in the Master Settings panel of the Project Settings. Whenever you delete a database, the stills that corresponded to that database become orphaned. All orphaned stills that lack a connection to any current database appear within the Orphan item in the Stills Navigator.

### Browse and Import Timeline Grades From Other Projects

The Gallery window lets you see and import grades in the timelines of other projects, even if they weren’t saved as stills first. When you open the Gallery Window and use the hierarchical disclosure controls of the Stills panel to open up and select a specific Database > User > Project > Timeline, you’ll see at least three browsable albums to the right: the Stills galleries that were created, the Memories, and at the bottom an album called Timeline Media. The Timeline Media album lets you browse the currently used grades for every clip in that timeline, making it easy to copy the ones you need to the current project’s Stills album or Memories.

This is particularly useful if you’re working on a series where and you find that you want to re-use different grades, looks, adjustments, or fixes from previous episodes in the current one. Previously, you’d have to remember to save every clip as a still to be able to browse the grades in this way. Now you can simply browse the clips in the Timeline directly.
Importing and Exporting Stills

It’s possible to import still images in different graphics formats into the Gallery, which can be particularly useful when a client provides reference images to which they’d like you to refer. It’s also possible to export stills from the Gallery, which is good for sending a series of reference stills for approval to a remote client. In both cases, you can choose whether to import or export images with an accompanying LUT.

For both import and export, DaVinci Resolve supports the following file formats: DPX, CIN, TIFF, JPEG, PNG, PPM, BMP, and XPM.

To import one or more still images:
1. Right-click anywhere on the gray background of the Gallery.
2. Choose one of the following commands:
   - Import: Imports image files, along with a matching DRX file, if one is present in the selected directory.
   - Import With Output LUT: Imports an image and DRX file, along with a matching LUT file, if one is present in the selected directory.
3. When the Import Stills dialog appears, choose the type of files you want to import from the “Files of type” pop-up menu, then navigate to the files you want to import, select them, and click Import.

To export one or more still images:
1. If you want to export Gallery stills with labels that have been added to them, right-click anywhere in the background of the Gallery and choose “Use labels on still export” in the contextual menu so it becomes checked.
2. Right-click one of the selected stills, and choose one of the following commands:
   - Export: Two files are saved for each still you selected. An image file in the format of your choice, and a DRX (DaVinci Resolve eXchange) file that contains the grading metadata that was saved with that Gallery still.
   - Export With Display LUT: If you have a Video Monitor Lookup Table specified for the current project in the Color Management panel of the Project Settings, this command will output the image as it is processed by the specified LUT. A DRX file is also output containing the grading metadata that was saved with that Gallery still.
When the Export Stills dialog appears, choose a file format to export to from the "Files of type" pop-up menu, then choose a location, type a name into the Save As field, and click Save.

Each of the selected stills is exported with all accompanying files. Each file uses as its prefix the name you typed into the Export Stills dialog, followed by an underscore, the still ID number of the selected still, and the three-letter file extension.

Using and Organizing Memories

Stills and memories contain identical information, and can be split screened, copied, appended, exported, and can display their node graph just like any other still. However, stills that are assigned as a memory make them easier to access via keyboard shortcuts, and from dedicated buttons on the DaVinci control panel.

Memories are hidden by default, but you can reveal them by clicking the Memories button, to the right of the Gallery list button at the top-left of the Gallery.

The Memories thumbnail display makes it easy to keep track of which stills have been assigned to which memories in situations where you're using multiple memories to copy grades throughout a program.

To copy stills and memories back and forth, do one of the following:

- Drag a still onto a memory bank.
- Drag a memory into the Gallery.

**TIP:** In this way, memories can be used to copy stills from one album to another.

To save the current clip's grade to a memory for future use, do one of the following:

- Choose Color > Memories > Save Memory A–H (Option-1 through 8).
- Using the DaVinci control panel, press CRNT on the Transport or T-bar panel, then press the letter of the memory bank you want to save to. Use the SHIFT UP button to save to another memory sharing the same button.
- If you save a grade to a memory that already contains something, the previous memory is overwritten.
To apply a memory to the current clip in a timeline, do one of the following:

- Right-click a memory and choose Apply Grade.
- Choose Color > Memories > Load Memory A–H (Command-1–8).
- Using the DaVinci control panel, press the letter of the memory bank you want to apply. Use the SHIFT UP button to apply a memory that shares the same button.

To clear a memory:

Right-click a memory, then choose Clear.
Chapter 116

Grade Management

The Color page offers numerous ways of saving grades, copying grades, creating and altering groups of clips to share grades, rippling grades and adjustments, and managing multiple versions of grades. All of these procedures enable you to work faster by leveraging work you’ve already done to apply to other clips that can benefit from the same adjustments, or by applying changes across multiple clips all at once.

Using Versions to Manage Grades

Working quickly requires a mastery of the numerous grade management features built into DaVinci Resolve. These features are designed to help you copy and ripple grades to individual clips, among manually defined groups of clips via the Node Editor’s Clip mode, or among automatically linked clips that share the same source clip in the Media Pool (when using Remote versions). Multiple versions of grades are supported for every clip, as are various options for previewing, overwriting, and appending these versions.

Choosing to Copy Grades Manually or Automatically Using Versions

Each grade you apply to a clip is a version. Each clip can have multiple versions, although only one version can be applied at a time. By default, the first grade applied to every clip in a timeline is a local version named “Version 1.” A clip’s version name and/or number appears underneath the clip thumbnail, to the right. You can also see the version name, along with a list of all the other versions that are currently available to that clip, by right-clicking a clip in the Timeline and looking for the version names that appear underneath the Local Versions submenu.

NOTE: Double-clicking the version name underneath a clip's thumbnail in the Timeline toggles the version names to the codec used by each clip. Double-click again to toggle back.

There are two different types of versions in DaVinci Resolve, each of which provides a different method of grade management and linking among the clips and timelines of a project.

- **Local versions**: The default mode of grade management. Clips using local versions are unlinked, so each clip has its own grade which is not shared with any other clips in any other timelines. Changing the grade of a clip using a local version has no effect on any other clip in that project.

- **Remote versions**: An alternate mode of grade management that you can enable. All clips using remote versions that share the same source clip in the Media Pool are automatically linked, in all timelines, and share the same set of grades.
If you use local versions to grade all your clips, you don’t have to worry about one clip’s grade being accidentally copied to other clips that happen to come from the same file in the Media Pool, which can make it easier to work. On the other hand, you need to manually copy every grade that you want to duplicate, even among clips that clearly come from the same take or angle. You can always create a group to share a grade among clips using local versions, but that’s an extra step.

Switching to use remote versions, instead, puts you into a mode where clips using remote versions that share the same media file are automatically linked together. This gives you a convenient shortcut for grading your program, since a grade that’s applied to one linked clip is automatically copied to every other clip it’s linked to, which can be convenient when grading a series of headshots appearing throughout a program that come from the same interview take. Another use of remote versions is when you’re importing a new edit of an already graded timeline. Using remote versions, you can set your project up so that new incoming timelines are automatically relinked to the previous timeline’s grades.

The only disadvantage to using remote versions is that when you find you need to make individual adjustments to clips that are linked, it’s an extra step to either create another version, or switch that clip to use a local version, in order to keep its adjustment separate. This will be discussed in more detail later in this chapter.

Mixing Versions

Each clip is capable of having multiple local and remote versions at the same time; you get to choose which to apply. Which type of versioning is best depends on the type of project you’re working on, the way in which the media was shot, and how you like to work. The following sections explain the differences in workflow.

Using Local Versions by Default

Since local versions are the default method of grading when you first create a new project (unless you’ve edited your settings presets), you don’t need to do anything to enable this mode at first. As the name implies, local versions are local to the Timeline in which they appear, so local versions are not rippled to linked clips, and they’re not shared among different timelines. This makes it easy to avoid accidentally having grades copied when you don’t want them to be, but you lose the conveniences that automatic linking can provide.

However, you can always switch the clips in a timeline to use remote versions if you change your mind, either individually, or all together.

Using Remote Versions to Enable Automatic Linking

Remote versions let all clips from the same source media file in the Media Pool share their grades automatically, either within a single timeline, or across multiple timelines in the same project. However, to enable the convenience of remote grades, you need to put DaVinci Resolve into this mode of working using the Settings window.

To enable remote grades to be used:

1. Open the Project Settings, open the General Options panel, and turn off “Use local version for new clips in timeline” in the Color section.

Turning this option off only affects clips that are added to Timelines from that point onward. You can keep track of which clips use remote versions by the (R) that appears when you double-click the area underneath the thumbnail to hide the codec name in the Thumbnail timeline.
Turning off “Use local version for new clips in timeline” to enable remote grades to be used by default

How Automatic Linking Works

When clips using remote versions have been added to a timeline, any other clips in any timeline that (a) use remote versions also, and (b) refer to the same file in the Media Pool are linked. Selecting a clip using a remote grade in the Color page that is automatically linked to one or more clips displays a small "linked" badge at the right of that clip’s timecode in the Thumbnail timeline.

TIP: The Timeline Filtering pop-up in the Color Page toolbar has an option named “Common Media Pool Clips” that only shows clips in the Timeline that are linked to the currently selected clip.

Adjustments that you apply to a remote version of one linked clip are automatically rippled to every other clip it’s linked to, which can save you an enormous amount of time when you’re getting started with a new program. For example, if every reverse angle from the same take in a particular angle of coverage is automatically linked using remote versions, then the grade you apply to one reverse angle clip will ripple to every other reverse angle clip throughout the Timeline.

Timeline with three automatically linked clips shown, and codec names hidden to reveal the (R) that shows these clips are using remote grades
So long as remote versions are enabled, there are other ways that linked clip relationships are formed. If, after conforming an AAF, XML, or EDL, you used the Split Clips button in the Color page to split one conformed clip into many, each of the clips you split would be linked, since they too would share the same source media in the Media Pool.

Finally, automated linking also occurs for clips that appear in multiple timelines that also use remote versions. As a result, the grade you apply to one linked clip is automatically rippled to every other clip it's linked to.

**NOTE:** Media management or media consolidation operations that split large source media files into many individual media files will defeat automatic linking within the same timeline, since each clip will be conformed to its own individual media file.

---

**Starting with Remote Versions, Then Switching to Local Versions**

It's possible to combine the best aspects of remote and local versions into a single workflow, taking advantage of your ability to freely switch from one to the other. Since remote versions make it easy to copy grades among clips that are similar, you can switch to using remote versions first, and then grade your way through the Timeline until you get to the point where you need to start making much more specific changes to individual clips. Then, it's easy to either switch each linked clip that needs individual adjustment to use a local version, or to use the Copy Remote Grades To Local command (described later) to copy the current remote version of each and every clip to a local version, at which point you can make all the specific tweaks you need to without worrying about changes being accidentally copied.

---

**Creating a Master Timeline**

DaVinci Resolve version 9 and earlier would automatically create a Master Timeline whenever you added clips to the Media Pool. This changed in versions 10 and later, which by default have no Master Timeline. However, if you want to create a Master Timeline in order to use it as you would have before, this is easy to do.

If you want a Master Timeline to have a single timeline that always contains all clips currently in the Media Pool, there's a way you can create one. However, you need to do it immediately upon creating a new project, before adding any media to the Media Pool. Once you've added one or more clips to the Media Pool, the option you need to do so will be disabled.

**To create a new Master Timeline:**

1. Create a new project, open the General Options panel of the Project Settings, and turn on the “Automatically match master timeline with media pool” checkbox in the Color section. If you also want all clips to use Remote versions as you grade by default as in previous versions of DaVinci Resolve, you can turn off the “Store grade with local version by default” checkbox.
2. Click Save.
4. When the New Timeline Properties window appears, turn the Empty Timeline checkbox off, and click Create New Timeline.

Now, in addition to the new Timeline, a Master Timeline appears in the Timeline list.
Once created, the Master Timeline contains every clip in the Media Pool of the current project. If you color correct the clips in the Master Timeline, you’ll find there’s only one set of versions available, found underneath the Local submenu of the Color Page timeline’s contextual menu. It’s important to understand that local versions within the Master Timeline are in fact the remote versions found in every other timeline of that project.

In fact, it would be fair to say that the remote versions found in other timelines are actually the Master Timeline’s versions. When you grade a clip in the Master Timeline, those grades ripple out to every other instance of that clip, in every other timeline within that project, via remote versions.

Sharing of remote versions among the Master Timeline and newly conformed timelines is why you can grade a collection of clips that you import into DaVinci Resolve without any editorial structure, grade and output offline media, and then reimport a project file that relinks to the original clips along with their grades. It’s also why you can grade clips in one timeline, and then import additional re-edited timelines via AAF, XML, or EDL, which automatically inherit all remote versions of grades that were created in previous timelines.

**Differentiating Clips with Individual Versions**

If you’ve enabled DaVinci Resolve to add clips with remote versions, there are times when you may want to suspend automatic linking. As convenient as automatic grade rippling among linked remote versions is, there are many instances where you may need to stop it. For example, if the Media Pool contains a source media file with the entire content of an interview, then every clip that has been conformed to that source media will be linked, which is ordinarily good since you’d expect they’d all share the same grade. However, if the DP fiddled with the exposure of the camera in the middle of the interview, such that some clips are lighter and others are darker, you may find yourself needing to make different adjustments to clips from different parts of the interview.

One way of doing this, which can be useful in timelines where you only need to make a few of these kinds of changes, is to create a new remote version for every clip to which you need to make individual adjustments. Since each version is its own grade, and differently named versions don’t link to one another, this is a simple solution.

**To suspend linking by creating a new remote version:**

1. Move the playhead to the clip you need to alter individually.
2. Do one of the following:
   - Choose Color > Grade Version > Add (Command-Y).
   - Right-click the thumbnail in the Timeline, and choose Remote Versions > Create New Version.
   - Using the DaVinci control panel, press ADD VERSION on the T-bar panel.

3. Grade the new version that’s appeared.

While this method works well, keep in mind that multiple linked clips using the same version number will always be linked with one another. In other words, suppose Clip 1, Clip 3, and Clip 5 are linked using the default Version 1, which has a strong blue grade applied.
Then, you set Clip 3 to use Version 2 with a different grade, tinted red. Clip 3 is now unlinked from Clips 1 and 5.

Setting the second of the three clips to use another version with a different remote grade sets it apart.

However, switching Clip 5 to also use the red-tinted Version 2 means that Clip 3 and Clip 5 are now linked together, but Clip 1 is no longer linked.

Setting the third of these clips to share the same remote version as the second clip now links those two together, omitting the first clip.

Every new remote version you create, and every change you make, becomes available to all other clips in all other timelines that comes from the same source Media Pool clip as the shot you’re working on. However, any clip can use any version, and which version is used by a linked clip is not rippled.

For example, Timeline 1 contains a clip named Max CU, which has three remote versions. Timeline 5 also contains Max CU, which is currently set to use Version 2. If you open Timeline 1 and add one more remote version to Max CU, that new version will also be available to Max CU in Timeline 5, but it will still be set to use Version 2.

**Switching Clips Between Local and Remote Versions**

You can also suspend remote version grade linking by switching individual clips to use local versions. This makes it easy to create a situation where some clips are linked, and other clips are not. Keep in mind that each clip has both local and remote versions, so you can switch from one to the other without losing anything.

**To suspend linking by setting individual clips to use a local version:**

- Right-click a clip thumbnail, choose the submenu of the corresponding remote version you want to copy, and choose Copy to Local. The remote version is copied to a local version, which now appears as the current version that’s used.

You can also set every clip in the entire timeline to use local versions. If you switch an entire timeline to local versions, then no clip in that timeline will be linked to any other unless you create a group (covered later in this chapter). This is the default state, but it’s useful even when you’ve switched to using remote versions when you want to grade one timeline differently from the others in a project, for example when doing a trim pass for another video or stereo 3D format, or when grading another cut, such as a trailer, that uses the same media but requires a different look.
To suspend linking by switching from remote versions to local versions:
Right-click any clip thumbnail, and choose one of the following commands:

- **Use Local Grades**: Switches all clips to their local versions. If there are already local versions defined for each clip, those will appear. If there are no local versions yet defined, each clip will be ungraded.

- **Copy Remote Grades to Local**: Copies the currently assigned remote version of each clip to a local version.

Because Undo is used only for individual clip operations, the Use Local Grades and Copy Remote Grades To Local commands cannot be undone. However, switching a timeline from remote to local versions is not a one-way trip. You can select Use Remote Grades to switch every clip in a timeline back to the remote versions at any time.

To switch a timeline back to using remote versions:
Right-click any clip thumbnail, and choose Use Remote Grades.

Furthermore, you can also copy the local grades you made to be remote grades, for instances where you started grading with local grades, and you want to switch to remote grading using your local grades as a starting point. Be aware that when you do this in a timeline with many clips that share the same source media, the grade of the very last shared clip in the Timeline will be the only remote grade that’s used for those auto-linked clips.

To copy each clip’s local grade to a remote grade for every clip in the current timeline:
Right-click any clip thumbnail, and choose Copy Local Grades to Remote.

If you’re switching back and forth between local and remote versions, keep the following rules in mind:

- If you select Use Remote Grades, change your remote grades, and then Copy Remote Grades To Local on that timeline again, you’ll overwrite all of your previously graded local versions. This is a good workflow if you don’t like what you’ve done with your local versions, and you want to start over by recopying the remote versions.

- If you select Use Remote Grades, change your remote grades, and then select Use Local Grades, you’ll return to your previously graded local versions, as they were before you selected Use Remote Grades. This is a good workflow if you just want to switch back to your remote versions in order to copy the remote versions of specific clips to local versions.

**Working with Versions**

Each clip can have as many local and remote versions as you like. There are commands for creating, renaming, and deleting the versions that are available to each clip when using the pointer, keyboard shortcuts, or the DaVinci control panel. When using the DaVinci control panel, the buttons affect whichever type of version (remote or local) is currently applied to the current clip.

Additionally, DaVinci Resolve 15 introduced the ability to batch create, rename, load, and delete versions for multiple clips that are selected at the same time.

To create a new local or remote version quickly for one or more selected clips, do one of the following:

- Choose Color > Grade Version > Add (Command-Y).

- Using the DaVinci control panel, press ADD VERSION on the T-bar panel.
A new version is created, identical to the type of version that was previously selected (remote or local), named “Version x” where x is the number of the versions that have been created. All keyframes and motion tracking are copied from the previously selected version to the new one.

**To create a new version for one or more selected clips, with the option to set a name and whether to copy keyframes:**

1. Right-click one of the selected clip thumbnails, and choose one of the following:
   - Local Versions > Create New Version
   - Remote Versions > Create New Version

2. Type a name for the version in the dialog that appears, and choose either “Copy all marks” or “Copy the first mark only,” depending on whether or not you want to copy all the keyframes into the new version.

   **NOTE:** Motion tracking will be copied regardless of whether “Copy all marks” is selected or not.

3. Optionally, you can choose one of the preset version names from the pop-up list. These names are defined in the Versions section of the General Options panel of the Project Settings.

4. Click OK.

**To delete a specific version for one or more selected clips:**

Right-click one of the selected clip thumbnails, choose the submenu of the remote version you want to delete (it can’t be the currently selected version), and choose Delete.

**To delete all versions for one or more selected clips:**

Right-click one of the selected clip thumbnails, and choose one of the following commands from the contextual menu corresponding to the scope of the versions you want to delete:

- Local Versions > Delete All Versions
- Remote Versions > Delete All Versions
- Delete All Versions

All versions are deleted as specified, except for the currently selected version, which is now the only one remaining.

**To load a particular remote or local version for one or more selected clips, do one of the following:**

Right-click one of the selected clip thumbnails, choose the submenu of the corresponding remote version you want to copy, and choose Load.

**To rename the version of one or more selected clips:**

1. Right-click one of the selected clip thumbnails, choose the submenu of the corresponding remote version you want to rename, and choose Rename.

2. In the Version Name dialog, type a name into the text field. Optionally, you can choose one of the preset version names from the pop-up list. These names are defined in the Versions section of the General Options panel of the Project Settings.
Selecting a Version name from the dropdown list, the names on the list come from assignments made using the Versions section of the General Options panel of the Project Settings.

3 Click OK.

That name now appears underneath the clip thumbnail in the Timeline.

If you’re going to use predefined names for versions, you need to define these in the Versions group of the General Options panel of the Project Settings. Ten pop-up menus let you choose from preset version names, or enter your own. These names will appear in the pop-up menu of the Version Name dialog.

The Versions section of the Project Settings

The Importance of “Version 1”

There are specific operations in DaVinci Resolve where “Version 1,” otherwise known as “the default version,” is the only version that’s used, regardless of how many other versions are available, or which version was previously selected. The default version can be named anything you want, but whatever its name, the default version is the first version in the list, and it’s important. Here are some examples:

- **Importing additional timelines that use the same clips:** In this case, if you’re importing timelines and “Use local version for new clips in timeline” is disabled in the Color section of the General Options panel of the Project Settings, then only the default version of each clip is relinked.

- **Whenever you switch a timeline between local and remote versions:** In this case, every clip in the Timeline will be switched to the default version, regardless of what you had selected previously.
Consequently, if you plan to reconform your clips to a newer version of the edit that you’re importing, or pursue other workflows that are off the beaten path, it’s a good idea to make sure, no matter how many versions you end up creating, that the most important grade is always copied back to the default version.

**To copy any version quickly to the default version:**
1. Choose Color > Memories > Save Memory A (Option-1). You can use any memory you want, but Memory A is convenient for this example.
2. Choose Color > Default Version (Command-U).
3. Choose Color > Memories > Load Memory A (Command-1) to apply the saved memory to the default version.

**To copy any version quickly to the default version using the DaVinci control panel:**
1. Press CRNT and then press A (or any memory button you like). These controls are available on either the Transport or T-bar panel.
2. Press DEFAULT VERSION on the T-bar panel.
3. Press A (or whichever Memory button you used) to apply the saved memory.

**To jump immediately to the default version, do one of the following:**
- Choose Color > Default Version (Command-U).
- Press DEFAULT VERSION on the T-bar panel.

**Deleting Unused Versions**
In cases where you want to make absolutely sure there’s no alternative to the grade you want a clip to have, there’s an easy way to delete all versions except for the version that’s currently in use, thereby making it the default version.

**To eliminate either local or remote versions except for the current version:**
1. Choose the local or remote version you want a clip to use.
2. Right-click the thumbnail of the clip you want to eliminate extra versions from, and choose Delete Unused Versions from the contextual menu.
   
   If you selected a local version, all unused local versions will be deleted, but remote versions will be left alone. Similarly, if you selected a remote version, all unused remote versions will be deleted, but local versions will be left alone.

**To eliminate all other local and remote versions except for the current version:**
1. Choose the version you want a clip to use.
2. Right-click the thumbnail of the clip you want to eliminate extra versions from, and choose Delete All Versions from the contextual menu.

Regardless of whether you selected a local or remote version, all other local and remote versions not in use will be deleted.

**Rendering Versions**
When the time comes to render your clips in the Deliver page, each clip's currently selected version will be rendered. If you need to render a different version for a given clip, you can either make sure it's selected in the Color Page timeline before you open the Deliver page, or use the Versions submenu in the Color mode of the Deliver page Thumbnail timeline. This contextual menu also provides access to the Stereo 3D commands, the Edit PAR (Pixel Aspect Ratio)
command, and a command for updating the Render Window Timeline thumbnails to reflect any changes you’ve made in case they haven’t updated automatically.

Additionally, the Commercial Workflow output option, located in the Deliver page, provides a method of rendering multiple versions for each clip when outputting your project in Source Order (as individual media files). There are two additional options in the Version submenus of each clip in the Thumbnail timeline contextual menu that let you control which versions are rendered when you use Commercial Workflow.

- **Render Disabled:** Turning this option on excludes that version from being rendered when Commercial Workflow is enabled.
- **Render Flat Pass:** Turning this option on forces the selected version to render with the grade turned off, essentially outputting the original media.

For more information on rendering versions using the Commercial Workflow option, see Chapter 158, “Rendering Media.”

### Copying Grades

There are various methods you can use to copy grades from one clip to another. Which is appropriate to your need depends on your style of working with DaVinci Resolve.

#### Protecting Adjustments with the Copy Grade Options

Before going into the myriad of ways that grades can be copied from one clip to another, you should know of a series of options, available from the contextual menu of the Gallery (right-click anywhere in the gray area of the Gallery), that let you carefully specify grading, sizing, and stereo data to be preserved when overwriting grades in clips you’re copying to. There are three options:

- **Copy Grade: Preserve number of nodes:** Lets you choose 0–10 nodes to be protected when applying a grade. When set to 1, the first node of the copied grade is ignored, but all other nodes are copied. When set to 5, the first five nodes of a copied grade are ignored, as long as there are at least five nodes in the grade of the clip you’re copying to. This option is useful for colorists who routinely use the first few nodes for shot matching and scene balancing, with additional nodes applying individual or stylistic adjustments.

- **Copy Grade: Preserve Camera Raw Settings:** When enabled, the camera raw Source settings of the current clip are preserved, letting you apply stylistic grades from unrelated clips without overwriting clip-specific source settings.

- **Copy Grade: Preserve Input Sizing:** When enabled, Input Sizing adjustments are not overwritten by those of the copied grade.

- **Copy Grade: Preserve Convergence:** When enabled, Convergence adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.

- **Copy Grade: Preserve Floating Windows:** When enabled, Floating Windows adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.

- **Copy Grade: Preserve Auto Align:** When enabled, Auto Alignment adjustments in the Stereo 3D palette are not overwritten by those of the copied grade.

- **Copy Grade: Preserve Dolby Vision™ Analysis Metadata:** When enabled, Dolby Vision Analysis Metadata is not overwritten by that of the copied grade. Only available if you’re set up to do Dolby Vision grading. For more information, see Chapter 7, “Data Levels, Color Management, and ACES.”
- **Copy Grade**: Preserve Dolby Vision™ Trim Metadata: When enabled, Dolby Vision Trim Metadata in the Dolby Vision palette is not overwritten by that of the copied grade. Only available if you're set up to do Dolby Vision grading. For more information, see Chapter 7, “Data Levels, Color Management, and ACES.”

### Clip Grades and Timeline Grades in Saved Stills

Every time you save a still into the Gallery or a memory, it contains both the Clip grade, and the Timeline grade, if one is applied. Which grade is applied when you copy from a still depends on which mode you’re in, which is selectable from the pop-up menu in the upper right-hand corner of the Node Editor.

![Node Editor Clip and Track selector](image)

If you’re in Clip mode, you’ll only copy the saved clip grade. If you’re in Timeline mode, you’ll only copy the saved timeline grade.

### Choosing Which Aspect of a Grade to Copy with All/Color/Sizing

When copying grades using the techniques described in this section, you can use the All/Color/Sizing setting that are available via the Keyframe Timeline Mode submenu of the Mark menu, the pop-up menu that’s visible at the upper-right of the Keyframes Editor, or your control panel. When copying a grade in conjunction with the settings in this menu, the following rules apply:

- **All**: When All is selected, both the grade and the sizing are copied.
- **Color**: Only the grade is copied, the target clip retains its original Input Sizing settings.
- **Sizing**: Only the Input Sizing is copied, the target clip retains its original grade.

### Choosing How to Copy Keyframes

When working with saved grades that have keyframes, you can choose how these keyframes are copied via a setting in the Gallery contextual menu. There are three options:

- **No Keyframes**: No keyframes are copied. The state of the grade at the frame used to save the still is what is applied to the target clip or clips.

- **Keyframes Aligning Source Timecode**: Keyframes are copied aligning the source timecode of the saved grade with the source timecode of the target clip. This is the ideal setting when you're copying a grade back to the clip it came from originally, or to a duplicate of that clip elsewhere in the Timeline, and you want the keyframes to align with the same frames as before. If there is no source timecode overlap, keyframes will be pasted aligning with the start frame of the edit, the same as the third option (below).

- **Keyframes Aligning Start Frame**: Keyframes are copied aligning the start frame of the clip that still was saved from with the start frame of the target clip. This is the ideal setting when you're copying a grade with keyframes from one clip to a completely different clip, with different timecode.
To control how keyframes are copied when you're copying grades:
Right-click anywhere in the gray background area of the Gallery, and choose one of
these options from the Apply Grades Using submenu.
From that point on, keyframes, should they exist, will be copied using the selected method
whenever you copy a grade using any of the previously described methods.

Copying Grades Using the Mouse
An incredibly easy way of copying a grade from one clip to another, or from a still or memory in
the Gallery to a clip, is by using the third button of your mouse, usually mapped as the
“middle-click” of the mouse scroll wheel.

To copy a grade from a clip or still to one or more clips using the pointer:
1 Select the clip thumbnail you want to copy the grade to in the Timeline; a single
selected clip appears highlighted orange. If you want to copy a grade to several clips,
you can either Command-click multiple non-adjacent clips, or Shift-click a continuous
range of clips; multiple selected clips appear highlighted red.
2 Middle-click the clip thumbnail, Gallery still, or memory you want to copy the
grade from.
The grade of the clip you middle-clicked is copied to the previously selected
clip or clips.

TIP: If you’re using a trackpad, third-party software may allow you to define a “three-
finger-click” that works the same as mouse button 3. If you’re a pen and tablet or
trackball user, you may be able to define a stylus or other button to perform the same
button-3 action.

If you don’t have access to a middle-click on the pointing device you’re using, there’s another
way of doing this using a contextual menu command.

To copy a grade from a clip or still to one or more clips using the Apply Grade command:
1 Select the clip thumbnail you want to copy the grade to in the Timeline; a single
selected clip appears highlighted orange. If you want to copy a grade to several clips,
you can either Command-click multiple non-adjacent clips, or Shift-click a continuous
range of clips; multiple selected clips appear highlighted red.
2 Right-click the clip thumbnail, Gallery still, or memory you want to copy the grade from,
and choose Apply Grade from the contextual menu.
The grade of the clip you middle-clicked is copied to the previously selected
clip or clips.

Copy Forward Commands
Another simple way of copying grades is to use the equals (=) and minus (–) keys on the
keyboard to copy grades forward from one or two clips behind the currently selected clip. This
is a great way to copy grades in scenes with a shot-reverse-shot structure, where you’re cutting
between two angles of coverage, each of which uses the same grade.
To copy grades forward:
- To copy a grade from one clip back: Choose Color > Apply Grade From One Clip Prior, or press Equals (=).
- To copy a grade from two clips back: Choose Color > Apply Grade From Two Clips Prior, or press Minus (–).

To copy grades forward using the DaVinci control panel:
- To copy a grade from one clip back: Press Comma (,).
- To copy a grade from two clips back: Press Colon (:).

Copying Using Memories
Memories are virtually identical to stills, except that they're labeled with a letter (A–Z) for easy access via keyboard shortcuts or DaVinci control panel buttons. A memory bank above the Gallery browser provides a visual reference of which saved grade is assigned to which letter. This makes it easy to keep track of multiple saved memories in instances where you’re copying them to several different clips throughout a scene or program.

For example, you might save a memory for each angle of coverage in a complicated scene, making it easy to copy grades forward. In another example, you might save a memory for the grade applied to each interview subject’s headshot in a documentary, so you can copy that grade forward as you work through the documentary.

To save the current clip’s grade to a memory for future use, do one of the following:
- Choose Color > Memories > Save Memory A–H (Option-1–8).
- Using the DaVinci control panel, press CRNT on the Transport or T-bar panel, then press the letter of the memory bank you want to save to. Use the SHIFT UP button to save to another memory sharing the same button.

If you save a grade to a memory that already contains something, the previous memory is overwritten.

To apply a memory to one or more clips in a timeline, do one of the following:
1. Choose one or more clips in the Thumbnail timeline to copy to. This can be the current clip, or it can be a range of clips that you select by Command-Clicking or Shift-Clicking.
2. Do one of the following to copy a grade to the selected clips:
   - Right-click a memory and choose Apply Grade.
   - Choose Color > Memories > Load Memory A–H (Command-1–8).
   - Using the DaVinci control panel, press the letter of the memory bank you want to apply. Use the SHIFT UP button to apply a memory that shares the same button.

To clear a memory:
Right-click a memory, then choose Clear.

Copying Using Preview Memory
You can also preview the effect of a memory or saved grade on the current clip, with the option to either keep it if it works, or go back to the previous grade if it doesn’t.
To Preview Memory:

1. Move the playhead to a clip for which you want to preview a memory.
2. Choose Color > Preview Memory (Option-Shift-P).
3. Do one of the following:
   - Right-click any saved still in the Gallery and choose Apply Grade.
   - Choose Memories > Load > Memory A–H (Command-1–8).

   The selected grade or memory is now being previewed.

4. Now, do one of the following to either accept or reject the memory:
   - If you like the effect, then you can leave it be and move on to another clip.
   - If you don’t like the effect, then choosing Color > Preview Memory (Option-Shift-P) again reverts the clip to the original grade.

To Preview Memory using the DaVinci control panel:

1. Move the playhead to a clip on which you want to preview a memory. You can use the PREV SCENE and NEXT SCENE buttons to move quickly.
2. Press PVW MEM on the T-bar panel, and then press the letter of the memory bank you want to preview. Use the SHIFT UP button to apply a memory that shares the same button.
3. Do one of the following:
   - If you like the grade you’re previewing, there’s no need to do anything else. Simply move to another clip and continue working.
   - If you don’t like the grade you’re previewing, press PVW MEM again and the clip’s grade will revert to its original state. Pressing PVW MEM repeatedly toggles the current clip between its original and the previewed grade.

Copying from Stills in the Gallery

As mentioned previously, each still you store in the Gallery contains the grading information as well as the image of the frame it was saved from. This saved grade can be applied to any clip in the Timeline.

**IMPORTANT** Copied grades overwrite any previously existing grades on the clip or clips you copy to.

To apply a grade from a still to one or more selected clips in a timeline:

1. Choose one or more clips in the Thumbnail timeline to copy to. This can be the current clip, or it can be a range of clips that you select by Command-clicking or Shift-clicking.
2. Do one of the following to copy a grade to the selected clips:
   - Right-click a still in the Gallery and choose Apply Grade.
   - Middle-click a still in the Gallery.
   - Double-click a still to wipe it in the Viewer against the current clip in the Timeline, then right-click the Viewer and choose one of the options from the Apply Grade submenu.
To apply a grade from a still to the current clip using the DaVinci control panel:

1. Select the clip you want to copy a grade to using the PREV SCENE or NEXT SCENE buttons of the Jog/Shuttle panel.
2. Press NEXT STILL or PREV STILL to select the still with a grade that you want to copy from.
3. Press PLAY STILL to wipe the selected still against the current clip.
4. Press SHIFT UP and then press PLAY STILL to copy the grade from the selected still to the current clip.

Append Node Graph

You can also append a saved grade to any clip in a timeline. This adds the entire node graph of the saved still to the end of the node tree of the current clip. In other words, the current clip’s grade isn’t overwritten, the applied grade is added to the end of it.

By planning ahead, you can save fragmentary grades that create specific effects or adjustments using only a few nodes. You can then use these fragmentary grades as a toolkit that you can add to other grades in order to mix and match different adjustments and effects.

For example, you could create a three-node glow effect, save it, and then apply that effect at the end of a completely different clip’s grade.

Appending grades places them after the original nodes

To append a saved grade or memory as individual nodes, do one of the following:

- Drag a still or memory from the Gallery onto a connection line in the Node Editor; when the plus icon appears, drop it and its nodes will be appended within the node tree starting at that connection.
- Right-click a still or memory in the Gallery, and choose Append Node Graph.

Ordinarily, when you append the node graph from a memory or still to another node graph, you end up adding a whole shedload of new nodes. This may be exactly what you need, but in situations where you want to keep things a bit tidier, you also have the option of appending node graphs as compound nodes.
To append a saved grade or memory as a compound node:

Command-drag a still or memory from the Gallery onto a connection line in the Node Editor; when the plus icon appears, drop it and its nodes will be appended to the node tree as a single compound node.

**NOTE:** When you append the nodes from a gallery still to a grade, how keyframes are applied depends on the “Apply Grades Using” setting of the Gallery. For more information, see Chapter 115, “Using the Gallery.”

To append a saved grade or memory using the DaVinci control panel:

1. Select the clip you want to append a grade to using the PREV SCENE or NEXT SCENE buttons of the Jog/Shuttle panel.
2. Press NEXT STILL or PREV STILL to select the still with a grade that you want to append.
3. Press PLAY STILL to wipe the selected still against the current clip.
4. Press SHIFT UP and then press NEXT STILL to append the nodes of the grade from the selected still to the current clip.

Once you’ve appended a compound node, you can open it up to access and modify its contents as you would any other compound node. For more information on compound nodes, see Chapter 117, “Node Editing Basics.”

**Aligning Keyframes to a Specific Frame While Copying Grades**

If you need to copy a grade with keyframes so that the start keyframe of the copied grade aligns with a specific frame of the Timeline, you can do so using the following procedure:

**To copy a grade and align its keyframes to a specific frame of the Timeline:**

1. Save a grade with keyframes as a Gallery still by right-clicking the Viewer and choosing Grab Still.
2. Choose the clip you want to copy the saved grade to in the Thumbnail timeline.
3. Double-click the Gallery still to wipe it against the current clip in the Viewer.
4. Move the playhead to the frame of this clip you want the first keyframe of the saved grade to be aligned with.
5. Right-click the Viewer and choose Apply Grade > Align Keyframes to Current Frame.

**Copying Individual Nodes and Settings**

Copying grades from clip to clip copies everything except for keyframes and motion tracking. However, there is one way you can copy the motion tracking from one clip to another, and that’s by copying and pasting individual node settings. This can save time when you’re assembling complicated node trees by recycling specific nodes or node settings from previous grades.
Copy settings from one node to another

The simplest thing you can do is to copy all of a node’s settings, and paste them into another node. This makes it easy to duplicate things like windows, qualifier settings, keyframing, or motion tracking that you want to reuse in another node as the basis for another operation. This is also a quick way to manually ripple a change you make in a node to that same node in another clip’s grade.

To copy a node’s settings from one clip to another, do one of the following:

- Option-drag one node onto another. When you drop it, the settings of the node you dragged overwrite those of the node you dropped onto.
- Select a node with settings you want to copy and choose Edit > Copy (Command-C). Then, select a node you want to paste these settings to either in the current grade or in the grade of another clip, or create a new node, and choose Edit > Paste (Command-V) to paste the settings you copied. These pasted node settings overwrite any other settings that node previously used.

Paste Attributes on the Color Page

You can copy the settings of one node and paste a subset of those settings to another selected node by choosing Edit > Paste Attributes (Option-V). A Paste Attributes window appears that shows you which node you’re copying from, and which node you’re pasting to, and provides controls for choosing whether you want to paste keyframes and how to align them (Start Frames or Source Timecode), as well as a series of checkboxes for choosing which palettes, windows, and OFX/ResolveFX you want to apply. You can only paste all parameters from a specified palette; there’s no current provision for pasting specific parameters from within a given palette, with the exception of pasting specific windows and their accompanying trackers.
Copying From the Node Graph of Other Clips or Gallery Stills

When constructing new grades, you may sometimes find it convenient to copy existing nodes or node settings from the grade of another clip or gallery still. This can be easily accomplished by exposing the node tree of any still that’s saved in the Gallery, or any clip in the Thumbnail timeline, and using the controls found in the floating node graph to copy individual nodes or node adjustments to the current clip’s grade shown in the Node Editor.

Copying Clip Settings Using Display Node Graph

In Clip mode, the floating Node Graph window has four sets of controls you can use to choose how to copy nodes and adjustments:

- **Clip Node Graph:** By default, the Clip node graph is displayed at the left. You can drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node’s settings or onto a connection line to insert it as a new node.

- **Timeline Node Graph:** (Only available if there is a Timeline grade) You can switch to the Timeline grade, if there is one, by either clicking the second button in the Node Graph title bar, or by choosing Timeline from the pop-up menu at the upper right-hand corner of the floating Node Graph window.

- **Apply Color/PTZR/Source/All buttons:** With the Clip panel selected, four buttons let you selectively copy the entire grade, the sizing, the source settings, or all settings at once to the current clip.

Copying Node Settings Using Display Node Graph

In Node mode, the floating Node Graph window displays all of the available Color Attributes found within each node, instead of the Apply Color/PTZR/Source/All buttons:

- **Node Settings:** Use the checkboxes to choose which node adjustments get copied and which do not. After you’ve checked the settings you want to selectively copy, dragging a node from the floating node graph onto nodes in the Node Editor copies or appends the selected attributes into the target node, leaving all other attributes alone. For Windows and OpenFX, you have the option of also copying any motion tracking that’s available.
The Node panel open with the Color Corrector and Blur attributes selected for copying.

**Ability to Open Compound Nodes in “Display Node Graph”**

When you right-click a Gallery still or a thumbnail and choose Display Node Graph for a grade that uses compound nodes, you can right-click any compound node and choose “Show compound node,” or Command-double-click a compound node to open it and see its individual nodes.

Opening a compound node in a floating Node Graph window

**How to Copy Nodes Using Display Node Graph**

The following procedures describe how to open the floating node graph in different situations.
To copy individual nodes or settings from any still in the Gallery:

1. Click the thumbnail in the Timeline of the clip you want to copy nodes to. Its node graph will appear in the Node Editor.

2. Right-click a still in the Gallery you want to copy nodes from, and choose Display Node Graph. A floating Node Graph window appears displaying that still’s node tree.

3. (Optional) While the Gallery Node Graph window is open, you can select any other still, and this window will update to show the currently selected still’s node graph, ready for you to copy from.

4. In the floating Node Graph window, choose Clip if you want to copy overall clip attributes, or choose Node to copy individual node attributes.

5. Do one of the following to copy nodes or settings to the Node Editor.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node’s settings. If you open the Node panel and choose specific attributes, only those attributes will be copied to the node you drag onto.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node. If you open the Node panel and choose specific attributes, only those attributes will be copied to the new node that’s created.
   - In Clip mode, click Apply Color to copy the entire grade from the floating node graph to overwrite the current grade in the Node Editor.
   - In Clip mode, click Apply PTZR to copy the sizing from the floating node graph to overwrite that of the current clip.
   - In Clip mode, click Apply Source to copy the source settings from the floating node graph to overwrite those of the current clip.
   - In Clip mode, click Apply All to copy every setting from the floating node graph to the current clip.
   - In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite the settings of that node that you selected.
   - In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node with only the settings that you selected.

6. While the floating Node Graph window is open, you can also select any clip in the Thumbnail timeline to change the grade that’s displayed in the Node Editor, ready for you to copy to.

7. Click Close when you’re finished.

To copy individual nodes or settings from any clip in the Timeline:

1. Click the thumbnail in the Timeline of the clip you want to copy nodes to. Its node graph will appear in the Node Editor.

2. Right-click the thumbnail of another clip you want to copy nodes from, and choose Display Node Graph.

**NOTE:** The Display Node Graph command only appears in the contextual menu of a clip in the Thumbnail timeline that is not currently selected.
3 (Optional) In the floating Node Graph window, choose Clip if you want to copy overall clip attributes, or choose Node to copy individual node attributes.

4 Do one of the following to copy nodes or settings to the Node Editor.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite that node’s settings. If you open the Node panel and choose specific attributes, only those attributes will be copied to the node you drag onto.
   - In Clip mode, drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node. If you open the Node panel and choose specific attributes, only those attributes will be copied to the new node that’s created.
   - In Clip mode, click Apply Color to copy the entire grade from the floating node graph to overwrite the current grade in the Node Editor.
   - In Clip mode, click Apply PTZR to copy the sizing from the floating node graph to overwrite that of the current clip.
   - In Clip mode, click Apply Source to copy the source settings from the floating node graph to overwrite those of the current clip.
   - In Clip mode, click Apply All to copy every setting from the floating node graph to the current clip.
   - In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto an existing node to overwrite the settings of that node that you selected.
   - In Node mode, select which attributes you want to copy, and then drag any node from the floating node graph to the current grade shown in the Node Editor, and drop it onto a connection line to insert it as a new node with only the settings that you selected.

5 (Optional) While the floating Node Graph window is open, you can also select any clip in the Thumbnail timeline to change the grade that’s displayed in the Node Editor, ready for you to copy to.

6 Click Close when you’re finished.

Rippling Adjustments Among Multiple Clips

If you’ve graded a sequence of clips and find yourself needing to make a quick change to several clips all at once, you can use the Color > Ripple Node Changes to Selected Clips/Current Group commands to quickly copy changes made to one clip to several others. However, these commands require that you follow certain rules in order to get the results you want.

Node rippling uses the number of each node to determine what changes should ripple to which nodes. In other words, changes made to Node 3 will ripple to Node 3 of every other selected clip, or to Node 3 of every other clip in the current group (depending on which command you use).

Rippling changes from one clip to several others requires that all clips share the same number of nodes, at least for the nodes you’re rippling. If you try to ripple a change to one or more clips that don’t have a node with the same number as the one you’re rippling, then no change will be rippled to those clips.
To ripple a change in one node to several selected clips:

1. Select the clip you want to use to make the change so that it’s the current clip, outlined in orange.
2. Now, Command-click or Shift-click to select the range of clips you want to ripple your change to, so that they’re all selected red.

The orange outlined clip is the current clip you’re modifying, and the clips highlighted in red are the ones you’re rippling this change to.

You don’t have to select the clips you’re going to ripple your change to prior to making the change, but it may be easier to keep track of what you’re doing if you set everything up in advance. The clip you’re changing should be outlined in orange, and the clips you’re rippling the change to should be highlighted in red.

3. Select a node to modify. Ideally, every selected clip should have a node sharing the same number as the one you’re modifying. If some clips don’t, then those clips won’t inherit the change you’re going to be rippling.

4. Make whatever changes you need to, adjusting any of the palette controls in the Color page you need to, except for Camera Raw, Sizing, and Data Burn, which aren’t node-specific.

5. When you’re happy with the change you’ve made, choose Color > Ripple Node Changes to Selected Clips.

The change you’ve made should ripple to every other selected clip with a node of the same number, and in a few moments the thumbnails of those clips should update to show the change.

If you’ve created a group, it’s even easier to ripple node adjustments to the other clips in the group.

To ripple a change in one node to the current group:

1. Select the clip you want to use to make the change so that it’s the current clip, outlined in orange. It must be part of a group for this to work.

2. Select a node to modify. Ideally, every selected clip should have a node sharing the same number as the one you’re modifying. If some clips don’t, then those clips won’t inherit the change you’re going to be rippling.

3. Make whatever changes you need to, adjusting any of the palette controls in the Color page you need to, except for Camera Raw, Sizing, and Data Burn, which aren’t node-specific.

4. When you’re happy with the change you’ve made, choose Color > Ripple Node Changes to Current Group.

The change you’ve made should ripple to every other clip in the current group that has a node of the same number, and in a few moments the thumbnails of those clips should update to show the change.
Appending a Node to Multiple Clips

If you’ve made an adjustment to a node in one clip that you’d like to apply to several other clips, you can quickly do that using the Color > Append Node to Selected Clips command. You can do this as a prelude to using one of the Ripple Node Change commands, as it’s a quick way to make sure several previously ungraded clips have the same nodes, but you can also do this as a quick way to apply the same node change to several clips, regardless of whether they have matching node trees.

To append a node to other selected clips:

1. Select the clip you want to use to make the change so that it’s the current clip, outlined in orange.
2. Select the node you want to append to other clips.
3. Now, Command-click or Shift-click to select the range of clips you want to ripple your change to, so that they’re all selected red.
   The clip you’re changing should be outlined in orange, and the clips you’re rippling the change to should be highlighted in red.
4. Choose Color > Append Node Changes to Selected Clips.
   The selected node should be appended to the end of the node tree of each selected clip, and in a few moments the thumbnails of those clips should update to show the change.

Scroll Copy Grades Using the DaVinci Control Panel

Scroll mode lets you quickly preview the effects of many different grades applied to clips in the Timeline on the currently selected clip, with the option to either accept or reject the previewed grade to which you’ve “scrolled.” This can be useful for checking to see if any of the previous grades you’ve created in a scene will work for the currently selected clip.

To use Scroll mode:

1. Move the playhead to the clip to which you potentially want to copy a new grade. You can use the PREV SCENE and NEXT SCENE buttons to move quickly.
2. Do one of the following to enter Scroll mode:
   – Press SCROLL on the Transport panel.
   – Press MODES, above the fourth trackball on the Center panel, then press the SCROLL MODE soft key.
3. Now, do one of the following to preview different grades from other clips:
   – Press the PREVIOUS SCENE and NEXT SCENE soft keys to move from clip to clip in the Timeline, previewing each grade to the current clip.
   – Turn the SCROLL SCENES knob to scroll smoothly along multiple clips in the Timeline.
   – Turn the SCROLL FRAMES knob to scroll along different frames of any clip, previewing the effects of keyframed grades at different points in time.
– Press the TOGGLE DECK KEYS soft key to use the transport controls on the Transport panel to play through the Timeline, previewing grades as you go.

– Press a number on the keypad of the Transport panel, and then the SCENE NUMBER soft key, to jump to a clip and preview its grade.

As you scroll from clip to clip, a red outline indicates the clip with the grade being previewed, and an orange outline indicates the current clip to which you’re previewing each scrolled grade.

4 When you’re finished, do one of the following to either accept or reject a scrolled grade:

– Press EXIT AS WAS if none of the grades you scrolled through was suitable. This exits Scroll mode and leaves the clip as it was previously.

– Press EXIT AS IS if you’ve found a grade that works for the current clip. This exits Scroll mode and copies the scrolled grade.

When you press the TOGGLE DECK KEYS soft key in Scroll mode, each of the Transport Control buttons on the Transport panel functions as a means of previewing the grades of other clips in the Timeline.

• STEP FWD: Move to the next clip and preview its grade.

• STEP REV: Move to the previous clip and preview its grade.

• FWD: Plays (scrolls) forward at 1 scene per second, previewing each new grade as it appears.

• REV: Play (scrolls) the clips in reverse at 1 scene per second, previewing each new grade as it appears.

• FFWD: Shuttles (scrolls) forward through the Timeline at 4 scenes per second, previewing each new grade as it appears.

• RWD: Shuttles (scrolls) reverse through the Timeline at 4 scenes per second, previewing each new grade as it appears.

Rippling Changes Using the DaVinci Control Panel

DaVinci Resolve has a mechanism for rippling specific changes made to one clip to a range of other clips in the Timeline. This is only possible using the controls of the DaVinci control panel.

The general idea of the ripple function is that you select a clip, make a change, and then ripple that change to a range of other clips. This rippled change can be applied to the same node in each clip, or the change can be added as an appended node within each rippled clip.

The Ripple mode that’s used when you press the RIPPLE VALUE button can be changed in the Color panel of the User Preferences. There are four options.

• Exact values changed: Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if Lift in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain setting of 0.75. Only parameters you adjust are rippled.

• Percent value changed: Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Lift level of 1.00 and is changed to 0.90 units, then the Lift setting of each clip you ripple will have a relative reduction of 10% relative to its previous value.
• **Unit value changed:** Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the effected parameter. For example, if the current clip had a Lift of 0.80 and you increased it to 0.90, each rippled scene’s master gain level increases by 0.10.

• **All values are copied:** The current clip’s grade is rippled to the specified clips in its entirety. No comparison is made with the original clip’s parameters, and all memory parameters are rippled.

The following procedure describes in detail how you can use the DaVinci control panel to ripple a change to a range of other clips. While this procedure may appear complicated, it’s just that there are several options. Once you learn the sequence of commands, this process is actually quite fast.

**To ripple a change using the Ripple Mode soft key commands:**

1. (Optional) Press MODES, then press RIPPLE MODES. Four commands appear mapped to the middle soft keys of the Center panel, which can be used later to execute different types of ripple operations.

2. Move the playhead to the clip you want to adjust.

3. Adjust the current clip that you want to ripple to other clips in the Timeline.

4. Define the range of clips you want to ripple to using the number pad on the Transport panel. The following combinations will work:
   - An absolute range of clips is defined by entering two clip numbers separated by a comma. For example, if you want to ripple the current change to clips 10 through 15, you’d press “10 , 15”
   - To specify every clip from the beginning of the Timeline, use the Minus (–) key. For example, to specify a range of clips from the beginning to clip 20, you’d press “– , 20”
   - To specify every clip to the end of the Timeline, use the Plus (+) key. For example, to specify a range of clips from the clip 50 to the end, you’d press “50 , +”
   - To specify every clip in the whole Timeline, press “– , +”

5. (Optional) You can control whether the rippled change is applied in an appended node, or an existing node, in every rippled clip:
   - If you want to apply the rippled change as a new node that’s appended to the end of every rippled clip’s grade, press SHIFT DOWN.
   - Otherwise, the rippled change will be applied to the same node in every rippled clip that you made your adjustment to in the current clip. In other words, if you made a change to Node 2, it would be rippled to Node 2 of all the clips you specified. If one of the rippled clips doesn’t have the same number of nodes, you may get an error.

6. To execute the ripple, do one of the following:
   - Press RIPPLE VALUE on the Transport panel to ripple a change using the currently selected Ripple Mode in the User Preferences.
   - Press one of the Center panel soft keys corresponding to the ripple function you want to perform. There are four soft keys:
     - **STATIC RIPPLE:** Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if Lift in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain setting of 0.75. Only parameters you adjust are rippled. Identical to the “Exact values changed” ripple setting.
– **RELATIVE RIPPLE**: Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Lift level of 1.00 and is changed to 0.90 units, then the Lift setting of each clip you ripple will have a relative reduction of 10% relative to its previous value. Identical to the “Percent value changed” ripple setting.

– **ABSOLUTE RIPPLE**: Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the affected parameter. For example, if the current clip had a Lift of 0.80 and you increased it to 0.90, each rippled scene’s master gain level increases by 0.10. Identical to the “Unit value changed” ripple setting.

– **FORCED RIPPLE**: The current clip’s grade is rippled to the specified clips in its entirety, overwriting all previous nodes and parameters in the rippled clips.

The adjustment you made in step 4 is applied to the designated range of clips.

Admittedly, that was a long and detailed procedure, but the actual button sequences are straightforward once you put them together. Here are some examples of button sequences that ripple an adjustment you’ve just made in different ways:

- **“10 , 15” then SHIFT DOWN then RIPPLE VALUE**: Copies the change you’ve made to the current clip, and applies it as a new node that’s appended to the end of clips ten through fifteen.

- **MODES then RIPPLE MODES then “34 , 45” then FORCED RIPPLE**: Copies the entire grade of the current clip, using it to overwrite the grade of clips 34 through 45.

- **MODES then RIPPLE MODES then “– , +” then SHIFT DOWN then RELATIVE RIPPLE**: Copies the change you’ve made to the current clip as a relative percentage, and applies it as a new node appended to the end of every single clip in the entire Timeline.

**WARNING** Once you ripple a change in this manner, there is no going back. Since undo is a per-clip operation, there is no global undo for changes made to the entire Timeline. Proceed with caution.

### Using Shared Nodes

This is probably one of the biggest improvements added in DaVinci Resolve 15 for working colorists. You can turn individual Corrector nodes into Shared nodes, which can then be copied to multiple clips to enable linked adjustments right from within the clip grade. This means that the clip grade can freely mix both clip-specific nodes and Shared nodes, all within the same node tree. This makes Shared nodes fast to use as there’s no need to create groups or switch to a group node tree (covered in the next section) to reap the benefits of linked adjustments among multiple clips.
What Are Shared Nodes Good For?

Shared nodes are similar to group grades, except that they don’t require grouping and can be added to any normal grade. Changes made to a Shared node are automatically rippled to all other instances of that node in the grades of other clips. Furthermore, you can add as many Shared nodes to a grade as you like, and you can arrange them in any order to control the order of the operations they apply. And, of course, you can intersperse them with ordinary Corrector nodes.

Shared nodes are extremely flexible. For example, you can use Shared nodes to:

- Add a Color Space Transform Resolve FX or a LUT to the beginning of every clip from a particular source
- Add a base correction to every talking head shot of a particular interviewee
- Add a shot matching adjustment to each clip from a particular angle of coverage within a scene
- Add a stylistic adjustment to every clip in a specific scene
- Make your base adjustments when grading with remote versions, so those adjustments remain linked when you copy your remote versions to local versions for fine tuning

In fact, you can mix and match Shared nodes among differently overlapping sets of clips to accomplish any or all of the above at once. For example, you can add one Shared node to make an adjustment to every clip from a particular camera, add a second Shared node to each of those clips that are in a particular scene, and then add a third Shared node to whichever of those clips happen to be a closeup of the lead actress, before adding one or two regular Corrector nodes that aren’t shared to make clip-specific tweaks.

**IMPORTANT** At the time of this writing, there are two limitations when using Shared nodes. Grades using Shared nodes cannot use the Smart or User cache, and Shared nodes cannot be used in collaborative workflows. It is hoped that these limitations are temporary.

Creating Shared Nodes

Creating a Shared node is easy, assuming you’ve created a node that has an adjustment you’d like to share among multiple clips.

**To create a Shared node:**

Right-click any Corrector node and choose Save as Shared node.
Locking Shared Nodes

Once you turn a node into a Shared node, that node is automatically locked, preventing you from accidentally making adjustments to it that would affect all other grades using that same Shared node.

To toggle the locked status of a Shared node, do one of the following:
- Right-click any Shared node and choose Lock Node from the contextual menu.
- Open the Keyframe Editor, and click the Lock icon in the track header of that node’s keyframe track.

Copying Shared Nodes

Because Shared nodes are essentially Corrector nodes within clip grades, they’re easy to work with. Once you’ve created one or more Shared nodes, there are a variety of ways you can copy them to the grades of other clips in your program to take advantage of the linked adjustments they let you make.

Ways of copying Shared nodes among multiple clips:
- **Add a Shared node to another clip’s grade using the Node Editor contextual menu:** Once you save a node as a Shared node, it becomes available from the bottom of the Add Node submenu of the Node Editor contextual menu, making it easy to add any Shared node to any clip. If you customize the label of the Shared node, that custom label appears in the contextual menu, making it easier to find what you’re looking for.
- **Add Shared nodes to a basic grade you’ll be copying to other clips:** If you create one or more Shared nodes when you initially build a grade, copying that grade to other clips naturally copies the Shared nodes as well.
- **Save a Shared node as a Gallery still and apply it to other clips:** If you save a grade with a Shared node in it to the Gallery, then every time you copy that Gallery still to another clip, you copy its Shared node.
- **Create a Shared node and append it to a selection of additional clips:** If you’ve already graded several clips in a scene, you can add a Shared node to the end of one of the clips grades and make sure it’s selected, then select all of the other clips in the scene and choose Append Node to Selected Clips.
- **Use Shared nodes to preserve linked adjustments when copying remote grades to local grades:** If you use Shared nodes to make your base adjustments when you grade using Remote Versions to automatically copy those grades to other clips that come from the same source media, those adjustments will remain linked when you copy your remote versions to local versions for fine tuning.

You can also choose options in the Gallery that dictate what happens when you copy a grade that has shared nodes within it.

Converting Shared Nodes Back to Corrector Nodes

Sometimes you need to stop a node from being shared. For example, if you want to copy a grade from another scene to use as the starting point for a new grade, chances are you don’t want any shared nodes to continue being shared as you customize that grade for the new scene. In this instance, you can convert the Shared node back to a regular Corrector node, make any adjustments you need to customize it for the new scene, and then turn that node into a brand new Shared node that’s specific to the new scene.
To convert a Shared node back to a Corrector node:

- Right-click any Shared node, and choose Convert to Corrector from the contextual menu.

Deleting Shared Nodes

If you’ve created a Shared node that’s being used in multiple clips, and you decide you want to eliminate the linked relationship among these nodes so they all work independently, you can “delete” a specific Shared node. This leaves the now unlinked nodes intact within each node tree in which they appear, but clears their effect. Additionally, that Shared node is removed from the Add Node submenu.

To Delete a Shared node:

Right-click any Shared node, and choose a node to delete from the Delete Shared Node submenu.

Using Adjustment Clips

You can also apply a single grade to multiple clips in the Timeline using Adjustment clips that have been superimposed over numerous other clips in the Timeline. They can be used to apply a single grade to all clips in a scene, or to add further color adjustments or trims to a section of clips via a second grade that’s applied on top of the individual clip grades that are already applied.

Adjustment clips are a great way to add adjustments to multiple clips that you may be making frequent changes to. If you make changes to a grade in an Adjustment clip, that change is automatically applied to all clips underneath it in the Timeline. Additionally, grades applied via adjustment layers can be turned off by disabling the adjustment layers, either one at a time, or by disabling an entire track with adjustment layers in it.
Adjustment clips can be edited into the Timeline on the Edit page, and are available from the Effects bin of the toolbox in the Effects Library. When an Adjustment clip is superimposed above one or more clips in the Timeline, all effects that are applied to the Adjustment clip are also applied to all clips underneath it.

Adjustment clips can be used to apply the following types of effects:

- ResolveFX and OpenFX plug-ins
- Inspector parameters, including Composite, Transform, Cropping, and Dynamic Zoom
- Fusion page effects
- Color page grading and sizing

Effects clips are a fast and easily revised way to apply one or more grades and effects to a range of clips.

TIP: Multiple adjustment layers can be grouped together so that you can apply Group and Clip grades to adjustment layers, linking multiple adjustment layers together in situations where you want to apply the exact same trim or stylistic adjustment to multiple scenes in non-contiguous areas of the Timeline.

Using Groups

Grouping is one of DaVinci Resolve’s most powerful features for organizing grades amongst multiple clips. Groups are manually created collections of clips with automatic linking relationships that make it easy for you to control the rippling of grades among sets of clips that you define. When clips have been grouped together, selecting one member of the group reveals a group “linked” badge at the top-right of each clip’s thumbnail belonging to the group.

The green link icon indicates this clip is in a group

You can create as many groups within a single project as you need. You can add or remove shots from the current group, and the current group is defined by the last shot you’ve selected (if it belongs to a group, that’s the new current group).

As introduced in DaVinci Resolve 11, the grading of grouped clips is easier than it has ever been. Once grouped, you can choose from one of four Node Editor modes to grade the current clip. Which mode you choose determines whether that grade will automatically ripple to every other member of that group, or whether the grade will only affect that one clip. In this way, you can combine multiple node trees, some which will ripple, and one which won’t, to create the final look of each clip in that group.
Creating and Managing Groups

The following procedures describe how to create, load, modify, and delete groups.

**To create a new group:**
1. Select one or more clip thumbnails in the Timeline. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a noncontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
2. Right-click one of the selected clip thumbnails, and choose **Add Into New Group**.
3. Type a name into the field of the **Group Name** dialog, and click **OK**.
   
   The new group is created, and the clips you had selected now appear with the “linked” group badge above the thumbnails.

**To load a different group, do one of the following:**
- Move the playhead to another clip that’s a member of that group.
- Right-click any clip belonging to any group, and choose **Group > “Name of group” > Load**.
   
   The selected group now becomes the current group. Using the **Add Into Current Group** command will add a clip to the newly loaded group.

**To add one or more clips to an existing group:**
1. Load the group you want to add clips to.
2. Select one or more clip thumbnails in the Timeline. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a noncontiguous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
3. Right-click one of the selected clip thumbnails, and choose **Group > “Name of group” > Assign to Group**.
   
   The selected clips now appear with the “linked” group badge above the thumbnails.

**To remove one or more clips from an existing group:**
1. Select one or more clip thumbnails in the Timeline that you want to remove from a group. You can select a contiguous range of clips by clicking one and then Shift-clicking another, or you can make a discontinuous selection by Command-clicking individual clip thumbnails anywhere in the Timeline.
2. Right-click one of the selected clip thumbnails, and choose **Remove From Group**.
**To rename a group:**

1. Right-click any clip belonging to any group, and choose Group > "Name of group" > Rename.

2. Type a new name into the field of the Group Name dialog, and click OK. The group is renamed. The new name appears as a new submenu of the Timeline contextual menu.

**To delete a group:**

- Right-click a clip belonging the group you want to delete, and choose Group > "Name of group" > Delete.
- This clears the group, while preserving the last applied grade within each clip.

**Using Group Modes to Control Which Grades Ripple and Which Don’t**

When you create a group and then select any clip that is a member of that group, additional Node Editor modes become available that let you apply multiple levels of grades to the clips in that group.

For clips that aren’t grouped, two dots at the top of the Node Editor let you switch between Clip and Timeline modes via a single click. If you’re working on a clip that’s part of a group, four dots will be displayed to allow fast access to the Pre-Clip and Post-Clip Group modes as well.
Node trees you create using the Group Pre-Clip and Group Post-Clip modes automatically ripple changes to every member of a group. Node trees created with the Clip mode are specific to each clip. Node trees created with the Timeline grade affect the entire Timeline, all at once. Combining node trees made using these different modes makes it easy combine clip-specific changes with group-wide changes that make grading faster.

- **Group Pre-Clip:** Node trees assembled in this mode affect every clip in the group simultaneously. Pre-Clip adjustments are useful for creating an overall grade that you want to use as a starting point for the scene, such as when you need to normalize a group of log-encoded clips in a specific way, or when you want to create a base grade that generally improves every clip in a scene.

- **Clip:** The Clip grade corresponds to the local or remote version associated with that clip. Node trees assembled in the Clip mode only affect the specific clip that’s selected. All Local and Remote versions you create are in Clip mode. Clip adjustments are useful for matching clips to one another in a scene, doing clip-specific secondary adjustments, or making any other sort of adjustment that you only want applied to the current clip, rather than to the group as a whole. Clip adjustments are applied after Pre-Clip adjustments.

- **Group Post-Clip:** Node trees assembled in this mode also affect every clip in the group simultaneously, but these adjustments are applied after the Clip adjustments. Post-Clip adjustments can be useful for applying a creative look to an overall scene, so that later revisions to a scene’s look can be accomplished with a single set of adjustments that automatically affect the entire group.

- **Timeline:** Node trees assembled in this mode affect every single clip in the entire Timeline. Timeline adjustments are useful when you have a single change that you want to apply to every single clip at once.

The image processing of each Node Editor mode is sequential, making it easy to keep track of the order of operations affecting a particular clip.

**An Example of Grading a Group of Clips**

This section shows an example of how you might approach grading a group of clips using the different Node Editor modes that are available. Keep in mind that this is only one of many possible approaches you could take to the use of groups, and was chosen because it exercises everything you can do to a single grade.

To get started, select a series of clips that you want to group, and right-click one of them and choose Create New Group to group them together, entering a name and clicking OK when prompted. One convenient advantage of simply creating groups from a selection is that you’re not limited to selecting a continuous range of clips in the Timeline. Another advantage is that you can use the View > Timeline Thumbnail Mode > Source (C-mode) command, or Timeline filtering, to isolate the range of clips you want to use for creating a group.

There are different ways you might choose to group clips together:

- All clips within a particular scene
- All clips recorded from a specific camera
- All headshots of a particular person
- All clips from a particular angle of coverage
- All exteriors of a particular location
The list could go on and on, but you get the idea. You can group any selection of clips together that have reason to share a common grade. In this example, a series of shots from an exterior scene are selected and made into a group.

Once you've created a group, choose Group Pre-Clip from the Node Editor mode pop-up. This is the first grade that’s applied, as the underlying grade that affects the entire group. Using this node tree, adding a LUT to normalize the clips, a Color Wheel adjustment, and some Curve adjustments to tune the color provide a primary grade that now affects every single clip in the group.

With this accomplished, you can see there’s some variation among the clips in the scene that needs to be corrected in order for every clip to match. Choose Clip from the Node Editor mode pop-up. Grades that you make in Clip mode only affect the clip to which they're applied, so now you can work clip by clip using the Image Wipe and Split-Screen controls to compare clips and make whatever adjustments are necessary to make each one match the main look for the scene.
Once all the clips are balanced with one another, you can choose Post-Clip Group from the Node Editor mode pop-up. This lets you add one more grade on top of the Pre-Clip and Clip grades that you’ve already applied, that you can use for any number of things. In this example, a single stylistic adjustment is applied that now affects all of the clips at once. If a client wants to see something different, you can easily make the necessary changes to one clip, and all other clips in that group will immediately be altered as well.

A stylistic adjustment applied to the Group Post-Clip mode

At this point, the scene is graded via a well organized set of corrections. If the client later wants a change affecting the underlying primary grade that everything is built on, you can adjust the Pre-Clip grade. If you spot an inconsistency with your shot matching at any point, you can make a fast tweak to the relevant Clip grade. And if the client wants a stylistic change, you can make any necessary adjustments to the Post-Clip grade to change the overall look of the whole scene. In each case, groups give you total control over which adjustments will ripple across the whole group, and which adjustments will be clip-specific.

Using Undo in Groups
Each Node Editor mode has a separate undo stack, meaning that separate multiple-level undo is saved for Group Pre-Clip, Clip, and Group Post-Clip.

Saving Stills and Grades in Groups
When you save a still for a clip that’s part of a group, the result is that the still reflects the look of the combined Pre-Clip, Clip, and Post-Clip node trees, but the grade that’s saved within depends on the Node Editor mode you had selected when saving the still. For example, if the Node Editor is set to Group Pre-Clip, then you’ll only save the Pre-Clip grade; the Clip, Group Post-Clip, and Track grades will be ignored. Copying a saved grade to a clip in a group results in that grade being copied to the node tree of whichever Node Editor mode is currently open.

Collapse Group Grades
If you want to take a clip out of a group, but you want its grade to continue incorporating all adjustments made in the Pre-Group and Post-Group Node Editor modes, you can use the Collapse Group Grades command to copy all nodes in the Pre-Group and Post-Group grades to the Clip grade. When you do this, Pre-Group nodes are added before any pre-existing nodes in the Clip grade, and all Post-Group nodes are added after, in order to maintain the correct order of operations.
To flatten all group grades into a single Clip mode node tree:

Right-click a clip’s thumbnail in the Thumbnail timeline, and choose Collapse Group Grades from the contextual menu.

Using Collapse Group Grades on a clip always removes that clip from whatever group it was previously a member of. This can also be an easy way of creating a single flat node tree in preparation for saving a grade to the Gallery for applying to other clips that aren’t themselves in groups.

Groups and Versions

Local or Remote versions you create relate only to the Clip grade. Group Pre-Clip and Group Post-Clip grades cannot be versioned.
Exporting Grades and LUTs

If you find it necessary to exchange grades with other workstations, there are two ways you can do so directly: by exporting grades, or LUTs. This section discusses the export of Grades; for more information about exporting LUTs, see Chapter 123, “Using LUTs.”

To export a grade:

1. Save the grade you want to export as a still in the Gallery.
2. Right-click the saved still in the Gallery, and choose Export.
3. Choose a location for the resulting still image and saved grade files, type a name into the Save As field, and click Save.

Two files are saved. A DPX formatted file contains the still image of the frame that was stored. A DRX (DaVinci Resolve eXchange) file contains all the grading information.

To Import a grade:

1. Right-click anywhere in the gray area of the Gallery, and choose Import.
2. Choose the DPX file that was exported from your DaVinci Resolve workstation, or someone else’s. The accompanying DRX file must be in the same location, although you can’t select it directly.

The still you imported appears in the Gallery, containing the grading information you wanted to import.
Chapter 117

Node Editing Basics

This chapter covers the basics of using the Node Editor in DaVinci Resolve to manage all of the adjustments you decide to apply to a clip, as well as the fundamental procedures for editing and organizing nodes within a tree that are the basis for creating more sophisticated effects.
## Contents

- **Node Editor Basics** 2299

- **Grading Order of Operations** 2316
Node Editor Basics

By default, every clip has one node in the Node Editor that contains the first corrections you make. However, you also have the option of creating multiple nodes, where each node contains one or more corrections that affect the image.

The specific arrangement of nodes you create lets you exert precise control over the order of operations performed by your grade, which provides many advantages. This section covers different ways of creating, editing, and arranging node trees to harness the full power of DaVinci Resolve.

Thumbnail-Optional Nodes

The Node Editor option menu provides a Show Thumbnails option that lets you disable or enable the thumbnails attached to each Corrector node.
How Many Nodes Do I Need to Use?

In this chapter and the ones that follow, you’ll learn many different techniques for combining adjustments and nodes in different ways to achieve highly specific effects. Consequently, new DaVinci Resolve users often wonder, how far do I go? There is no right answer, but suffice it to say that some of the world’s leading colorists achieve stunning results in as few as three or four nodes, while others routinely build carefully organized hierarchies of ten to twenty nodes, or more. The number of nodes you use is often dependent on the quality of media you’ve been given to work with, as well-lit footage usually requires less work than material shot run-and-gun with available light, that typically needs many more adjustments to achieve an acceptable result. Furthermore, the number of nodes you may use can also depend on what kind of program you’re working on, with commercial spots affording the colorist enough time in the schedule to build truly massive grades that adjust every little detail, and narrative features and television shows requiring you to work faster and do more within fewer adjustments in order to stay on track. The real answer? Each grade requires as many nodes as are necessary. No more, no less.

The Node Editor Interface

As you work within the Node Editor, you may find the need to zoom into or out of it to get a better look at the node tree, and to pan around the working area to deal with large collections of nodes.

To expand the size of the Node Editor’s working area:

- Drag the border between the Node Editor and the Viewer to the left or right to make it wider or narrower.
- Right-click anywhere within the Node Editor (except on a node) and choose Toggle Display Mode, which hides the Viewer and moves the Node Editor to the right of the Gallery, enlarging it considerably. Right-click and choose Toggle Display Node again to return to the default layout.
- You can toggle Display mode using the DaVinci control panel by pressing SHIFT UP and the DISPLAY/CURSOR button above the fourth trackball on the Center panel.

To zoom and pan within the Node Editor, do one of the following:

- Use the Node Editor’s zoom slider to shrink or enlarge the nodes in the Node Editor.
- Click the Pan tool (the hand icon) at the upper left-hand corner of the Node Editor, and drag anywhere within the gray area of the Node Editor to pan around.
- Press the H key to toggle between selection and pan modes in the Node Editor.
- Middle-click and drag anywhere within the Node Editor to pan around.
- Right-click and choose Zoom In or Zoom Out.
- Right-click and choose Zoom to Window to fit the node tree to the current size of the node graph.
- Right-click and choose Original Size to return the node graph to the default size.
The Components of a Node Tree

Ambitious grades may require trees of multiple nodes to create the necessary effect. This section covers the mechanics of putting nodes together into the structures that are described in more detail later in this chapter.

Every node you add is a “Corrector” node, which is capable of either primary or secondary correction, depending on whether or not you enable the Qualifier/Window/Matte controls. Even “Serial” and “Parallel” nodes are simply Corrector nodes that are added in series or in parallel to the previous node in the node tree; the names are a consequence of how they’re added.

Each Corrector node has two inputs and two outputs, which lets you separately manage the RGB image-processing channel, and the Key channel that defines areas of isolation for image processing operations, or transparency for compositing. RGB inputs and outputs are light green and round, located at the top left and right of each node. Key inputs and outputs are blue and triangular, located at the bottom left and right of each node. These inputs and outputs let you control the flow of image and isolation channels coming into and going out of each node in the tree.

Nodes are attached to one another via “connections,” seen as lines that connect one node to another. Image data flows from left to right, starting with the Source input all the way at the left of the Node Editor, through each node in the tree, and ending at the Node Tree output at the right of the Node Editor.
Here’s an explanation of the different components of a basic node tree where all nodes are connected in serial, one after the other, and how they work together:

- **Source Input:** The green source node to the far left is the clip’s image data as processed by the Sizing and Source decode settings, ungraded. The Source input feeds RGB data to the grade, and is connected to the RGB input of the first node in your tree. If necessary, you can connect the Source input to more than one Corrector node, creating multiple simultaneous streams of image processing emerging from the original source state of the image that you can eventually recombine in different ways using the Parallel or Layer Mixer nodes.

- **Nodes:** Each node in the node graph represents a collection of image processing operations that can be enabled or disabled separately from any other node in the graph. By separating operations into multiple nodes, you’re able to precisely control the order of all image processing operations in DaVinci Resolve to create many different corrections and effects. The round green RGB inputs and outputs are used to connect these nodes together. Each node’s thumbnail image shows how the clip looks at that particular stage of the grade, giving you a visual indication of what each node is doing, and small badges below each node show you which specific operations are being applied by that node.

- **RGB Inputs and Outputs:** The round green inputs and outputs at the upper right and left of each node are used to connect the RGB image that’s output from one node to the RGB input of the next node. For a Corrector node to have an effect, you must connect both its RGB input and its RGB output to neighboring nodes in the tree. Furthermore, every single node in the Node Editor must be connected for a grade to be enabled; having any disconnected node in the node tree disables that grade until it’s fully connected.

- **Key Inputs and Outputs:** The blue triangles at the bottom right and left of each node are used to route the key channel generated by a node’s Qualifier or Window controls, or imported via a Matte clip that you previously associated with a clip in the Media page. When you connect the key output of one node to the key input of another, you basically copy the first node’s key to the second node. You can also combine the key outputs of multiple nodes in various ways using the Key Mixer node.

- **Node Tree Output:** The RGB output of the last node in a tree must be connected to the green Node Tree output node, which “completes the circuit” of image processing, and passes that correction on to the next stage in the DaVinci Resolve image processing pipeline. If the output is not connected, the node tree is disabled and has no effect on the clip. You can only connect one RGB output at a time to the Node Tree output.

- **Second Source Input (for RED HDRx):** You can access the alternate highlight exposure of RED HDRx media by exposing this optional second Source input. For more information, see “Mult-Channel RED HDRx Support” in Chapter 112, “Channel Splitting and Image Compositing.”

- **Second Source Input (from Fusion page):** You can also create additional sources to route in masks or mattes created in the Fusion page for use as keys in the Color page.

- **Alpha Output:** It’s possible to create regions of transparency for compositing directly in DaVinci Resolve by connecting a key output to an optional Alpha output.

For more information, see Chapter 119, “Combining Keys and Using Mattes.”
Node Badges and Labels

Nodes appear with various labels and badges to help you identify what each node is contributing to the overall grade. How long a label and how many badges appear depends on the size of each node, as set by the Node Editor’s Zoom slider.

- **Node number:** Nodes are numbered in the order in which they appear in the node graph, making it possible for you to select specific nodes by number via the DaVinci control panel. If you insert new nodes or rearrange existing nodes, the node numbering will change to reflect each node’s new order.

- **Adjustment badges:** As you apply various operations within a node, small badges appear at the lower right-hand corner underneath the thumbnail that indicate which palettes have been used to adjust that node. How many badges are able to appear depends on how far in or out you’re zoomed into the Node Editor, and whether or not there are Color Space or HDR labels. At larger node sizes, more badges can appear within the width of the node. Each palette in the Color page has a unique badge. If you apply more operations than a node has area to display, a single “downward arrow” badge appears.

- **Animation badge:** Nodes with animated parameters display a keyframe badge.

- **Color Space labels:** If you switch a node to use a color space other than RGB, that color space’s three letter label appears at the lower left-hand corner of the node.

Labeling Nodes

Nodes can be labeled to identify a particular node’s function in your grade. This can make it easier to revise a grade months later. Node labels are also saved when you save a still, so labels can also make it easier to decipher a saved grade down the road. At each node’s default size in the Node Editor, nodes can appear with up to 12 characters of text, although larger nodes can accommodate more text.

**To label a node:**

1. Right-click a node and choose Change Label.
2. Type the label text you want and press Return.
   The label you entered appears above the node in the Node Editor.

**To edit a node’s label:**

Once a node has a label, you can change the label at any time by double-clicking it.

Selecting Nodes

The node that’s currently selected in the Node Editor is highlighted in orange, and is referred to as the current node. When you adjust any of the parameters or settings in the Color page, you’re adjusting parameters within the current node. You can only select one node at a time.
To select a node, making it the current node, do one of the following:

- Click any node in the node graph.
- Choose Color > Nodes > Previous Node (Option-Shift-Semicolon) or Color > Nodes > Next Node (Option-Shift-Apostrophe). When you do this, the last node loops around to the first one, and vice versa.
- Using the Transport panel of the DaVinci control panel, press the PREV NODE or NEXT NODE buttons. When you do this, the last node loops around to the first one, and vice versa.
- Using the Transport panel of the DaVinci control panel, enter the number of the node you want to select using the keypad, and then press the SELECT NODE button.

The selected node appears highlighted in orange. You also have the ability to select multiple nodes, in preparation for doing things like moving them or creating compound nodes (covered later in this chapter).

To select multiple nodes:

- Command-click each of the nodes you want to simultaneously select.
- With the Node Editor Selection tool chosen (at the upper left-hand corner of the Node Editor) simply drag to select multiple nodes using a bounding box.

When you select multiple nodes, each one appears highlighted in white, with the exception of the current node, which remains orange.

When you select another clip in the Timeline, the default behavior is that the last node that was selected when you worked on that clip is the one that's selected when you move to that clip again. However, a setting in the Color panel of the User Preferences called “Switching clips,” lets you change this behavior. For more information on this option, see Chapter 3, “System and User Preferences.”
Disabling Nodes

In the process of creating a node tree, it’s often useful to turn one or more selected nodes off to disable their effect on your grade. It’s also useful to turn the entire node tree off and on in order to see “before and after” views of the current clip. Disabled nodes are not processed during rendering, and they remain disabled when you save that grade along with a still in the Gallery and then apply that grade to another shot.

Disabling Individual Nodes

Disabling a single node is useful for temporarily disabling adjustments that you don’t think you want to use but don’t want to discard (however you should remember that it’s alarmingly easy to inadvertently turn these nodes back on again). It’s also good for giving your client a before and after preview of the last adjustment.

To toggle individual nodes off and on, do one of the following:

- Click the number of any node in the node graph to disable that node by itself.
- Select a single node, and choose Color > Nodes > Enable/Disable Selected Nodes (Command-D).
- On the DaVinci control panel, press the DISABLE CURRENT button (on the T-bar panel).

Disabling Multiple Nodes All At Once

If you select more than one node in the node tree, using any of the methods of turning nodes off and on described above (including Command-D) will toggle Enable/Disable Selected Nodes. Please note that the current node outlined in orange is always considered to be part of the selection.

This makes it easy to do before/after comparisons of any combination of nodes doing complicated adjustments by selecting them, while leaving un-selected nodes doing base adjustments that you want to leave enabled alone.

Disabling All Nodes

In addition to the Bypass All Grades command, disabling all nodes of a grade at once is another easy way of disabling a grade to provide a before and after of the original state of the clip (or the color managed state of the clip if Resolve Color Management (RCM) is enabled). More importantly, it’s a good way to disable all nodes of a grade in preparation for walking your client through each operation in that grade node by node, as you turn each node on in turn while narrating how it’s improving the image.

To turn every node off and on at once, do one of the following:

- Choose Color > Nodes > Enable/Disable All Nodes (Option-D) to toggle all nodes off and on.
- On the DaVinci control panel, press SHIFT-DOWN and then the DISABLE CURRENT button (on the T-bar panel).

**IMPORTANT** When you turn every node off and then on again, every node is re-enabled, even nodes that had previously been individually disabled.
Turning Grades and/or Fusion Effects Off

The Bypass Color Grades and Fusion Effects button/pop-up commands in the Viewer’s title bar are also available via View > Bypass Color and Fusion menu commands. Turning off Fusion effects in the Color page is an easy way to improve playback performance on low power systems when you just need to make a quick set of grading adjustments. Toggling grades off and on is also a convenient way to quickly get a before and after look at a shot where the before goes all the way back to the source.

If you choose Toggle Bypass or click the Viewer control, you’ll turn off whatever is checked in the optional menu, which lets you choose whether or not you want to bypass both Color and Fusion, or just one or the other.

Resetting Nodes

If you’re dissatisfied with your current operations and want to start over, there are three ways you can reset nodes in the Node Editor. These are available as items in the Color menu, and buttons on the DaVinci control panel’s T-bar panel.

- **Reset Selected Node Grade**: Resets the currently selected node, eliminating all keyframes, to the default parameter settings.
- **Reset Grades and Keep Nodes**: Resets every node in the current node tree, without affecting the node tree’s structure; all nodes remain where they were. However, each node has been reset to the default parameter settings.
- **Reset All Grades and Nodes**: Deletes every node and keyframe, and restores a single node set to the default parameter settings.

You can also reset nodes using the mouse, which can be a quick thing to do if you’re already working in the Node Editor to accomplish other things.

**Methods of resetting nodes with the mouse:**

- **To reset a selected node**: Right-click that node and choose Reset Node Grade from the contextual menu.
- **To reset all grades and nodes**: Right-click anywhere in the background of the Node Editor, and choose Reset All Grades and Nodes from the contextual menu.
Previewing and Restoring Node Trees

There are two other methods of quickly dealing with unwanted changes you’ve made to node trees, without needing to use undo.

- **Preview Memory:** Lets you preview the effect of any saved grade on the current clip. To preview, choose Color > Preview Memory (Option-Shift-P), and then right-click any saved still in the Gallery (or Memory) and choose Add Correction. In fact, you can use Add Correction to try out as many stills as you like. If you like any still’s effect, then you can leave it be. If you don’t like any of the stills you previewed, then choosing Color > Preview Memory again reverts the clip to the original grade.

- **Original Memory:** This command lets you quickly revert a clip’s grade to its original state when you first selected that clip. This is useful for getting immediately back to a clip’s original grade if you’ve made a series of changes that you then regret. Selecting another clip in the Timeline and then reselecting the clip you made changes to resets what is considered to be the current grade.

Caching Specific Nodes to Improve Performance

You can flag specific nodes to be cached, along with all nodes appearing upstream in that node tree. By caching nodes using processor-intensive effects, you free up real time capability for the remaining downstream nodes in a grade. Choosing Playback > Render Cache > User only caches nodes that you’ve flagged for caching.

When you choose Playback > Render Cache > Smart mode, DaVinci Resolve automatically caches any nodes that use Motion Blur, Noise Reduction, or OFX plug-ins, without you needing to do anything.

**To flag a node and all corrections made in upstream nodes for caching:**

Right-click any node and choose Node Cache > On from the contextual menu.

Editing Node Trees

There is no limit to the number of nodes you can create and connect to one another, and you can make as many or as few parameter adjustments as you like within each node. The following procedures describe the ways you can add nodes to the node graph as you build each grade’s node tree.

**Adding Nodes**

The simplest thing you can do to add to the complexity of a node tree is to add additional nodes, in order to add more adjustments to the current grade. You can add nodes so that they’re automatically attached to nodes that are already in the node tree, for immediate adjustment, or you can add unattached nodes to empty areas of the node tree in preparation for assembling a particularly complicated and specific node tree to accomplish a difficult task.
Methods of adding nodes to the tree using a mouse, tablet, or trackpad:

- **To add any kind of node to the node graph using the mouse:** Right-click any node in the node tree, and choose the type of node you want to add from the Add Node submenu of the contextual menu.

- **To add a disconnected node to the node graph:** Right-click anywhere within the node graph’s background, then choose Add Node > Corrector from the contextual menu. Disconnected nodes have no effect on a node tree until they’re connected.

Methods of adding nodes to a currently selected node in the tree using the keyboard or control panel:

- **To add a serial node after the currently selected node:** Press Option-S key, choose Color > Nodes > Add Serial from the menu, or press the ADD SERIAL button on the T-bar panel of the DaVinci Resolve control panel.

- **To append a serial node to the very end of the node tree:** Press Option-K, choose Color > Nodes > Append Node from the menu, or press the APPEND NODE button on the T-bar panel of the DaVinci Resolve control panel.

- **To add a serial node before the currently selected node:** Press Option-S, or choose Color > Nodes > Add Before Current, or press SHIFT DOWN and then ADD SERIAL on the T-bar panel of the DaVinci Resolve control panel.

- **To add nodes in parallel to the currently selected node:** Press Option-P, choose Color > Nodes > Add Parallel from the menu, or press the ADD PARALLEL button on the T-bar panel of the DaVinci Resolve control panel.

- **To layer nodes with the currently selected node:** Press Option-L, choose Color > Nodes > Add Layer from the menu, or press the ADD LAYER button on the T-bar panel of the DaVinci control panel.

- **To add an outside node to the currently selected node:** Press Option-O, choose Color > Nodes > Add Outside Node from the menu, or press the ADD OUTSIDE button on the T-bar panel of the DaVinci control panel.

Adding Nodes with Windows Turned On

There are also dedicated commands for adding serial nodes with Circular/Linear/Polygon/Curve windows automatically turned on, for convenience.

**To add a node to the tree with a Window automatically enabled:**

Choose an item from the Nodes menu, or press the button on the T-bar panel of the DaVinci Resolve control panel that corresponds to the following:

- **Node + CPW:** Circular Power Window (Shift-C)
- **Node + LPW:** Linear Power Window (Shift-Q)
- **Node + PPW:** Polygonal Power Window (Shift-G)
- **Node + PCW:** PowerCurve Window (Shift-B)

Whenever you add a node to a tree, it’s numbered consecutively to come after the next most recent node you’d added, regardless of the order in which it appears in the node tree. For example, if you’ve already added three nodes, and then you decide to add another node in between Nodes 1 and 2, the new node will be Node 4, and the order of the nodes will be 1, 4, 2, and 3.
Deleting Nodes

If there’s a node that you no longer need, you can choose to remove it completely from the node tree to remove its effect permanently.

To delete a node, do one of the following:

- Select a node, then press the Forward-Delete key.
- Right-click a node, and choose Delete Node.
- Using the DaVinci Resolve control panel, select any node, and press the DEL-CURRENT button (on the T-bar panel).

After you’ve deleted a node, the node to the left and right of the node you deleted are automatically connected so that the node tree is unbroken. Also, all the nodes in a tree are renumbered after the deletion of any node, so there’s no discontinuity in node order. For example, if you have three consecutively numbered nodes in a tree and you delete the second one, the node that was formerly number 3 is renumbered to be 2.

Connecting and Disconnecting Nodes

For a node tree to work, every node in the Node Editor must be connected into a working node tree, from the Source input, through each node in the tree, to the Node Tree output. Any disconnected node will result in that clip’s grade being disabled. However, you may find the need to disconnect some parts of a node tree in order to reconnect them in different ways.

To connect two disconnected nodes:

Click and drag a connection from the RGB or key output of one node to the corresponding RGB or key input of another, and when the line highlights, release the mouse button.

To change the connection from one node to another:

Move the pointer over the second half of any connection line between two nodes until it highlights blue, then click and drag it to reconnect it to another input, on that node or another.

To disconnect two nodes, do one of the following:

- Position the pointer over the left-hand side of a node connection so it highlights, and click it to delete it.
- Click a link to select it (selected links turn orange), and then press the Delete or Forward-Delete key.
- Right-click a link and choose Delete Link.

To overwrite a node’s previous connection:

- You can drag a connection to a node input or output that’s already connected, which will overwrite the previous connection with the new one you’re dragging. When you do this, the connection that’s about to be overwritten appears highlighted in orange.
- You can connect any node’s RGB or Key output to as many inputs as you want, but you can only have one connection going to a node’s input. The exception to this is a node with multiple inputs, designed to combine the output of multiple nodes. These include the Parallel, Mixer, and Key Mixer nodes.
Extracting a Node

Sometimes you need to remove a node from its current position in the node tree, such that the nodes to the left and right of it automatically reconnect to one another, saving you from having to reconnect them manually. This is called extracting a node.

**To extract a node, do one of the following:**
- Select a node, and choose Color > Nodes > Extract Current Node.
- Select a node, and press E.

Keep in mind that disconnected nodes in the node tree suspend grading altogether, so you’ll want to either reconnect that node to another part of the node tree, or delete it; you cannot leave it disconnected in the Node Editor.

Inserting a Node

If there’s a disconnected node in the Node Editor, there’s a simple way you can insert it into the node tree between any two other nodes. This also works for nodes that you’re dragging into a node tree from another source, for example, from the exposed node tree of a still in the Gallery.

**To insert a disconnected node between two other nodes:**

Drag a disconnected node, or a node from another node tree, onto the connection between any two other nodes in a node tree; when a plus icon appears over the node you’re dragging, drop it to insert the node.

Rearranging Node Order

The order in which nodes are connected in your tree affects the result of a grade. For example, if you boost the highlights in the first node, and then you try to isolate a portion of the picture in a second node that you now realize has been clipped, you may need to change your order of operations to optimize your corrections.

**To swap the contents of two nodes:**

Command-drag any node and drop it onto another node to swap the operations within each node. The nodes won’t appear to have moved, but you should be able to tell from the node badges underneath that the operations have been reversed.

**To move a node to any other position in the node tree:**

1. Double-click any node in the node tree and press E to extract it, removing it from the tree so that it becomes unattached.
2. Drag the now-unattached node to the connection line between any two other nodes in the tree, and when a small plus icon appears, drop it to automatically connect that node at that position in the node tree.

Copying and Pasting All Settings From One Node to Another

The simplest thing you can do is to copy all of a node’s settings and paste them into another node. This makes it easy to duplicate things like windows, qualifier settings, keyframing, or motion tracking that you want to reuse in another node as the basis for another operation. This is also a quick way to manually ripple a change you make in a node to that same node in another clip’s grade.
To copy a node’s settings from one clip to another, do one of the following:

- Option-drag one node onto another. When you drop it, the settings of the node you dragged overwrite those of the node you dropped onto.

- Select a node with settings you want to copy and choose Edit > Copy (Command-C). Then, select a node you want to paste these settings to either in the current grade or in the grade of another clip, and choose Edit > Paste (Command-V) to paste the settings you copied. These pasted node settings overwrite any other settings that node previously used.

**NOTE:** There are additional methods of copying nodes and individual node settings. For more information, see Chapter 116, “Grade Management.”

Keeping Node Trees Organized

It’s a good idea to keep the arrangement of your nodes in the node graph clean and neat. It’ll make it easier to read your tree if you need to revisit a grade later on, and it will also make it easier for other colorists working on the same project to figure out what you’re doing. The following procedures describe how to rearrange the nodes in your tree, and the node tree working area, to help you keep on top of your grades.

**To move nodes within the Node Editor:**

- Drag any node to a new position.
- Command-click or drag a bounding box around multiple nodes that you want to move, and drag them all to a new position.

Of course, it’s easy to get carried away. If you’ve been working furiously on a complex grade and you find yourself staring at a riot of disorganized nodes, it’s easy to quickly reorganize your node graph using a pair of commands in the Node Editor contextual menu.

**To clean up the node graph, right-click the Node Editor and choose one of the following commands:**

- **Cleanup node graph with curves:** Moves all nodes in the node graph so they appear in an evenly spaced grid. Connection lines are curved around nodes to minimize clutter.
- **Cleanup node graph without curves:** Moves all nodes in the node graph so they appear in an evenly spaced grid. Connection lines cut across nodes as necessary.
Using Compound Nodes

Another node structure you can use to keep complex node trees organized is the compound node. You can Command-click to select any number of nodes in the node tree (selected nodes are highlighted red), and then use the “Create Compound Node” command to nest all selected nodes inside of a single node.

The resulting compound node that’s created has as many inputs and outputs as are necessary to accommodate the connection lines that attached the nodes you selected to the rest of the node tree.

You can use compound nodes to organize complicated node trees by nesting sets of nodes that work together to do a specific thing within a single node. You can also turn a set of nodes that you’re using to create a specific effect into a compound node in preparation for saving to the Gallery. Creating a library of effects in this way makes it easy to reuse them via the Append Grade command, without the undue burden of adding lots more nodes to your grade later on.
Methods for creating and working with compound nodes:

- **To create a compound node**: Command-click each node you want to nest inside of a compound node to select them with a red highlight. Then, right-click one of the selected nodes, and choose Create Compound Node from the contextual menu.

- **To edit a compound node**: Either hold the Command key down while double-clicking the compound node you want to open, or right-click any compound node and choose Show Compound Node from the contextual menu. The contents of that node appear in the Node Editor, taking the place of the overall node tree.

- **To exit a compound node you’re editing**: To return to the top level node tree, click the leftmost item in the path control at the bottom of the Node Editor.

- **To label a compound node**: Right-click a compound node, choose Change Label from the contextual menu, and type a new label for that node. Press the Return key when you’re finished.

- **To decompose a compound node**: Right-click the compound node you want to decompose, and choose “Decompose Compound Node” from the contextual menu. The compound node disappears, replaced by the original nodes within. Please note, if you had applied an adjustment to the compound node itself, that adjustment is lost when you decompose it back into its constituent nodes. If you want to preserve the compound node adjustment itself, you can copy it, then decompose the node, and then create a new node and paste the adjustment you’d copied.

Adding Inputs and Outputs to Compound Nodes

When you open the contents of a compound node using the Show Compound Node command, you can make whatever adjustments you like to the node tree within, but you also have the option of right-clicking within the Node Editor and choosing Add Source to add an input to the compound node, or Add Output to add an output. Adding more inputs and outputs lets you set up the node to connect to the rest of your node tree in more complicated ways. Disconnected inputs and outputs have no effect on your grade.

Furthermore, you can also use the Add Alpha Source and Add Alpha Output contextual menu commands to add KEY inputs and outputs to a compound node, making it easy to route key or alpha channel data to other connections in the enclosing node tree.

Nesting Compound Nodes

Compound nodes can also be nested within other compound nodes, if necessary.

Grading Compound Nodes

After you've created a compound node, you can select it to make one or more adjustments using the compound node itself, which effectively adds those adjustments after all other adjustments that take place via the nodes that are inside of the compound node. This gives you the opportunity to “trim” the effect that compound node is having on your grade, or to limit it using a qualifier or window.

To adjust the individual nodes nested within a compound node, you need to first open the compound node. Then, you can select and adjust any node as you ordinarily would.
Identifying Nodes

As you make various adjustments to nodes, small badges appear underneath that indicate what each node is actually doing. Since nodes are capable of holding multiple adjustments, any given node may have multiple badges; how many badges a node can show depends on the zoom level of the Node Editor. Larger nodes will show more badges, whereas smaller nodes will show fewer badges, hiding whichever badges don’t fit.

Another nice organizational feature of the Node Editor is an automatic tooltip that appears whenever you hover the pointer over a particular node, that shows you a concise list of all the operations applied to that particular node.

Putting Nodes into HDR Mode

When using various grading controls in the Color page to grade wide-latitude images for HDR output, you may find it useful to enable the HDR mode of the node you’re working on by right-clicking that node in the Node Editor and choosing HDR Mode from the contextual menu.

This setting adapts that node’s controls to work within an expanded HDR range. Practically speaking, this makes it easier to work with wide-latitude signals using controls that operate by letting you make adjustments at different tonal ranges such as Lift/Gamma/Gain, Custom Curves, Soft Clip, and so on.
Clip vs. Timeline Grading

Ordinarily, the Node Editor has two modes. The default Clip mode lets you create individual grades for each clip or group in the Timeline. However, the Timeline grade mode lets you apply a single grade simultaneously to every clip in the Timeline, as seen in the Thumbnail timeline in the following screenshot.

A paragon of sophisticated grading, the author applies a red edge vignette to every clip in the project simultaneously using the Timeline grade.

There are a variety of reasons you might want to do this. For example, if you’re working on a commercial spot, you might elect to use Clip grades to do general correcting and scene-to-scene balancing, and then use the Timeline grade to apply a single stylistic grade to the entire spot simultaneously. That way, any changes the client wants made to the style of the grade can be instantly applied to the whole spot.

Another example would be using the Timeline grade to apply corrections meant to address QC issues running throughout a program, desaturating highlights or selectively darkening a specific shade of red wherever it appears.

To switch between Clip and Timeline grading modes:

Choose the mode from the pop-up menu at the top right of the Node Editor.

Click the dot in the Node Editor toolbar that corresponds to the Clip or Timeline mode.

Two dots show whether you’re in Clip or Timeline mode; these can be clicked to switch.

NOTE: When you reset the Timeline grade using the Color > Reset All Grades and Nodes command, the Output Sizing parameters are reset as well.

Two dots at the top of the Node Editor let you switch between Clip and Timeline modes via a single click. If you’re working on a clip that’s part of a group, four dots will be displayed to allow fast access to the Pre-Clip and Post-Clip Group modes as well. For more information about group grading, see Chapter 116, “Grade Management.”
Timeline Grades and Saved Stills
When you save a Gallery still, the Clip and Timeline grades are both saved. However, when you apply a grade from that still, you only apply either the Clip grade, or the Timeline grade, depending on which mode the Node Editor is in. For more information on saving and applying grades, see Chapter 116, “Grade Management.”

Grading Order of Operations
As you construct grades more carefully in the Color page, it may help you to know what the precise order of operations are in the image processing pipeline of DaVinci Resolve. While you can control the order of operations for node-specific adjustments by being careful about what you do in which nodes, the order of pre-grade, non-node specific, and post-grade operations are all fixed.

The following illustration shows DaVinci Resolve’s order of operations:
This chapter covers the four fundamental node structures you can use to combine Color page adjustments in even more detailed ways. These methods let you control your order of operations and re-combine multiple versions of the graded image in much more specific ways.
Serial, Parallel, and Layer Node Tree Structures

There are several ways you can organize nodes in a tree. Each method lets you control a group of image processing operations in different ways to achieve specific results. This section covers how to use Serial nodes, Parallel nodes, and Layer nodes, as well as how to use LUTs, work with HDR media that lets you combine two different exposures using two different Source inputs, and apply additional project-wide adjustments using the Timeline grade.

Serial Node Structures

The simplest, and most common node structure is a serial cascade of nodes, where a linear series of nodes is connected, one after another.

Much of the time, this method of constructing a tree of multiple operations is all you need to do. It’s a simple and intuitive way of organizing your adjustments, similar in principle to the stacks of layers used in other grading and compositing applications to apply multiple operations to a clip.

Controlling What Feeds a Node’s RGB Input

When you create a grade using serially arranged nodes, each node’s output is used as the next node’s input, so the order in which the nodes are arranged determines the order of image processing operations.

In the following screenshot, the node tree shows a series of three operations that are applied to a log-exposed, low-contrast clip. The first node expands clip contrast and increases saturation. The second node isolates the sky to intensify its color. The third desaturates and warms the image. At right, you can see the result of this node tree.

If, instead, we reversed the order of Nodes 2 and 3, the result will be a less effective key.
By comparison, Node 3 pulls a less than optimal key from the image data fed it by Node 2.

Because the secondary operation is sampling the desaturated image, rather than the source, the HSL Qualifier’s key has less image data to work with, and thus you get an inferior result.

**Parallel Node Structures**

Another way to organize your corrections is to use a Parallel node structure, which lets you apply two or more overlapping adjustments at a single stage of a node tree. You can use the Parallel node structure for organizational reasons when there is a group of secondary corrections that you want to apply all at once. You can also use this structure for the unique way it blends overlapping image adjustments.

The Parallel Mixer node that makes this possible has multiple RGB inputs and a single RGB output. This lets the Parallel Mixer mix together multiple Corrector nodes, outputting a single image as a result.

When you add a Parallel node to an existing node, DaVinci Resolve automatically adds one Corrector node below the current node, and adds a Parallel Mixer node to its output.

**TIP:** If you want to create a series of Parallel nodes that connect to the output of the currently selected node, create a Serial node before you create your first Parallel node.

If you’re manually connecting another node to a Parallel Mixer node, you must first create an additional input to connect it to.

**To create an additional, unconnected input on a Parallel Mixer node:**

Right-click a Parallel Mixer node and choose Add One Input.
Ordinarily, the RGB input of every Corrector node that’s connected to a Parallel node is connected to the output of the same node. This results in a stack of nodes that take the same state of the image as their input. This makes it easy to apply multiple secondary operations without worrying about whether or not a change to one will affect the keys of the others.

Further Parallel nodes can be added as you wish with each using a common source.

If you add another node in parallel, the Parallel Mixer automatically adds another input. You can have as many nodes in parallel as you need.

The adjustments made by all nodes that are connected to a Parallel Mixer are combined equally, regardless of which nodes are highest. In the following example, a separate overlapping window is applied by each of three nodes in parallel.

The Parallel Mixer blends all input nodes together.

As you can see in the image at right, the three tints created by the overlapping windows are all mixed together equally; the colors blend with one another as if they are optically mixed. Most of the time, this is exactly what you want when you’re blending overlapping naturalistic color adjustments.
Converting Parallel Mixers to Layer Mixers

On the other hand, if you need your overlapping color adjustments to have priority over one another, or if you want to combine multiple adjustments using composite modes, then you may want to use the Layer Mixer node instead. If you’ve created a Parallel Mixer structure and you want to convert it to a Layer Mixer, you can.

**To change a Parallel Mixer node into a Layer Mixer node:**
Right-click a Parallel Mixer node and choose Morph Into Layer Mixer Node.

Layer Mixer Node Structures

The Layer Mixer is structurally quite similar to the layout used by the Parallel Mixer. However, there are two key differences. First, the Layer Mixer node combines multiple adjustments with priority given to the image adjustment in the lowest overlapping node input. Second, you have the option of combining all of the Corrector nodes that are connected to a Layer Mixer using one of several different composite modes, to create a wide variety of visual effects.

Because of their similarities, layering nodes with the Layer Mixer works in much the same way as creating a Parallel node structure.

Layer Mixer Prioritization

In the following example, the same node structure from the Parallel Mixer example is shown, this time with the three overlapping color adjustments mixed together using the Layer Mixer.

Now, instead of the three adjusted color tints being blended, you can see that the blue tint, which is connected to the lowest input of the Layer Mixer, is dominant and covers the overlapping regions of the two other adjustments. Meanwhile, the green tint, which is connected to the middle input of the Layer Mixer, covers the overlapping portion of the orange tint, which is connected to the highest input of the Layer Mixer.

Rearranging which connections are attached to which Layer Mixer inputs changes each node’s priority, and like the Parallel Mixer, you can add more inputs if you need to connect more nodes manually.
The Layer Mixer’s prioritization is most useful when you have an overlapping adjustment that you need to override any other adjustments happening on that stack. In the following example, two nodes are connected to the Layer Mixer node. Node 2 is applying a high-contrast, cool look to the entire clip. Node 3 isolates the skin tone, which is unflattering with the background stylization, and applies a different, more naturalistic adjustment.

Using the layer mixer, grades on Node 3 will have a greater priority over Node 2, so the final grade combines the high contrast from Node 2 with the adjusted skin tone from Node 4.

Because of the Layer Mixer’s prioritization, the adjustment made to the woman’s skin tone completely covers the adjustment made to the node that comes above it, providing the best of both worlds with one simple adjustment.

**TIP:** If you want to “solo” overlapping nodes that are connected to the Layer Mixer to see their individual adjustment, turn on Highlight (Shift-H, or the HILITE button on the Transport panel of the DaVinci control panel). This lets you view just that node’s effect, regardless of what other node adjustments are overlapping.

### Using Composite Modes With the Layer Mixer

You have the option of combining the adjustments made by all nodes connected to a Layer Mixer node using the same Composite modes that are available when compositing clips in the Timeline. This lets you combine different overlapping image adjustments using compositing math to achieve creative effects or utilitarian fixes.

The following simple example shows two overlapping Corrector nodes connected to a Layer Mixer node that’s set to the Add composite mode. Node 3 has no adjustment, but Node 5 has an extremely high-contrast curve adjustment applied, along with a blur, that effectively isolates the highlights of the image and feathers them out.
Combining two nodes using the Layer Mixer set to Add to create a glowing effect

By adding both treatments together, a hot glow has been created, blowing out the highlights of the image. Many, many other effects are possible using the different composite modes that are available. For more information on composite modes, see Chapter 41, “Compositing and Transforms in the Timeline.”

**TIP:** Scrolling through the submenu of Composite modes in a Layer Mixer node’s contextual menu gives you a live update in the Viewer of how each transfer node affects the image.

### Adjusting Layer Node Strength Using Key Output Gain

Whether you’re combining overlapping corrections, or mixing different adjustments using Composite modes, you’ll run into situations where you want to reduce the influence of one overlapping adjustment relative to the other nodes that are connected to the Layer Mixer node. This can be accomplished using each overlapping node’s Key Output Gain parameter, located in the Key palette.

**Using the Output Gain parameter in the Key palette**
Key Output Gain defaults to 1.00, but lowering this value reduces the strength of that node’s contribution to the Layer Mixer. Using the previous example, selecting Node 4 (the high-contrast image used to create the glow), opening the Key palette, and reducing the Key Output Gain parameter to 0.50 reduces the intensity of the Glow effect by half.

You can use Key Output Gain to mix the proportion of any number of overlapping adjustments in order to create the perfect combination for your purposes.

**TIP:** You can also use the Key Output Gain parameter to mix the proportion of adjustments being combined using the Parallel Mixer node.

**Converting Layer Mixers to Parallel Mixers**

You can easily convert a Layer Mixer to a Parallel Mixer should you discover that you need to mix your overlapping corrections evenly rather than combine them with priority. Keep in mind that you’ll lose the ability to use Composite modes.

**To change a Layer Mixer node into a Parallel Mixer node:**

Right-click a Parallel Mixer node and choose Morph Into Parallel Node.
Combining Keys and Using Mattes

A key is the actual image channel that’s generated by different secondary operations to isolate specific portions of images to work on. This chapter covers different ways you can manipulate and combine keys from multiple nodes, or propagate keys among nodes. It also shows different ways you can use mattes that are imported from other applications, as well as how to use the Key palette to further manipulate keys in different ways.
Introduction to Manipulating and Combining Keys

Each node’s key input and key output makes it possible to route key channel data from one node to another so you can apply isolated corrections. Furthermore, the Key Mixer lets you combine a variety of keys from different nodes to create more detailed keys with which to tackle complex operations. This section covers all the ways you can recombine key data, as well as how keys can be used in conjunction with the Alpha output to create regions of transparency in a clip for compositing right within DaVinci Resolve.

Outside Nodes

Whenever you use a Power Window or HSL Qualifier to limit a correction within one node, a special node structure lets you automatically create a second node, called an Outside node, to apply additional adjustments to the inverse of the region you isolated in the previous node. Outside nodes are really just Corrector nodes with the Key Palette’s Key Input Invert control enabled, which makes it easy to apply separate corrections to an isolated subject and to its surroundings.

To add an Outside node to a node, creating a secondary correction:

1. Select a node that has been limited using a Power Window or HSL Qualifier.
2. Do one of the following:
   • Choose Nodes > Add Outside (Option-O).
   • Right-click a node choose Add Outside Node.

Press the ADD OUTSIDE button on the T-bar panel of the DaVinci control panel.

A new node is created immediately after the selected node, with the RGB and key outputs of the first node automatically connected to those of the new node.
When selecting the new node and opening the Key palette, you can see that the Key Input’s Invert control is on by default, which is what inverts the key from the previous node.

The Key Input Invert control is on by default for each node.

If, instead of using the Outside node to invert the incoming key, you want to copy the existing key in order to perform another operation to the same isolated region, you can disable the key input’s Invert control.

Feeding Keys From One Node to Another

One of the most powerful aspects of the Node Editor is the ability to create keys based on a specific part of the node tree, and feed the result into a completely different correction somewhere else in the node tree. This is one of the reasons for the separate key input and output on every Corrector node.

The key that’s created whenever you use the HSL Qualifier, create one or more windows, or use an external matte can be output from one node’s key output and fed to the key input of any other node in a tree. There are many reasons to do this, but the following example shows a common problem you can solve with this technique.

Using a key from one node to make an adjustment with a different node:

1. Use Node 1 to apply a basic primary correction, increasing contrast and balancing the color to achieve a pleasing ambient color temperature.

2. Add a Serial node (Node 2), followed by a Layer Mixer node which also adds Node 4 (as seen in the following screenshots). Then, completely desaturate Node 4 and add contrast to make it super-high contrast black and white, desaturate Node 2 just a bit, and right-click the Layer Mixer node to choose the Overlay blend mode with which to combine these two layers.

The result is a highly stylized image, but the skin tone on the actor’s face and hands in the resulting image are too monochromatic, and you want to give them some differentiation. Simply adding another node after the Layer Mixer and keying the skin tone may not work well because the low level of saturation will make a key difficult to pull.
3 Add another node after the Layer Mixer (Node 5 in the screenshot), and then right-click in the gray background area of the Node Editor, and choose Add Node > Corrector to create an unattached node, (Node 6).

4 Connect the RGB output of Node 1 to the RGB input of Node 6, and then connect the key output of Node 6 to the key input of Node 5. Now you’re ready to pull a high-quality key from the very first correction in Node 1, skipping all the complication coming afterwards.

5 Use the HSL Qualifier in Node 6 to pull a good strong skin tone key based on the primary image. Given the way the node tree is now set up, that key is fed to Node 5, and will limit whatever adjustments you make there.

6 Now, you can make your adjustment to Node 6’s grade, to lower the contrast, brighten, and increase the saturation of the actor’s skin tone. As a result of this operation, the background remains desaturated and contrasty, while the actor’s skin tone has the brighter quality we need for the shot.
This example could have been handled in a variety of different ways, but the point is that you can add nodes that connect to the state of the image at any part of a node tree, and use them to generate keys to feed to any other node, regardless of what’s happening to the picture in between.

**Connecting Key Outputs to RGB Inputs, and Vice Versa**

There’s another way you can manipulate a key from one node using another in the Node Editor, and that’s to connect the key output from one node to the RGB input of another node. When you do this, you can use any of the controls of the second node to manipulate the key, and you can then use the result by connecting the RGB output of the second node to the key input of a third node.

Connecting a key output to an RGB input to adjust a key with a second node’s controls

In the node tree shown above, Node 2 pulls a key, Node 4 manipulates the key, and Node 3 uses the key to make a color adjustment.
Keep in mind that a key is just a grayscale image. Setting up this kind of node structure lets you use any of the second node’s controls, such as the Custom Curves, Noise Reduction or Motion Blur controls, Sharpen, Midtone Contrast, Lift/Gamma/Gain, Contrast, or Log controls, to manipulate the key in ways you couldn’t do using only the Matte Finesse controls.

While this technique may not be necessary for conventional color isolations, it can come in very handy when making tricky isolations with hard to key subjects, or when using one of the Qualifier modes to pull a key to create transparency for compositing using the Node Editor’s Alpha output. In this instance, you can connect the RGB output of a node used for key manipulation directly to the Alpha output. In the example, Node 1 pulls a key, and the RGB is connected to Node 2 which is used to color correct the foreground image. The key from Node 1 is connected to the RGB of Node 3, which manipulates the key to clean it up prior to connecting it to the Alpha output block at the bottom right of the Node Editor.

Furthermore, this capability also lets you create keys in other ways besides using the Qualifier palette controls. In the following example, the Contrast and Custom Curve controls in Node 3 create a high-contrast matte of the windows which is blurred. The RGB output of Node 3 is then connected to the KEY input of Node 2, where the resulting key can be used for a variety of adjustments; in this case, to tint the product within the image green. Alternately, this technique could be also be used to create transparency via the Alpha output.

Interconnecting key and RGB inputs and outputs is a powerful capability that lets you create many kinds of workarounds for uncommon situations.
Using External Mattes

The External Matte node has evolved over the years. What was once purely a means for importing matte channels for defining opacity and limiting adjustments has expanded to become a way to import the RGB channels of a media file to be used for overlaying grain, texture, and stylized distress onto an image, and even as a way to use the channels of a clip itself as a matte.

Matte clips can be added to your project in one of two ways:

- You can add mattes using the Media page, either by attaching them to a clip so a particular matte is only available to a particular clip as part of a Clip grade, or you can add timeline mattes that stand alone in the Media Pool, which are then available to any Track grade.
- You can also add a matte to a clip using the Media Pool in the Color page, by dragging a clip from the Media Pool to the Node Editor. When you do so, that clip is turned into an external matte in the current grade, which you can use as a matte for secondary adjustments, or as a compositing layer (in conjunction with the Layer mixer) for mixing textures or images with your grade. That clip is also automatically attached to the Media Pool clip that corresponds to the clip you’re grading, as a clip matte, to help you keep track of which clips are using other clips as mattes.

For more information about adding matte clips in the Media page, see “Adding and Removing External Mattes” in Chapter 11, “Adding and Organizing Media with the Media Pool.”

Whether attached or unattached, mattes operate within a grade using EXT MATTE (external matte) nodes. EXT MATTE nodes have the following outputs:

- **EXT MATTE Outputs**: Four blue triangular key outputs let you output the channels contained within the EXT MATTE node, but which channels are available affects what is output. If the EXT MATTE node’s source clip has RGBA channels, then these are available as Alpha, Red, Green, and Blue key outputs that you can attach to any other node’s key input. On the other hand, if the EXT MATTE node’s source clip only has RGB channels, then the key outputs that are made available are Y (luma), Red, Green, and Blue, and a “Use Lum for Alpha Output” setting in the Node Editor contextual menu lets you use the Y channel as a matte.
An interesting aspect of these four outputs is that each one is dedicated to individual A, R, G, and B color channels. Ordinarily, External Matte clips are written with matte data written simultaneously to all three RGB channels. However, you could also render separate pure primary-colored mattes to each color channel (a so-called “disco” matte), so that the Red channel has one matte, the Green channel another, and the Blue channels still another, thereby exporting three separate mattes within a single media file, for convenience. If you add another matte to the Alpha channel, you can even export four mattes within a single file. You can then use each one of these mattes individually by connecting the correct output of the EXT MATTE node. (Note: For backward compatibility, projects from versions of DaVinci Resolve previous to 12.5 continue to output RGBY from the triangular outputs, not YRGB.)

- **RGB Output**: A round green RGB output lets you connect the RGB image data of a matte clip to any other clip’s RGB input. This is especially useful when you’re combining a matte clip with the current clip using a Layer Mixer node, to create a textured composite of some kind.

### External Mattes to Limit Adjustments

Going back to the External Matte node’s original use, mattes are typically grayscale media files that represent image opacity, and are meant to be used either as alpha channels for creating opacity within a corresponding RGB clip, or as a matte for limiting effects.

An example of a matte channel would be the key created by a green screen keyer. If you output just the key, that would be an external matte. If you receive an external matte along with an effects clip, you can attach the matte to its corresponding RGB clip in the Media page. Then, you can access that matte via an External Matte node in the Node Editor, so you can use the key it outputs to limit different kinds of corrections you want to apply.

In the following example, the keyed matte of a green screen composite clip is used to apply different corrections to the inside and outside of a keyed composite, in order to make the subject match the background more convincingly.

A matte attached to clip Makeup_Green.mov, as seen in the Media Pool

### To use a clip matte to limit an adjustment within a Clip grade:

1. Right-click any node, and choose the attached matte you want to use from the Add Matte submenu of the contextual menu.

   By default, the EXT MATTE node that appears has its first output connected to the triangle output of a node you want it to limit.

2. Select the node to which the EXT MATTE node is attached, and add an Outside node to make it possible to add adjustments on either side of the matte.
Node Editor displaying the influence of the external matte on multiple nodes when the keys are linked

3 If necessary, select Node 1, and use the Key palette controls to modify the incoming key, inverting or blurring it as necessary to create the isolation you need.

**NOTE:** Don’t select the EXT MATTE node, because it exposes different controls in the Key palette for transforming, flipping, looping, and freezing the matte.

At this point, you can add adjustments to the inside and the outside of this composited shot to improve the composite.

(Before/After) An external matte is used to apply separate grades to the foreground and background of a previously composited clip
Ideally, external mattes are exported so that they match the size and duration of the RGB clip they’re supposed to accompany. If they don’t match or if you’re using some other grayscale clip as an external matte to create some sort of effect, then there are parameters in the Key palette that you can use to retime or transform a matte so it works better in your grade.

**To slip the sync of a matte relative to the clip it’s attached to:**

1. Select the Ext Matte node you want to slip.
2. Open the Key palette, and raise or lower the Offset parameter until the matte is perfectly aligned with the clip it’s supposed to match.

**To transform a matte:**

1. Select the Ext Matte you want to transform.
2. Open the Key palette, and turn off the Lock Matte checkbox.
3. Use the Pan, Tilt, Zoom, Rotate, Width, Height, HFlip, or VFlip parameters to adjust the matte so it has the correct geometry.

It’s worth mentioning that you can attach as many external mattes to a single clip in DaVinci Resolve as you like. For example, if a CGI shot has been delivered with a set of isolation mattes for each of three characters in the scene, you can import all three mattes and use them to isolate adjustments that you want to make in the Node Editor.

**Extracting External Mattes from OpenEXR Layers**

OpenEXR media is capable of containing multiple layers and multiple alpha channels, which can also be accessed from EXT MATTE nodes. As a result, DaVinci Resolve uses a slightly different but related procedure for accessing these mattes.

**To extract OpenEXR layers as external matte nodes:**

1. Right-click any node, and choose the .exr clip name from the Add Matte submenu of the contextual menu.
   By default, the EXT MATTE node that appears has its first output connected to the Connect one of the EXT MATTE node’s triangular key outputs to the key input of a node you want it to limit.

2. Double-click the EXT MATTE node to select it, then right-click it and choose which layer you want to use from the Select Matte submenu.
Right-clicking an OpenEXR file’s EXT MATTE node to choose which layer to use

OpenEXR files with multiple RGBA layers (or passes) embedded within them (RGBA + RGBA + RGBA and so on) or OpenEXR files with multiple alpha channels (RGBA + A + A) expose multiple entries in this submenu. Whichever one you choose is the layer that will be used as a matte by that EXT MATTE node.

Once you’ve extracted an OpenEXR layer, you can use it as you would any other EXT MATTE node described in this section, to limit adjustments (as seen above), or to add texture or transparency (as seen in the following sections).

**Using External Mattes to Add Texture**

You can also use external mattes as creative tools, to add grain and texture. For example, you might use a more abstract animated matte, or a grayscale film scan of dirt and dust, to apply correction for effect.

Light leak and dirt and dust images From Warren Eagles’ Scratch FX collection (FXPHD), designed to add texture to your grades
Once attached to a clip, external mattes can be exposed in the Node Editor, and their key output can be used just like any other key in a node tree.

**To use a clip matte to create texture for a Clip or Track grade:**

1. When applying a matte as part of a Clip or Timeline grade, right-click any node and choose the attached or timeline matte you want to use from the Add Matte submenu of the contextual menu. Unattached mattes appear in the Add Matte > Timeline Mattes submenu.

2. Disconnect the EXT MATTE node’s key output connection to the Key input of the node it’s connected to by default.

3. Add a Layer Mixer to the end of the node tree.

4. Disconnect the bottom Corrector node’s RGB input, and then connect it to the EXT MATTE node’s round RGB output.

5. Right-click the Layer Mixer node, and choose Overlay from the Composite Mode submenu to blend the Ext Matte node most effectively with the grade.

6. If necessary, you can use the grading controls of the Corrector node to which you’ve attached the EXT MATTE node to change the characteristics of the texture clip, desaturating it for instance. You can also select the EXT MATTE node itself, open the Key palette, and use the Transform, Offset, Loop, or Freeze controls described later to change how the matte appears.

**TIP:** If you want the texture you create to be unaffected by blur or sharpening operations within the grade, be sure to add it to the very end of the node tree.
Using External Mattes to Create Transparency

You can also use an EXT MATTE node to create transparency in a clip, for compositing with clips underneath it on the Timeline.

To use a clip matte to create transparency in a clip:
1. Right-click any node, and choose the attached matte you want to use from the Add Matte submenu of the contextual menu.

   Adding an EXT MATTE node to a Clip grade applies the effect to only that clip, whereas adding an EXT MATTE node to a Track grade applies the effect to the entire Timeline.

2. Right-click any empty area of the Node Editor, and choose Add Alpha Output to reveal the Node Tree output on the right that lets you assign a key to be used to define clip transparency.

3. Connect one of the EXT MATTE node’s triangular key outputs to the Alpha output at the right of the Node Editor.

   The node setup for using an external matte to composite two layer

   The areas of the matte defined by the key are now rendered transparent.

   The final composite created using the external matte node

Key Palette Controls for the External Matte Node

When you select an EXT MATTE node, the Key palette displays different parameters only for mattes. Be aware that you must turn off the Lock Matte checkbox before you can make adjustments to transform the matte.
The Key Palette showing a texture layer added as an EXT MATTE node

- **Transform**: Standard Pan, Tilt, Zoom, Rotate, Width, and Height parameters let you transform a matte to fit the image better.
- **Flip Image**: Two buttons let you flip the matte clip horizontally or vertically.
- **Offset**: Adjust this parameter to offset the start point of a matte clip.
- **Freeze**: Turning on this checkbox freezes the matte clip on a single frame. Adjust the Offset parameter to choose which frame to freeze on.
- **Loop**: Turning on this checkbox enables matte clips to loop endlessly, which lets shorter matte clips cover longer durations.
- **Lock Matte**: When turned on, locks the sizing of a matte to whatever changes are made to the Input Sizing of that clip, so the matte transforms to follow the clip.

You can also use external mattes as creative tools. For example, you might use a more abstract animated matte, or a grayscale film scan of dirt and dust, to apply correction for effect.

### Using the Key Mixer

The Key Mixer node lets you mix keys output from multiple Corrector nodes, combining them in different ways to create a single key output. This makes it possible to build much more intricate keys than you can with a single qualifier or set of four windows. In particular, the Key Mixer node is the only way to combine multiple keys made using qualifiers and windows, adding, subtracting, or intersecting them to create a highly specific result.

### Adding Two Keys Together

In the following example, you’ll learn how to set up a Key Mixer to combine the keys output by two Corrector nodes in a node tree. Then you’ll learn how to change the way the input keys are combined using the Key palette.

**To combine two or more keys using the Key Mixer:**

1. Right-click anywhere on the gray area of the Node Editor, and choose Add Node > Key Mixer.
2. Create two Corrector nodes, then attach their RGB inputs to the RGB output from an appropriate node in the main part of the tree, and attach their key outputs to the key inputs of the Key Mixer.
3 Next, attach the key output of the Key Mixer node to the key input of the node you want to use to make the correction. Remember, the objective is to use the key that’s output by the Key Mixer to limit the adjustment being made using another node, in this case Node 3.

![Node tree setup](image)

Setting up the node tree you’ll need to combine two keys together

Keep in mind, especially since this is a significant reordering of nodes in the Node Editor, that every node needs to be connected properly for the overall grade to work.

4 Now that the node structure is fully connected, use windows, qualifiers, or both to create keys in each of the nodes that you connected to the Key Mixer. In this example, Node 2 is isolating the main skin tone, and Node 5 is isolating the blue of his jeans and hood.

By default, all keys connected to the Key Mixer are added together, as you can see in the Key Mixer’s thumbnail.

![Key Mixer example](image)

Combining multiple keys with the Key Mixer

If you wanted, you can use the controls in the Key palette to change this, in order to isolate the intersection of two keys, or to subtract one key from another. This is covered in the next section.

5 Continuing with the previous setup where both keys are added together by default, selecting Node 3 and dropping the saturation to be very faint stylizes the entire background, while leaving the various hues of the man we’ve isolated alone.
Subtracting One Key from Another

The way multiple keys are combined within the Key Mixer depends on a pair of Key Input buttons you can toggle using the Key palette. In the following example, a partial green tint is washed throughout the midtones of the image using a qualifier, but you want to exclude the man’s skin tone from this operation. Using the Key Mixer, you can subtract one key from another to accomplish this with ease.

To change the Key Input settings for a node connected to a Key Mixer:

1. In this example, Node 2 is isolating part of the midtones of the image, and feeding its key through the Key Mixer to Node 4, which is using it to apply a partial blue tint. However, in preparation for subtracting the skin tone from this operation, Node 3 is isolating the man’s skin tone.
To reveal the controls you’ll use to change how the key from Node 3 interacts with the key from Node 2, double-click the Key Mixer node to select it.

Open the Key palette; a list of all input links that are connected to the Key Mixer appears at the right.

Within each list entry is the input name (Input Link 1, Input Link 2, etc.), a Matte control, a Mask control, a gain parameter, and an offset parameter.

- **To subtract Node 3’s key from that of Node 2:** Turn on both the Key Input Matte button and the Key Input Invert button for Input Link 2.

- **To subtract Node 2’s key from that of Node 3:** Turn on both the Key Input Matte button and the Key Input Invert button for Input Link 1.
• To limit the output to the intersection of both keys: Turn on the Key Input Matte button for either Input Link 1 or Input Link 2.

![Key Mixer](image)

Turning on Matte for Input Link 1 to output the intersection of two mattes

• To invert the resulting matte you’ve created: Turn on the Output Link Invert button.

When you’re finished, if you choose to subtract Node 3’s key from that of Node 2, the result should resemble the following screenshot.

![Screenshot](image)

The result of subtracting a key of the man’s face from a key of the overall midtones of the image, and using that to add a selective green tint

**Adding Inputs to Key Mixer Nodes**

New Key Mixer nodes have two key inputs by default. If necessary, additional inputs can be added in order to combine even more keys with one another.

**To add inputs to the Key Mixer:**

Right-click a Key Mixer node, and choose Add One Input.

When combining three or more keys, the interaction of keys using the Key palette controls becomes even more complex, but the rules outlined above still apply.
Using the Key Palette

For example, the Key Input Invert control is always enabled when you add an Outside node, which is why the Outside node applies adjustments to the inverse area of the previous node. If you turn this control off, that node’s key will exactly mirror the original key being fed to it from the previous node.

The controls that are available in the Key palette vary depending on what kind of node you have selected:

- **Corrector Nodes:** Have three sets of parameters. Key Input parameters let you make adjustments to keys being fed through a node’s Key Input connection. The Key Output parameters let you make adjustments to the key data being output by a node’s Key Output connection, and includes the incredibly powerful Offset Gain parameter that governs the strength of that node’s contribution to the overall grade. Finally, the Qualifier parameters let you make adjustments to the internal key created with the HSL Qualifier or Window controls. This functionality is covered more extensively in the next section.

- **Ext Mattes:** Have two sets of parameters. Transform parameters let you make geometric transformations to a matte so it fits the clip it’s being applied to better. An Offset control lets you slip the sync between an external matte and the clip to which it’s applied. This functionality is covered in the section on external mattes.

- **Key Mixer Nodes:** Have two sets of parameters that are dependent on which of the connections attached to a Key Mixer’s key inputs is selected. Input parameters let you adjust how much of a contribution a key makes to the total key mix, and whether the contribution is additive or subtractive.

The Output parameters let you adjust the inversion and strength of the key that’s output by the Key Mixer. This functionality is described more extensively in the Key Mixer section.

Layer Mixer and Parallel Mixer nodes have no adjustable controls in the Key palette.

Using the Key Palette to Affect Corrector Nodes

When you open the Key palette for a selected Corrector node, you can adjust the following parameters:

![Key palette showing controls when a node is selected](image-url)
Key Input Controls

- **Input invert**: Inverts the key being fed into the key input. Off by default.
- **Input matte**: Lets you switch the key input between Matte and Mask modes. In Matte mode (on by default) the key input combines via intersection with keys generated internally using the Qualifier or Windows palette. In Mask mode, the key input is added to the internal key instead.
- **Gain**: Controls the strength of the key connected to the key input.
- **Offset**: Controls the contrast of the key connected to the key input.
- **Blur Radius**: Blurs the key connected to the key input.
- **Blur H/V Ratio**: Alters the horizontal/vertical ratio of the blur that’s being applied to the key input.

Key Output Controls

- **Qualifier invert**: Inverts the overall key.
- **Gain**: Using the key output, this parameter governs the strength of that node’s contribution to the overall grade. Setting Gain to 0 results in that node having no effect at all, while the default setting of 1.00 applies the full strength of any adjustments made with that node. The maximum setting of 2.00 increases the intensity of any part of the key output that’s less than 100 percent white. You can also use this parameter to keyframe the key output to fade that node’s contribution in or out with one set of keyframes.
- **Offset**: Lets you adjust the contrast of the Output key. This has no effect if the entire key is 100 percent white (a solid key).

Qualifier Controls

- **Qualifier invert**: Inverts the key created by that node’s Qualifier palette.
- **Qualifier matte**: Lets you switch the interaction of the keys generated by the Qualifier and Window palettes between Matte and Mask modes. In Matte mode (the default), the Qualifier and Windows palettes combine via intersection. In Mask mode, they’re added together instead.
- **Gain**: Lets you raise or lower the strength of the key generated by the Qualifier palette.
- **Offset**: Lets you adjust the contrast of the key generated by the Qualifier palette.
Using the Key Palette to Adjust Key Mixer Controls

When you open the Key palette for a selected Key Mixer node, you can adjust the following controls:

![Key palette showing controls when a Key Mixer is selected](image)

- **Input list**: A list of every input that’s connected to the Key Mixer. Each entry on the list has the following controls:
  - **Input name**: The name of each node connection attached to that key mixer, such as Input Link 1, Input Link 2, and so on.
  - **Input invert**: Inverts the key being fed into this particular input. Off by default.
  - **Input mask**: Lets you switch the key input between Matte and Mask modes. In Matte mode (on) the key input combines via intersection with other inputs connected to the Key mixer. In Mask mode (off by default), the key input is added to the other key inputs connected to the Key mixer.
  - **Gain parameter**: Decreases or increases the intensity of that input matte’s contribution to the resulting output matte.
  - **Offset parameter**: Adjusts the contrast of that input matte’s contribution to the resulting output matte.

- **Output invert**: Inverts the overall result of the various Input Link interactions.
- **Gain**: This parameter increases or reduces the strength of the resulting output key. Setting Gain to 0 results in all inputs being set to black, while the default setting of 1.00 outputs the combined mattes at full strength. The maximum setting of 2.00 increases the intensity of any part of the key output that’s less than 100 percent white, which can have the practical effect of “growing” soft edges. You can also use this parameter to keyframe the key output to fade that node’s contribution in or out with one set of keyframes.
- **Offset**: Lets you adjust the contrast of the Output key.
The Many Uses of Key Output Gain

Several of the techniques discussed in here and in “Secondary Qualifiers,” can be further customized using the Key Output Gain parameter, which makes it easy to control the strength of a node’s effect on your grade with a single adjustment. In the following example, two simple Serial nodes are applied to a clip, with the first one expanding image contrast, and the second one using a variety of controls to add some extreme warmth to the highlights.

![A tint applied only to the highlights of the image](image)

If you decided that you want to reduce the amount of warmth added by the second node without readjusting the controls you used to create the effect, you could open the Key palette and lower the Key Output Gain parameter to fade the effect with a single adjustment.

![Four versions of this grade shown using the Versions option of the Split Screen controls, with Output Gain set to 1, .75, .5, and .25 for comparison](image)

This principle also works for controlling the strength of individual nodes that are being combined in parallel, that are combined using the Layer node, or for simply fading out the effect of any node in the node tree you want to “turn down” a bit.
This chapter begins by showing node structures you can use to isolate, split apart, convert, and recombine the image channels of clip in different ways. This includes ways of using the additional image channels that are provided in some types of media.

The second part of the chapter shows ways that you can do image compositing right in the Color page, with techniques for using external mattes for compositing, and using qualifier keys to do green- and blue-screen compositing against other layers in the Timeline.

Isolating, Splitting, and Converting Color Channels

DaVinci Resolve provides two different methods of making channel-specific adjustments, depending on whether you need to apply an adjustment to just one channel within a single node, or apply separate adjustments to all three channels across several nodes.

Enabling, Disabling, and Converting Node Channels

Within the contextual menu of each node in the Node Editor is a series of four options:

- Expanded choices for choosing a color space and gamma for image processing within a node, and for disabling channels

While the ability to change the color space in which a particular node’s operations work from the RGB default has been available for many versions, the list of available color spaces was greatly expanded in DaVinci Resolve 15 (all the previous options such as Lab (CIE), HSL, and YUV are still there). Additionally, you have the option of choosing the gamma that node works with as well, with a similarly long list of options.

Choosing a node-specific color space and gamma does not directly alter the image, as with the Color Space Transform ResolveFX plug-in. Instead, changing a node’s color space and gamma alters what type of image channels the red, green, and blue controls affect, and how the adjustments you make within that node are applied. For example, this lets you make a temperature adjustment with a node’s gamma set to Linear, which in some instances may be mathematically advantageous.

Additionally, three checked Enable Channel 1–3 options let you turn individual channels off or on, limiting which channel that node’s adjustments will actually affect.

In the following example, you’ll see how to use these features to selectively sharpen just the Y’ (luma) of an image without affecting the chroma, which can be a more subtle effect than simply sharpening the entire image.

To use channel disabling and color space conversion to sharpen luma only:

1. Add a node with which to apply the sharpening you want to the current clip.
2. Right-click the new node, and choose YUV from the Color Space submenu of the contextual menu.
3. Apply sharpening by doing one of the following:

- Using the node’s contextual menu, uncheck Enable Channel 2 and Enable Channel 3, which correspond to the U (Cb) and V (Cr) channels, leaving only Channel 1 (Y) enabled. Then, open the Blur palette, and drag the ganged Radius sliders down to sharpen the Y channel.

- You can also just open the Blur palette, ungang the Radius sliders, and drag the red slider down to sharpen the Y channel, since any control with three gangable sliders will automatically assign those sliders to whichever channels are used by the currently selected Color Space.

(Before) The original image. (After) Sharpening applied to only the Y’ channel of the image

As you can see, while the Blur palette ordinarily provides separate R, G, and B controls that can be unganged from one another, the Color Space submenu lets you apply sharpening to the channel definitions of other colorspaces, providing many other corrective and creative possibilities with the same controls.

**Supported Color Spaces for Conversion**

The Color space submenu available when you right-click a node in the Node Editor supports four different color spaces that you can set each node to work within. When you choose a color space other than RGB, all channel-specific controls (the Custom curves, Soft curves, RGB Lift/Gamma/Gain sliders, and RGB mixer) operate on the particular channels of that color space, rather than the default YRGB channels. By switching color spaces, you can achieve very different kinds of adjustments by swinging values among mathematically different axes.

YUV converts the image into Y’, Cb, and Cr channels. The Y’ channel governs luminance, while the Cb and Cr are color difference channels that work within the broadcast model of color.
HSL converts the image into Hue, Saturation, and Lightness channels. Lightness is identical to Luminance, while Hue and Saturation are exactly as described.

LAB operates on the L, A, and B channels. The L channel governs luminance, while the A and B channels are color difference channels; A adjusts color on an axis from magenta to green, B adjusts color on an axis from yellow to blue.

Splitting Channels with the Splitter/Combiner Nodes

Another method of applying corrections to individual color channels is using the Splitter/Combiner nodes, which break the Red, Green, and Blue channels apart into separate node tree branches, each capable of accepting multiple serial and parallel nodes of image adjustment. There are two ways you can create a Splitter/Combiner node structure.

Methods of adding Splitter/Combiner nodes:

• **To add a premade Splitter/Combiner node structure:** Choose Nodes > Add Splitter/Combiner Nodes (Option-Y). A Splitter and Combiner node appear already connected to three Corrector nodes, one for each color channel.

• **To manually construct a Splitter/Combiner node structure:** Right-click in any empty area of the Node Editor, and choose from the Add Node submenu to create a Splitter node, a Combiner node, and three Corrector nodes, wiring them together as necessary to create the desired effect.

The Splitter Combiner node structure

The Splitter node takes an incoming image and provides individual outputs for each color channel (top/red, middle/green, bottom/blue). When you connect each of these outputs to a Corrector node, that color channel automatically connects to all three internal channels of that node, so that the default three nodes in a Splitter/Combiner structure are internally processing red/red/red, green/green/green, blue/blue/blue. The Combiner then pulls the Red, Green, and
Blue channels out of each node connected to its three inputs, and reassembles them into a single RGB image again. Of course, what happens in between the Splitter and Combiner is entirely up to you.

One of the simplest ways of showing the possibilities of this node structure is to combine it with Node Sizing in the Sizing palette. Using Node Sizing, you can correct for misaligned channels in older archived video, or create channel misalignments for creative looks. In the following example, a simple Node Sizing adjustment to a split Blue channel will create an interesting “prism vignette” effect.

**To use Node Sizing on individually split channels:**

1. Choose Nodes > Add Splitter/Combiner Node (or press Option-Y) to add a premade Splitter/Combiner node structure to the Node Editor.

2. Select the middle of the three Corrector nodes appearing in between the Splitter and Combiner nodes (Node 5 in the following screenshot).

3. Open the Sizing palette, choose Node Sizing from the Mode pop-up, and then raise the zoom parameter by a small amount; this example uses 1.014.

As you can see in the screenshot, just the Green channel has been zoomed in on across the entire image. This is only possible using Node Sizing. This is cool, but not quite what you need.

4. Open the Window palette, add a Circular window, turn on its Invert control, and transform it to be a very soft, horizontally aligned vignette. This limits the individual scaling done to the Green channel to just the outer edge of the image, similar to a lens with excessive chromatic aberration.

You could easily keep going, applying varying amounts of zoom with different window shapes to each of the other color channels, and perhaps adding some blur to enhance the effect, but this example should show the creative potential available when using this technique.
Multi-Channel RED HDRx Support

The RED EPIC, SCARLET, DRAGON, and WEAPON cameras are all capable of shooting in an HDR mode that effectively "brackets" two different exposures of each frame. The resulting image data stores two channels of image data: the regular exposure, and a "highlight exposure" that's underexposed by a user-selectable margin (+3, +4, +5, or +6 f-stops difference).

By default, the Input bar in the node graph feeds the regular exposure to your grade's node tree. To take advantage of the additional "highlight" exposure, you can add an additional Source input to the node graph that feeds a second stream of image data that you can mix with the regular exposure in different ways.

**NOTE:** You can also take advantage of the highlight exposure of RED HDRx media by enabling and adjusting the Magic Motion controls in the Camera Raw palette.

To set up a node tree combining the normal and highlight HDR versions:

1. Using the first default node (Node 1), grade the image to see if you even need to use the alternate exposure that's available. We'll assume for this example that you do. In this example, the sky of the default exposure is pretty blown out, but there may be detail that can be retrieved using the highlight exposure.

2. Create a Layer Mixer node by choosing Nodes > Add Layer (Option-L), or press the ADD LAYER button of your control panel.

   Two nodes are created, a Layer Mixer node that's added after Node 1, and a third node (Node 3) that's connected to a second RGB input of the Layer Mixer node in parallel to Node 1.
3. Right-click anywhere within the node graph (except on a node) and choose Add Source from the contextual menu. A second Source input appears underneath the first, which outputs the highlight exposure of the image as a separate image stream.

4. Delete the connection between the top Source input and Node 3, and then connect the bottom Source input to the RGB input of Node 3. Immediately, the image in the node thumbnail and Viewer updates to show the darker, underexposed version of the HDR image. This is because, by default, the Layer Mixer is mixing 100% of Node 3 over Node 1.

5. Select Node 3 and use one of the following two procedures to create a useful combination of the two exposures:

   - To create a mix of the two exposures, open the Key tab, and drag the Key Output Gain slider to lower the contribution of Node 3 to the overall image (you can also do this using the DaVinci control panel by pressing the KEY MODE soft button, and then using the Post Mix Gain rotary control). Using dynamics (keyframing), this is a good way to animate a dissolve from the regular exposure to the highlight exposure if you're going from a dark environment to a bright environment in the same take and you want to create a smooth transition between both exposures.

   - TIP: You can also use the Blend Type and Blend Bias parameters in the Camera Raw palette to blend the two exposures without building a dedicated node tree.
To use the highlight exposure to selectively put detail back into the image (for example, to retrieve blown-out windows), use a Power Window, HSL Qualification, or a combination of the two to isolate the region you want to retrieve in Node 3. (Be careful if you’re using HSL Qualification to combine both exposures, as keyed edges can be tricky to blend.)

Isolating a region of the image to replace using the highlight exposure image of a RED HDRx clip

Final node display with isolations

A Note About RED HDRx Media and Performance

Since RED HDRx media records two complete streams of image data, DaVinci Resolve must simultaneously decode two separate tracks whenever you add a second Source input. (If you don’t add the second Source input, only the first stream is decoded.)

Because of this, whether you’re relying on your computer’s CPU to decode RED media, or you’re using a single RED ROCKET or RED ROCKET-X card, you’ll get half the performance when using the highlight stream of an HDR clip.

To improve performance, you can enable the Smart Cache by choosing Playback > Render Cache > Smart (or by pressing the CACHE MODE button on the T-bar panel of your DaVinci Resolve control panel repeatedly until you toggle to User mode). This automatically caches all raw source clips to the current codec set in the Render Cache Format parameter of the Master Settings panel of the Project Settings. Alternatively, you can enable the User Cache, and cache all HDRx clips manually by right-clicking them and choosing Render Cache Fusion Output > On (or by pressing the CACHE MODE button of your DaVinci Resolve control panel). DaVinci Resolve renders all cached clips while you’re paused, so the next time you play a cached clip, it will play at full speed.

If you regularly use RED HDRx media, two RED ROCKET or RED ROCKET-X cards are recommended for optimal decoding performance.
Introduction to Compositing Using the Alpha Output

While DaVinci Resolve can use the alpha channel of imported media for compositing, the Alpha Output in the Node Editor is an optional output that you can turn on to create clip transparency using operations inside DaVinci Resolve to create composites against other clips on lower video tracks. There are many ways of using the Alpha Output, but this section will focus on three examples.

Using a Qualifier Key to Create Transparency

In this first example, the Alpha Output will be used to composite a green screen clip with a background plate.

In preparation for this composite, the background plate is on track V1 of the Timeline, and the green screen clip has been superimposed on track V2.

To create a chroma-key composite in the Color page:

1. Right-click anywhere within the gray area of the Node Editor and choose Add Alpha Output to add the Alpha Output at the right of the node graph.

An Alpha Output appears underneath the Node Tree output at the right of the Node Editor.
2 You’ll want to use Node 1 to color correct the image to optimize it for keying. In this example, the foreground plate is log-encoded, so a LUT is added to Node 1 to normalize it.

3 Add a Serial node after Node 1 and connect its key output to the Alpha Output. This is a fast way to build this composite if you’re confident that the corrections you’ve made in Node 1 won’t adversely affect the key (or if you know they’ll improve it by expanding the contrast of a flat-contrast source clip).

Alternately, you could create a second processing branch by adding a disconnected node (Node 2), connecting the Source node to its RGB input, and then connecting its key output to the Alpha Output you just added. Creating a second image processing branch from which to pull your key lets you key directly from the source (assuming the source is fit to key without adjustment), avoiding any problems that grading the first node could introduce to the key.

4 Use the Qualifier controls of Node 2 to key out the green background, and then turn on the Invert checkbox to create the proper composite. In this example, we’re using the 3D Qualifier mode to pull a high-quality key.
An HSL Qualification to key the green feeding the Alpha Output to create transparency

5 If there's green spill in the composite (or blue in cases where you're keying a bluescreen) you can turn on the Despill checkbox to eliminate it.

6 You can also use a Power Window to garbage matte out any elements you don’t want intruding into the shot, using the Tracker palette if necessary to make the window follow the motion of the foreground subject.

7 If necessary, you can add another node to the output of Node 2 to make whatever corrections are necessary to the background plate clip to make the composite blend more seamlessly. For example, with this additional node selected, you could right-click the background clip and choose "Shot Match to This Clip" to use the automatic shot matching in DaVinci Resolve to adjust the foreground to match the background.
With all this set up, you end up with a nice green screen composite that's visible in both the Color and Edit pages.

Using a Matte to Create Transparency

If you’ve been provided with a separate Matte clip for defining clip transparency, you can use that Matte clip within the node tree of a superimposed clip to create a composite using the Alpha Output.

To create a composite using an external matte:

1. To associate an external matte with a clip, open the Media page, select the clip you want to add a matte to in the Media Pool, navigate to the matte file using the Library browser, and then right-click the matte file and choose Add as Matte. For more information on importing mattes, see Chapter 119, “Combining Keys and Using Mattes.”

2. Open the Color page and select the foreground clip in the Thumbnail timeline, then right-click Node 1 in the Node Editor and choose the matte you added from the Add Matte submenu.

   An EXT MATTE node appears underneath Node 1, with the first of its four key outputs connected to Node 1’s key input. (Working with external mattes is covered in more detail in a prior section of this chapter.)

3. Now, right-click anywhere within the node graph (other than on a node) and choose Add Alpha Output from the contextual menu.

   An Alpha output appears underneath the Node Tree output.

4. Drag a connection line from the second key output of the EXT MATTE node to the Alpha output.
You should now see a successful composite, with the external matte creating a region of transparency in the foreground clip through which the background clip shows through.

Before and after the final composite, created by connecting an EXT MATTE node to the Alpha output in the node graph.

Use an OFX Plug-in to Create Transparency

If you’ve installed an OFX plug-in capable of keying, you can right-click the node you’ve applied it to and choose Use OFX Alpha to route the key created by the plug-in out the key output of that node. When Use OFX Alpha is enabled, the HSL Qualifier and Window palette output is ignored, the only key that’s output is from the OFX plug-in.
Once Use OFX Alpha is enabled, and you've created a key using your OFX plug-in of choice, you can right-click anywhere within the node graph (other than on a node) and choose Add Alpha Output from the contextual menu to make the Alpha output appear, and you can then connect the key output from the node with the OFX plug-in to the Alpha output to use it to create transparency.

**NOTE:** When Use OFX Alpha is enabled for a node, you cannot use a window to create a garbage matte within that node as you would when keying with the HSL Qualifier. To create a garbage matte with which to exclude unwanted and unkeyable elements from the edges of the picture, you'll need to combine the key from a window in another node with the key output by the OFX plug-in using a Key Mixer node.
Compositing Entirely Within an OFX Plug-In

Certain OFX plug-ins that are capable of combining two image streams to create a composite can be used as of DaVinci Resolve version 11.1 by exposing a “second layer input” on the node to which that plug-in has been applied. This makes it possible to composite the image you’re grading with the RGB output from an EXT MATTE node.

To create a composite using an OFX plug-in:

1. Open the OpenFX Panel, use the Library to find the OFX compositing plug-in that you want to use, and drag it onto the appropriate node to apply it. The above example shows the Boris Effects plug-in “BCC Composite,” which mathematically combines two image streams using one of a long list of blending modes.

2. Right-click the node with the OpenFX plug-in applied to it, and choose Second Layer Input from the contextual menu. A second RGB input should appear on the left of the node, underneath the first.

3. Open the Media page, locate the clip you want to composite in the Library, and import it as an unassigned matte.

4. Open the Color page again, right-click the node with the OpenFX plug-in applied to it, and choose Add Matte > Track Mattes > “name of matte imported in step 3” from the contextual menu.
5 By default, the EXT MATTE node that appears is connected via one of its key outputs. Delete the key connection, and drag a new connection line from the EXT MATTE node’s RGB output to the second RGB input of the node with the OpenFX plug-in.

The composited image, node tree, and OFX parameters shown side by side

6 At this point, the node tree is wired up to composite the clip with the EXT MATTE image, and you need only adjust the parameters of the OpenFX plug-in to achieve the result you desire.
Chapter 121

Keyframing in the Color Page

The Color page has a dedicated Keyframe Editor, found at the right of the palette area, that you can use to animate grading changes from one frame to another. Because grading is a fundamentally different task than editing, the Color page Keyframe Editor operates somewhat differently from the Curve Editor in the Edit page.
Contents

Introduction to Keyframing

Whether it’s referred to as keyframing, dynamics, or marks, DaVinci Resolve provides an interface for automatically interpolating color adjustment parameters in various ways from one setting to another. For example, if you have a clip with varying exposure settings, you can animate a series of contrast adjustments using Dynamic keyframes to make the changes in exposure less distracting.

In another example, suppose you’re grading a documentary, and an archival clip that’s edited in the middle of the Timeline actually consists of six different shots from a program in the eighties. If you’re in a hurry, you can insert Static keyframes (marks) at the cut points of each of these shots, creating instant one-frame transitions between different adjustments made to that clip’s grade, which allows you to create unique adjustments for each shot within the clip.

In both cases, you use the Keyframe Editor to create a series of keyframes with which to change parameters from one value to another. In this section, you’ll learn how to work with the Keyframe Editor to set up these kinds of animated changes.

The Keyframe Editor Interface

The Keyframe Editor has all the controls necessary to create and modify keyframes for the currently selected clip. If necessary, you can even make it wider in a single screen layout by clicking its expand button (at the top right of the Keyframe Editor). If you have two computer displays, you can use the Color page’s Dual Screen layout which places the Keyframe Editor on a second screen and uses the entire width of the monitor, for even more room.
The Keyframe Editor consists of the following components:

- **Timeline Ruler**: Mirrors the record timecode of the currently selected clip; dragging within the Timeline Ruler moves the playhead, and a timecode display to the left shows the current frame.

- **Keyframe track header**: Each node in the current grade has a corresponding keyframe track, Sizing has its own keyframe track, and the track header contains controls you can use to manage the keyframing.

- **Enable/Disable button**: A round white button lets you enable or disable that track’s corresponding node.

- **Lock button**: Lets you prevent any changes from being made to that track’s corresponding node. Nodes that have been locked show a lock icon. You can also lock or unlock nodes by right-clicking a node in the Node Editor and choosing Lock Node from the contextual menu.

- **Auto-Keyframe button**: Turn this button on to automatically create a Dynamic keyframe every time you adjust any parameter within that node.

- **Track disclosure triangle**: Exposes individually keyframable groups of parameters underneath the main keyframe track.

- **Keyframe tracks**: To the right of the track header, the keyframe tracks are where you create and edit the keyframes that animate parameter changes. A topmost “master keyframe track” shows every keyframe applied on every keyframe track in the Keyframe Editor, even keyframes applied to a keyframing track hidden inside a track with a closed disclosure triangle.
• **Keyframes:** Each keyframe appears as a small diamond for a Dynamic keyframe or as a circle for a Static keyframe. Dynamic keyframes are associated with dissolves while Static keyframes (marks) act instantly. Grades are linked to the preceding keyframe, which may be a default one on the first frame of the master clip. Keyframes can be selected by clicking on them, or moved by dragging them to another position in the keyframe track.

• **FX track:** ResolveFX or OFX plug-ins that have been added to a grade as a standalone node have a separate track for creating animated effects. Every parameter of that track is keyframed via a single consolidated keyframe track. If you apply multiple plug-ins as multiple nodes, each has a separate FX track.

• **Sizing track:** The Pan, Tilt, Zoom, Rotate, and Convergence (in Stereo 3D projects) parameter have an entirely separate track for creating animated pan and scan adjustments.

• **Track selection bar:** A colored bar shows the currently selected scope of keyframing: all tracks at once, just the current correction node, or the Sizing settings, as defined by the Keyframe Timeline mode discussed in the next section.

Ordinarily, the Keyframe Editor takes up the rightmost bottom third of the Color page. However, you can make it wider to have more room to work if you have a scene requiring complex keyframing.

**To expand and collapse the Keyframe Editor:**
Click the Expand/Collapse button at the top right corner of the Keyframe Editor. The Keyframe Editor widens or narrows accordingly.

**To zoom into and out of the keyframe tracks:**
• Use the Zoom slider to zoom into or out of the Keyframe Editor.
• Right-click any keyframe track and choose Maximum Zoom to zoom all the way in.
• Right-click any keyframe track and choose Reset Zoom to fit the entire clip into the available width of the Keyframe Editor.

**All/Color/Sizing**

Perhaps the most important control for keyframing, the Keyframe Timeline mode, lets you switch the scope of what tracks get keyframed when you use the Start Dynamic or Add Static Keyframe commands, either from the keyboard or via the buttons of your control panel. This command alternates among three modes:

• **All:** The default mode. Adds keyframes to every track in the Keyframe Editor, keyframing every parameter in every node all at once, including the Sizing settings. In this mode, an orange bar appears highlighting the topmost “master keyframe track.”

• **Color:** Only adds keyframes to the node currently selected in the Node Editor. In this mode, a green bar appears highlighting the keyframe track corresponding to the node currently selected.

• **Sizing:** Only adds keyframes to the Sizing track, which is useful when you’re keyframing “pan and scan” style transforms. In this mode, a blue bar appears highlighting the Sizing track.

• **EXT MATTE:** Only appears if there’s an external matte node in the node tree. Lets you keyframe external matte-specific parameters in the Key palette.
Even though All is the default setting, it may be to your advantage to switch to the Color or Sizing keyframing modes to avoid creating a lot of unnecessary keyframes. Even though keyframing everything all at once is a fast way to work, the extra keyframes may slow you down when you later need to make adjustments to nodes that didn’t need to be keyframed in the first place.

To change the keyframing mode, do one of the following:

- Choose an option from the Keyframe Mode pop-up at the top right of the Keyframe Editor.
- Choose an option from the Mark > Keyframe Timeline Mode submenu.
- Press the ALL/COLOR/Sizing button on the Transport panel of the DaVinci control panel repeatedly until you’ve chosen the mode you need.

**Tip:** This control has one other function. Choosing a mode also affects what is copied when you use the various grade management tools in DaVinci Resolve. For example, if you choose Color, then you can copy a clip’s color grade without copying its sizing. If you choose Sizing, then you can copy the sizing without copying the color grade. For more information, see “Copying Grades” in Chapter 116, “Grade Management.”

### Keyframing Methods

There are two different types of keyframes used by DaVinci Resolve to create automated changes. Each type of keyframe interpolates parameters differently.

#### Dynamic Keyframes (Dynamics)

Dynamic keyframes are the most conventional type of keyframe you’ll use, and are the type of keyframe used for creating animated changes from one state to another. For example, if you need a grade to become brighter over time to compensate for a change in lighting conditions, you’ll use Dynamic keyframes.

Nearly every parameter and control in the Color page can be keyframed, but it’s important to understand that the Interface controls do not animate to match whatever dynamically keyframed changes are taking place. Instead, visible Interface controls that correspond to keyframed changes will jump from their initial position at one keyframe to their final position when the playhead reaches the next keyframe.

This can be most confusing with Curves, which can be interpolated using Dynamic keyframes just like any other control or parameter. Just keep in mind that the actual settings are animating, even though the controls are not.

To animate a node using Dynamic keyframes:

1. Move the playhead in the Keyframe Editor’s Timeline ruler to the frame where you want to begin a change.
2. Do one of the following to place a Dynamic keyframe at that frame:
   - Choose Mark > Add Keyframe (Command-`).
   - Press the START DYNAMIC button on either the T-bar or Transport panels of the DaVinci control panel.
   - Turn on the Auto Keyframe button for the track you want to animate in the Keyframe Editor.

Dynamic keyframes are diamond-shaped.
3 If necessary, adjust your clip at this first position of your animated change. If you’re using Auto Keyframe, then you have to make an adjustment for a keyframe to be created.

4 Now, move the playhead to the frame that is at the second position of the animated change you’re making, and create another Dynamic keyframe if you’re creating keyframes manually, or make another adjustment if Auto Keyframe is on.

5 After you’ve created this second keyframe, make whatever adjustments are necessary to the clip to create the final look you need.

At this point, playing from the first keyframe to the second keyframe should show a smoothly animated change from the first adjustment to the second. When you’re finished, make sure you turn Auto Keyframe off if it was enabled.

**Static Keyframes (Marks)**

Static keyframes, or marks, are keyframes that are used to create abrupt, one frame changes from one state to another. They’re typically used to mark edit points separating one shot from another when multiple shots appear within a single clip. However, Static keyframes are also useful in any situation where you need a sudden change from one setting to another, such as when creating a lightning effect.

To automate a node using Static keyframes:

1. Find the frame at which you want the abrupt change to take place, and place a keyframe at that frame by doing one of the following:
   - Choose Mark > Make Static Keyframe (Command-`).
   - Press the MARK button on either the T-bar or Transport panels of the DaVinci control panel.

   Static keyframes (marks) are round.

2. Move the playhead to any frame before the keyframe to make changes to the entire segment of the clip leading up to the keyframe, or move the playhead to any frame after the keyframe to make changes to the entire segment of the clip appearing after the keyframe. The playhead does not need to be on top of the keyframe, but if it is, you’ll be adjusting the second portion of the clip.

**NOTE:** If you’re using Static keyframes to automate grading changes between multiple shots appearing within a single clip, keep in mind that you can’t add nodes from one keyframe to the next as you would if you had split the clip in the Edit page.
Mixing and Converting Dynamic and Static Keyframes

Typically, if you’re creating multiple animated changes within a clip, you’ll want to use all Dynamic keyframes. Similarly, if you’re creating a series of abrupt changes, you’ll use all Static keyframes. However, you can mix Dynamic and Static keyframes together, so long as you keep in mind the following rules:

If you add a Dynamic keyframe to the right of a Static keyframe: There will be no interpolation from the Static keyframe to the Dynamic keyframe. However, if you add a Static keyframe to the right of a Dynamic keyframe, there will be interpolation.

No dynamic interpolation following the static keyframe

If you accidentally create the wrong kind of keyframe, it’s easy to convert it into the type of keyframe you need.

To change one kind of keyframe into another:
1. Click the keyframe you want to convert to select it.
2. Right-click the selected keyframe, and choose either Change to Dynamic Keyframe or Change to Static Keyframe.

Try Creating Keyframed Changes in a Separate Node

One tip to keep in mind is that you don’t have to create keyframed changes within the same nodes you’re using to create other adjustments. If you want to create some automated changes without altering the nodes you’ve already adjusted, you can simply create a new node in which to make your keyframed changes. That way, if you don’t like the result, or you somehow find yourself hopelessly tangled up in a needlessly complicated set of keyframes, it’s easy to reset either just the keyframes or the entire node without affecting the rest of your grade.

Keyframed Nodes Have a Badge

Nodes with keyframed parameters display a keyframe badge in the Node Editor, to make them easy to find. Note that keyframe badges won’t appear when you simply add a keyframe but only once there’s an actual keyframed adjustment being made.
Using Specific Keyframing Tracks

If you're simply using the Color mode of the All/Color/Sizing command to do keyframing, then you'll be adding keyframes to every parameter of the currently selected node whenever you apply a single keyframe. However, often that's overkill in situations where you only need to keyframe a single setting or group of settings.

For example, you may find that you need to keyframe a color adjustment in order to change the color temperature and brightness when the camera pans across a window, but you don't want to keyframe the Windows palette controls because you want to adjust them independently. This can be done by opening a Corrector track to expose the keyframing tracks within.

Individual keyframing tracks within a Color Corrector node

Keyframing tracks let you keyframe different sets of similarly functioning parameters separately from one another. For example, there's one keyframing track for all the color adjustment parameters, and another keyframing track governing the parameters found within the Qualifier palette.

To reveal a node's keyframing tracks:

1. Click the disclosure triangle next to the number of the node you're keyframing.

To keyframe an individual keyframing track manually:

1. Make whatever adjustments you need to the currently selected node, and click its disclosure triangle to reveal its keyframing tracks.

2. Move the playhead in the Keyframe Editor to where you want to add the first keyframe, then right-click within the keyframing track you want to animate, and choose Add Static Keyframe or Add Dynamic Keyframe (this example shows a Dynamic keyframe).

   A keyframe appears at the position of the playhead in that keyframing track.

3. Move the playhead in the Keyframe Editor to where you want to add the next keyframe, then right-click within the keyframing track and again choose either Add Static Keyframe or Add Dynamic Keyframe (this example shows a Dynamic keyframe).
Now, you can make whatever changes you need to the controls governed by the keyframing track you keyframed, in order to create the necessary animated effect.

**Tip:** You can also animate individual keyframing tracks using automatic keyframing, explained in more detail later in this chapter.

### Corrector Keyframing Tracks

All of the parameters governing the adjustment of color and contrast controls, as well as various effects, Power Windows, and other adjustments are sorted into various sub-tracks within the Corrector track.

- **Linear Win:** Controls parameters corresponding to the Linear window.
- **Circ Win:** Controls parameters corresponding to the Circular window.
- **Polygon Win:** Controls parameters corresponding to the Polygon window.
- **PowerCurve:** Controls parameters corresponding to the PowerCurve window.
- **Gradient Win:** Controls parameters corresponding to the Gradient window.
- **Color Corrector:** Controls all parameters found in the Camera Raw, Color Wheels, Primary Controls, RGB Mixer, and Curves palettes.
- **Qualifier:** Controls all parameters in the Qualifier palette.
- **Defocus:** Controls all parameters in the Blur and Key palettes.
- **NR:** Controls the Spatial and Temporal Noise Reduction and Motion Blur parameters found in the Motion Effects palette.
- **OFX:** Controls all parameters of whichever OFX plug-in is applied to the current node.
- **Node Format:** Controls all parameters of the node sizing mode of the Sizing palette for the current node.

### ResolveFX Keyframe Tracks

The Color Page Keyframe Editor supports viewing and editing keyframes for ResolveFX and OpenFX plug-ins in the Color page in one of two ways:

- Plug-ins that have been added to a Corrector node appear within the hierarchical list of keyframe tracks that appear within that node’s top-level keyframe track.
• Plug-ins that have been added as standalone nodes appear within a new FX track of the Keyframe Editor. Each plug-in that’s added as a separate node has a separate FX track.

The keyframe track of a ResolveFX plug-in added as a standalone node

The Sizing Keyframing Tracks

The Sizing keyframing tracks govern sizing transforms and stereoscopic adjustments separately from the color controls.

• **Input Sizing**: Controls the Input Sizing parameters found within the Sizing palette.
• **Convergence**: Controls the Convergence parameter in the Stereo 3D palette.
• **Float Window**: Controls the Left, Right, Top, and Bottom Position/Rotate/Softness Floating Windows parameters.
• **Auto Align**: Controls the Pitch and Yaw parameters in the Stereo 3D palette.

**TIP**: Output Sizing can only be keyframed when you choose Track mode in the Node Editor.

The Ext Matte Node’s Freeform Isolation Track

If your node tree has an External Matte, the EXT MATTE node exposes a Freeform Isolation track in the Keyframe Editor. This is useful for time offsets or Sizing repositioning of the Ext Matte image.

Automatic Keyframing

Every track in the Keyframe Editor has an Auto-Keyframing button that can be turned on or off. When auto-keyframing is enabled for a particular track, every change made to a parameter or control associated with that keyframe track automatically generates a keyframe.

Used with a keyframing track, auto-keyframing makes it simple to set up animated changes to specific adjustments within a node. This is a lot easier than manually placing keyframes one by one.

On the other hand, turning on auto-keyframing for the Corrector track correspondingly enables auto-keyframing for every keyframing track belonging to that node. In this case, keyframes will automatically be placed on whatever keyframing track corresponds to the parameters or controls you adjust.
