DaVinci Resolve 21

Leading the Creative Video Revolution

Welcome

Welcome to DaVinci Resolve for Mac, Linux and Windows!

DaVinci is the world's most trusted name in color and has been used to grade more Hollywood films, TV shows, and commercials than anything else. With DaVinci Resolve, you get a complete set of editing, advanced color correction, professional Fairlight audio post production tools and Fusion visual effects combined in one application so you can edit, compose, grade, mix and master deliverables from start to finish, all in a single tool!

DaVinci Resolve has the features professional editors, colorists, audio engineers and VFX artists need, and is built on completely modern technology with advanced audio, color and image processing that goes far beyond what any other system can do. With this release, we hope to inspire creativity by letting you work in a comfortable, familiar way, while also giving you an entirely new creative toolset that will help you cut and finish projects at higher quality than ever before!

We hope you enjoy reading this manual. With its customizable interface and keyboard shortcuts, DaVinci Resolve is easy to learn, especially if you're switching from another editor, and has all of the tools you need to create breathtaking, high end work!

The DaVinci Resolve Engineering Team

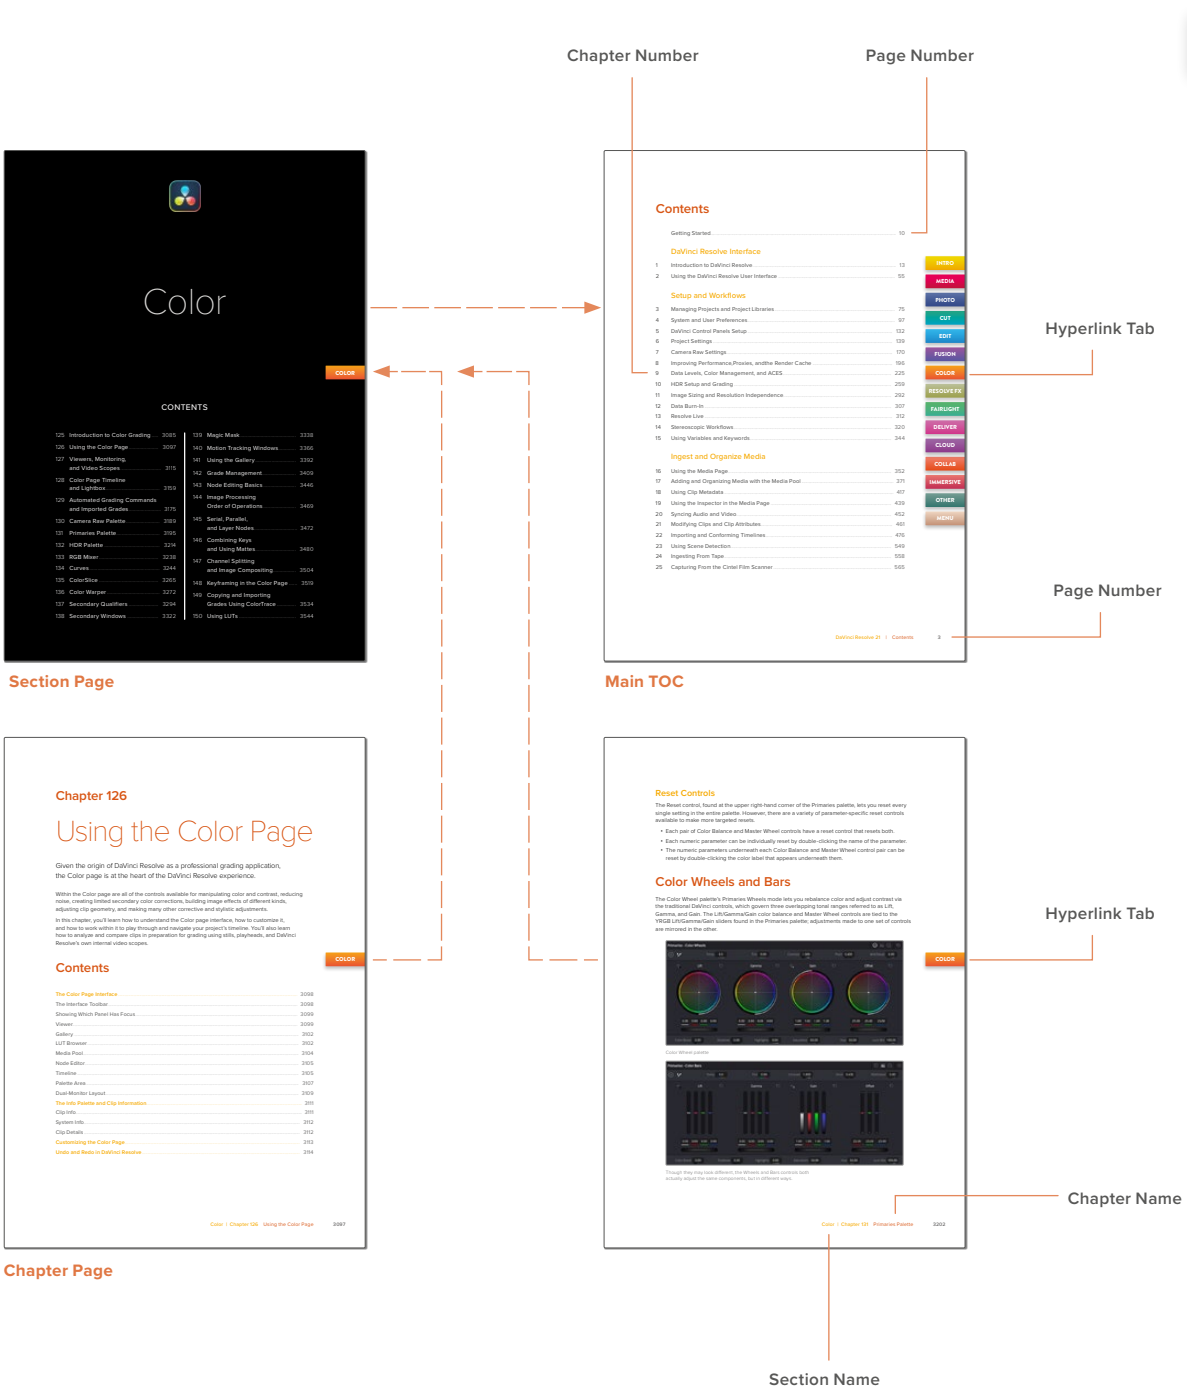
DaVinci Resolve 21

Getting Started

When you install DaVinci Resolve and then open it for the first time, there are a few things you're going to want to know before you begin learning how to work.

Automatic DaVinci Resolve Updates

To make it easier to ensure you're using the latest version of DaVinci Resolve, you can now choose DaVinci Resolve > Check For Updates to notify you of new versions and download them when available.



Why Is This Manual So Big?

Over the years, DaVinci Resolve has evolved to encompass professional editing, compositing, and audio mixing tools and workflows in addition to the grading tools that were the original core of DaVinci Resolve. Each one of these domains of functionality is incredibly deep. Consequently, the documentation has grown with each new page, tool, and parameter that's been added, to make life easier and to solve the countless problems that can emerge during the postproduction process.

While it is regretted that this user manual contains such a staggeringly overwhelming amount of information, our emphasis has always been to ensure that (hopefully) every control and workflow you encounter in DaVinci Resolve is explained somewhere within the contents of these pages. Consequently, we hope that you find the hyperlinked table of contents (TOC) and search functionality of your preferred PDF browser helpful in finding the information you need, along with context and tips to help you get the most out of the tools provided.

Navigation Guide

For ease of use navigating this manual, each table of contents (TOC) listed on this manual are hyperlinked, and by clicking on each title or page number, you will be taken to the appropriate part of the manual. On the right hand side of each page includes a hyperlink tab. As you hover the pointer over the tab and by clicking on the tab you will be taken to main TOC page.

2 Using the DaVinci Resolve User Interface 55

Chapter 1

Introduction to DaVinci Resolve

DaVinci Resolve integrates editing, compositing and motion graphics, color correction, audio recording and mixing, and finishing within a single, easy to learn application. The editing, compositing, grading, and audio tools found in DaVinci Resolve should be immediately familiar to experienced artists who've used other applications, but they're also approachable to folks who are new to post-production.

Additionally, dedicated tools available for on-set workflows integrate tasks such as media duplication, shot and metadata organization, and on-location look management into a complete toolset that lets you smoothly segue from the camera original media being acquired in the field to the organization and use of that media in a wide variety of post-production workflows with DaVinci Resolve at their heart. In particular, the tight integration in DaVinci Resolve means that you can freely move from one task to the next of your project's workflow without skipping a beat, making it easy to back up and organize a shoot's media before immediately diving into editing, while switching over to add a quick composite or to color-correct clips in the middle of your editing spree, and then getting right back to cutting, with a bit of mixing to make sure things sound right, all without needing to export projects or launch other applications.

And you can go further, using the collaborative features of DaVinci Resolve to enable multiple artists, for example an editor, a colorist, and assistants, to work together on the same timeline simultaneously, for the ultimate integrated workflow.

Of course, no post-production professional works in a vacuum, and DaVinci Resolve makes it easy to work with other facilities by importing projects and exporting project exchange formats and rendered or managed media among applications such as Apple's Final Cut Pro X, Adobe's Premiere Pro, Avid's Media Composer and Pro Tools, Autodesk's Flame Premium, and many other applications via robust support of XML, AAF, and EDL import and export workflows.

This chapter introduces the DaVinci Resolve user interface (UI), explaining where to find each group of features, and how the highly focused and tightly integrated Media, Edit, Fusion, Color, Fairlight, and Deliver pages work together to let you pursue nearly any post-production workflow you can imagine. After this brief tour, the rest of Part 1 of this manual provides much more in-depth information about project management, preferences, project settings, and other topics of general interest for getting started.

The Project Manager

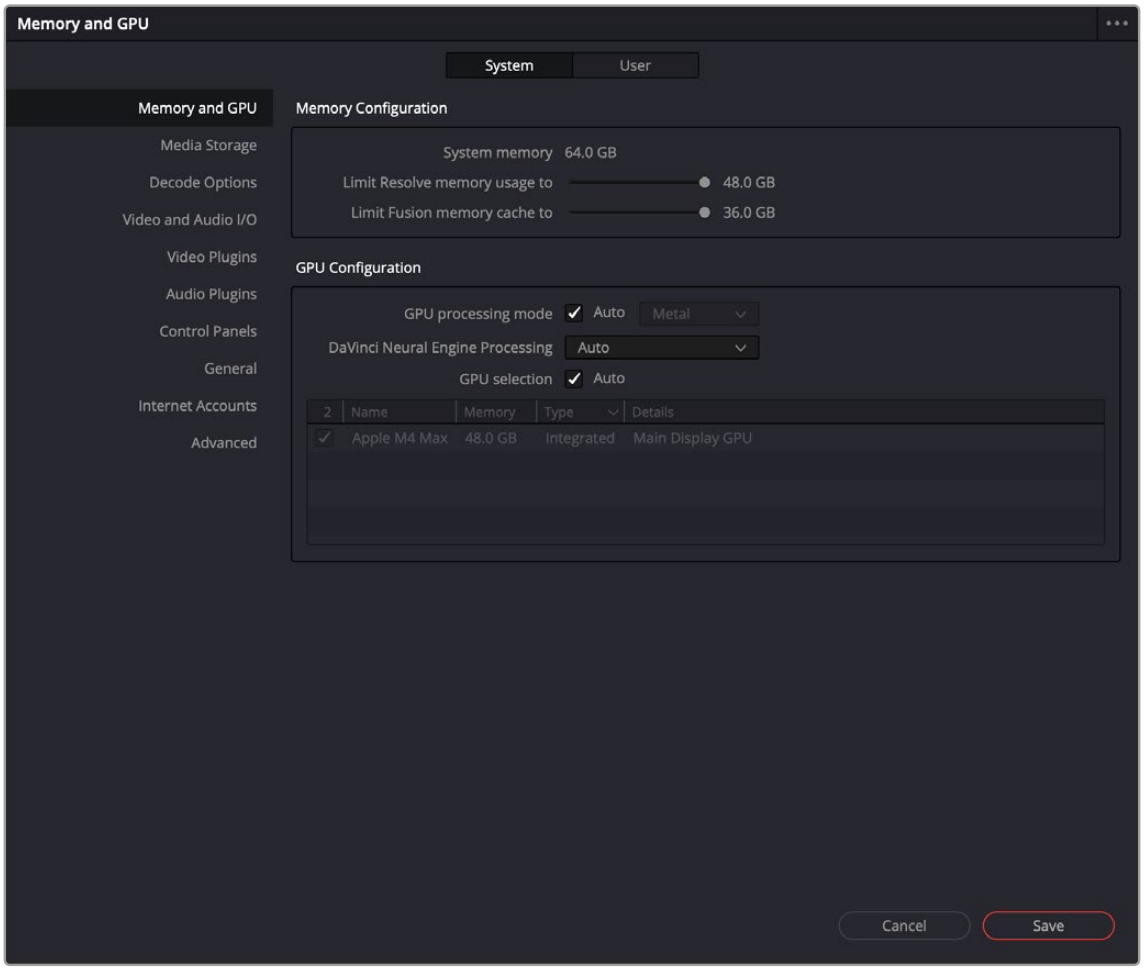
For most users, Project Manager is the first window you'll see when you open DaVinci Resolve. The Project Manager is a centralized interface for managing all projects belonging to the user who's currently logged in, whose name appears at the upper right-hand corner in a project title bar. The Project Manager is also the place where you import and export projects to and from DaVinci Resolve, whether you're moving projects around from user to user, or moving projects from one DaVinci Resolve workstation to another. Finally, the Project Manager also lets you organize the project libraries that are used to manage everything in DaVinci Resolve using the Project Library sidebar.

To open any project, double-click it. To create a new project, double-click the Untitled Project icon, or click the New Project button.

The Project Manager shows all projects belonging to the current user.

For more information on Project Manager, jump to this chapter: Managing Projects and Project Libraries

Preferences and Project Settings



Once you open a project, you have the option of adjusting the system and user preferences that govern the installation of DaVinci Resolve on your workstation, and the project settings governing the currently open project. When you first install DaVinci Resolve, the most important of these settings is selected via the installer's onboarding questions. However, if you're opening DaVinci Resolve for the first time, you should check these settings to make sure they're optimal for your system.

Individual Preferences and Settings Based on Login

As of DaVinci Resolve 16, there are individual preferences and settings for each login account on a given computer. This means that multiple artists can each have their own login, and DaVinci Resolve will maintain separate workspace layouts and preference states for each artist, depending on who's logged in.

Preferences

The Preferences window, divided into the System preferences and User preferences panels, lets you set up the overall environment of your DaVinci workstation, choosing what hardware to use with DaVinci Resolve and your preferred user interface settings. To open it, go to DaVinci Resolve > Preferences.

The DaVinci Resolve preferences window lets you set up your environment

A quick overview of the most important system and user preferences appears below, with guidance about which settings you should adjust when you first set up DaVinci Resolve on your workstation. For more information, jump to this chapter: System and User Preferences.

System Preferences

The System preferences let you configure the hardware DaVinci Resolve works with. If you have a system that doesn't change very often, then you may only rarely use the Preferences window. On the other hand, if you're working with a mobile system with changing video interfaces, control panels, and scratch volumes, then you may use this window more frequently.

NOTE: Whenever you change certain core system settings in Preferences, you may have to quit and restart DaVinci Resolve for those changes to take effect.

Memory and GPU

Lets you choose various options governing how to use the GPUs attached to your computer, and how to configure Viewers in different pages. This panel also provides an overview, for reference, of all hardware and computer characteristics that are relevant to DaVinci Resolve running smoothly, including a listing of installed GPUs.

Media Storage

This is a list within which you define the scratch disk used by your system. The first volume in this list is where Gallery stills and cache files are stored, so you want to make sure that you choose the fastest storage volume that's connected.

Decode Options

These settings let you select various hardware options for decoding RAW files and H.264/H.265. It also lets you choose to use the easy DCP decoder and the ability to refresh growing any files (files that are in the process of being written) in the Media Pool.

Video and Audio I/O

The preferences in this panel let you choose which video and audio Capture and Monitor interfaces you want DaVinci Resolve to use on your workstation. If you have multiple Blackmagic Design I/O interfaces connected to your computer, you can choose between them.

Video Plugins

If you have any third-party Open FX plugins installed, you can see them and enable/disable them here.

Audio Plugins

If you have any third-party VST plugins installed, you can see them and enable/disable them here.

Control Panels

Lets you choose and configure (if necessary) a control panel that's connected for use during grading in DaVinci Resolve.

General

Lets you choose from a variety of settings that modify DaVinci Resolve's behavior. The LUT Locations section lets you point DaVinci Resolve to any external folders containing LUTs for use in your project.

Background Tasks

Lets you activate and choose what operations take advantage of background rendering.

Internet Accounts

The Internet Accounts panel serves as a login manager for the Blackmagic Cloud and other social media sites.

Advanced

This tab is used for special DaVinci Resolve configurations and SAN parameters that are applicable to older file systems.

User Preferences

User preferences govern the setup of the user interface in DaVinci Resolve, letting you customize it to work the way you like.

UI Settings

A Language drop-down menu at the top lets you specify which language the DaVinci Resolve user interface displays. Additional checkboxes let you choose options for which project to open during startup, and how to configure the Viewers that appear in every page of DaVinci Resolve.

Language and Spelling

This panel lets you set your preferred language for AI tools such as Auto Transcription. By default, the input language is set to auto. You can also customize the internal spell checker accordingly.

Project Save and Load

This panel contains the all-important auto-save controls, including the Live Save option that enables Resolve to incrementally save your changes as you work.

Editing

Numerous controls in this panel let you customize the editing experience in the Edit page, including default settings to use when making new timelines, and general settings that govern standard effects durations and trim behaviors.

Color

These controls let you customize the grading experience in the Color page, with options controlling video scope display, the look of UI overlays, and other color-specific functions.

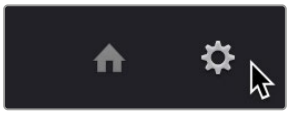
Fairlight

These controls let you customize the editing experience in the Fairlight page with options controlling video offset, automation, and general settings.

Playback Settings

These controls let you customize how DaVinci Resolves handles video playback. If your playback is too slow, adjusting these settings may help.

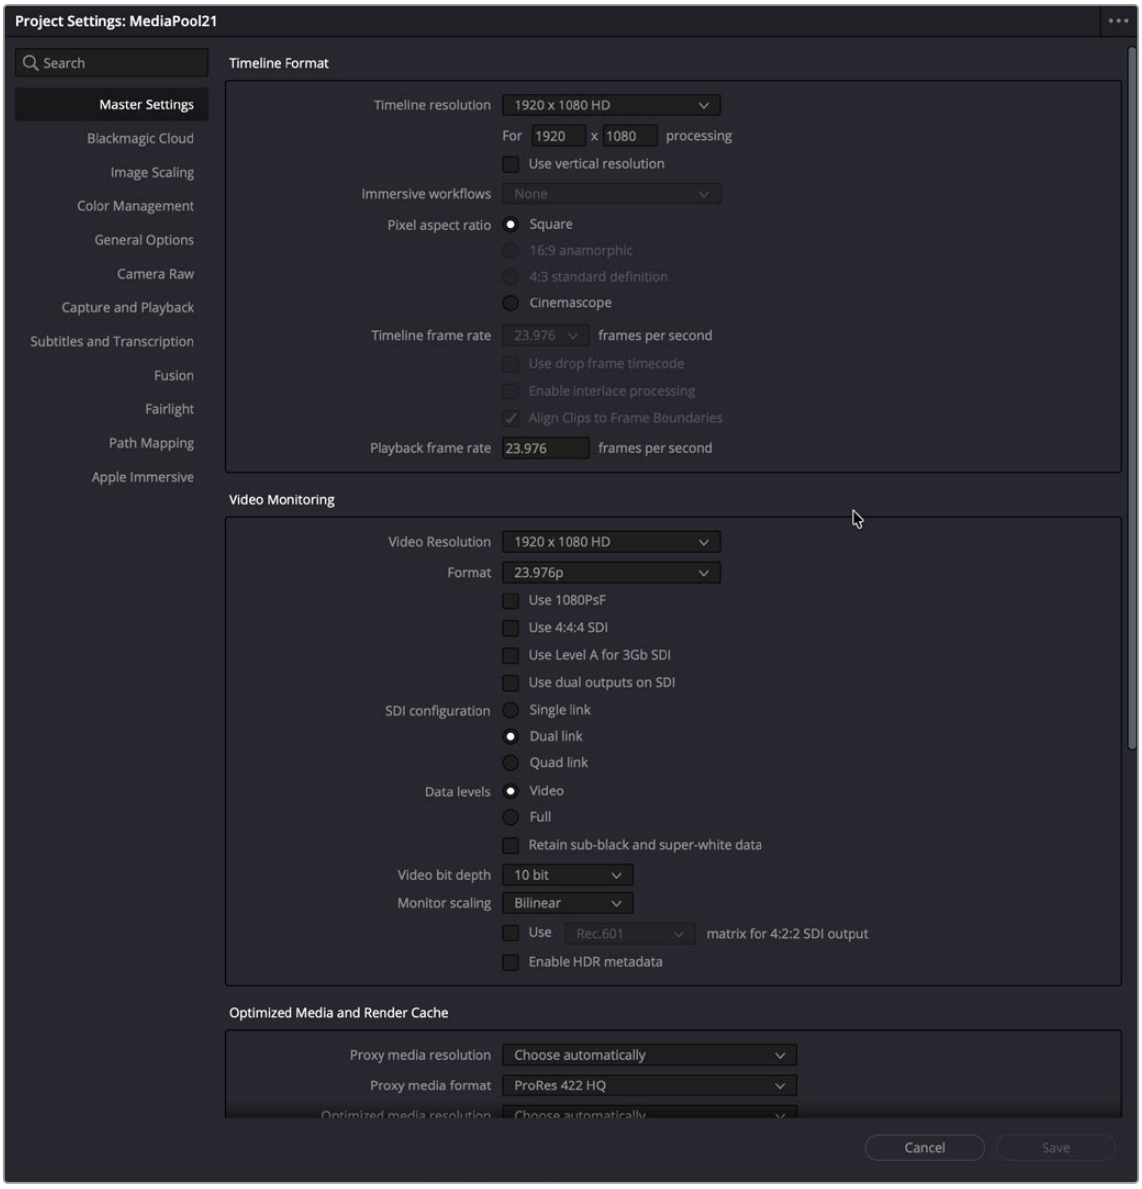
Control Panels



These controls let you customize the settings of your connected control surface.

Metadata

These controls let you customize the Metadata Presets.



Project Settings

Once you've created a project, all project-specific settings are found in the Project Settings window. To open the Project Settings window, just click the gear button at the bottom right on any page.

Project Manager and
Project Settings buttons

The Project Settings open in the middle of the screen, divided into a series of panels which can be selected from a sidebar to the left. Each panel contains a collection of related settings that affects some category of DaVinci Resolve functionality. To open a panel of settings, simply click its name in the sidebar at the left.

The Project Settings show all project-specific settings and attributes.

The Master Settings define the principal attributes of a project, such as the timeline resolution, timeline frame rate, color science, and bit depth. Image Scaling settings define how clips that don't match the timeline resolution are scaled to fit. There are other panels for Color Management, Camera Raw, Capture and Playback, etc.

For more information on Project Settings, jump to this chapter: System and User Preferences.

Switching Among Pages

Buttons for switching pages appear at the bottom of the UI.

DaVinci Resolve is divided into seven main pages of functionality, each of which facilitates a different specialization of a typical post production workflow, and each of which can be accessed using buttons at the very bottom of the DaVinci Resolve interface. These buttons are organized in order of workflow, and they're always available, letting you quickly switch between importing media, fast editing, detailed editing, compositing, grading, audio mixing, and outputting your project in a structured manner.

Minimizing the Resolve Page Bar

If you right-click anywhere within the Resolve page bar at the bottom of the DaVinci Resolve UI, two options appear in a contextual menu: Show Icons and Labels, and Show Icons Only. If you show icons only, the Resolve Page bar at the bottom takes less room.

The Page bar showing icons only, to save space

Switching Pages Using Keyboard Shortcuts

You can also switch pages using the following keyboard shortcuts, which can be referenced from the Workspace > Switch to Page submenu.

Hide Pages You Don't Use

You can leave the page navigation bar showing and just hide the buttons of specific pages. For example:

- If you like the quick navigation of this bar but there are pages you simply don't want to use
- If you're setting up a DaVinci Resolve workstation for an artist making specific contributions to a project, and you want to hide easy access to pages of functionality they won't (or shouldn't) be using; this can be especially useful in collaborative workflow projects

You can disable/re-enable each page's buttons using the Workspace > Show Page submenu. Effects and adjustments that have been applied on hidden pages continue to affect the current project, they're only hidden, and you can still navigate to them using the Workspace > Switch to Page submenu commands or keyboard shortcuts.

Hide Page Navigation Altogether

If you're an artist that only uses a single page of the DaVinci Resolve experience, or if you want more screen real estate to work with given your existing computer display's limited resolution, you can choose Workspace > Show Page Navigation to hide the page navigation bar at the bottom of the DaVinci Resolve user interface. While this bar is closed, you can still navigate to other pages using the Workspace > Switch to Page submenu commands or keyboard shortcuts.

To toggle the Show Page Navigation function:

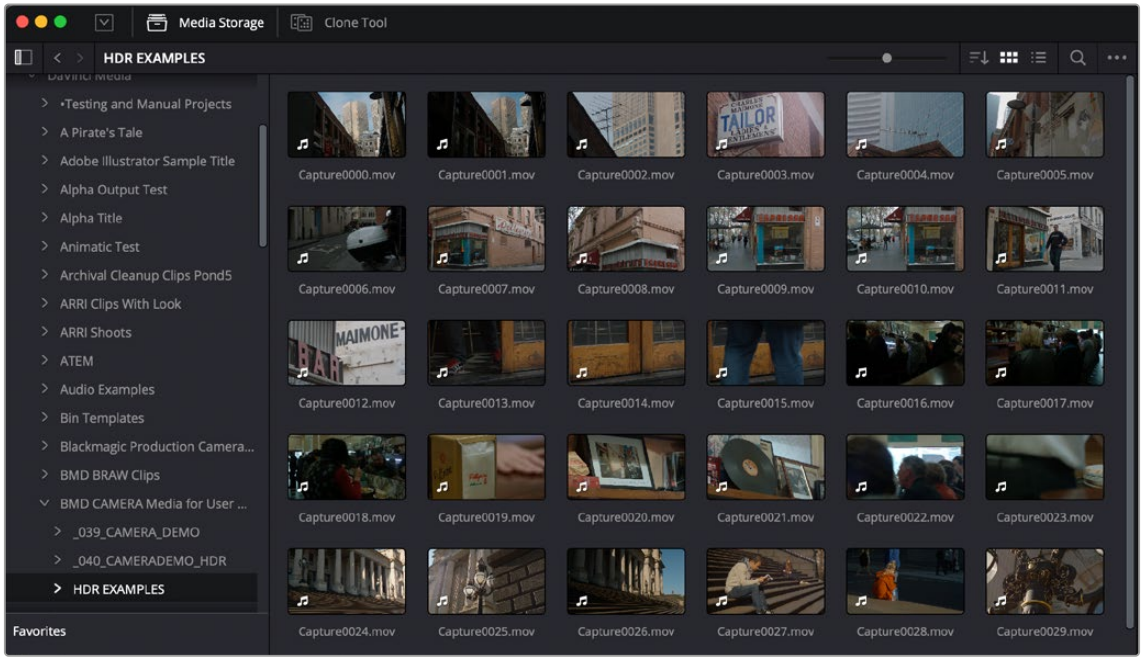
Check Workspace > Show Page Navigation.

With this interface element hidden, you can use keyboard shortcuts to access the individual pages (Shift - 2 through 8), Project manager (Shift - 1), and Project Settings (Shift - 9). You can also access these functions from DaVinci Resolve's main menu bar.

The Media Page

The Media page is the primary interface for clip import, media management, and clip organization in DaVinci Resolve. It's central to the way DaVinci Resolve works that the source media used by a project is organized separately from the project data that you import and manage in the Edit page. In this way, you can manage and update the clips used by timelines in the current project with ease, switching between offline and online media, reorganizing clips, and troubleshooting any problems that occur.

Media page



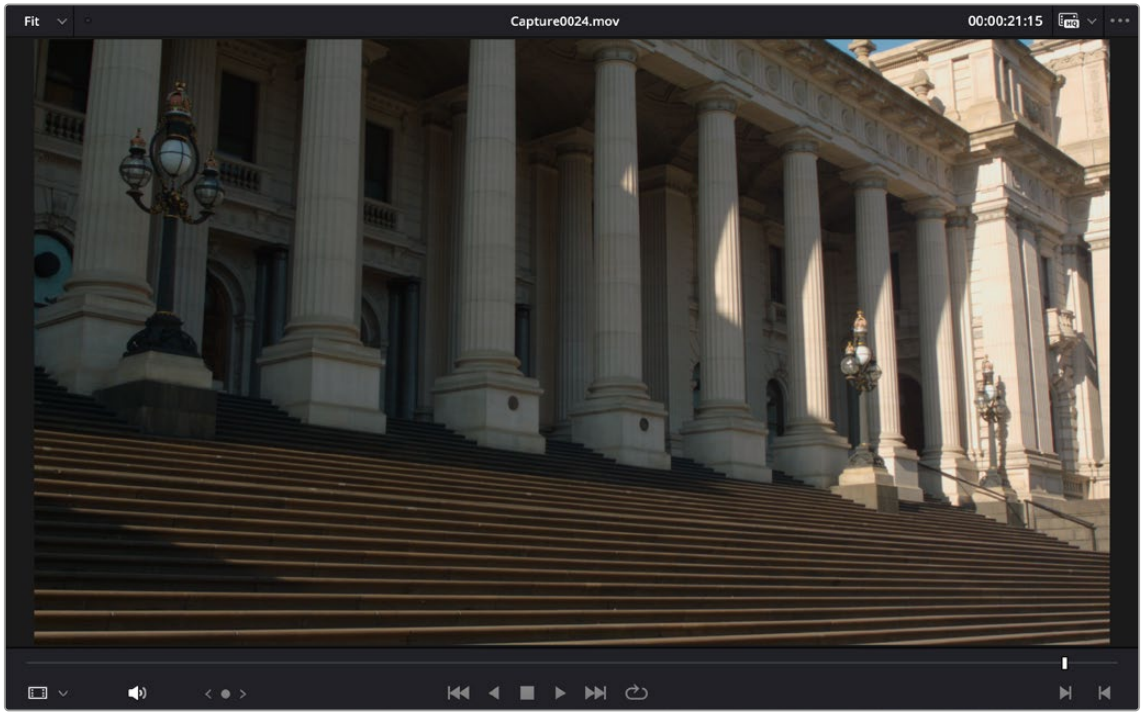
The Media page also contains much of the core functionality that will be used for on-set workflows, and in the ingest, organizational, and sound-syncing steps of digital dailies workflows. This chapter covers most of the functionality found in the Media page, including functions in detail that are referenced throughout this manual.

The Media page is divided into six different areas, designed to make it easy to find, select, and work with media in your project. Much of the functionality and most of the commands are found within the contextual menus that appear when you right-click on clips in the Library, File Browser, or Media Pool.

For more information on using the Media page, jump to this chapter: Using the Media Page.

The Media Storage Browser

The Media Storage browser shows a list of all volumes that are currently available to your Resolve workstation. It's used to locate media that you want to import manually into your project.

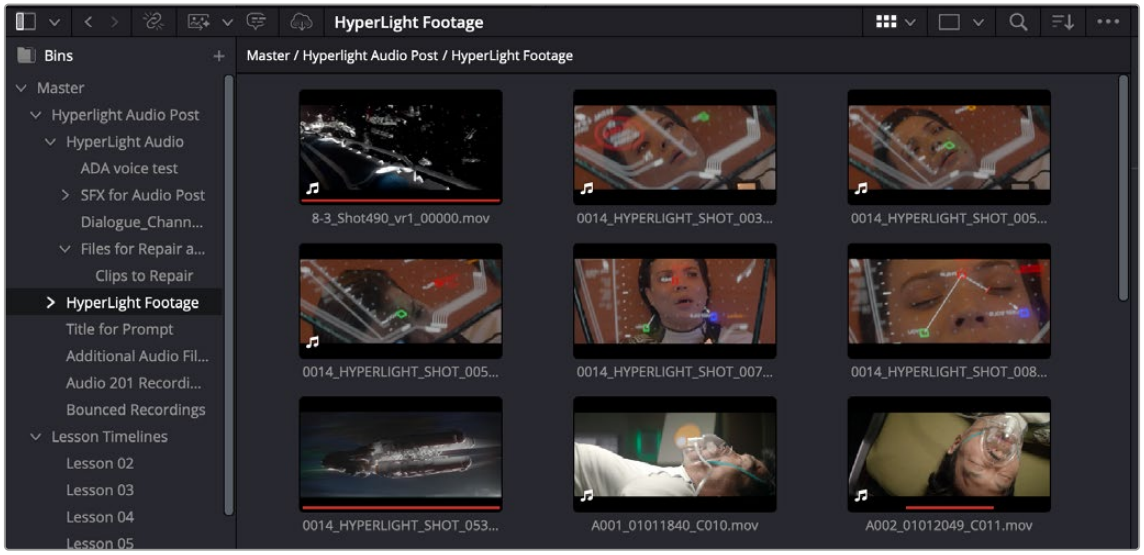


Media Storage with scrubbable Clip view

Viewer

Clips that you select in any area of the Media page show their contents in the Viewer. A jog bar appears at the bottom, letting you drag the playhead directly with the pointer, while a jog control between the mode drop-down and transport controls lets you move through a long clip more slowly. The full width of the jog bar represents the full duration of the clip in the Viewer. The current position of the playhead is shown in the timecode field at the upper right-hand corner of the Viewer. Simple transport controls appear underneath the jog bar, letting you Jump to First Frame, Play/Stop, and Jump to Last Frame. Audio levels can be adjusted by right-clicking on the speaker icon and dragging the slider.

You can also put the Viewer into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (Command-F), so that it fills the entire screen. This command toggles Cinema Viewer mode on and off.

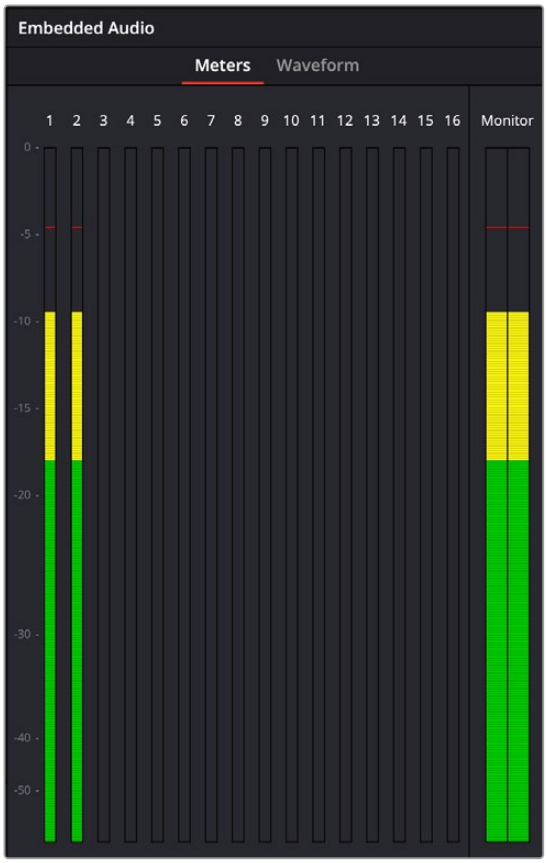


If you have two monitors connected to your computer, you can make the Viewer fill one entire screen and keep the Resolve UI in the other monitor by choosing Workspace > Full Screen Viewer On, and selecting the display you wish to use for the Viewer.

Media page Viewer

Media Pool

The Media Pool contains all of the video, audio, and still image media that you import into the current project. It also contains any media that's automatically imported along with timelines that have been imported into DaVinci Resolve. Ordinarily, all media imported into a project goes into the Master bin. However, your media pool can be organized into as many user-definable bins as you like, depending on your needs. Media can be freely moved from one bin to another from within the Media Pool. It also appears on the Edit, Fusion, Color, and Fairlight pages, making it possible to browse and open clips and timelines everywhere they're relevant.



Media Pool showing the selected bins' clips

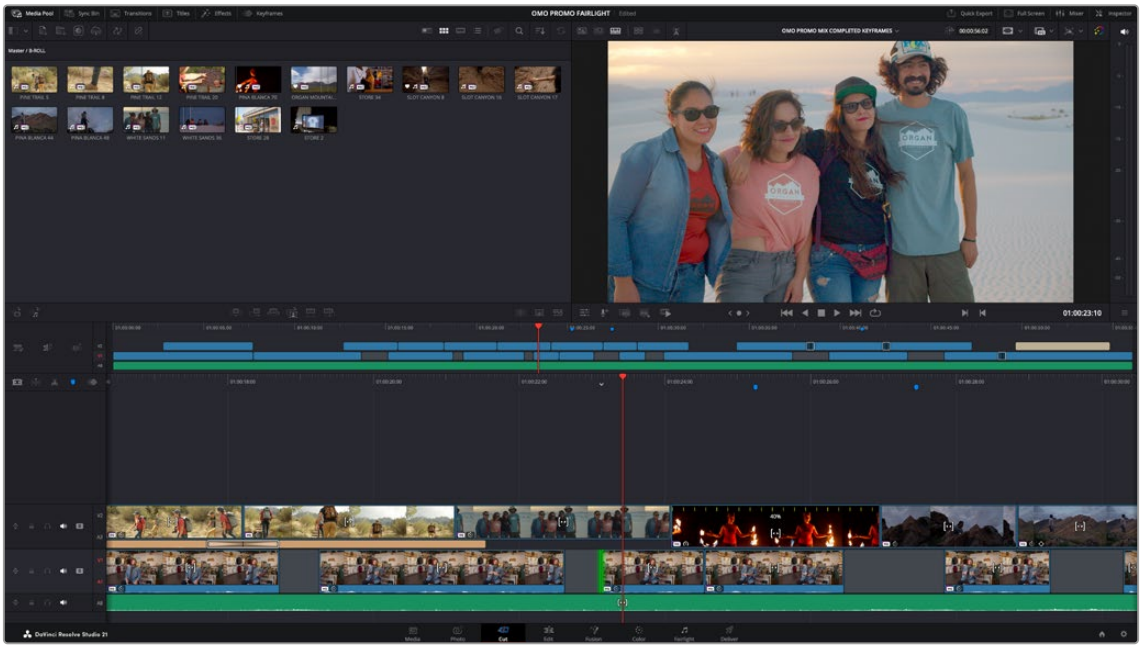
Metadata Editor

When you select a clip in any area of the Media page, its metadata is displayed within the Metadata Editor. If you select multiple clips, only the last clip's information appears. The Metadata Editor's header contains uneditable information about the selected clip, including the file name, directory, duration, frame rate, resolution, and codec. A series of editable fields within the editor lets you review and edit the different metadata items that are available. A drop-down menu at the upper right of the Metadata Editor also lets you choose from many different sets of metadata fields and checkboxes, each grouped for a specific task or workflow.

Clip Metadata Editor

Audio Meters exposed

Audio Panel



The Audio panel can be put into one of two modes via a pair of buttons above the audio meters. In the default Meters mode, Audio Meters are displayed that show the levels of audio in clips you're playing. In Waveform mode, you can load audio clips side by side with video clips opened in the Viewer in order to sync them together manually. The Audio panel can also be hidden.

The Cut Page

The Cut page is a focused environment for fast editing. It's useful in situations where you need to quickly cut a news segment, build an episode of web content, edit a straightforward program, experiment with multiple arrangements of a scene, or put together a first assembly edit.

The Cut page is also a good introductory editing interface for people who are new to editing, as it presents a streamlined set of tools that are fast to learn and simple to use. Whatever your background, you'll find the Cut page to be a valuable addition to your editing experience in DaVinci Resolve.

The default workspace of the Cut page consists of the Media Pool, a single Viewer, and the Timeline area. These three regions let you quickly import and organize clips, edit clips, and even export the result, all from within the Cut page.

The Cut page

For more information on the Cut page, jump to this chapter: Using the Cut Page.

The Media Pool

The Media Pool appears in the Cut page as well, and contains all video clips, audio clips, graphics, and other media that you import into your project. You can create Bins with which to organize all of this media, to make it easier to find what you need quickly. These bins are opened via the bin drop-down at the upper left-hand corner.

Each piece of media you import, whether it's video, audio, or graphics, appears as an individual clip, and they can be selected, scrubbed for fast viewing, reorganized into bins, opened into the Viewer for playback, or edited into a timeline using the edit buttons or via drag and drop.

Owing to the Cut page's mission to make editing faster, the Media Pool has different options for viewing (such as the Strip view) and customizing.

The Strip View mode

The Viewer

The Viewer lets you see clips from the Media Pool or clips in the Timeline play, and has numerous controls to control what you see and how things play.

The single Viewer in the Cut page

The Viewer has four mode options. Which option is currently in use can be seen, and switched, by four buttons in the upper left-hand corner of the Viewer.

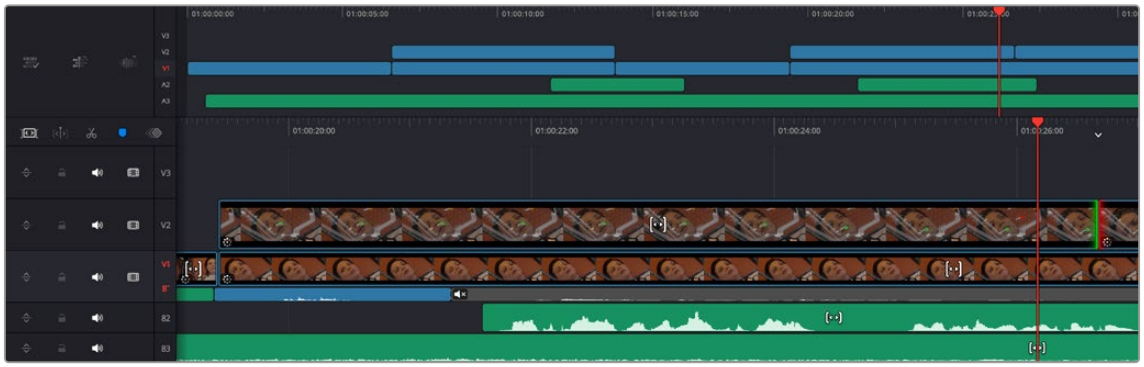
The Viewer modes buttons

The Different options are entered automatically by various actions (from left to right):

- You can double-click any clip to open it into the Viewer as a Source Clip.
- You can view an entire bin full of clips in the Source Tape.
- You can play your edited program in the Timeline.
- You can see all of your synced material at the same time in the Multi Source Viewer.

Clicking the Tools button in the lower left of the Viewer reveals an effects toolbar that you can use to add and edit clip effects, right within the Viewer with no Inspector needed. The Tools button reveals a variety of controls over sizing, cropping, audio, speed effects, stabilization, dynamic zoom, and compositing.

The Tools bar shown opened



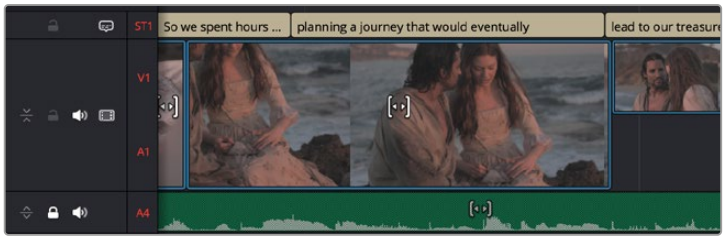
Audio Meter

An audio meter to the right of the Viewer shows you a graphical representation of the audio levels playing in the current clip or in the Timeline as you play through the Viewer, via animated vertical bars that are tinted to indicate how loud the levels are.

The Timeline

The word “timeline” refers both to an edited sequence of clips which constitutes a program that is stored in the Media Pool, and to the area of the Cut page interface where you can open this sequence of clips to see its contents, and for playback and editing.

For the Cut page user, the timeline is divided into an Upper Timeline at the top, and a larger and more detailed Timeline Editor showing a zoomed in portion of the timeline around the playhead at the bottom. Working together, these two views of your edited sequence make it possible to navigate your entire project and cut in great detail.



The Timeline of the Cut page, comprising the Upper Timeline and the zoomed in Lower Timeline

Three icons at the upper left-hand corner of the Timeline lets you choose a variety of timeline tasks. They are composed of Timeline Options, Timeline Actions, and Edit Actions.

The Timeline is divided into multiple tracks, with each track capable of holding a sequence of clips in order to create a program. The main tracks, which are labeled numerically, combine a clip's video and audio into a single item in the Timeline, for simplicity. Editing the In or Out point of a clip edits the video and audio together.

The Action icons in the Cut page

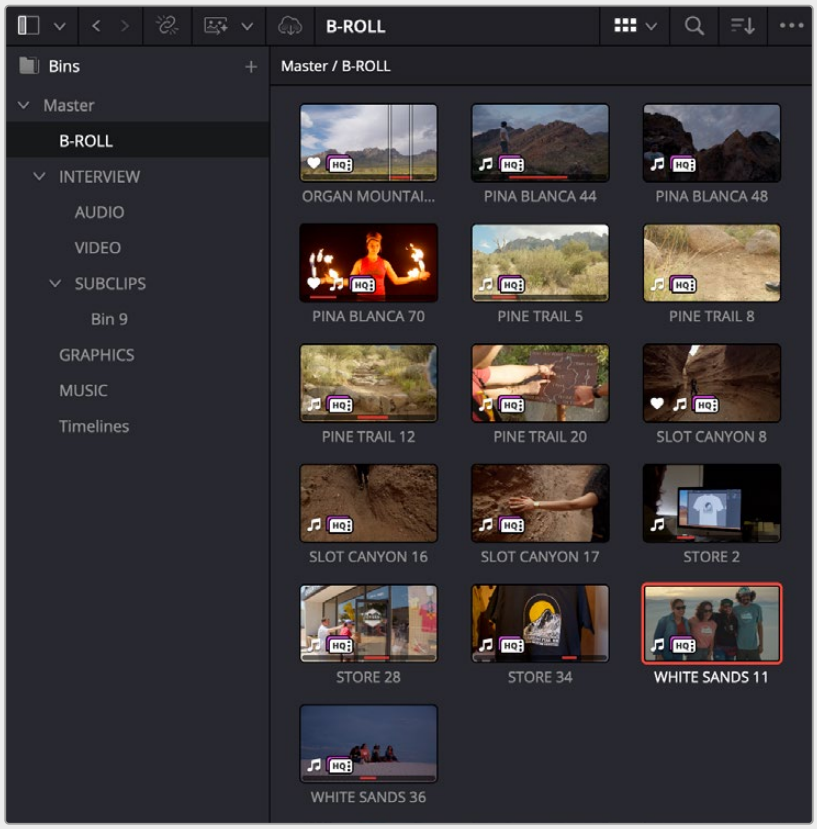
Video+Audio tracks in the Cut page Timeline

TIP: In the Edit page, Video+Audio clips are presented as separated Video and Audio items on different tracks. When you open the Fairlight page, audio is presented on tracks with lanes, where each audio channel can be seen. In this way, each page gives you different sets of controls over the contents of the timeline that are appropriate for each page.

The Edit Page

The Edit page exposes a source-record style NLE that incorporates many specialized features for both creative editing and finishing. The Edit page is divided into three main regions: the browsers found at the left, the Viewers at the top, and the Timeline at the bottom, all of which work together to let you import, edit, and trim timelines with a flexible variety of tools and methods.

The Edit page

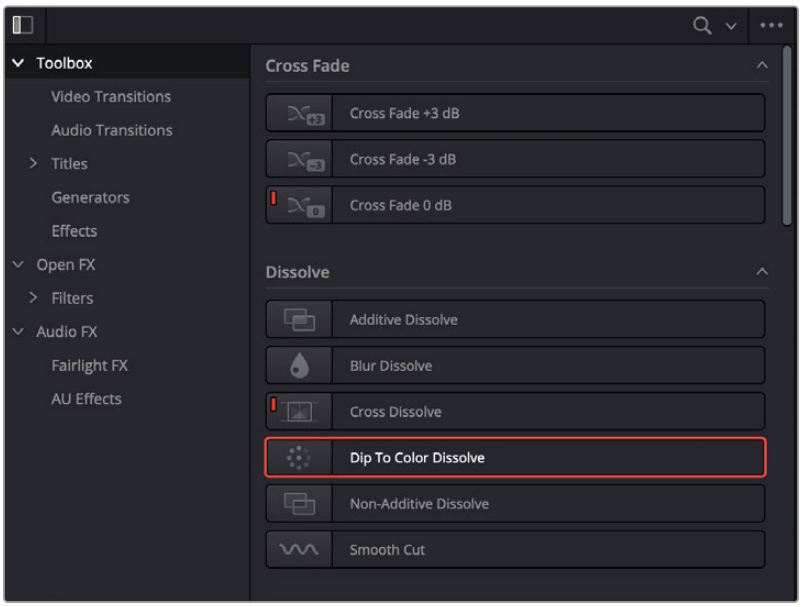


For more information on the Edit page, jump to this chapter: Using the Edit Page.

The Media Pool

As with everywhere else it appears in DaVinci Resolve, the Media Pool lets you organize and peruse all of the media and timelines in a project. DaVinci Resolve projects may contain one or more edited timelines (sometimes called a sequence in other applications).

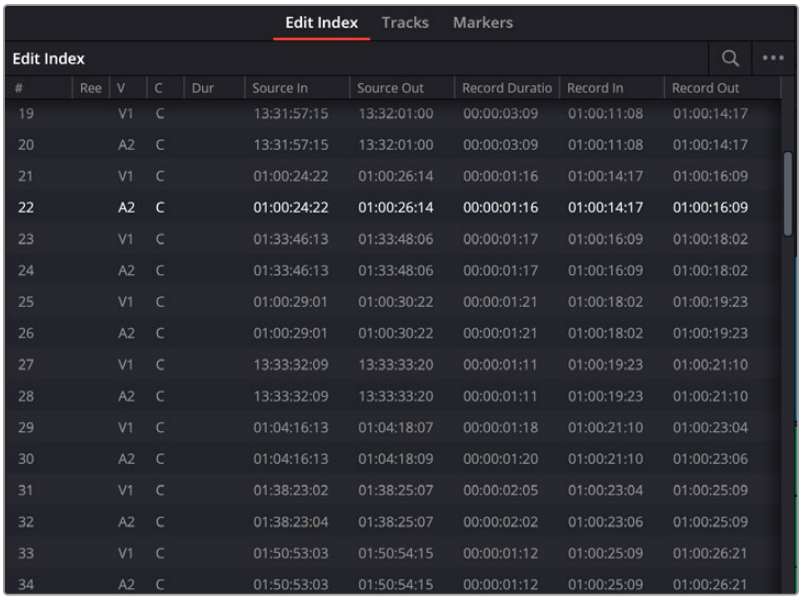
The Media Pool in the Edit page is identical to that shown on the Media, Fusion, Color, and Fairlight pages, and shows you all of the source clips and timelines that are available for editing. A Bin list at the left shows a hierarchical list of folders that you can use to organize your media.



By default, the Media Pool has a single bin, named Master, but you can add more bins as necessary to organize your clips, opening any of them to expose their contents with a single click. The Bin list can be hidden or shown via the button at the upper-left of the Media Pool. A browser to the right shows the contents of the currently selected bin.

The Media Pool in Thumbnail mode

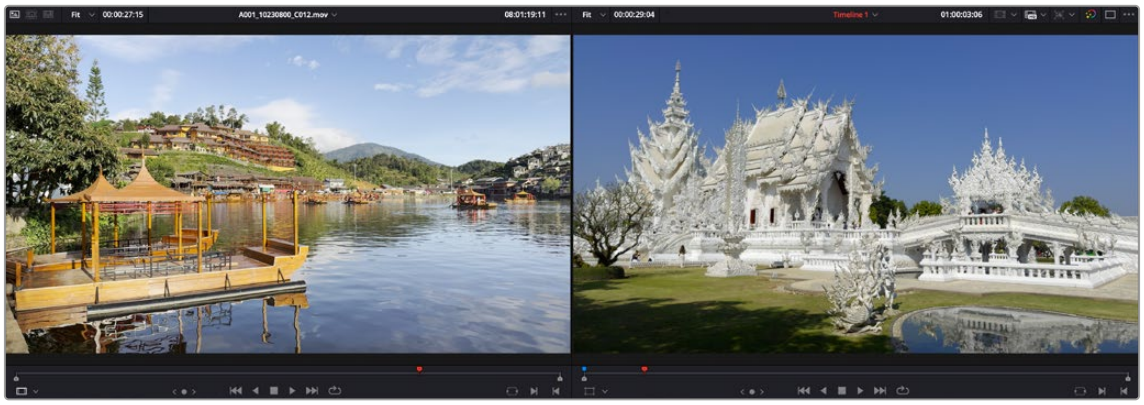
Effects Library Browsing



The Effects Library contains a folder with the different video transitions, title effects, generators, and filters that are available for editing in the timeline. The Effects Library has two panels, a Toolbox panel that contains the default Transitions, Titles, and Generators that Resolve comes with, and an OpenFX panel that contains any OpenFX transitions and generators you might have installed on your system.

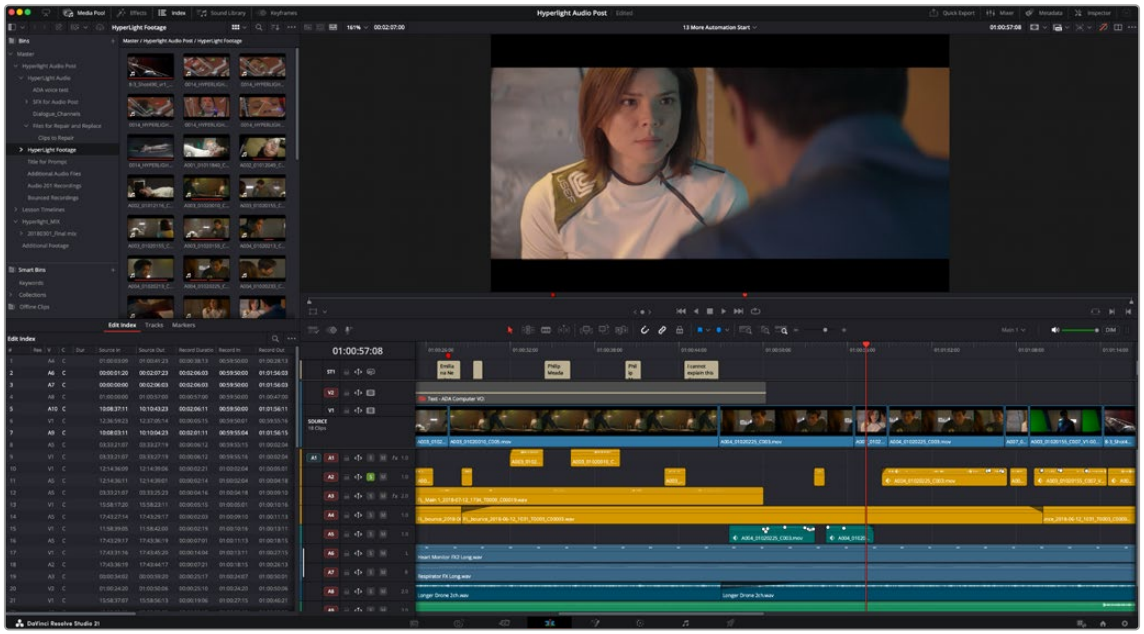
The Effects Library

Edit Index



Clicking the Index button opens the Edit Index. By default, this shows an EDL-style list view of all the edit events in the current timeline. Whichever timeline is selected in the Timeline list displays its events here; each clip and transition is shown as an individual event, each of which contains multiple columns of information. If you re-edit a timeline, your changes are automatically reflected in this list.

Edit Index List shown open



Source/Offline and Timeline Viewers

The Source Viewer lets you view individual clips from the Media Pool to prepare them for editing. Meanwhile, the Timeline Viewer shows the frame at the position of the playhead in the Timeline. You can select either viewer by clicking, and the name of the viewer that currently has focus appears in orange. The color shown in the Source Viewer usually reflects that of the original source media, while the Timeline Viewer shows whatever grading you've done in the Color page.

Source and Timeline Viewers

If you want to change the Edit page layout to hide the Source Viewer, you can choose Workspace > Single Viewer Mode to hide the Source Viewer and instead use just a single viewer to contextually display either a selected Source Clip or the current frame of the Timeline.

Single Viewer mode

In Single Viewer mode, whatever you select in the media pool or timeline determines which controls appear in the Viewer, which lets you do nearly everything you can do with two simultaneously open viewers.

You can also put either the Source or Timeline Viewers into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (Command-F), causing whichever viewer is currently selected to fill the entire screen. This command toggles Cinema Viewer mode on and off.

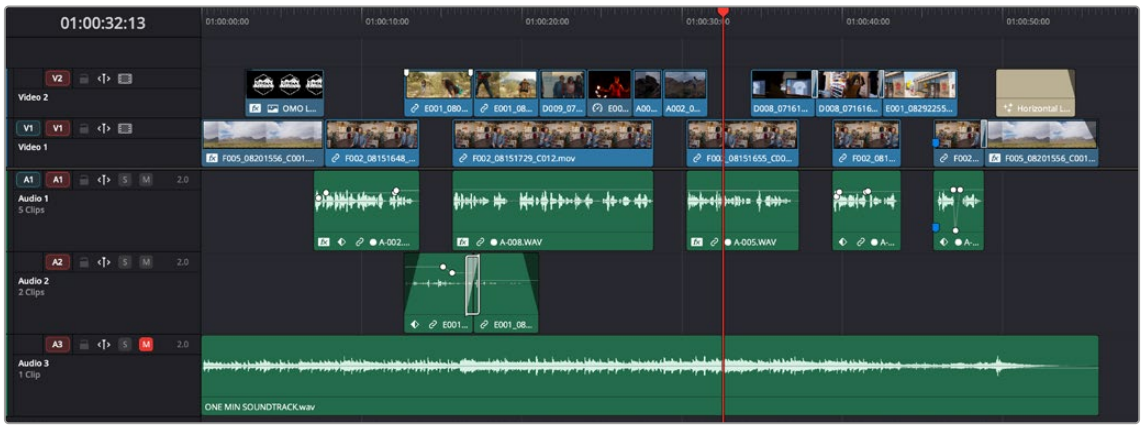
Inspector

The Inspector can be opened to let you customize compositing, transform, and cropping parameters for clips, as well as clip-specific retime and scaling options. Furthermore, the Inspector lets you edit the parameters of transitions, titles, and generators used in the Timeline, in order to customize their effect. Ordinarily, the Inspector opens alongside the Source and Timeline Viewers, but on smaller displays, opening the Inspector switches the Edit page to a single-viewer mode, showing you the Timeline item that you're inspecting alongside the Inspector with that clip's parameters.

The Inspector, opened and showing a clip's parameters

Toolbar

Eleven buttons starting from the left, running along the top of the Timeline, let you choose different tools for performing various editing functions.



Buttons in the toolbar

Timeline

The Timeline shows whichever timeline you've double-clicked in the Timelines browser. It's the workspace where you either edit programs together from scratch, or import sequences from other applications to work on inside of Resolve. You can only have one Timeline open at a time.

The Timeline is divided into audio and video tracks, each of which has a series of header controls at the left that let you choose destination tracks for editing, name tracks, and turn tracks on and off, among other things. The appearance of the Timeline can be customized using the Timeline View Options drop-down in the toolbar.

An edited timeline

Floating Timecode Window

A timecode window is available from the Workspace menu on every page, including the Edit page. Choosing this option displays a floating timecode window that shows the timecode of the Viewer or Timeline that currently has focus. This window is resizable so you can make the timecode larger or smaller.

A new floating timecode window is available

Motion Graphics and Visual Effects in DaVinci Resolve

To begin with, DaVinci Resolve has a wealth of effects in both the Edit and Color pages for creating titles, transforming and animating clips, compositing and creating transparency effects, cutting mattes, applying filters, image stabilization, lens dewarping, and so on.

Then of course there's the Fusion page, which adds considerably more powerful VFX and motion graphics capabilities via its node-based interface and deep toolset of effects nodes, keyframing and curve editing controls, and 2D and 3D compositing features.

To use DaVinci Resolve to the best effect, it's prudent to begin to think of the Edit, Fusion, and Color pages as complementary sets of controls.

- For editors, the Fusion and Color pages are really just two giant inspectors; one filled with every compositing tool you could hope to use, and the other filled with every control for color and visual adjustment you could want, each of which are only one click away.

- For compositing artists, the Edit page can be considered a robust shot management interface as well as an opportunity to do VFX work that's deeply integrated with the edit of the program you're working on.
- For colorists, the Edit page is a refined environment for dealing with conform issues and taking care of myriad finishing tasks quickly and easily, that itself is only one click away.

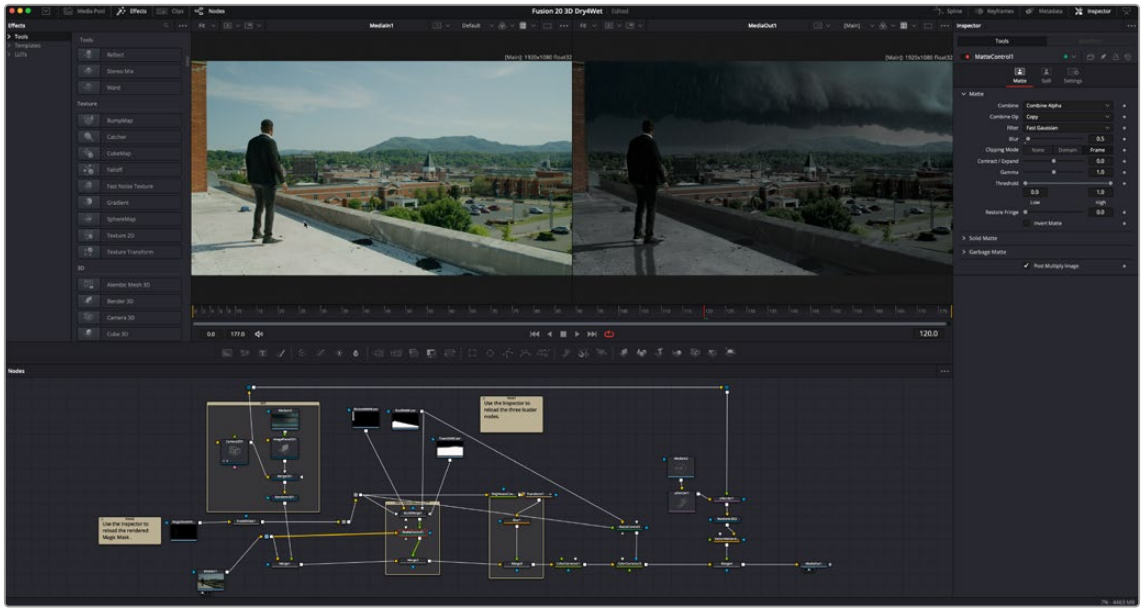
  For more information on the effects that are available in DaVinci Resolve, jump to any of these sections: Editing Effects and Transitions and Color Page Effects.

VFX Connect

As robust as the built-in compositing capabilities of DaVinci Resolve now are, when you run into instances where the various capabilities found in the Edit, Fusion, and Color pages aren't enough to achieve the effect you require, you can use the VFX Connect features of DaVinci Resolve to send one or more clips from the Edit page Timeline to Blackmagic Fusion, the powerful node-based compositing application from Blackmagic Design, in order to do more robust compositing and effects work there. Furthermore, the VFX Connect feature can also be used to round-trip media to and render results from third-party applications such as The Foundry's Nuke, Autodesk Flame, or Blender.

This is a simple round-trip operation that lets you send clips from the DaVinci Resolve timeline to Fusion or another application, where you'll add effects and do whatever work needs to be done before rendering a finished effect file that, if properly named, will automatically appear back in your timeline. When you use VFX Connect with Blackmagic Design Fusion, a project file is automatically generated and the render path is automatically named for automatic linking from the DaVinci Resolve timeline. If you use this feature with third-party applications, you'll need to set up the naming of your rendered effect file manually.

For more information, jump to this chapter: Introduction to Compositing in Fusion.



The New VFX Connect Clip dialo

The Fusion Page

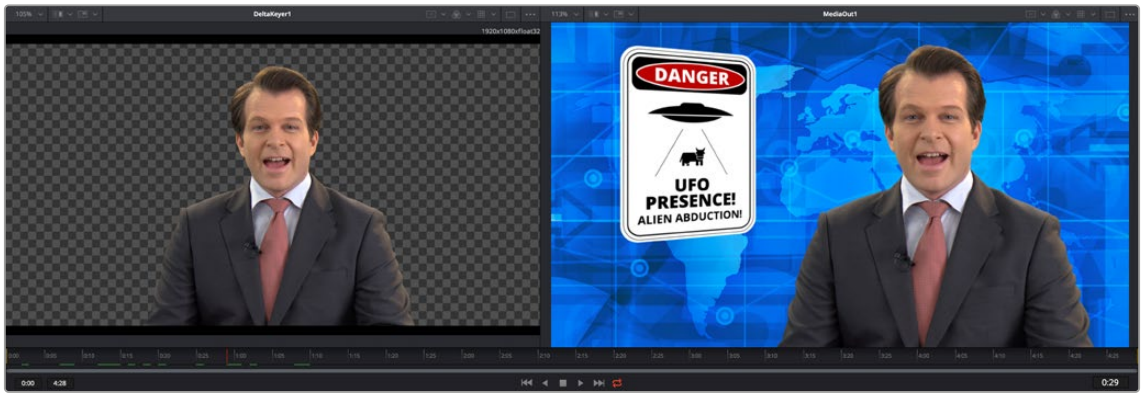
The Fusion page is intended, eventually, to be a feature-complete integration of Blackmagic Design Fusion, a powerful 2D and 3D compositing application with over thirty years of evolution serving the film and broadcast industry, creating effects that have been seen in countless films and television series.

Merged right into DaVinci Resolve with a newly updated user interface, the Fusion page makes it possible to jump immediately from editing right into compositing, with no need to export media, relink files, or launch another application to get your work done. Everything you need now lives right inside DaVinci Resolve.

The Fusion page showing Viewers, the Node Editor, and the Inspector

For more information on using the Fusion page, jump to this chapter: Introduction to Compositing in Fusion.

The Work Area



You'll probably not see this term used much, in favor of the specific panels within the work area that you'll be using, but your Work Area is the region at the bottom half of the Fusion page UI, within which you can expose the three main panels used to construct compositions and edit animations in the Fusion page. These are the Node Editor, the Spline Editor, and the Keyframes Editor. By default, the Node Editor is the first thing you'll see, and the main area you'll be working within, but it can sit side-by-side with the Spline Editor and Keyframes Editor as necessary, and you can make more horizontal room on your display for these three panels by putting the Effects Library and Inspector into half-height mode, if necessary.

The Work Area showing the Node Editor, the Spline Editor, and Keyframes Editor

Viewers

The Viewer Area area encompasses the Time Ruler and transport controls. The Time Ruler is the principal “timeline” of the Fusion page, which focuses exclusively on the current composition you’re working on and may consist of one clip or several. This area can be set to display either one or two viewers at the top of the Fusion page, chosen via the Viewer button at the far right of the Viewer title bar. Each viewer can show a single node’s output from anywhere in the node tree. You assign which node is displayed in which viewer. This makes it easy to load separate nodes into each viewer for comparison. For example, you can load a Keyer node into the left viewer, and the final composite into the right viewer, so you can see the image you’re adjusting and the final result at the same time.

Dual viewers let you edit an upstream node in one while seeing its effect on the overall composition in the other

Ordinarily, each viewer shows 2D nodes from your composition as a single image. However, when you’re viewing a 3D node, you have the option to set that viewer to one of several 3D views, including a perspective view that gives you a repositionable stage on which to arrange the elements of the world you’re creating, or a quad view that lets you see your composition from four angles, making it easier to arrange and edit objects and layers within the XYZ axes of the 3D space in which you’re working.

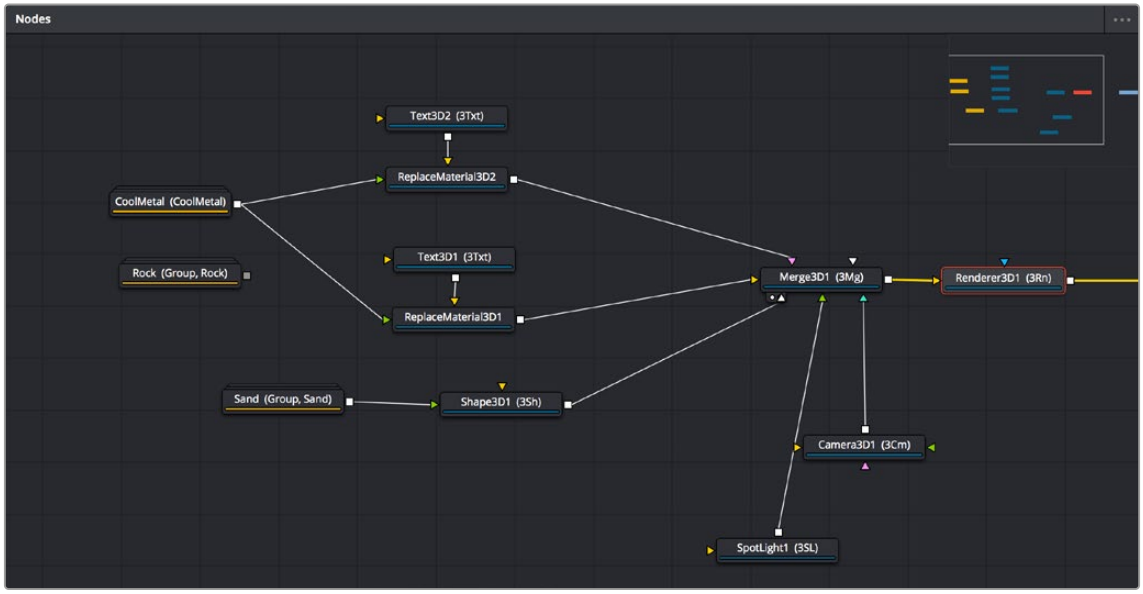
Toolbar

The toolbar, located underneath the Time Ruler, contains buttons that let you quickly add commonly used nodes to the Node Editor. Clicking any of these buttons adds that node after the currently selected node in the node tree, or adds an unconnected instance of that node if no nodes are selected.

The toolbar has buttons for adding commonly used nodes to the Node Editor

The toolbar is divided into six sections that group commonly used nodes together. As you hover the pointer over any button, a tooltip shows you that node's name.

Effects Library



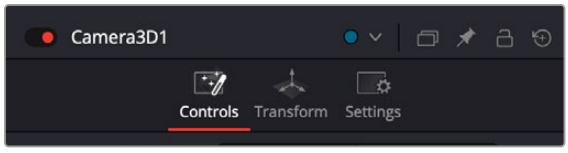
The Effects Library on the Fusion page shows all of the nodes and effects that are available in the Fusion page, including effects that come with DaVinci Resolve and third-party OFX, if available. While the toolbar shows many of the most common nodes you'll be using in any composite, the Effects Library contains every single tool available in the Fusion page, organized by category, with each node ready to be quickly added to the Node Editor. Suffice it to say there are many, many more nodes available in the Effects Library than on the toolbar, spanning a wide range of uses.

The Effects Library with Tools open

Node Editor

The Node Editor is the heart of the Fusion page, because it's where you build the tree of nodes that makes up each composition. Each node you add to the node tree adds a specific operation that creates one effect, whether it's blurring the image, adjusting color, painting strokes, drawing and adding a mask, extracting a key, creating text, or compositing two images into one.

The Node Editor displaying a node tree creating a composition

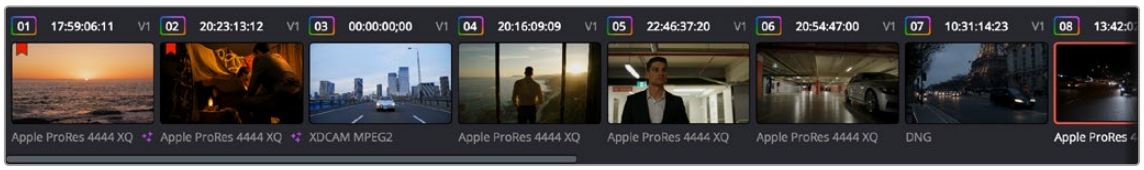


Inspector

The Inspector is a panel on the right side of the Fusion page that you use to display and manipulate the parameters of one or more selected nodes. When a node is selected in the Node Editor, its parameters and settings appear in the Inspector, ready for you to modify. The Fusion Inspector is divided into two panels. The Tools panel shows you the parameters of selected nodes.

The Modifiers panel shows you different things for different nodes. For all nodes, it shows you the controls for Modifiers, or adjustable expressions, that you've added to specific parameters to automatically animate them in different ways.

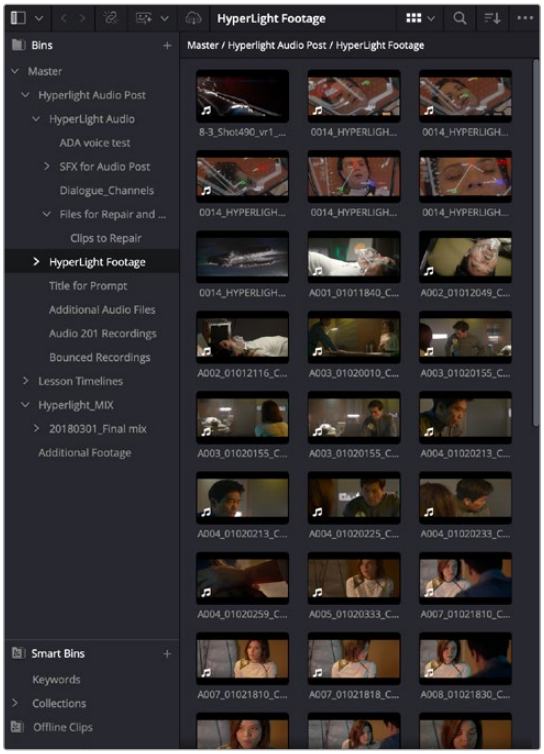
The Inspector shows parameters from one or more selected nodes



Nodes with different tabs expand the Controls, Transform, and Settings parameters

Additionally, many nodes expose multiple tabs' worth of controls in the Inspector, seen as icons at the top of the parameter section for each node. Click any tab to expose that set of controls.

Thumbnail Timeline

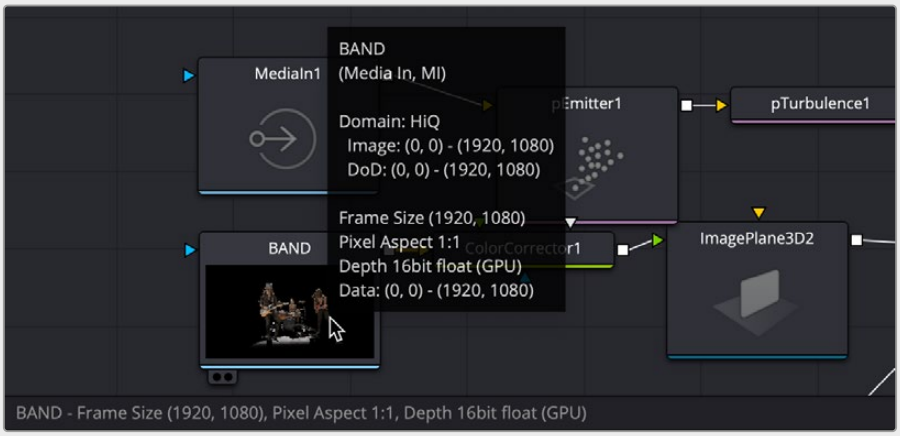


Hidden by default, the Thumbnail timeline can be opened by clicking the Clips button in the UI toolbar and appears underneath the Node Editor when it's open. The Thumbnail timeline shows you every clip in the current Timeline, giving you a way to navigate from one clip to another when working on multiple compositions in your project and providing an interface for creating and switching among multiple versions of compositions and resetting the current composition, when necessary.

The Thumbnail timeline lets you navigate the Timeline and manage versions of compositions

Media Pool

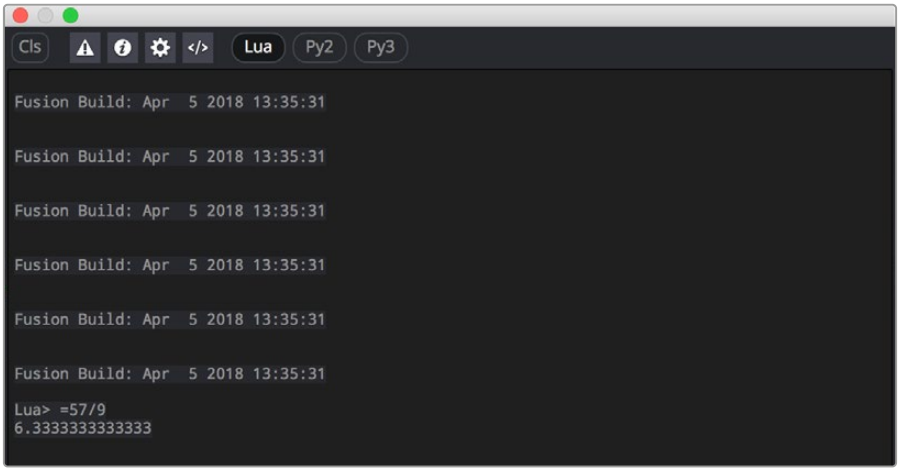
In the Fusion page, the Media Pool continues to serve its purpose as the repository of all media you've imported into your project. This makes it easy to add additional clips to your compositions simply by dragging the clip you want from the Media Pool into the Node Editor. The media you add appears as a new MediaIn node in your composition, ready to be integrated into your node tree however you need.



The Media Pool in Thumbnail mode showing video clips

Status Bar

The status bar at the bottom of the Fusion page, immediately above the Resolve Page bar, shows you a variety of up-to-date information about things you're selecting and what's happening in the Fusion page.



For example, hovering the pointer over any node displays information about that node in the status bar (as well as in a floating tooltip), while the currently achieved frame rate appears whenever you initiate playback, and the percentage of the RAM cache that's used appears at all times. Other information, updates, and warnings appears in this area as you work.

The status bar under the Node Editor showing you information about a node under the pointer and a floating tooltip

The Console

The console, available by choosing Workspace > Console, is a window in which you can see the error, log, script, and input messages that may explain something the Fusion page is trying to do in greater detail. The console is also where you can read FusionScript outputs or input FusionScripts directly. Occasionally, the status bar (described above) will display a badge to let you know there's a message in the console you might be interested in. The badge will indicate if the message is an error, log, or script message.

The Console window

The Color Page

The Color page is where you color correct, or grade, your program. It has all of the controls available for manipulating color and contrast, reducing noise, creating limited secondary color corrections, building image effects of different kinds, adjusting clip geometry, and making many other corrective and stylistic adjustments. The Color page is divided into seven main areas that work together to let you build a grade.

For more detailed information on the Color page, jump to this chapter: Using the Color Page.

The Color page

Viewer

The Viewer shows the frame at the current position of the playhead in the timeline. The contents of the viewer are almost always output to video via whichever I/O interface you have connected. At the top of the viewer is a header that displays the Project and Timeline names, as well as a Viewer Timecode display that shows the source timecode of each clip by default. The timeline name is also a drop-down display that lets you switch to any other timeline in the project. A jog bar (sometimes referred to as a scrubber bar) underneath the image lets you drag the playhead across the entire duration of the clip, while transport controls underneath that let you control playback. A toolbar at the top provides controls governing Image Wipes, Split-Screen controls, and Highlight display. Additional controls let you turn audio playback on and off, or adjust them by right-clicking on the speaker icon and dragging the slider. You can also choose which onscreen controls are currently displayed.

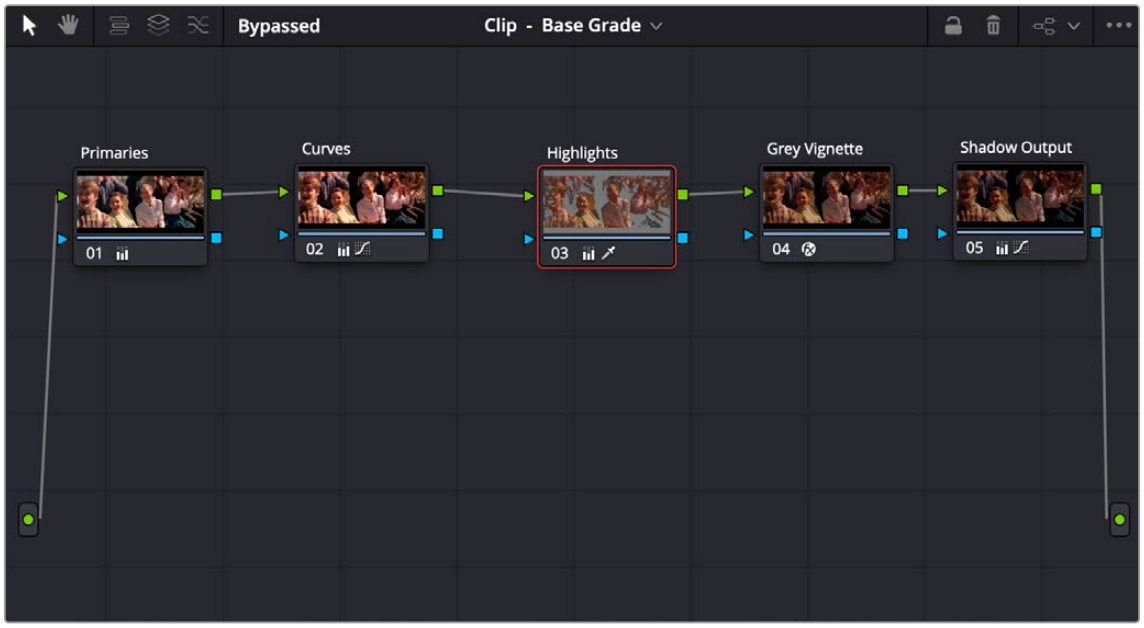
Viewer with transport controls

You can also put the viewer into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (Command-F), so that it fills the entire screen. This command toggles Cinema Viewer mode on and off. Two other modes, Enhanced Viewer (Option-F) and Full Screen Viewer (Shift-F), are available to provide more working area for tasks such as window positioning and rotoscoping.

Gallery

The Gallery is used for storing still frames to use as reference when comparing clips to one another. Each still frame also stores that clip's grade so you can copy it later; stills and grades are stored together. A button lets you open up the Album browser, used for organizing your stills. At the top of the gallery, Memories lets you store grade information that you can apply using a control panel or keyboard shortcuts. You can also open a larger gallery window within the Color page that provides more room for organizing your saved stills and grades.

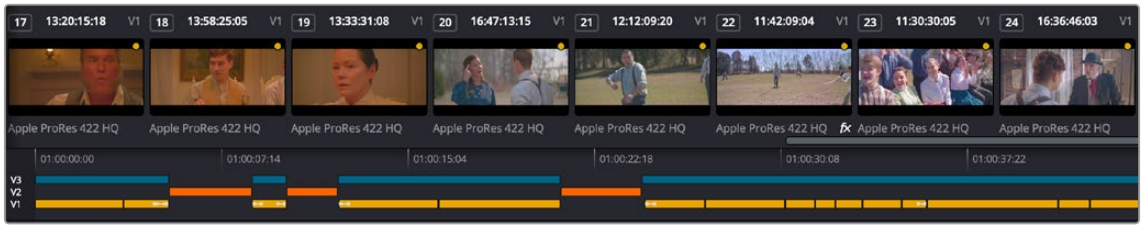
For more information on the Gallery page, jump to this chapter: Using the Gallery.



The Gallery has Memories, stills saved in albums, and your PowerGrades

Node Editor

The Node Editor is where you assemble one or more individual corrections (nodes) together to create multi-correction grades (seen as node trees). This is a powerful way of assembling grades, since different combinations of nodes let you create different corrections and very specific adjustments by reordering operations, combining keys, or changing the layer order of different adjustments.



For more information on the Node Editor, jump to this chapter: Node Editing Basics.

Node Editor to construct your grade processing signal flow

Timeline

The Timeline in the Color page reflects the contents of the Timeline in the Edit page, but has a different appearance that's tailored to the requirements of the colorist. However, the content is identical, and changes made to the Timeline in the Edit page are immediately seen in the Color page as you switch back and forth. The Color page timeline provides several ways of navigating the clips in your project, as well as keeping track of what has been done to which clips.

The Color page Timeline

The Timeline is divided into three parts, each of which shows different information and provides differing controls. A Timeline Ruler at the top lets you scrub the playhead across multiple clips, and can be zoomed out enough to show every clip in your entire program. Underneath, the Mini-Timeline (which can be opened or closed via a button at the right of the palette bar) shows a

small representation of the Timeline in the Edit page wherein each clip is as long as its actual duration. At the bottom of the Timeline is the Thumbnail timeline, in which each clip is represented by a single frame. The currently selected clip is outlined in orange, and information appears above and below each thumbnail such as each clip's source timecode, clip number and track number, version name, whether it's been graded, whether it's been tracked, if it's been flagged, and so on.

Left Palettes

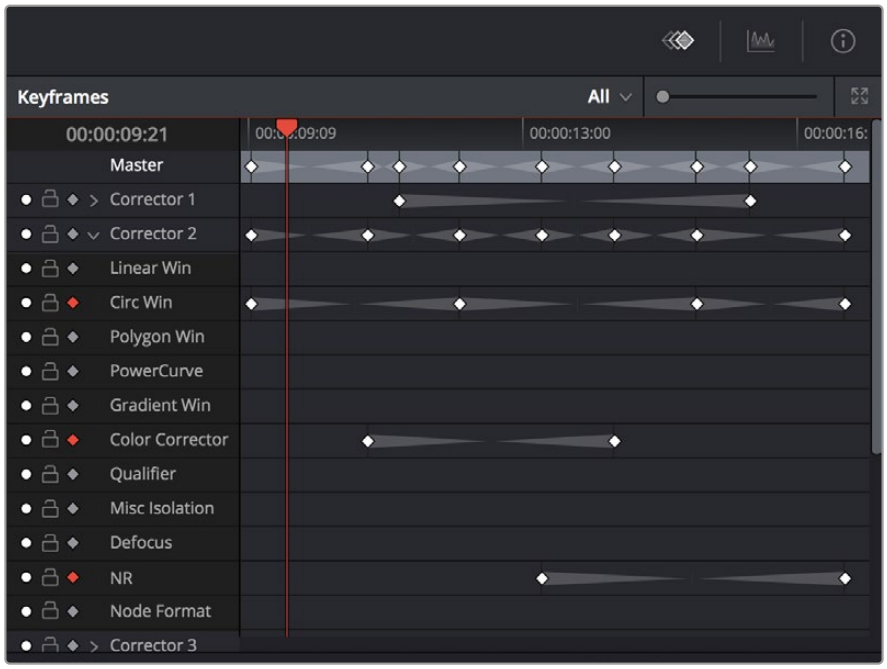
A series of palettes at the bottom left of the Color page provide access to different sets of grading tools, used principally for manipulating color, contrast, and raw media format settings. Each individual palette is opened by clicking the corresponding icon at the top of the Palette panel.

Left palette selection buttons in the top bar

The available palettes are the Camera Raw palette (for making metadata adjustments to raw media formats), the Color Match palette (for creating automatic grades by sampling on-camera color charts), the Color Wheels (graphical color balance controls and master wheels or sliders for adjusting YRGB Lift/Gamma/Gain), HDR Grade for enhanced High Dynamic Range grading, the RGB Mixer (for mixing color channels into one another), and the Motion Effects palette (with controls for noise reduction and artificial motion blur).

Center Palettes

At 1920x1080 resolution or higher, a second set of palettes is organized at the bottom center of the Color page. These palettes span a wide range of functionality, and the adjustments you make with them can be combined with those made using the Color palettes.



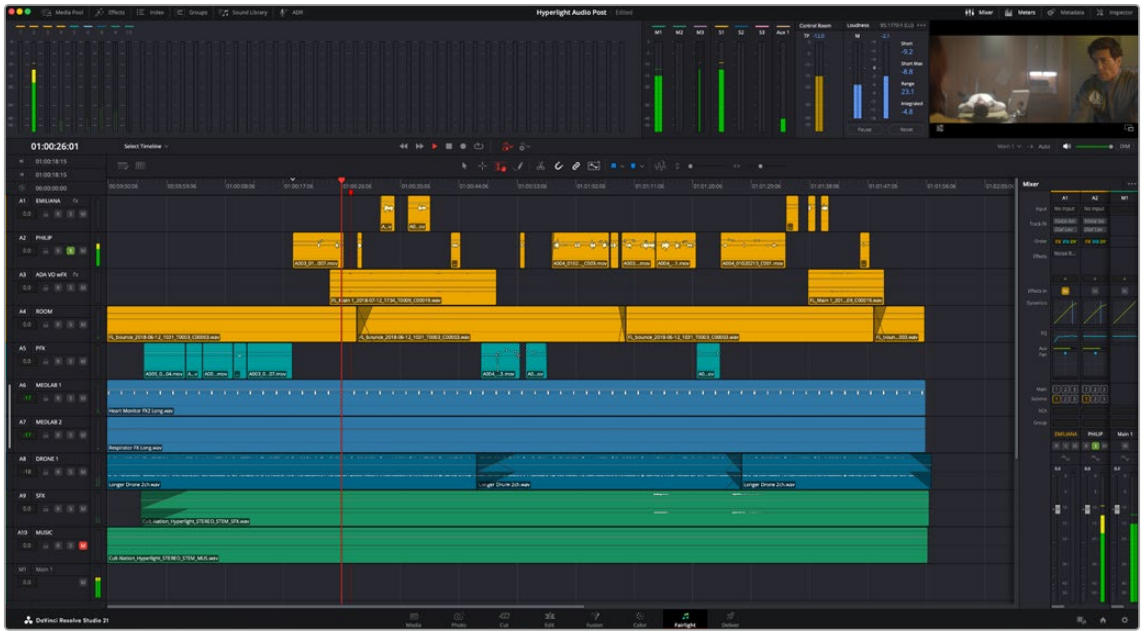
Center palette selection buttons

NOTE: At lower resolutions, the Left and Center palettes are merged to fit the DaVinci Resolve interface into a smaller area.

The eight available Center palettes include the Curves palette, the Color Warper palette, the Qualifiers palette, the Windows palette, the Tracker palette, the Magic Mask palette, the Blur palette, the Key palette, the Sizing palette, and the Stereoscopic 3D palette.

Keyframe Editor

The Keyframe Editor provides an interface for animating Color, Sizing, and Stereo Format adjustments over time. Each node in the Node Editor corresponds to a track in the Keyframe Editor, which lets you animate each node's adjustments independently.



Keyframe Editor displaying dynamic grade changes

Furthermore, each node's track can be opened up to reveal parameter groups, so that you can animate subsets of an individual node's functions independently of other functions within the same node.

The Fairlight Page

In single monitor mode, the Fairlight page is an optimized look at the audio tracks of your project, with an expanded mixer and custom monitoring controls that make it easy to evaluate and adjust the levels of your program in order to create a smooth and harmonious mix.

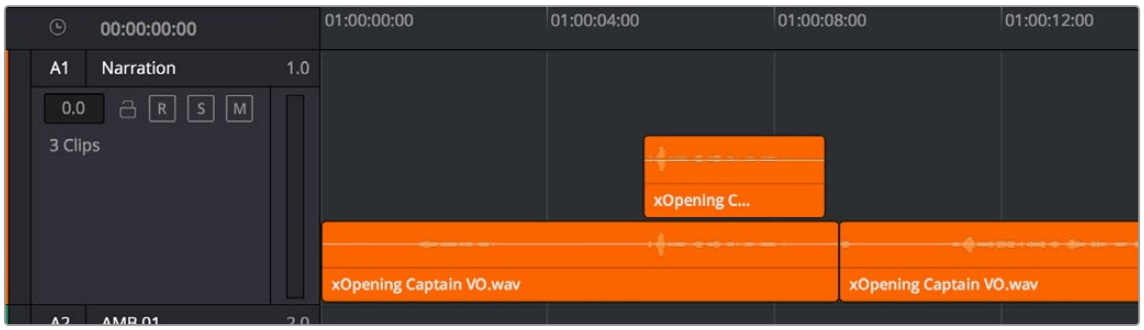
Fairlight page

About Audio Monitoring and Audio Input

The audio processing throughout DaVinci Resolve, including on the Fairlight page and audio processing using Fairlight FX plugins, is equally compatible with all platforms that DaVinci Resolve runs on, including macOS, Windows, and Linux.

DaVinci Resolve supports audio monitoring using:

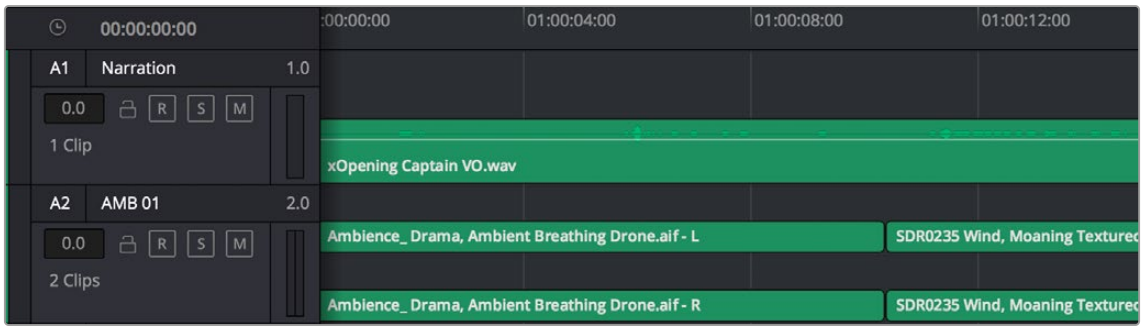
- The audio of a supported Blackmagic Design I/O device such as an UltraStudio or Decklink.
- Your macOS, Windows, or Linux workstation's on-board audio.
- Any Core Audio compatible, Windows compatible, or Advanced Linux Sound Architecture (ALSA)-supported third-party audio interface.
- The Fairlight Audio Accelerator, MADI Upgrade, and Fairlight Audio Interface.



DaVinci Resolve supports audio input using the embedded audio on an incoming SDI video feed when capturing incoming A/V source, via system audio and also via the Fairlight Audio Accelerator, MADI Upgrade, and Fairlight Audio Interface.

The Audio Timeline

The heart of the Fairlight page, the Audio Timeline presents the audio channels and tracks of the currently selected timeline differently than the Edit page does, in a one-channel-per-track format that's optimized for audio mixing and sweetening. The Audio page Timeline cannot be closed.

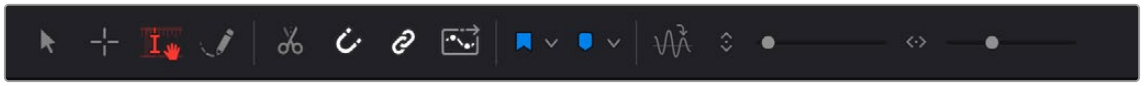


The Audio Timeline

Audio layering in a mono audio track

The Fairlight page of DaVinci Resolve supports multiple audio tracks, and each audio track may contain multiple lanes. The clips edited into the Timeline appear within each track, with the recorded channels within each clip occupying as many lanes as that clip has available. At the left of each track is a header area that contains a number of controls.

The Fairlight page differs in another unique respect from the Edit page timeline, in that it supports audio layering. Audio layering is a special audio editing mode that lets you superimpose multiple audio clips in the same track, and whatever audio clip is on top dictates which audio will play. In a way, when audio layering is enabled, superimposed audio clips are treated the same as superimposed video clips that all have opacity set to 100%, with clips on top obscuring (or muting) clips underneath.



Turning on Track Layers opens up space to edit more audio into each track

Audio layering is incredibly useful for any situation where you're combining pieces of multiple takes together to create a single VO, audio vocal track, or dramatic performance, as you can choose which pieces to prioritize via their superimposed position in the track, while you're preserving the other takes underneath in case you want them later.

TIP: Track Layering can be used on the Edit page as well.

Toolbar

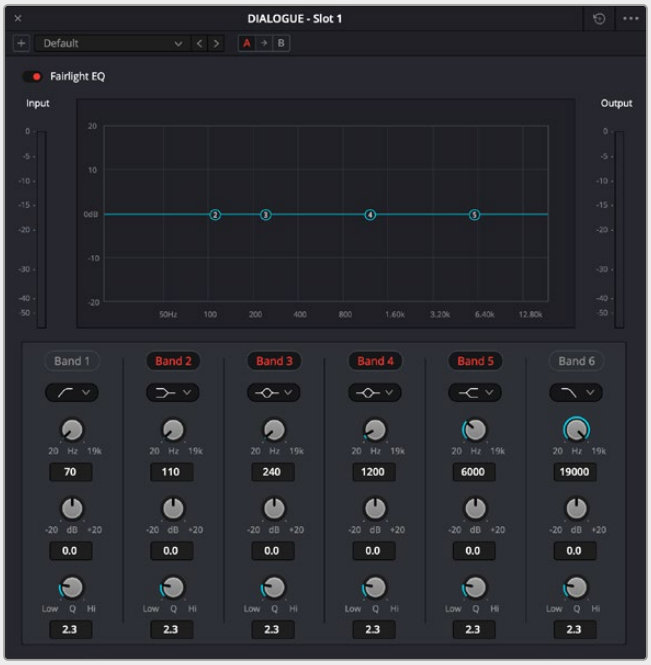
The toolbar has buttons that let you choose modes of audio-specific functionality and other buttons that let you execute commands, such as placing markers and flags.

Buttons in the Fairlight page toolbar

Mixer

The Audio Mixer, with channel strips corresponding to the tracks in the Timeline

The Audio Mixer provides a set of graphical controls you can use to assign track channels to output channels, adjust EQ and Dynamics, set levels and record automation, pan stereo and surround audio, and mute and solo tracks, all while you continue to edit.



The Audio Mixer exposes a set of channel strips with controls that correspond to the tracks in the timeline, one for each track, plus a Master strip corresponding to the Master audio track in the timeline, that lets you choose the number of audio channels to output, and also lets you adjust the overall level of the mix.

Dedicated Channel Strip Controls

The Mixer also has a series of dedicated channel strip controls that add powerful mastering capabilities to DaVinci Resolve. These include:

- EQ
- Dynamic
- Pan

EQ: Double-clicking exposes a four-band parametric equalizer with additional Hi and Lo Pass filters, that has both graphical and numeric controls for tuning the frequencies of the audio on each track. You can select from among four types of EQ filtering from the Equalizer Type drop-down menu, with options for Earth (the default), Air, Ice, and Fire. Each band has controls for the filter type (Bell, Lo-Shelf, Hi-Shelf, Notch), Frequency, Gain, and Q-factor (sharpness of the band).

The channel strip EQ window

Dynamics: Double-clicking exposes a set of dynamics controls with compressor, limiter, and expander or gate sections. The Equalizer button at the upper left-hand corner lets you turn all EQ on and off. The first section can be switched between working as an Expander or a Gate, with attendant Threshold/Range/Ratio and Attack/Hold/Release controls. The second section provides Compressor controls, while the third section provides Limiter controls. These controls may be used either singly or in concert to manage the dynamics of the audio on that track.

The channel strip Dynamics control window

Pan: A pan control compatible with stereo and surround panning. You can drag within this control to adjust pan, or you can double-click to expose a Pan window. What controls are available in the Pan window depend on the mapping of the audio track, but both stereo and surround panning controls are available, with corresponding numeric controls.

The Pan control window

The Monitoring Panel

The Monitoring panel shows all of the audio meters corresponding to the tracks in the Timeline, as well as the Master Output meter, Control Room meters, and a video viewer.

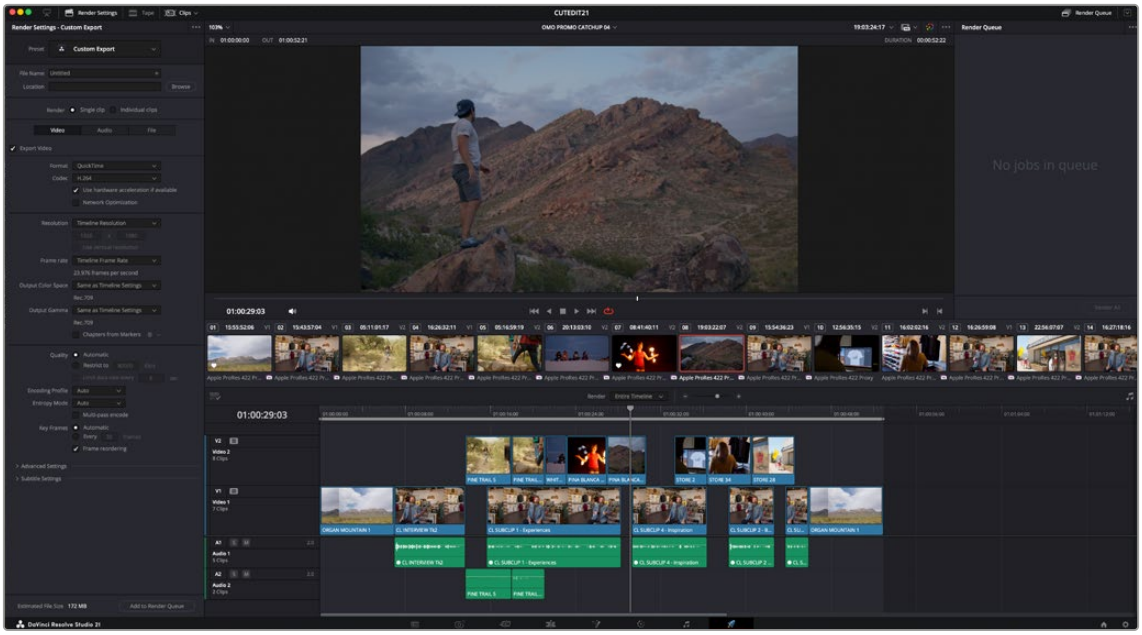
The Monitoring panel

At left, a row of audio meters corresponds to the channel strips of the Mixer, one meter for every audio track in the Timeline. To the right of these, all buses appear, showing you meters for the Mains and Subs (submixes) you're using to mix down your show. Farther to the right of these, a set of Control Room meters show you the monitored output and loudness meters for a precise analysis of your mix's perceived loudness.

Finally, a small viewer to the right of the Monitoring panel shows the frame of video at the position of the playhead. This viewer can be undocked via a button at the lower right-hand corner.

Floating Timecode Window

A timecode window is available from the Workspace menu on every page, including the Fairlight page. Choosing this option displays a floating timecode window that shows the timecode of the Viewer or Timeline that currently has focus. This window is resizable so you can make the timecode larger or smaller.

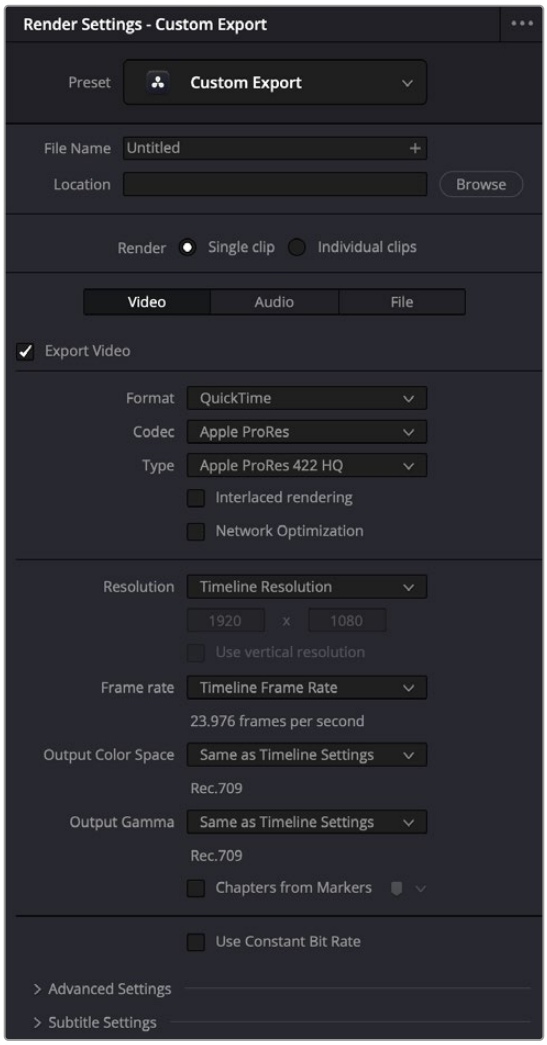


A new floating timecode window is available

The Deliver Page

Once you've finished grading your project, you need to either render it, or output it to tape to deliver it to your client. This is where the Deliver page comes in. The Deliver page can be used both to output digital deliverables, or to output tape, depending on which mode you enable. Either way, the Deliver page is divided into five areas of functionality, each of which lets you set up a different part of a render or output to tape.

The Deliver page is set up to let you queue a series of individual jobs, each of which can have different settings, or be set up to render different parts of the Timeline. In this way, you can output multiple deliverables, or re-render multiple areas of a timeline, as your needs require.



The Deliver page

For more information on using the Deliver page, jump to this chapter: Using the Deliver Page.

The Render Settings List

The Render Settings list contains the customizable settings that affect how media is rendered out of DaVinci Resolve. These settings are covered in more detail later in “Output Scaling.” The render settings you can choose from for outputting from DaVinci Resolve appear in three panels, separating the Video, Audio, and File information-based settings in a logical fashion. By default, this list shows only the most important criteria necessary for defining a render. However, additional controls can be exposed by clicking the “Advanced settings” disclosure triangle at the bottom of each group of settings.

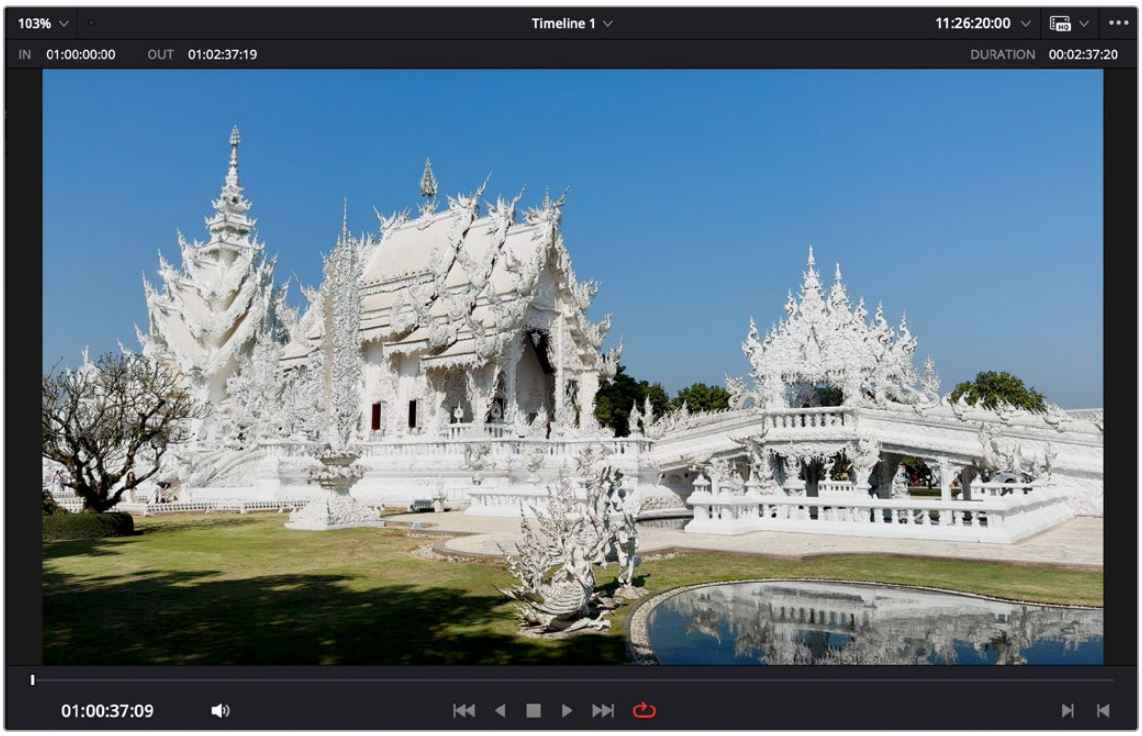
Render settings

The Deliver Page Timeline

This timeline mirrors the timeline seen in the Color page. You can use Timeline in the Deliver page to turn off tracks with clips you don’t want to include in the operation, define the range of clips you want to render or output to tape, and to choose which versions for each clip you want to output. You also have the option of switching the Deliver page timeline to look like the Color page timeline instead, if that’s what you’re more comfortable with.

The Deliver page timeline also has the Timeline Filter drop-down at the right-hand side of the toolbar. Using this drop-down to filter the contents of the Timeline lets you restrict the range of media you want to output in different ways. For example, if you’ve already rendered a timeline, but have since made

changes, you can use the Show Modified Clips option to display only the clips that have changed within a particular timeframe. Another possibility is to choose the Show Unrendered Clips option to show all clips that have not yet been rendered.

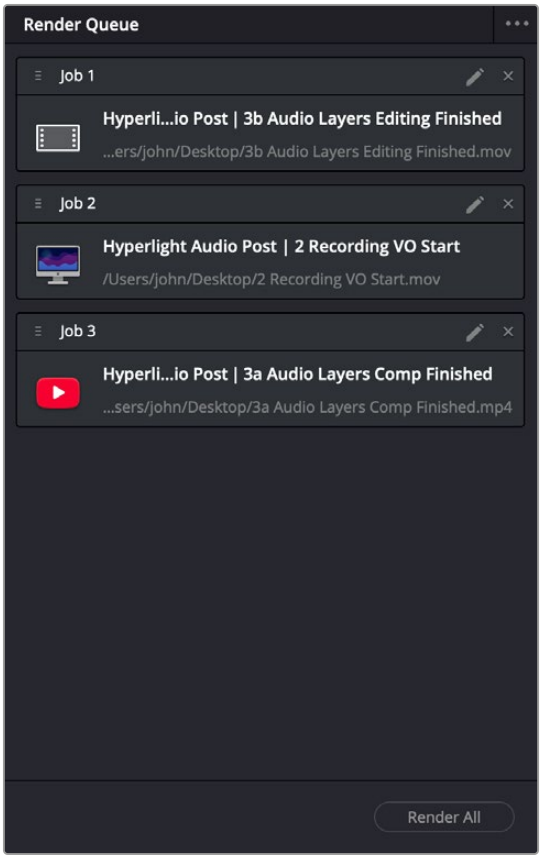


The Deliver page's Thumbnail and Mini-Timeline match the Color page

The Viewer

When rendering file-based media, the Viewer shows you exactly how the media being output will look using the current settings, and the transport controls move the playhead throughout the current timeline. Audio levels can be adjusted by right-clicking on the speaker icon and dragging the slider.

When outputting to tape, the Viewer shows you the tape output so you can set up insert or assembly edit points, and the transport controls move the tape in the deck if device control is enabled. You can also put the Viewer into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (Command-F), so that it fills the entire screen. This command toggles Cinema Viewer mode on and off.



Deliver page Viewer

The Render Queue

The Render Queue is a list of all the jobs you've queued up for file-based rendering. Each job can have an individualized range of clips and render settings, which you can use to render multiple sections or clips of a timeline, the same timeline output to multiple formats, or multiple timelines.

The Render Queue also has the option to show either just the jobs within the current project, or jobs queued up and saved within all projects for the current user.

The Render Queue displays all jobs

Chapter 2

Using the DaVinci Resolve User Interface

This chapter provides an overview of the various unspoken conventions and interaction methods employed by the DaVinci Resolve graphical user interface (GUI).

These include how the various buttons of your mouse, pen and tablet, or trackpad are used by different windows and interface widgets, how commands are distributed throughout the application using the menu bar, contextual menus, and option menus, and how to interact with fields and other controls.

While many of these conventions overlap with common user interface conventions found in the file system of your platform of choice, and with other media applications, some of these are unique to DaVinci Resolve, so this chapter is worth reviewing even if you consider yourself an expert user of other applications.

Basic Documentation Terminology

Here is a brief word about some of the basic terminology used in this manual for brand new users.

What Is the “UI” or “GUI”

In this documentation, UI refers to “user interface,” while GUI refers to “graphical user interface.” This refers to the windows, screens, and controls that let you create in DaVinci Resolve. If you didn’t know this, don’t be embarrassed, you’d be surprised how many times this question gets asked.

What Is “the Pointer”

Whenever this documentation refers to “the pointer,” the reference is to the on-screen arrow you use to click on elements of the user interface, which is controlled by the mouse, trackpad, pen and tablet, trackball, or any other device you may be using. Because there are so many different ways to control computers, simply referring to “the mouse” is inaccurate.

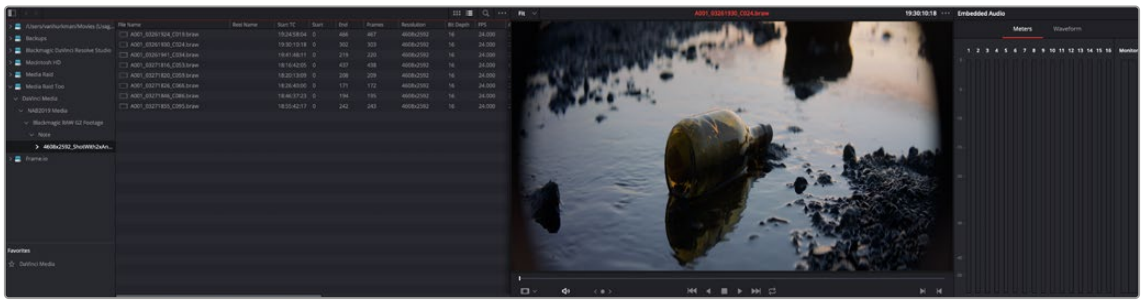
About Keyboard Shortcuts

This manual presents all keyboard shortcuts using the macOS conventions of the Command key and the Option key. For compatibility with Windows and Linux, the Control key in macOS is not used by default for any keyboard shortcuts (although it can be assigned if you customize your keyboard shortcuts).

All keyboard shortcuts that use the Option key in macOS use the ALT key in Windows and Linux, and all keyboard shortcuts that use the Command key in macOS use the Control key in Windows and Linux.

Customizing the DaVinci Resolve Interface

While the DaVinci Resolve interface may not seem very customizable at first, there are actually many ways in which you can tailor the panels found within each page to your specific needs.



Working Full Screen vs. Within a Floating Window

Depending on how you like to work, you can choose to work with DaVinci Resolve in a floating window with a title bar that can be resized, moved, minimized, and used alongside other windows. Or, you can choose Workspace > Full Screen to put DaVinci Resolve into Full Screen mode, where the title bar disappears and DaVinci Resolve takes up the full dimensions of your computer display.

Editors may prefer to work within a window if they’re working among multiple applications. Colorists and mixers may prefer Full Screen mode as it hides the light-colored title bar that some find distracting and provides a tiny bit more screen real estate for the rest of the application.

Panels and Panel Focus

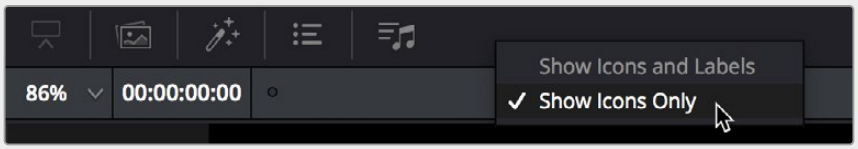
Each page of DaVinci Resolve consists of multiple panels. Each panel contains all the controls and information necessary for a particular aspect of that page’s functionality. In the following partial screenshot of the top of the Media page, the Media Storage panel lets you browse files, the Viewer is a panel that lets you watch video, and the Audio panel lets you see the strength of audio playing back via a set of audio meters. Each of these panels has separate controls, but they all appear within the main window of the DaVinci Resolve user interface.

Three panels side by side on the Media Page, showing Media Storage, the Viewer, and the Audio panel

Each panel you use has “focus,” meaning that clicking an item or control within a particular panel makes that panel the active panel, which serves to direct keyboard shortcuts that are shared among many panels to the particular panel you’re using. If you want to see which panel is in focus, you can turn on the “Show focus indicators in the User Interface” checkbox in the UI Settings panel of the User Preferences. When on, a red line at the top of the active panel indicates that it has focus.

Showing and Hiding Panels Using the Interface Toolbar

Each page in DaVinci Resolve has an Interface Toolbar that runs along the top. This toolbar contains buttons that let you show and hide different panels of functionality to accomplish different things:

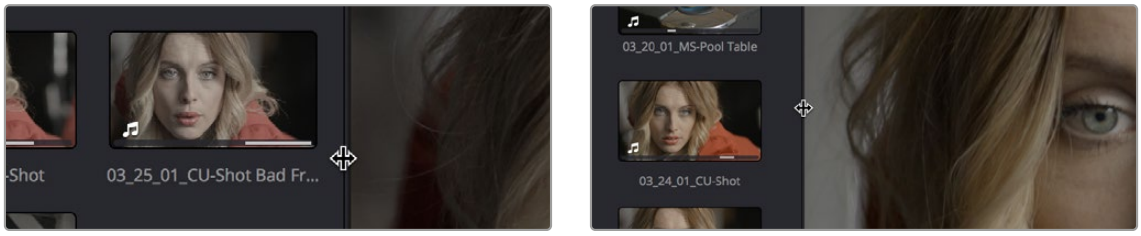


- You can show panels that aren’t displayed by default, since most pages have many available panels of functionality that are hidden until you need them.
- You can assign keyboard shortcuts to show and hide individual panels in your workspace for instant configuration of the UI. Keyboard shortcuts to toggle these panels on or off can be assigned using the Keyboard Customization window.
- You can switch which panel appears within a particular geographical location of the UI, for example switching between showing the Media Pool or Effects in the upper-lefthand corner of the Cut or Edit pages.
- You can hide panels you don’t need in order to create more room in the specific panels you’re working within.

The Interface toolbar for the Color page lets you customize the Color page controls

If you right-click anywhere within the UI toolbar, two options appear: “Show Icons and Labels” and “Show Icons Only.” If you show icons only, the UI toolbar becomes less cluttered.

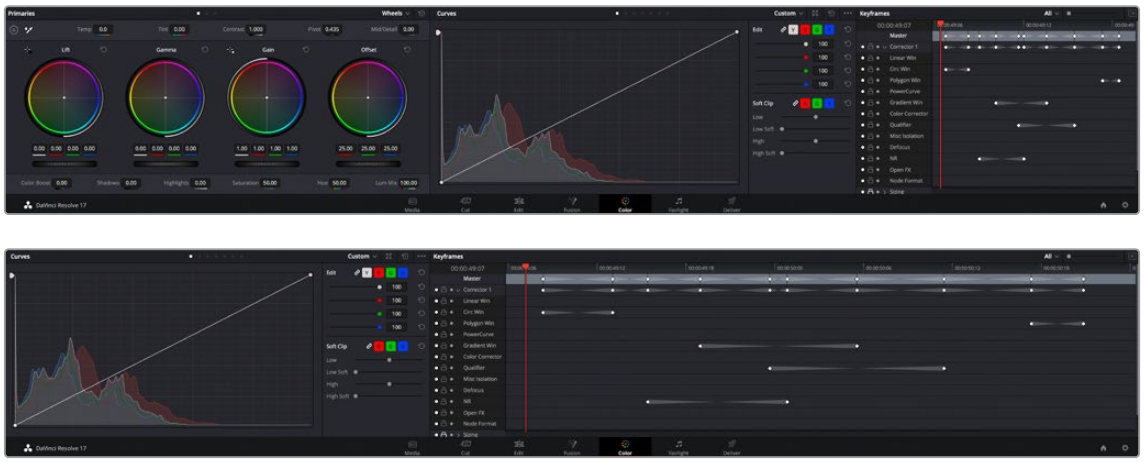
Each page has a different set of options that reflect the capabilities of that page.



The UI Toolbar for the Edit page, showing icons only, to save space

Showing and Hiding Panels in the Workspace Submenu

This function provides the ability to turn on or off panels by choosing them in the Workspace > Show Panel in Workspace drop-down menu. The exact panels, such as Inspector, Media Pool, Metadata, etc., are dependent on which page you are working in. Alternatively, you can assign these panels keyboard shortcuts as well.

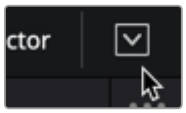


Adjusting the Size of Different Panels

You can resize adjacent panels in the interface by positioning the pointer at the border between any two panels, and dragging it to enlarge one and shrink the other.

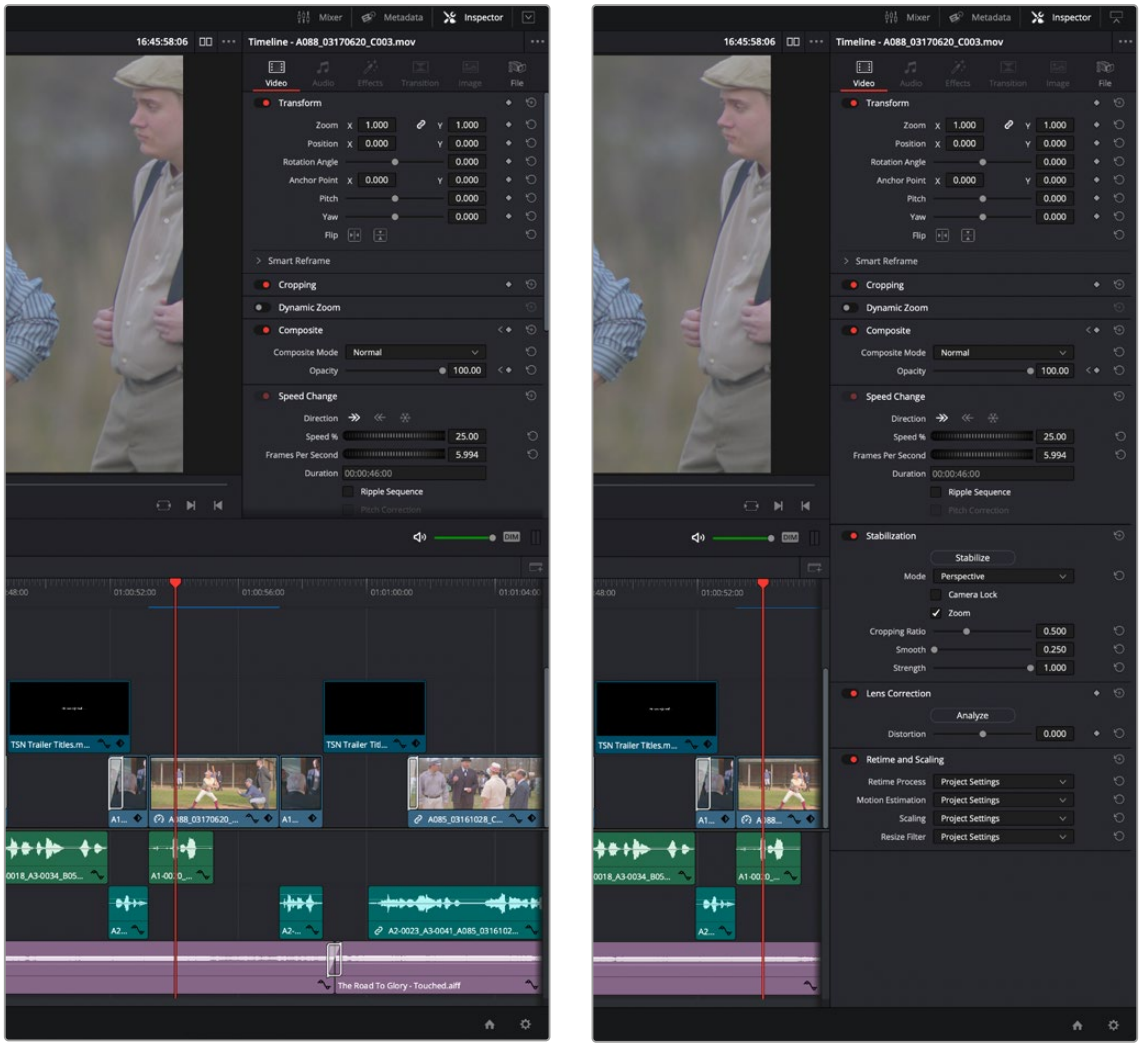
(Before/After) Resizing UI regions

Certain panels and palettes can be expanded, in the process rearranging another part of the UI, by clicking a small gray Expand button. For example, an expand button at the top right of the Keyframe Editor in the Color page can be clicked to make the Keyframe Editor wider, while at the same time hiding controls at the center to make room.



(Before/After) Expanding the Keyframe Editor

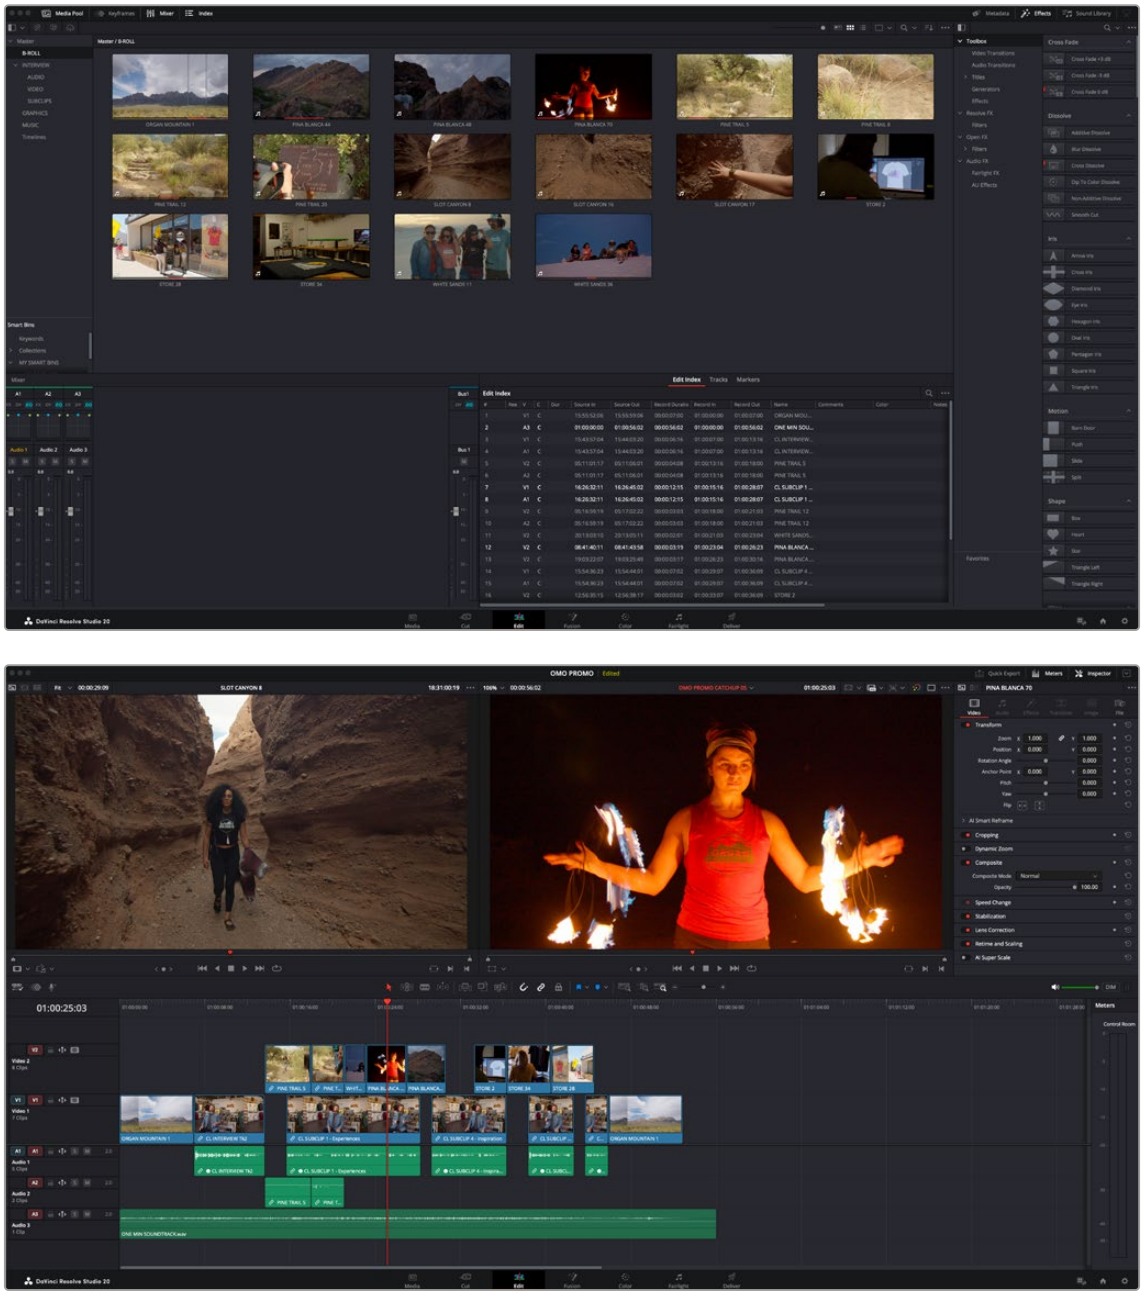
Certain vertically oriented panels, such as the Media Pool, Effects Library, Metadata Editor, and Inspector, can be set to either half-display-height or full-display-height sizes to quickly create more or less room for contents or controls whenever necessary. This is done by clicking a small button in the UI toolbar that toggles between expanding or contracting the UI element it controls.



The button for expanding a panel to full height

The button for contracting a panel to half height

The result is that the panel in question expands or contracts. The following screenshots show the Inspector of the Edit page in half height mode, where the Timeline is given room to expand, and in full height mode, where the Timeline becomes shorter, but there's more room in the Inspector to see all of the controls.

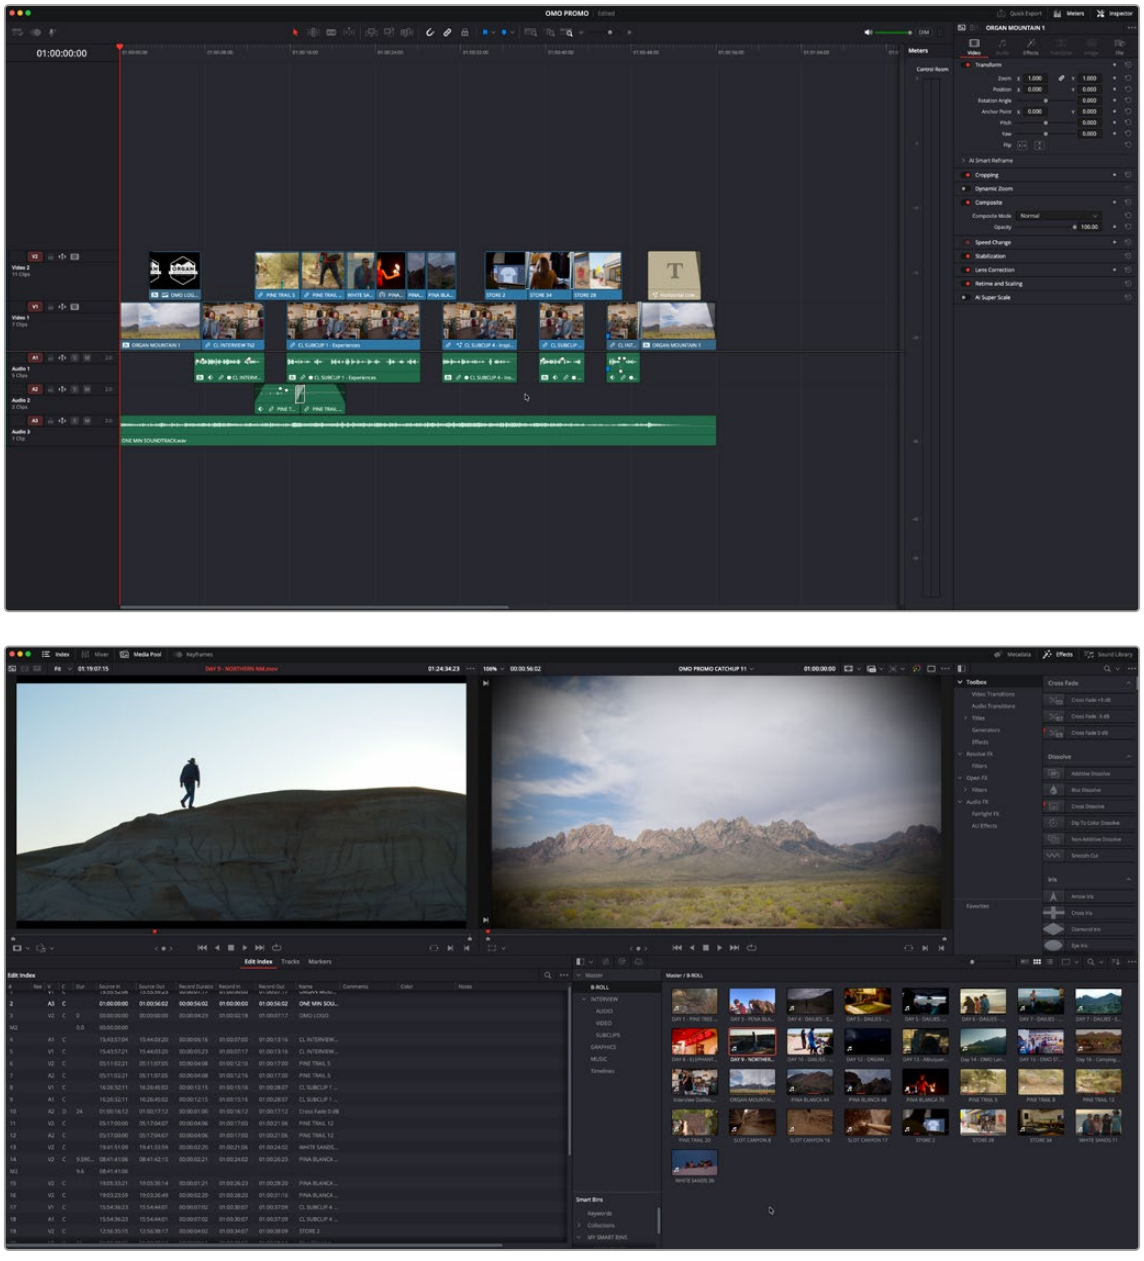


(Left) A half-height Inspector with more room for the Timeline,
(Right) A full-height Inspector with more room for controls

Using Single- vs. Dual-Monitor Layouts

The Media, Edit, Color, and Fairlight pages can be switched between single-screen and dual-screen layouts by choosing Workspace > Dual Screen > On. Each dual-screen layout makes it possible to see many more controls at once, often in a larger workspace that lets you manage more clips, more Gallery stills, etc. The second screen of a dual-screen layout can be resized but not reorganized.

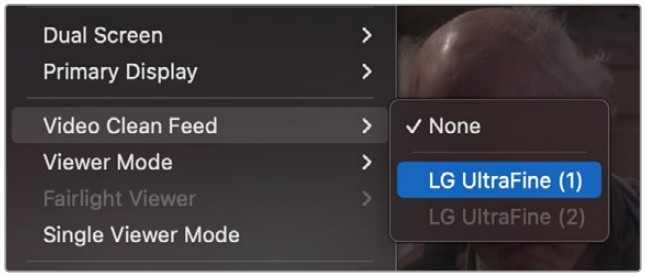
If you have an single ultra-wide monitor, you can also use the dual-monitor layout, and DaVinci Resolve will scale the interface as if you had two normal monitors side by side.



The Edit page in Dual-screen mode

In Single-screen mode, you can choose which display shows the DaVinci Resolve UI by choosing Workspace > Primary Display > (Monitor Name). In Dual-screen mode, this reverses the contents of both monitors.

Using the Full Screen Timeline Option in the Edit Page



If you're working in the Edit page in Dual-screen mode and you need the biggest timeline you can get for working through your program, you can choose Workspace > Dual Screen > Full Screen Timeline to expose a layout with one large full-screen timeline, and all the other Edit page panels on the other screen.

The Edit page in Dual-screen Timeline mode

Video Clean Feed (Studio Version Only)

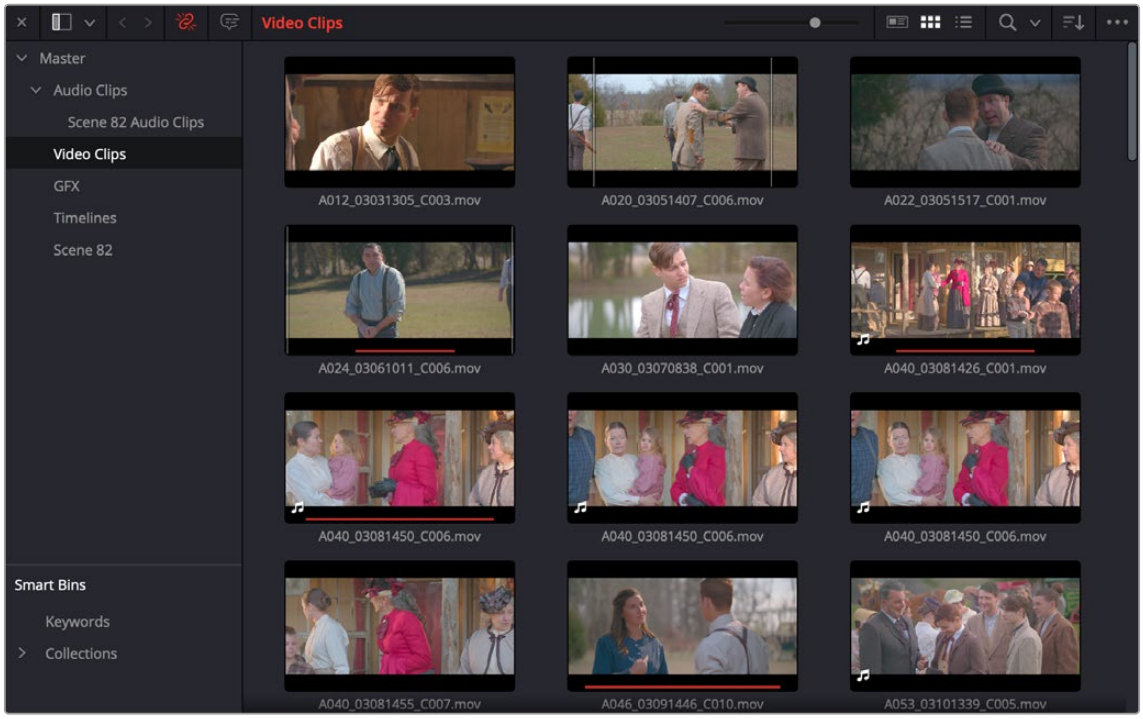
A full-screen Viewer for a secondary monitor connected directly to your computer is now available. To activate this monitor select Workspace > Video Clean Feed, and select your display in the submenu.

Selecting a monitor for full-screen display

Saving Custom Screen Layouts

If you've created a particular set of resized panels that you'll want to use often, you can save it, alongside other frequently useful screen layouts you may have saved.

Methods of working with custom screen layouts:

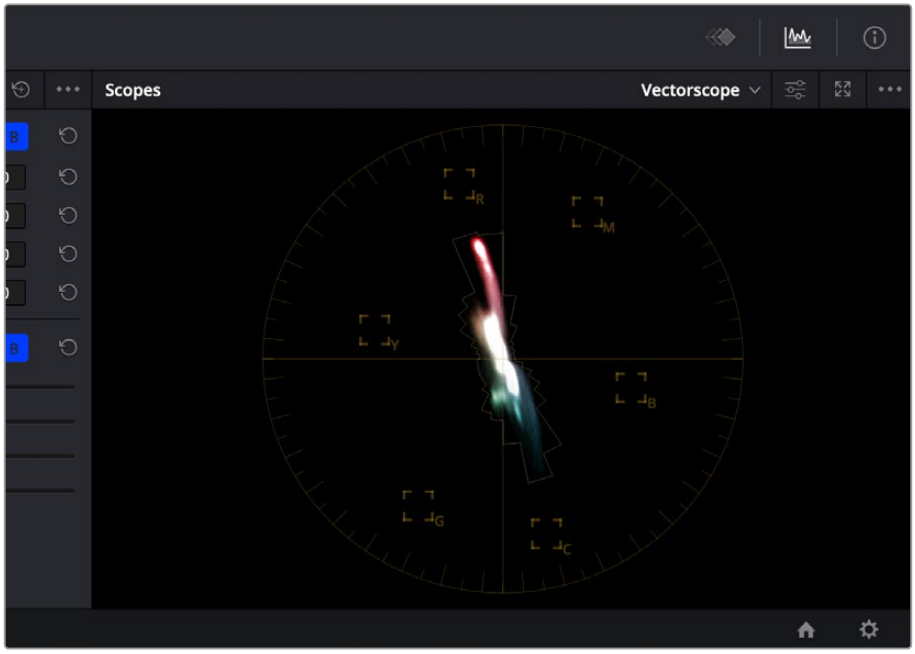


- **To save a custom screen preset:** Customize the various pages of DaVinci Resolve for the purpose at hand, then choose Workspace > Layout Presets > Save Layout As Preset. Enter a name into the Save Layout as Preset dialog, and click OK.
- **To choose a previously saved screen preset:** Choose Workspace > Layout Presets > LAYOUT NAME > Load. You can assign keyboard shortcuts for up to five different presets in the Keyboard Customization window (Application > Workspace > Layout Presets).
- **To update a previously saved screen preset:** Choose the layout you want from the Workspace > Layout submenu, make your changes, and then choose Workspace > Layout Presets > LAYOUT NAME > Update Preset.
- **To delete a screen preset:** Choose Workspace > Layout Presets > LAYOUT NAME > Delete Preset.
- **To export a screen preset for use on another DaVinci Resolve installation:** Choose Workspace > Layout Presets > LAYOUT NAME > Export Preset.
- **To import a screen preset:** Choose Workspace > Layout Presets > Import Layout as Preset.

Resetting to the Default Layout

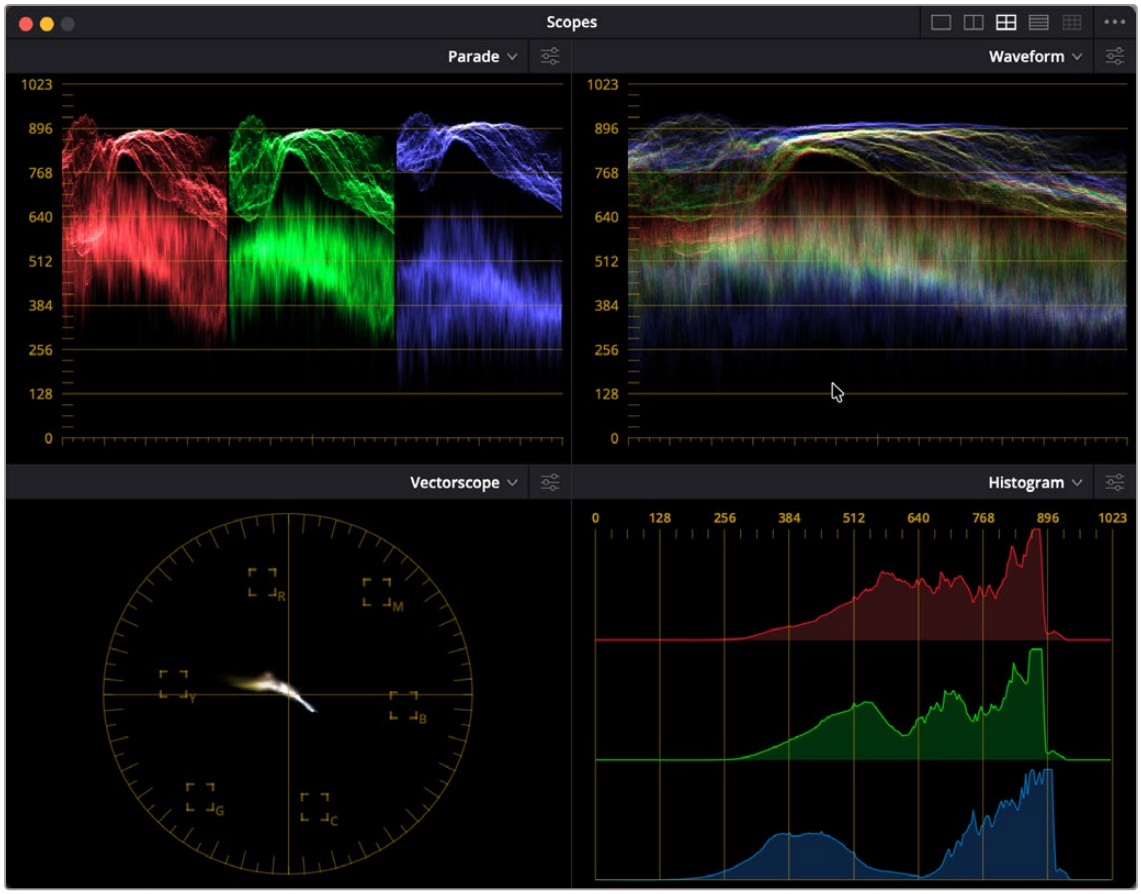
If you don't like the current layout and you want to go back to the default, choose Workspace > Reset UI Layout.

Undocking Specific Panels of the Interface



There are certain interface elements that can either be docked in their respective pages, or opened in separate windows.

A floating Media Pool window



Media Pool bins can be opened into floating windows simply by right-clicking on the bin and choosing Open As a New Window in the contextual menu. Even though you're opening up the contents of the selected bin, you're really creating another Media Pool, complete with Bin list, Browsing area, and all of the organizational controls found in the docked Media Pool. You can have as many floating Media Pools as you like. They can be dragged to other monitors, and they can be closed via a button at the upper left-hand corner of the title bar.

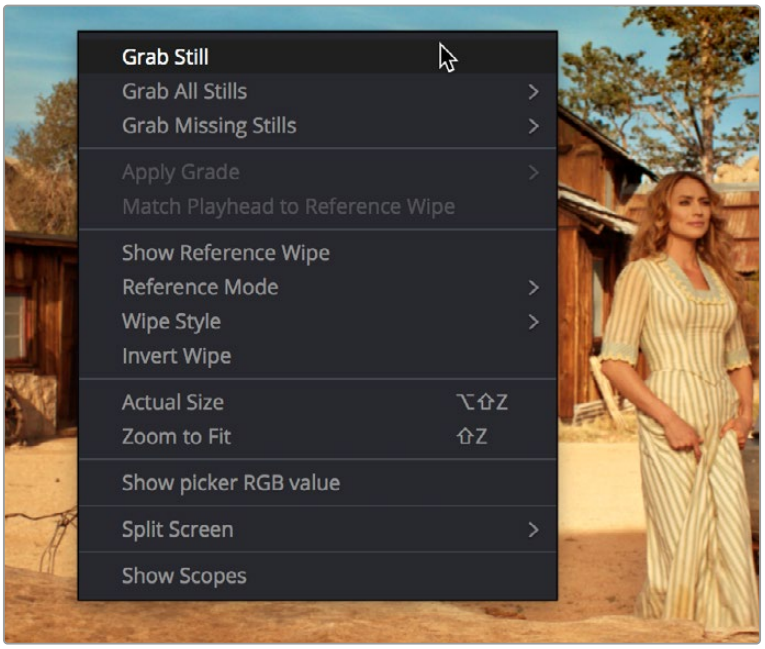
The video scopes let you precisely analyze the color and contrast of clips in the Color page. They can be exposed in their docked position to the right of the Color page palettes by clicking the Video Scope button in the Color page toolbar.

The video scope, docked next to the other palettes at the bottom of the Color page

Optionally, you can click the expand button at the top right of the video scope to open the video scopes into a floating window, within which you can display all four video scopes together, or individually, on any monitor connected to your workstation.

Video scopes in a floating window

Additionally, the Audio Mixer and video scopes are available in many of the dual-screen layouts available in DaVinci Resolve. The video scopes aren't just available in the Color page. They're also available in the Media and Deliver pages for whenever you need to evaluate the video signal more objectively, such as when you're setting up to capture from tape or scan from film, or when you're setting up for output.

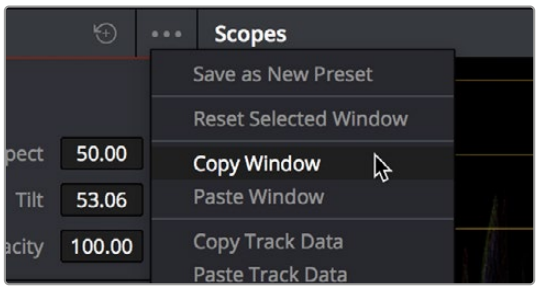


In the DaVinci Resolve single screen layout, the video scopes can be moved to a second computer display, if one's available, and will disappear temporarily if you change pages or switch to another application.

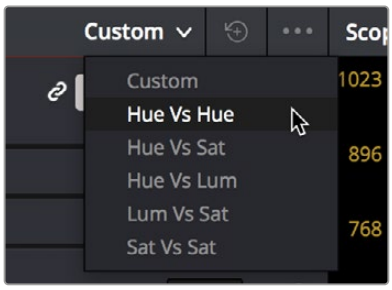
DaVinci Resolve User Interface Conventions

While each chapter covers the unique onscreen controls found in each page of DaVinci Resolve, this section summarizes how to use some of the more common controls you'll see.

Contextual Menus



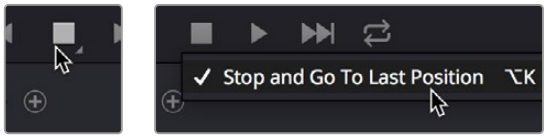
Nearly every panel on every page exposes additional functionality via contextual menus, which appear when you right-click on the appropriate item. Sometimes, different commands become available depending on whether you right-click the background of a particular panel, or directly on an item such as a still or node.



Contextual menus expose additional controls in the Color page Viewer

Drop-Down Menus

Most of the buttons and drop-down menus that appear in various toolbars are activated with a single click. For example, many panels, palettes, and windows expose an Option menu, that appears as three horizontal dots (people like to refer to these as the "three dot menus," but they're option menus), which expose additional options and/or commands that are related to that particular panel's function.

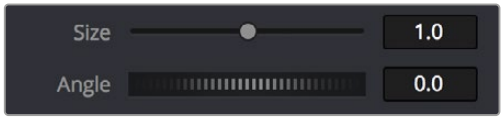


Option menus

Mode drop-down

Additionally, many (but not all) panels and palettes appear with a “Mode” drop-down at the upper right-hand corner that lets you choose a different type of function within that palette.

Some buttons, such as transport controls and toolbar icons, display a little downward facing arrow when you hover the pointer over them, to indicate that you can right-click on these controls to access checkmark options that govern the functionality of those controls.

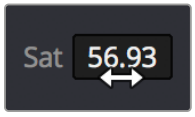


(Left) Hovering over a button to reveal it has a hidden menu,
(Right) Right-clicking a button to reveal options in a drop-down menu

Adjusting Parameters

Numeric parameters can usually be edited in a few different ways.

Sliders and Dials



Sliders can be dragged to change the value of a parameter within a specific range. If you see a dial, that means a value can be endlessly edited with no restrictions to the value. Sliders are typically best for making large coarse adjustments to parameters. The “virtual sliders” described next let you make finer adjustments.

A slider and a dial with their accompanying number fields

Virtual Sliders and Fields

When number fields appear, they can be used as a “virtual slider” by hovering the pointer over them until you see the “virtual slider cursor” and then clicking and dragging to the right to raise the value, or to the left to lower the value (white arrows indicate the direction of change). Typically, using a field’s virtual slider lets you make more precise adjustments than the actual slider to the left.

Using virtual sliders

Double-clicking fields containing most number values highlights the number so that you can type a new value using the keyboard, pressing Return to confirm the change.

Editing of Number Field Values Using Arrow Keys

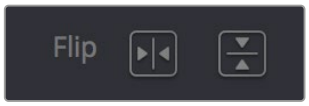
You can manually edit numerical parameter values by using the arrow keys to navigate and make adjustments to the decimal level in number fields.

To use the arrow keys to adjust numerical parameters:

1. Double-click to select a numeric value in a field, and a highlight appears around that value.
2. Use the left/right arrows to navigate the cursor to the right of the decimal value you want to adjust.
3. Use the Up/Down arrows to change the value of that decimal place.
4. If you select the entire number, the Up/Down arrows will adjust the minimum value.

This cursor is in place to adjust the tenths position using the Up and Down arrows.

Copy and Pasting of Number Field Values in Virtual Sliders

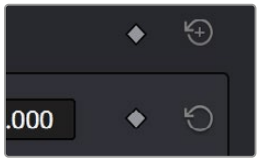


You can do standard copy/paste functions of any value in a field to any other field.

To copy and paste numerical parameters from a field:

1. Right-click on the source field and choose copy (Command-C) from the drop-down menu.
2. Right-click on the destination field and choose paste (Command-V) from the drop-down menu.

Icons and Buttons



Some controls are exposed as icons and buttons, which you simply click to invoke whatever functionality they encompass.

A pair of buttons with icons to illustrate their functionality

Resetting Parameters

To reset any editable parameter to its default setting, double-click its text label, or click the reset button, if one appears. Master reset buttons, typically found in the headers of groups of controls, reset all controls in that group. Individual reset controls that appear to the right of parameters typically only reset that one parameter. If you don't see a reset control, then double-clicking the name of the parameter should work.

Reset button

Using a Mouse or Other Input Device

Resolve uses all three buttons of a multi-button mouse, or the three buttons available on other type of input devices, when available. This section provides a brief summary of all the different ways these three mouse buttons can be used.

Left Button

The left button is always referred to as a click, as in, “click the auto select button.” You click to turn buttons or other controls on or off, to make selections, and to give areas of the Resolve UI focus so that keyboard shortcuts will do whatever is specific to that panel or area of the user interface.

Double-clicking the left button usually opens items that are openable, such as opening a clip from the Media Pool into the Source Viewer. You can also use double-clicking to do things like selecting nodes in the Node Editor of the Color page.

Right Button

The right button is referred to as a right-click, as in, “right-click a clip in the Media Pool.” Right-clicking an item or area of the Resolve interface usually opens a contextual menu, exposing additional commands that are specific to the item or area you’ve right-clicked.

However, some areas of the UI use right-clicking in special ways. For example, when you’re using a color adjustment curve in the Curve palette of the Color page, right-clicking a control point deletes that point.

Middle Button

The middle button (usually the scroll wheel button, but you may have to turn this on in the Mouse panel of the System Preferences) is referred to as a middle-click, which does different things in different places.

- In all pages, rolling the scroll wheel while the pointer is within a viewer lets you zoom into and out of the image being displayed when you need to do more detailed work.
- In all pages and panels, pressing and holding middle-click and dragging inside a panel allows you to scroll the view of the panel’s data in the direction that you drag.
- In the Color page, you can move the pointer over the Thumbnail timeline and roll up to scroll to the right or roll down to scroll to the left. You can also roll the scroll wheel while the pointer is within the Mini-timeline to zoom into or out of the currently displayed area. Rolling up zooms out, while rolling down zooms in.
- Middle-clicking and dragging within a viewer lets you drag the image to pan it around, which is useful after you’ve used the scroll wheel (or scroll behavior) of your mouse to zoom in.
- You can middle-click and drag within the Edit page Timeline to quickly pan around your edit.
- You can also use middle-click to copy a grade in the Thumbnail timeline of the Color page, by first selecting the clip that you want to copy TO (with a simple click) and then middle-clicking the clip or gallery still you want to copy a grade FROM.
- Lastly, if you’re drawing a Bezier window in the Color page Viewer using the Window palette, then middle-clicking a control point will delete that point.

TIP: If you’re using a pointing device that lacks a third button option, check to see if there are any third party utilities or drivers that can enable this for you.

Mouse, Trackpad, and Tablet Behaviors

Different input devices use different gestures to trigger specific behaviors in DaVinci Resolve. Here is a current breakdown of these gestures and the behaviors that they control.

Timeline Scroll Behavior

	Standard Mouse	Mac Magic Mouse	Trackpad	Tablet and Pen
Scroll timeline vertically	Scroll	**Magic Mouse 1 Finger Pan** Vertical and Horizontal panning	**2 Finger Pan** Vertical and Horizontal panning	—
Scroll timeline horizontally	command ⌘ + Scroll	**Magic Mouse 1 Finger Pan** Vertical and Horizontal panning	**2 Finger Pan** Vertical and Horizontal panning	—
Zoom timeline width horizontally With ability to zoom where cursor points Can be enabled in User Workspace preferences	alt option + Scroll	—	—	—
Zoom timeline track height vertically Zooms Video and Audio section separately	shift + Scroll	—	—	—
Drag Timeline with Hand Tool	Middle Mouse Button	shift + alt option + Left Button	—	—

Viewer Behavior

	Standard Mouse	Mac Magic Mouse	Trackpad	Tablet and Pen
Zoom towards mouse pointer Can change in preferences	 Scroll	—	 **Pinch to Zoom**  **2 Finger Pan** 	 **Press and hold the middle pen button** Wwhile moving it left and right on the tablet.
Free Pan	 Middle Mouse Button	 **Magic Mouse 1 Finger Pan**	 **2 Finger Pan**	 **Press and hold the middle pen button** Lift the pen nib a few millimeters above the pad, moving the pen will move the frame in the viewer.
Pan with Hand Cursor	 Middle Mouse Button	 Left Button	—	 **Press and hold the middle pen button** Lift the pen nib a few millimeters above the pad, moving the pen will move the hand in the viewer.
Tilt Up and Down	  Scroll	—	—	—

	Standard Mouse	Mac Magic Mouse	Trackpad	Tablet and Pen
Pan Left and Right	shift + command ⌘ + Scroll	—	—	—
Context Menu	Right Button	—	**2 Finger Touch**	**Right button on the pen.**

Gestures used in DaVinci Resolve for common input devices

Keyboard Shortcuts

Since the majority of DaVinci Resolve users are on macOS, this manual presents all keyboard shortcuts using the macOS conventions of the Command key and the Option key. For users of other systems, all keyboard shortcuts that use the Option key in macOS use the ALT key in Windows and Linux, and all keyboard shortcuts that use the Command key in macOS use the Control key in Windows and Linux.

TIP: To keep controls identical between macOS, Windows, and Linux, the Control key in macOS is not used by default for any keyboard shortcuts. However, you can assign your own keyboard shortcuts to the Control key if you like, opening up a whole new set of keyboard shortcuts for your own use on macOS.

Undo and Redo in DaVinci Resolve

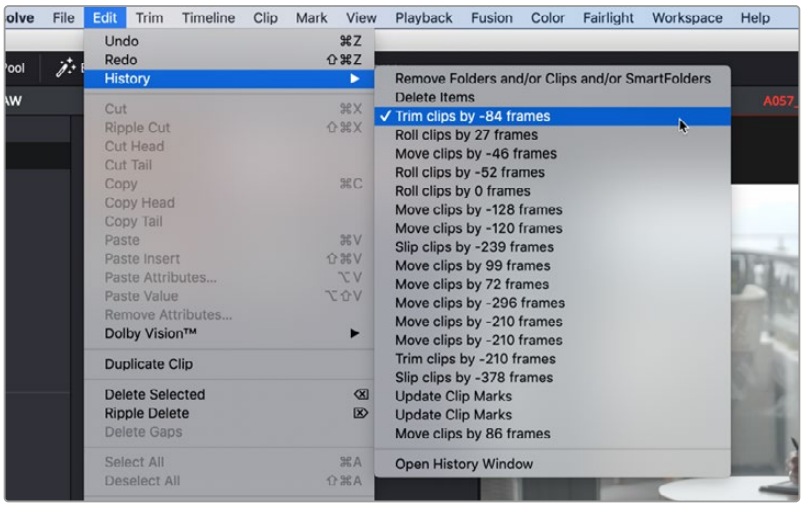
No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you've taken or commands you've executed, and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you've done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo “stacks” to help you manage your work.

- The Media, Edit and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
- Each clip in the Fusion page has its own undo stack, so that you can undo changes you make to the composition of each clip, independently.
- Each clip in the Color page has its own undo stack, so that you can undo changes you make to grades in each clip, independently.

In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you’re in.

To simply undo or redo changes you’ve made one at a time:



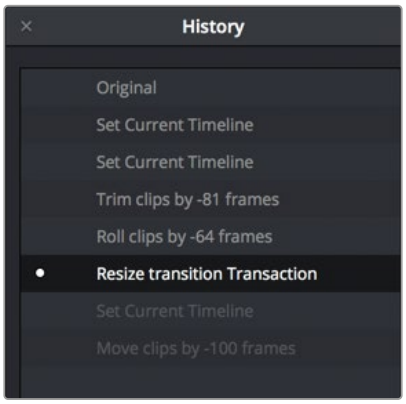
- Choose Edit > Undo (Command-Z) to undo the previous change.
- Choose Edit > Redo (Shift-Command-Z) to redo to the next change.

You can also undo several steps at a time using the History submenu and window. At the time of this writing, this only works for multiple undo steps in the Media, Cut, Edit, and Fairlight pages.

To undo and redo using the History submenu:

1. Open the Edit > History submenu, which shows (up to) the last twenty things you’ve done.
2. Choose an item on the list to undo back to that point. The most recent thing you’ve done appears at the top of this list, and the change you’ve just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what’s possible. However, if you’ve undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.

   Once you’ve selected a step to undo to, the menu closes and the project updates to show you its current state.



The History submenu, which lets you undo several steps at once

To undo and redo using the Undo window:

1. Choose Edit > History > Open History Window.

   When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you've done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.

2. When you're done, close the History window.

The Undo History window that lets you browse the entire available undo stack of the current page

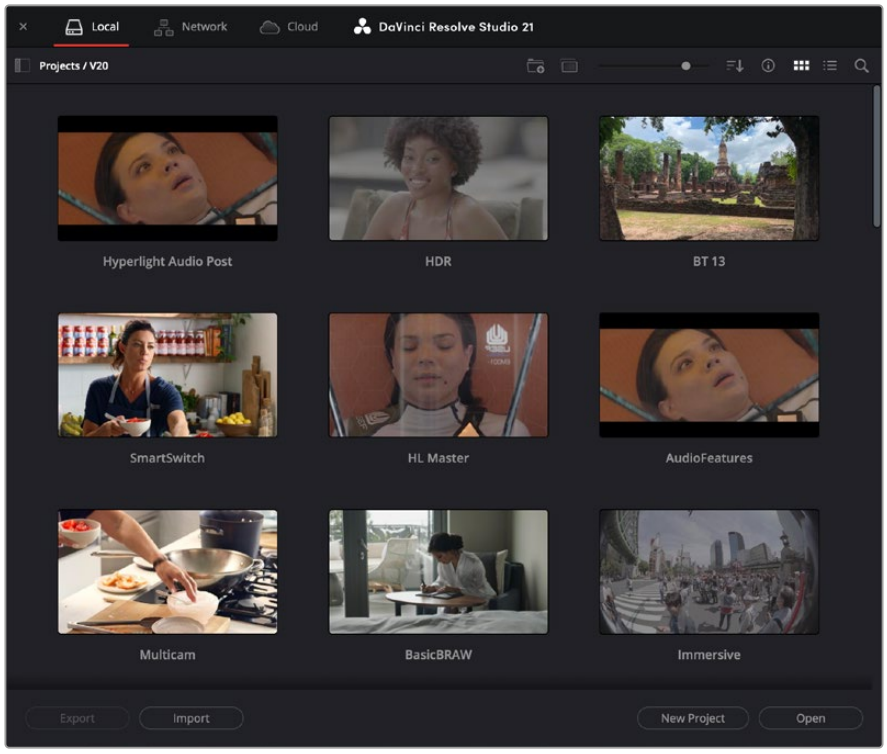
Chapter 3

Managing Projects and Project Libraries



This chapter covers how to use the Project Manager to organize the projects you're working on in DaVinci Resolve, as well as how to deal with managing the project libraries that serve as the organizational foundation of the Project Manager. You'll also see how to export and import projects, and how to archive a project and its media for long-term storage.

Using the Project Manager

Ordinarily, the Project Manager is the first window you'll see when DaVinci Resolve starts up. It's a convenient, centralized browser for creating, organizing, and managing all of your projects. Unlike other applications that rely on your file manager for organizing projects, DaVinci Resolve requires you to do most project organization in the Project Manager.

Project Manager

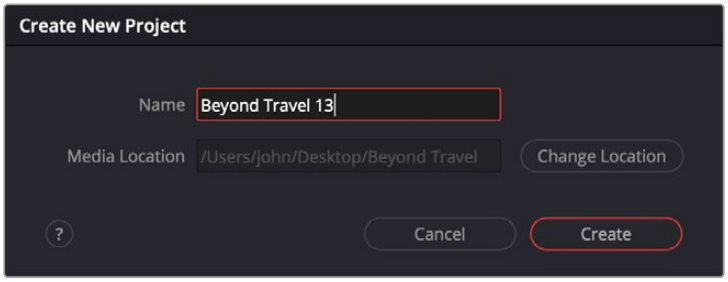
If you've already opened a project, you can reopen the Project Manager at any time by clicking the Home button at the bottom right-hand corner of the DaVinci Resolve window, in the Page Navigation bar. If you've hidden the Page Navigation bar at the bottom of the DaVinci Resolve window, you can open the Project Manager by choosing File > Project Manager.

The Project Manager button at the bottom-right corner of the DaVinci Resolve interface

Launching DaVinci Resolve for the First Time?

If you've just installed DaVinci Resolve and have opened it for the first time, it's time to set the preferences in order to specify your language, scratch disk volume, and hardware configuration for video and audio I/O and control panels (if you have one).

For more information on setting the preferences in DaVinci Resolve, jump to this chapter: System and User Preferences.



Creating a New Project

The first step into DaVinci Resolve is to create a new Project in the Project Manager, which is conveniently the first thing that opens when you launch the program. Each project contains links to all of the media, graphics, and sound files used in your film, as well as timelines where all the editing, color correction, motion graphics, and audio post work is done.

There are several settings, options, and preferences attached to each project (you can access them by clicking on the small gear icon in the very bottom right of the interface), and all of them are described in detail later in this section. However, actually creating a project requires only four steps.

Creating a New Project:

1. Click on the New Project button at the bottom of the Project Manager.
2. Type in a name for your project.
3. Observe the folder where any media created by DaVinci Resolve will be stored in Media Location. Make sure you have some space on this drive. Clicking on the Change Location button lets you select another drive/folder instead of the default.
4. Click the Create button.

The Create New Project dialog

Project Management

The Project Manager provides an in-application interface for creating, renaming, and deleting projects. Many of these commands exist within the contextual menu that appears when you right-click the background of the Project Manager.

Methods of project management:

- **To create a new project:** Double-click the Default Project icon, or click the New Project button at the bottom of the window. A new project is created, and DaVinci Resolve opens up the Media page. Once a project is open, you can alter its project settings by clicking the gear icon.
- **To open a previously saved project:** Double-click any Project icon, or Item if you're in List view. You can also select a project and click the Open button.
- **To open a project in Read-Only Mode:** Right-click a Project icon or Item, and choose Open in Read Only Mode. This lets you open a project without danger of altering it. If you make changes, you can use the Save As command to save a new copy of the project with a new name.
- **To rename a project:** Right-click a Project icon or Item, choose Rename, and type a new name in the dialog that appears, clicking OK when you're finished.
- **To load project settings from another project to the currently open project:** Right-click a Project icon or Item (other than the currently open project), and choose "Load Project Settings to Current Project." This lets you change a project's settings prior to opening it in cases where the project settings are causing some kind of problem that prevents you from opening the project.

- **To update the thumbnails of a project in the Project Manager:** Right-click any project, and choose “Update Thumbnails.”
- **To delete a project:** Select one or more projects, then either press the Backspace key, or right-click one of the selected projects and choose Delete. Click OK when a dialog asks you to confirm the operation.

NOTE: You cannot move or delete the currently open or loaded project.

Importing and Exporting DaVinci Resolve Projects (.drp Files)

DaVinci Resolve projects are saved with the file extension .drp and enable you to exchange files with other DaVinci Resolve users. If you double-click a DaVinci Resolve .drp file in the Windows or macOS file system, this will automatically open DaVinci Resolve, import that project into the Project Manager regardless of what kind of project library you’re using, and open that project so that you’re ready to work.

Importing and Exporting Projects in Local Project Libraries

If you’re using local project libraries to manage your projects, you can copy and import projects using the project folders in the file manager of either macOS or Windows. This method does not work for DaVinci Resolve on Linux.

Moving projects from one local project library into another using macOS or Windows:

1. Locate the local project library directory in which the project you want to copy is stored. If you don’t know where the designated local project library directory is, you can open DaVinci Resolve and check the directory path for the current local project library in the Project Libraries sidebar.
2. Copy the project folder from the source workstation to the designated local project library directory on the destination workstation. If you don’t know where the designated local project library directory is, you can open DaVinci Resolve on the workstation you’re copying the project to and check the directory path for the current local project library in the Project Libraries sidebar.
3. Once you’ve copied the project folder into the correct location, you’ll need to quit and reopen DaVinci Resolve. Afterwards, the imported project should appear in the Project Manager.

Importing and Exporting Projects in Network Project Libraries

If you’re using a network project library, another set of commands let you import and export projects using the .drp file format. You can also export .drp files from local project libraries if you want to export a more self-contained item to transport.

To import a .drp project file, do one of the following:

- Select the Import button at the bottom of the Project Manager, then find and select a .drp project file using the Import Project File dialog, and click Open.
- Drag the .drp file you want to import from your file system and drop it anywhere into the Project Manager window.
- Right-click any empty area of the Project Manager and choose Import, then find and select a .drp project file using the Import Project File dialog, and click Open.

To import a .drp project file and reconfigure the gallery path at the same time:

- Hold the Option key down while right-clicking any empty area of the Project Manager, and choose Import+, then find and select a .drp project file, and click Open. Upon opening, the gallery path will automatically be updated to that of your workstation.

To export the currently open project as a .drp file:

- Choose File > Export Project, and when the Save dialog appears, choose a location, enter a name, and click Save. The result is a self-contained file with a .drp file suffix saved at the location you chose.

To export a .drp project file from the Project Manager:

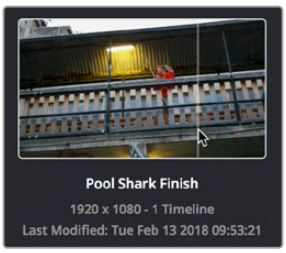
- Select the Export button at the bottom of the Project Manager, and when the Save dialog appears, choose a location, enter a name, and click Save. The result is a self-contained file with a .drp file suffix saved at the location you chose.
- Right-click a Project icon or Item in the Project Manager, then choose one of the following commands;

  Export Project: Exports project data with no LUTs and no stills. Best when you need to export the smallest possible file.

  Export Project With Stills and LUTs: Exports the project, including both still frames in the Gallery and LUTs used in grades. Best when you want to export the most self-contained file and you can't guarantee the recipient will have the same LUTs you do.

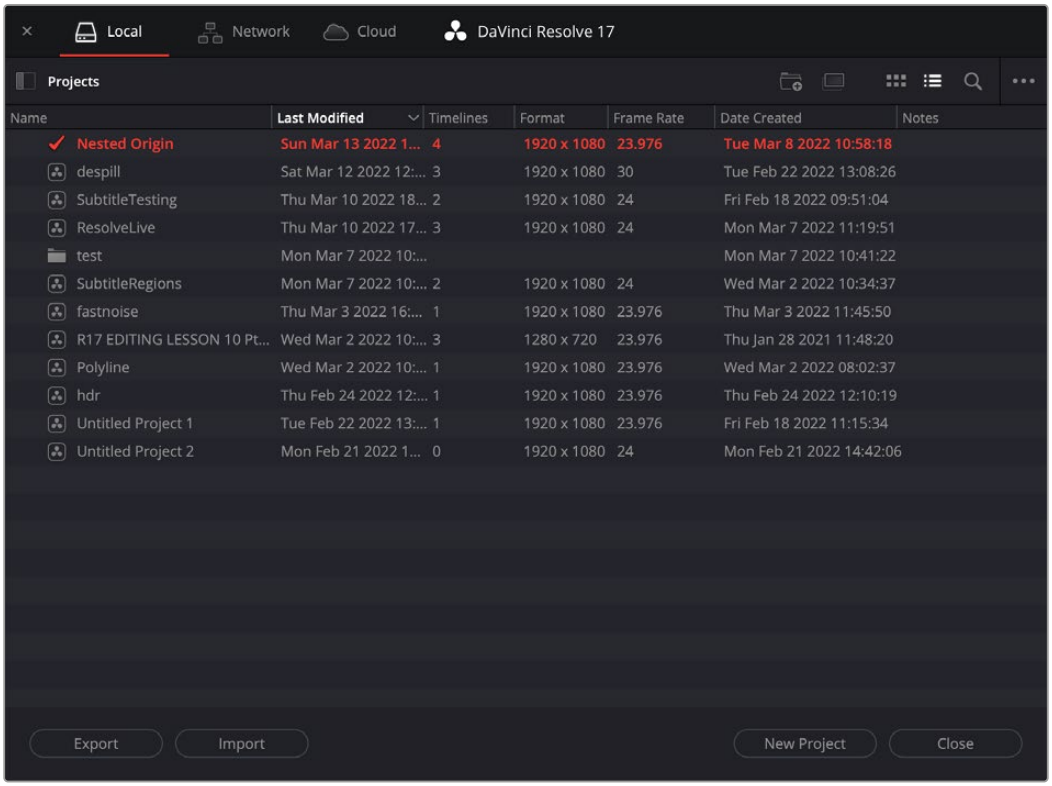
- When the Save dialog appears, choose a location, enter a name, and click Save. The result is a self-contained file with a .drp file suffix saved at the location you chose.

TIP: You can export multiple projects from the Project Manager at the same time by either command-clicking or lassoing the projects, right-clicking on one of them, and selecting Export Projects from the dropdown menu. All projects will be saved in the same location.



Project Manager View Options

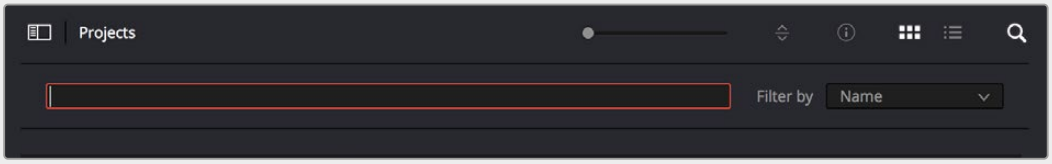
Four buttons at the top right let you control how projects are viewed in the Project Manager.



Select Thumbnail or List View

- **Zoom slider:** (Only appears in Thumbnail view) Lets you adjust the size of the thumbnails in Thumbnail view.
- **Project Sort Order dropdown:** (Only appears in Thumbnail view) Lets you choose the sort order of projects in Thumbnail view.
- **Information:** (Only appears in Thumbnail view) Lets you show or hide additional project information displayed underneath each project's thumbnail, including the frame size, number of timelines within, and when that project was last modified.
- **Thumbnail view:** Each project is represented by a large image that can be hover-scrubbed to reveal five representative images from that project.

Hover-scrub over Project icon; information is enabled



- **List view:** Every project appears as an item in a list that has seven columns: Name, Last Modified, Timelines, Format, Frame Rate, Date Created, and Note. You can click any column header to sort the contents of the Project Manager by that criteria; clicking the header a second time toggles that column between ascending and descending sorting.

Project List view

Searching for Projects

Clicking the magnifying glass button at the upper right-hand corner of the Project Manager exposes the Search Options, which can be used to locate one or more projects based on the metadata that's selected in the Filter By dropdown menu to the right of it.

Search field open with Filter by search criteria selected

Using the dropdown menu, you can choose to search by name, or by project format. Once you've chosen a criteria, begin typing into the search field, and the Project Manager will immediately and dynamically begin to be filtered by your search text.

Customize Project Poster Frames

You can set a custom Poster Frame for the Project thumbnail in the Project Manager directly from the Media Pool. This lets you visually categorize all your projects at a glance.

To set a Project Poster Frame:

1. Select a clip from the Media Pool for the new poster frame.
2. Scrub over the clip until the frame you want shows up in the thumbnail image.
3. Right-click the clip and select Clip Operations > Set Project Poster Frame.

Organizing Projects in Folders

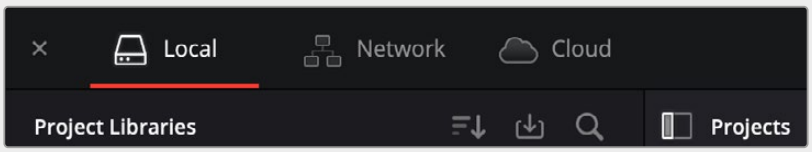
If you're organizing a lot of projects, you can create folders to put them into.

A folder in the Project Manager

Methods of working with project folders:

- **To create a folder:** Click the New Folder button, then enter a name into the Create New Folder dialog and click Create.
- **To delete a folder:** Right-click a folder, choose Delete, and click Yes when prompted. All projects inside a deleted folder will be deleted as well.
- **To rename a folder:** Right-click a folder, choose Rename, then enter a new name and click OK.
- **To copy a folder:** Right-click on a folder and choose Copy from the dropdown menu, or select the folder and press Command-C. Any projects enclosed inside that folder will also be copied.
- **To paste a folder:** Once a copy operation has been made, right-click on the background of the Project Manager and choose Paste from the dropdown menu, or press Command-V. You can paste into other project libraries, into other folders, or into the same location where a new version of the folder will have the word (Copy) appended to it. All enclosed timelines will copy over as well.
- **To open a folder:** Double-click a folder to open it and view its contents. At the upper left-hand corner of the Project Manager, a folder path view shows you which folder is open, as well as where you are within a nested series of folders if that's what you've set up.
- **To exit a folder:** Use the path control at the top of the Project Manager to click on a higher level in the folder hierarchy.
- **To move a project into a folder:** Drag the project onto a folder icon, and drop it to place it inside the folder.
- **To move a project out of a folder:** Open a folder, select one or more projects you want to move, then right-click the selection and choose Cut from the contextual menu. Then, navigate to the next place in the Project manager where you want to place the cut projects, right-click the background of the Project Manager, and choose Paste. The projects should appear in the new location.

Managing Project Libraries



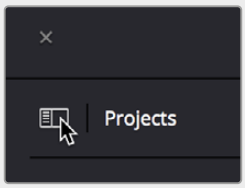
Unlike other applications which save self-contained project files to user-specified locations wherever you like in your file system, DaVinci Resolve takes a more centrally organized approach to project management, using project libraries. By default, DaVinci Resolve uses a local project library to keep track of every project you create. The Project Libraries sidebar lets you manage the projects found within this project library, which are saved to a specific directory on your system (particular to that project library). The default location of this local project library depends on the operating system you use.

However, you can create additional project libraries with which to store other projects, if you like. For example, you might create one project library each for each year in which you work. If you work on series television, you could create multiple project libraries for each program you work on. Or, you could create separate project libraries for each client you do work for. There's no hard and fast rule; ultimately how you use project libraries is entirely up to you and your individual organizational preferences.

Project Library Types

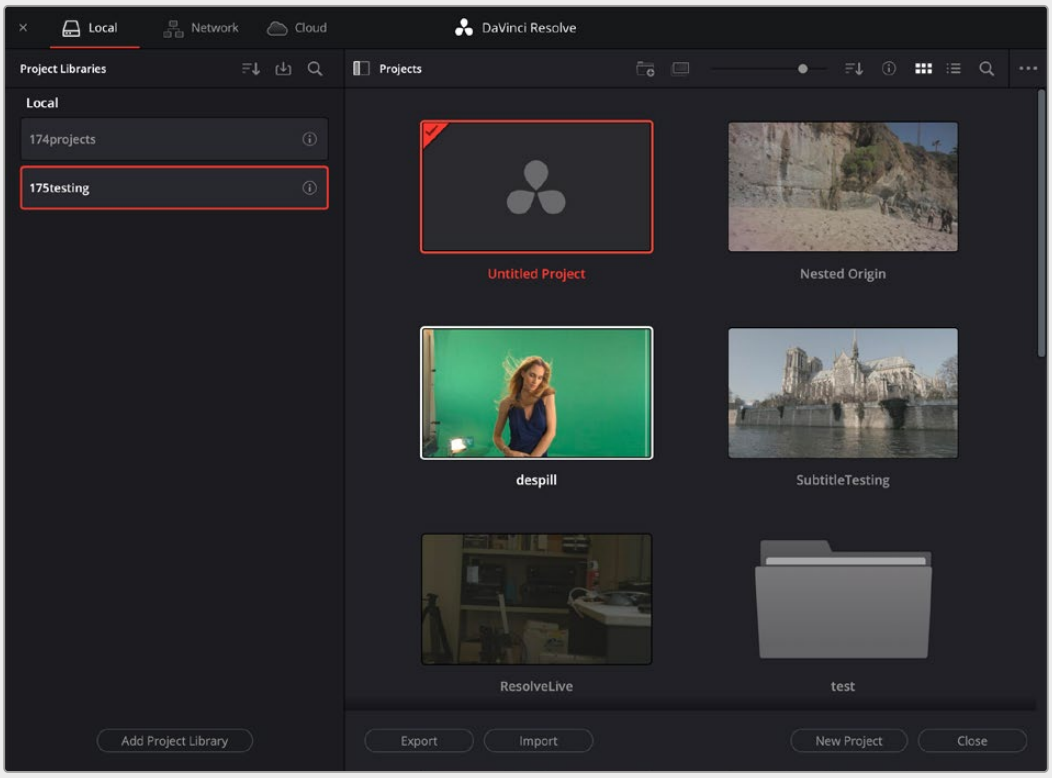
Project libraries can be stored in three different project library types which work similarly in function but have additional connectivity and sharing features based on your networking setup. You select the Library Type at the top left of the Project Manager.

- **Local:** Stores your project libraries locally on your workstation. This is the default and is best for individual users or single systems.
- **Network:** Stores your project libraries on an external computer that is connected to several workstations on the same local network. It also allows you to control user access to the project library. This is best for a facility composed of multiple workstations in the same building working on the same material.
- **Cloud:** Stores your project libraries in the Blackmagic Cloud. This allows several workstations to connect to the same project library over the internet. It also allows you to control user access to the project library. This is best for multiple people working on the same project from different locations around the world.



The three types of project libraries: local, network, and cloud.

For more information on setting up and configuring the different project library types, jump to this chapter: Managing Project Libraries and Project Servers.



Opening the Project Libraries Sidebar

If you already have multiple project libraries, then clicking the button at the upper-left hand corner of the Projects Browser reveals a sidebar at the left of the Project Manager that lists every project library on your workstation, with various options for managing these project libraries and for browsing the projects found within them.

You can use this sidebar to open different project libraries and browse the projects found inside.

Project Libraries sidebar button

Project Manager with the Project Libraries sidebar displayed

Moving Projects From One Project Library to Another on the Same Workstation

If you've used multiple project libraries to organize your projects, you can browse the contents of each project library to search for what you're looking for, and then copy one or more projects from one project library to another if you need to rearrange how they're organized.

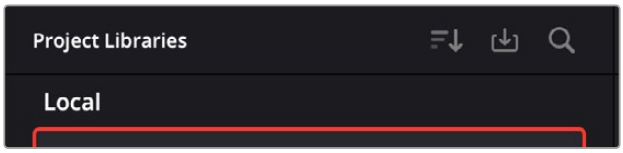
To view the contents of a project library:

1. Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2. Click to select a project library in the sidebar, and an orange highlight will appear

If you had a project already open, you'll be asked if you want to save it before closing, because all open projects must be closed prior to viewing the contents of another project library. Then, the projects corresponding to that user within the selected project library appear in the Project Manager window.

To import a project from another project library using the Project Libraries sidebar:

1. Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2. Click to select a project library in the sidebar, and if necessary use the dropdown menu at the right of the project library listing to choose a specific user. The projects corresponding to that user within the selected project library appear in the Project Manager window.
3. Select a project you want to import, and press Command-C to copy it.
4. Click to select the current project library again (the project library you want to work within).
5. Press Command-V to paste the project you copied. A copy appears in the current project library.



> For more information on shared project library setup and operation, jump to this chapter: Managing Project Libraries and Project Servers.

To import Project Settings from another project using the Project Libraries sidebar:

1. Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2. Select a project you want to import Project Settings to so that it's highlighted.
3. Right-click any project and choose "Load Project Settings to Current Project." That project's settings will be copied to the project you selected in step 2.

Managing Project Libraries in the Project Libraries Sidebar

Controls within the Project Libraries sidebar make it easy to create new project libraries (via the button at the bottom), upgrade project libraries that have been flagged (via circular badges), import and export project libraries (via buttons at the top), and reveal additional information about each project library (via buttons at the top of this sidebar).

Project Libraries sidebar controls

The three controls at the top of the Project Libraries sidebar have the following functions:

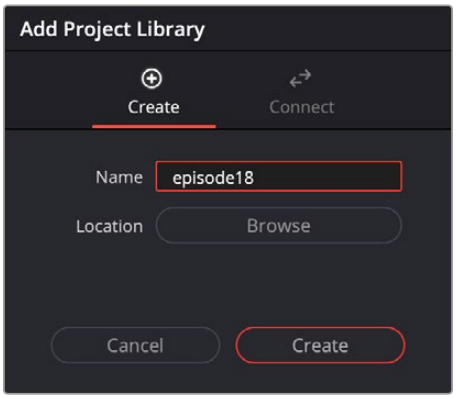
Sort Order dropdown menu: This menu lets you choose how to sort the various local and network project libraries displayed in the sidebar. You can sort by Project Library Name, Schema (by date), Status, or Location in Ascending or Descending order.

Restore: Imports .resolve.backup files to restore a backed up project library.

Show Search Field: Displays a search field and search criteria dropdown that lets you search for project libraries in the sidebar by Name, Schema, Status, or Location.

Clicking on the Display Project Library Details icon (the circled letter "i" to the right of the project library), shows additional information underneath each project library in the sidebar. What information depends on the type of project library. Local project libraries display their status

(compatible/incompatible) and location (directory path). Network and cloud project libraries display their schema (created and modified dates), their status (compatible/incompatible), their IP location, and below any members that have access to the project library.



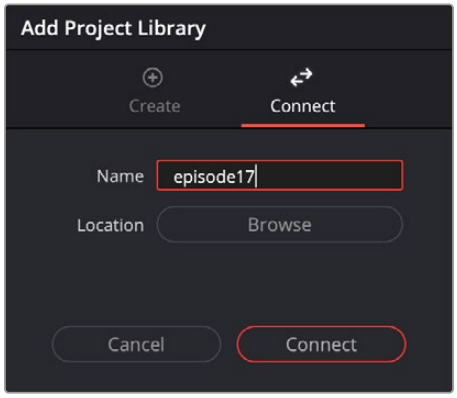
Creating and Connecting to Project Libraries

You can use local, network, and cloud libraries side by side for switching to the use of one or the other, depending on your needs. These instructions will show you how to set up local project libraries. Network and cloud libraries require additional configuration and setup first.

> For more information on network and cloud project libraries setup and operation, jump to this chapter: Managing Project Libraries and Project Servers.

To create a new local project library:

1. Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2. Click the Add Project Library button at the bottom of the sidebar.
3. Click on the Create tab. The Add Project Library window should look like the following screenshot:



Creating a local project library

4. In the remaining fields, do the following:
   a) Type a name for the new project library into the Name field
   b) Click within the Location field and use the Filesystem navigation dialog to choose where to put the directory that will contain all of the DaVinci Resolve project directories
5. Click Create, and the new local project library will appear in the local project library section of the Project Libraries sidebar.

To connect to an existing local project library:

1. Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2. Click the Add Project Library button at the bottom of the sidebar.
3. Click on the Connect tab. The Add Project Library window should look like the following screenshot:

Connecting to an existing local project library

4 In the remaining fields, do the following:

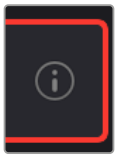
   a) Type a name for the new project library into the Name field.

   b) Click within the Location field and use the Filesystem navigation dialog to choose the location of the existing project library you wish to connect to.

5 Click Connect, and the new local project library will appear in the local project library section of the Project Libraries sidebar.

Duplicating Project Libraries

Local Project Libraries can be duplicated in the same database for backup or iteration purposes.



1 Right-click on the Library, and select Duplicate from the dropdown menu.
2 Select the Resolve Database folder in the file system browser. This can either be the same one you use for the original project or a new one.
3 Click on the Open button.
4 Rename the new Library in the Clone Library dialog.

Backing Up and Restoring Project Libraries

You can also back up project libraries by exporting them, and then reimport them later.

To backup/export a project library:

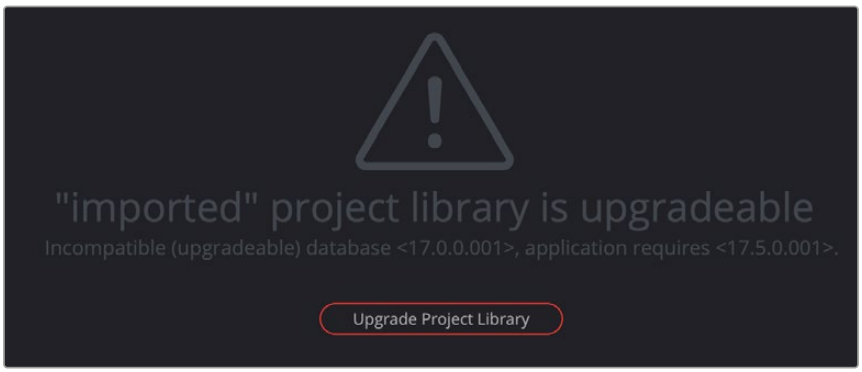
1 Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2 Select the project library you want to back up.
3 Click the Display Project Library Details icon (the circled letter “i” to the right of the project library).

The Display Project Library Details icon

4 Select the Back Up button.
5 Choose a location to which to save the backup in the Backup Project Libraries dialog, and click Save.

To import a project library:

1. Click the button at the upper-left hand corner of the Projects window to open the Project Libraries sidebar.
2. Click the Restore button at the top of the Project Libraries sidebar.



The Restore button

3. Find the project library you need to import using the file import dialog, and click Open.
4. In the Add Project Library dialog, do the following:
   a) Type a name for the new project library into the Name field. This will rename the imported project library but will not alter its contents. You can also name it the same as the original project library.
   b) Click within the Location field and use the Filesystem navigation dialog to choose the directory that contains the existing DaVinci Resolve project libraries.
5. Click Create, and the imported local project library will appear in the Local section of the Project Libraries sidebar.

Upgrading Project Libraries

Selected libraries display an upgrade warning in the Project Manager only when you've installed a new version of DaVinci Resolve and you have project libraries that were created in older versions of DaVinci Resolve that need upgrading.

The upgrade warning in the Project Manager indicates that the project library needs to be upgraded

It's generally a good idea to back up a project library prior to upgrading it, in case something goes wrong. In general, upgrading from a whole version release to the next whole version release of DaVinci Resolve usually requires an upgrade, while upgrading to a dot release of the same version may or may not. If the currently used project library requires an update, you'll be told on application startup.

To upgrade a project library from an old version of DaVinci Resolve:

Click on a project library that needs updating, and select the Upgrade Project Library button. A dialog appears to confirm if you really want to upgrade that project library. Click Upgrade to proceed.

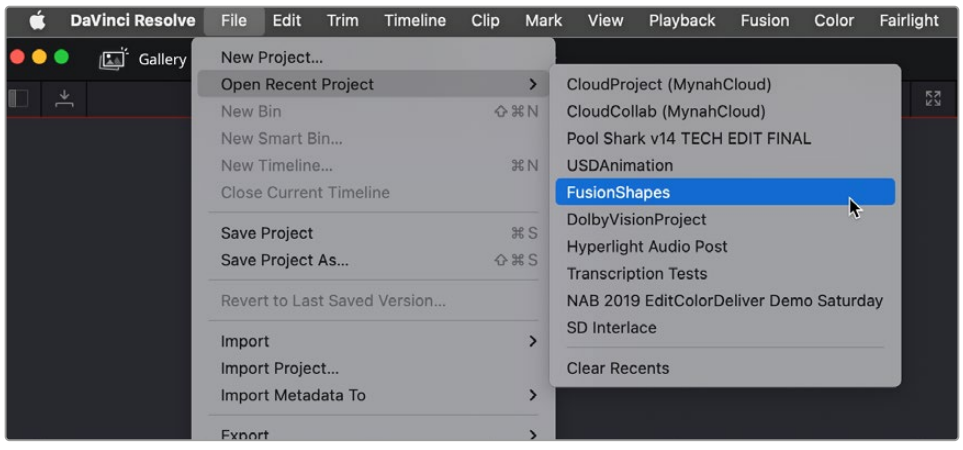
Disconnecting and Deleting Project Libraries

You cannot actually delete project libraries in DaVinci Resolve; you can only disconnect them so they don't appear in the Project Library list. However, disconnected project libraries can still be reconnected if you remember their name. The only way to completely delete a project library entry in PostgreSQL is to do so from the command line, or to use the PGAdmin III application that accompanies the PostgreSQL installation that's part of the DaVinci Resolve installation process.

To disconnect a project library you no longer need:

- Right-click a project library that is not currently selected, and choose Remove from the contextual menu. A dialog appears to confirm if you really want to disconnect that project library. Click Disconnect to proceed.

Locating Local Project Library Directories in Your File System



Because local project libraries have a link to a specific directory in your file system, there's a way of locating that directory.

To locate a project library on your system:

- Right-click any local project library, and choose "Reveal in Finder." A file system window opens up showing you the location of that local project library, inside which are all of its projects.

Quick Access to Recent Projects from the File Menu

You can open recent projects directly from the File > Open Recent Project menu, rather than having to go to the Project Manager and find it manually.

Opening a recent project from the File menu

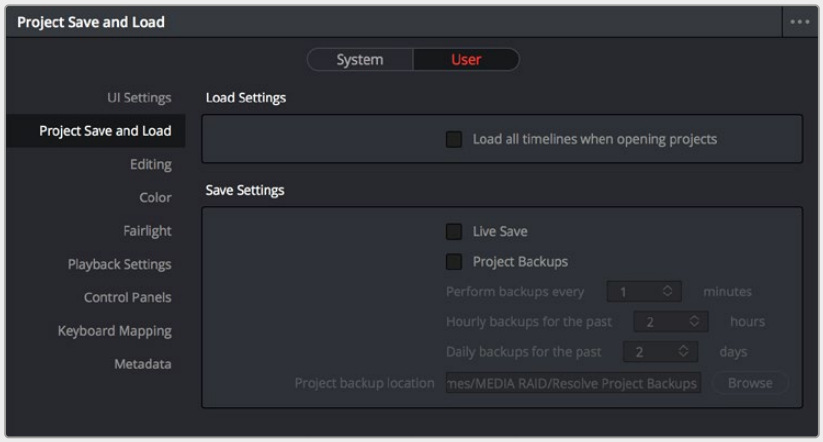
Saving Projects

Once you've created and opened a project, you want to make sure that you regularly save your work.

Methods of saving projects:

- Choose File > Save Project (Command-S).
- To save the current state of your project as a copy with a new name, choose File > Save Project As (Command-Shift-S), then enter a name into the Save Current Project window and click Save. If you chose to save as the same name as an existing project, a dialog box will appear, allowing you to confirm if you want to overwrite the existing project or to cancel out and choose another name.
- **Media Location:** You can optionally change the disk or location to which you want all DaVinci Resolve generated media in the project to be written. This does not affect where your original source material is stored (like video and audio clips), only where media created inside DaVinci Resolve itself (like new audio files generated by Voice Convert, or recorded using the Voice Over tool) is written.

To revert to the last saved state of a project:



- If you don't want to save, but you want to revert to last saved state of the project, choose File > Revert to Last Save.

As you work on your project, the word "Edited" appears to the right of the project name at the top of the DaVinci Resolve UI to let you know that you have unsaved changes. If you don't save in over 15 minutes, the word "Edited" turns yellow, and if you still don't save in over 30 minutes, it turns red to let you know that you probably should save. If you move the pointer over the word "Edited," a tooltip appears letting you know when the last save was performed.

The word "Edited" to the right of the project name lets you know you have unsaved changes

DaVinci Resolve also has two auto save mechanisms that you can enable in the Save Settings group of controls, called Live Save and Project Backups.

Auto Save controls in the User Preferences

Live Save

Enabling Live Save sets DaVinci Resolve to incrementally save changes as you make changes to your project, with no user intervention required. Disabling Live Save puts DaVinci Resolve back into a state where you have to manually save by pressing Command-S (this can be useful when doing demos when you don't want to save your changes to a project). Using Live Save is turned on by default and highly recommended to prevent the loss of work in the event you have a problem. It even works for previously unsaved projects that you've forgotten to save if anything goes wrong.

NOTE: When you use Collaborative Workflow to enable multiple artists to work together in the same project, Live Save is automatically turned on and cannot be disabled.

Project Backups

Turning on the Project Backups checkbox in the Project Save and Load panel of the User Preferences enables DaVinci Resolve to save multiple backup project files at periodic intervals, using a method that's analogous to a GFS (grandfather father son) backup scheme. This can be done regardless of whether or not Live Save is turned on. Each project backup that's saved is a complete project file, excluding stills and LUTs, which are omitted in order to save storage space.

Once you've enabled Project Backups for a long enough time, whatever saved project backups have been created are retrievable in the Project Manager via the contextual menu that appears when you right-click a project, by choosing Project Backups to open the backups list dialog.

The backups list dialog shows you all backups that are available for a particular project, and has controls for sorting the list via different columns, deleting some or all of the backups in the list, and loading backups that you want to retrieve. Opening a project backup does not overwrite the original project; project backups are always opened as independent projects.

To enable Project Backups:

1. Choose DaVinci Resolve > Preferences > User, and open the Project Save and Load panel.
2. Turn on the Project Backups checkbox.
3. Choose the settings that determine how many Project Backups will be maintained. Project Backups are saved on a first in, first out basis. Three fields let you specify how often to save new backups and how many backups to maintain, while the fourth lets you choose where the backups will be saved.

   Perform backups every X minutes: The first field specifies how often to save a new backup within the last hour you've worked. By default, a new backup is saved every 10 minutes, resulting in six backups within the last hour. Once an hour of working has passed, an hourly backup is saved and the per-minute backups begin to be discarded on a "first in, first out" basis." By default, this means that you'll only ever have six backups at a time that represent the last hour's worth of work.

   Hourly backups for the past X hours: The second field specifies how many hourly backups you want to save. By default, 8 hourly backups will be saved for the current day you're working, which assumes you're working an eight hour day (wouldn't that be nice). Past that number, hourly backups will begin to be discarded on a "first in, first out" basis.

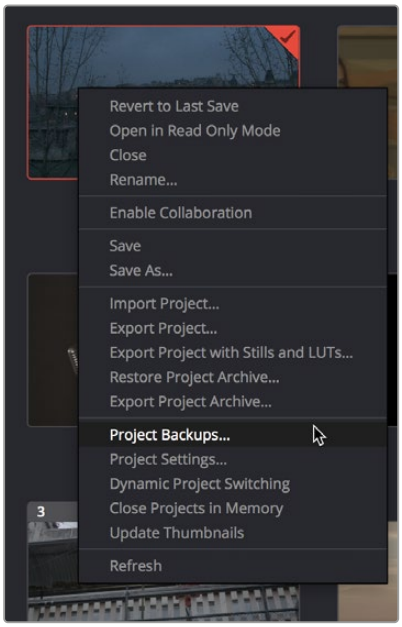
Daily backups for the past X days: The third field specifies for how many days you want to save backups. The very last project backup saved on any given day is preserved as the daily backup for that day, and by default daily backups are only saved for five days (these are not necessarily consecutive if you take some days off from editing for part of the week). Past that number, daily backups will begin to be discarded on a "first in, first out" basis. If you're working on a project over a longer stretch of time, you can always raise this number.

Project backup location: Click the Browse button to choose a location for these project backups to be saved. By default they're saved to a "ProjectBackup" directory on your scratch disk, although you could change this to a volume that better fits into your data backup methodology.

4 Click Save to confirm your change, and then close the Preferences window.

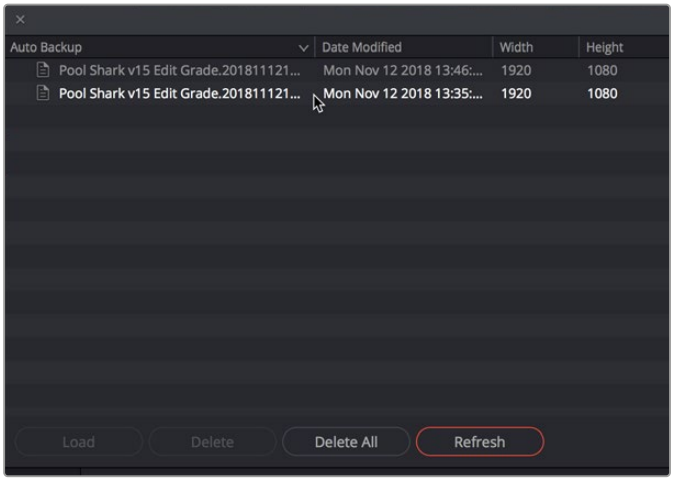
> **NOTE:** When using this feature, the very first backup that's saved for a given day may be a bit slow, but all subsequent backups should be unnoticeable.

Once one or more Project Backups have been saved, you can access them in the Project Browser.



To open a Project Backup that's been saved:

1 Open the Project Manager.



2 Right-click a project, and choose Project Backups from the contextual menu.

3 Select a backup that you want to restore from the Auto Backups list. If you don't see the particular backup you want, you can click the Refresh button to update the list, or you can try sorting by one of the columns (Auto Backup, Date Modified, Width, Height) to better navigate the list.

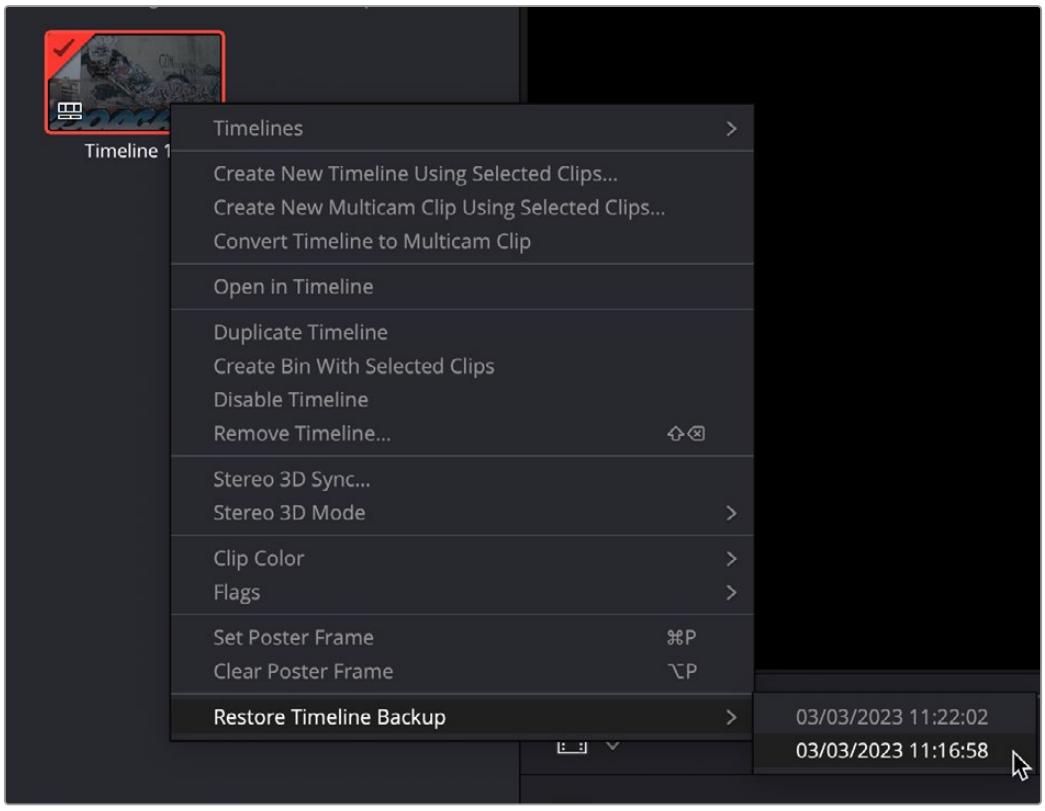
4 Once you've selected the backup you want to restore, you can click Load to open that backup as a new project. If the project it was saved from is already open, it won't be overwritten.

Restoring a project backup in the Project Browser

Selecting a backup that you want to restore

Timeline Backups

Turning on the Timeline Backups checkbox in the Project Save and Load panel of the User Preferences enables DaVinci Resolve to save multiple backups of a timeline at periodic intervals, using a method that's analogous to a GFS (grandfather-father-son) backup scheme. This can be done regardless of whether or not Live Save is turned on.



If you want to revert to a previous backup of a timeline, simply right-click on the timeline in the Media Pool, select Restore Timeline Backup from the contextual menu, and choose the backup from the list of options. Backups are organized by date and time, making it easy to find the specific timeline you want to restore.

There are certain times in the editing process where it makes sense to manually create a backup point before radically changing the remainder of your timeline. This can be done by duplicating the timeline (which is generally the safest), or you can also manually set a backup point for recall with the rest of your timeline backups.

To manually create a backup point with a custom name for a timeline, either:

- Select File > Create Timeline Backup (Option-Command-S).
- Right-click on your timeline in the Media Pool, and select Create Timeline Backup from the context menu.

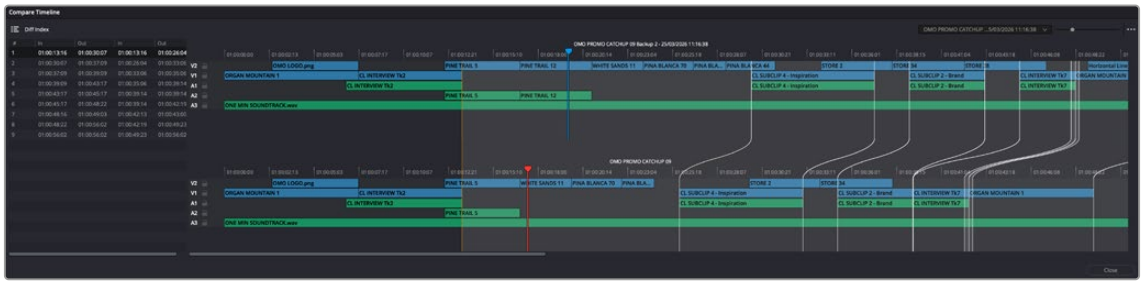
Restoring a timeline backup does not overwrite your current timeline. Instead the selected backup will be brought into the Media Pool as a new timeline, with the name "Backup" appended to it.

Restoring a timeline backup in the Media Pool

Timeline backups are only saved when changes have been made to a project. If DaVinci Resolve sits idle for any period of time, such as when your smart watch tells you to go outside and walk around the block, no additional project backups are saved, preventing DaVinci Resolve from overwriting useful backups with unnecessary ones.

Three fields let you specify how often to save a new backup, while the fourth lets you choose where the backups will be saved. These settings apply to both Project and Timeline backups.

- **Perform backups every X minutes:** The first field specifies how often to save a new backup within the last hour you've worked. By default, a new backup is saved every 10 minutes, resulting in six backups within the last hour. Once an hour of working has passed, an hourly backup is saved and the per-minute backups begin to be discarded on a first in, first out basis. By default, this means that you'll only ever have six backups at a time that represent the last hour's worth of work.
- **Hourly backups for the past X hours:** The second field specifies how many hourly project backups you want to save. By default, two hourly backups will be saved for the current day. Past that number, hourly backups will begin to be discarded on a first in, first out basis.
- **Daily backups for the past X days:** The third field specifies for how many days you want to save backups. The very last backup saved on any given day is preserved as the daily backup for that day, and by default daily backups are only saved for two days. Past that number, daily backups will begin to be discarded on a first in, first out basis. If you're working on a project over a longer stretch of time, you can always raise this number.
- **Project backup location:** Click the Browse button to choose a location for these backups to be saved. By default they're saved to a "ProjectBackup" directory on your scratch disk, although you could change this to a volume that better fits into your data backup methodology. This folder contains both Project and Timeline backups.



Restoring Deleted Timeline Backups

From the Media Pool Options menu, you can select Deleted Timeline Backups and examine deleted timelines and available backup files for each timeline. You can select backups to be restored or choose to permanently delete selected backups.

Compare Timelines with Timeline Backup Snapshots

To view your timeline changes against any of its previously backed up timelines, right-click on the timeline and select Compare with Timeline Backup, which will open up the Compare Timeline window.

The Compare Timeline window shows the two timelines stacked together, highlighting their differences. You can choose which backup to compare it to from via the dropdown menu at the top of the window. For more information on using the Compare Timeline window, jump to this chapter: Creating and Working with Timelines.

Comparing the current timeline against a previous backup.

Project Notes

Each DaVinci Resolve project now provides access to Project Notes, which is a simple “scratch pad” for keeping track of text notes associated with each project. These notes can be accessed using the File > Project Notes command, and there’s also a Project Notes command in the contextual menu for project icons in the Project Manager, which makes these notes accessible to everyone who’s connected to that project library.

Dynamic Project Switching

Dynamic Project Switching is an option in the Project Manager contextual menu that lets you open multiple projects into RAM simultaneously, so you can quickly switch between projects when you want to copy and paste clips, timelines, and node settings back and forth. If you plan on opening many projects, or even just a few very large projects, you should be sure your workstation has an appropriate amount of RAM installed or you could experience a slowdown in performance.

Switching among open projects using the Project Title dropdown at the top of the DaVinci Resolve UI

Methods of using Dynamic Project Switching:

- **To enable Dynamic Project Switching:** Open the Project Manager, right-click anywhere within the Project Manager and choose Dynamic Project Switching so that it’s checked. Dynamic Project Switching will remain enabled until you turn it off.
- **To open multiple projects in RAM:** Open any project, then reopen the Project Manager and open any other project. All projects you open are kept available in RAM.
- **To switch among open projects:** Choose File > Switch Project and select the project you want to switch to from the submenu. You can also choose other projects that have been opened into RAM from the dropdown menu that appears to the right of the project name at the top center of the DaVinci Resolve user interface.
- **To close a specific project:** Choose File > Close Project and select the project you want to close from the submenu. You may be prompted to save, after which the project closes.
- **To close all other open projects:** Open the Project Manager. All open projects appear with a check mark in the upper right-hand corner; the currently open project has an orange corner mark, while other projects open in memory have a gray corner mark. Right-click anywhere within the Project Manager, and choose Close Projects in Memory to close all projects other than the current one.

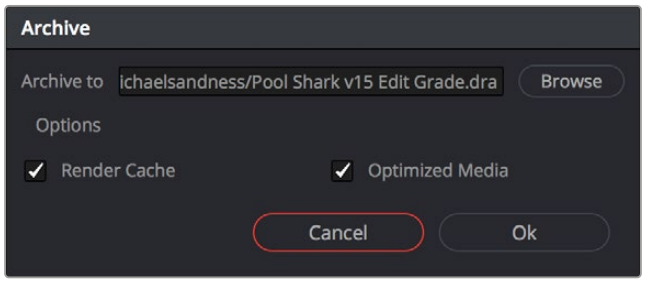
Using dynamic project switching, you can do the following:

- Copy and paste clips from the Media Pool of one project into another.
- Copy and paste timelines from the Media Pool of one project into another. When you paste a timeline from another project, all of the clips used in that timeline will be pasted to the same location as well.
- Copy and paste clips from a timeline in one project to a timeline in another.
- Copy a node’s settings from one project and paste them to a node in another project.

  You can also copy and paste clips, timelines, and node settings from one project to another without using dynamic project switching, but using switching makes this process faster.

Archiving and Restoring Projects

DaVinci Resolve has a convenient feature for quickly archiving every single media file used by a project, including subtitle files, along with the project itself, to a single location. This can be done to hand a project off to another DaVinci Resolve user, or to bundle a project and its media up for either short- or long-term archiving using the backup methodology of your choice. The process is simple.



To Archive a project:

1. Open the Project Manager.
2. Locate and right-click the project you want to archive, and choose Archive.

The contextual menu command for archiving projects

3. When the Archive Project window appears, choose a location to save the archive. Make sure you choose a volume that's large enough to accommodate the size of all the media from the project you're archiving, and click Save.
4. When the Archive dialog appears, verify the location the archive will be saved to, and choose which optional media you want to save within the archive. You can optionally save Optimized media and/or Render Cache media associated with a project.

A dialog letting you choose whether to save Optimized and/or Render Cache media

5. Click Ok, and a dialog with a progress bar will show you how long the archive operation will take to finish. If any errors come up, resulting from missing or offline media, they'll be presented at the end of the process.

The resulting archive that is written is a directory with the .dra file extension. Inside this folder are a series of subdirectories containing all of the media that's used by the archived project. Each directory of media files used is saved within a directory path that mirrors the exact path it came from, so you have a reference for where each clip came from originally.

To restore an Archived project:

1. Copy the .dra archive directory you want to restore to the volume where you want those media files to be. Restoring doesn't move this directory, it only adds the project file within to the Project Manager, so you should make sure the .dra archive directory is located on a storage volume with suitable performance for you to work.
2. Open the Project Manager, right-click anywhere, and choose Restore from the contextual menu. Choose the .dra archive directory you just copied, and click Open.
3. At the prompt, enter a unique project name for the restored project, and click OK. The project is restored to the Project Manager, and remains linked to the media located inside the .dra archive.
4. Alternatively you can simply drag the .dra folder from your file system directly into the Project Manager.

If, after restoring an archive, you want to move its media to another location, you can use Media Management to do a move operation for all clips in that project.

For more information on Media Management, jump to this chapter: Media Management.

Chapter 4

System and User Preferences

This chapter covers the settings used for customizing the DaVinci Resolve environment. System Preferences govern setup options that control the hardware and software environment, while User Preferences control various user controls within the software.

DaVinci Resolve Preferences

The DaVinci Resolve Preferences window contains workstation-specific settings for customizing how DaVinci Resolve works, divided into System and User panes, selectable via buttons at the top of this window.

To open the Project Settings window, do one of the following:

- Choose DaVinci Resolve > Preferences.
- Press Command-Comma.

TIP: You can open the preferences while the Project Manager is open when you first run DaVinci Resolve by pressing Command-Comma.

System Settings of the Preferences window

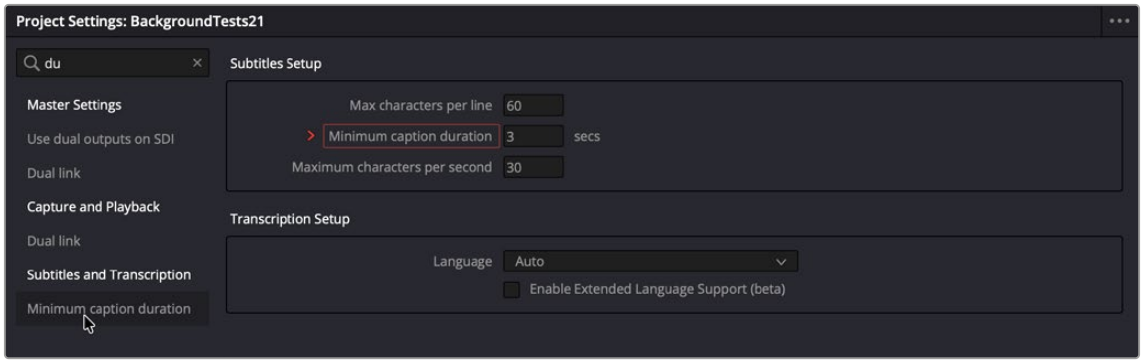
Adjusting Preferences

The System and User panes are each divided into a series of panels which can be selected from a sidebar at the left. Each panel contains a collection of related settings that affects some category of DaVinci Resolve functionality.

To alter any preference setting:

1. Click on the name of any group of settings in the sidebar at the left to open that panel.
2. Change whatever settings you need to change.
3. Click Save to apply the changes you've made and close the Preferences window.

If you've updated certain System Preferences, you'll be prompted to restart DaVinci Resolve, but if you've updated the User Preferences, this will probably be unnecessary.



Resetting Preferences

Resetting all preferences to their defaults is simple. Click the Option menu at the upper-right corner of the Preferences window and choose Reset System Preferences.

Searchable Preferences and Project Settings

DaVinci Resolve has search bars in both Preferences and Project Settings so you can easily locate a particular setting.

> To search, type the setting name in the search bar. A list of possible matches will appear as you type. You can then click on a setting name, which takes you to its corresponding page. It will also briefly highlight the setting name, making it easier to locate.

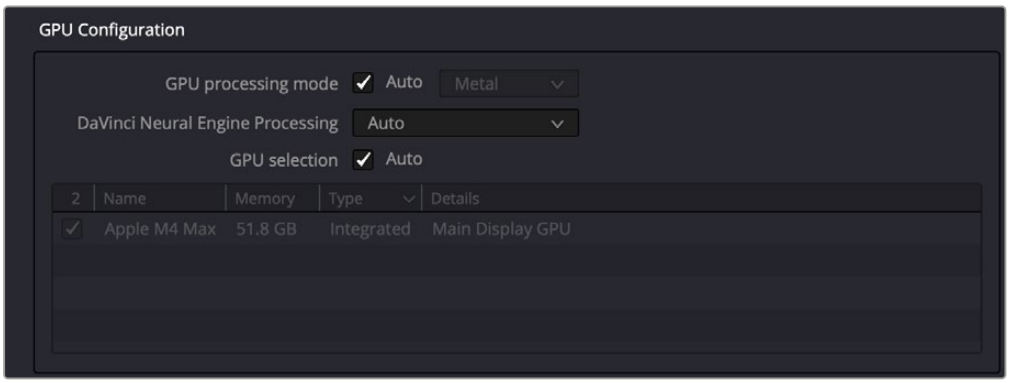
Type the name of a setting in the search bar, then click on your chosen result from the list. This brings you to that setting's page and highlights it, making it easy to locate.

System

The System pane of the Preferences window consists of a series of panels that configure the computer and other hardware that comprises your DaVinci Resolve workstation.

Memory and GPU

The top section of this panel provides Memory Configuration options, while the bottom section of this panel provides controls over how GPU processing is handled.



Memory Configuration

This section has the following preference settings handling memory usage.

- **System Memory:** The total available RAM on your workstation is listed here.
- **Limit Resolve Memory Usage to:** This preference limits the total amount of system memory that Resolve uses, keeping memory available for other applications. The maximum and default setting for this preference is 75 percent of your system's RAM.
- **Limit Fusion Memory Cache to:** Lets you limit how much RAM the playback cache on the Fusion page is allowed to use. Depending on the length of clips you're working on in the Fusion page, the playback cache can occupy a considerable amount of available memory. The amount you allocate here is taken from the total amount of memory allocated by the "Limit Resolve Memory Usage to" setting.

GPU Configuration

This section lets you choose how GPU processing should be handled.

Options for configuring the GPUs on your workstation

- **GPU processing mode:** Lets you set DaVinci Resolve to use the OpenCL, CUDA, or Metal GPU computing APIs for doing effects processing. Which is best depends on the GPUs that are installed in your computer. Most users can leave this set to Auto to let DaVinci Resolve choose what's appropriate. Otherwise, here are specific recommendations. If you have a macOS system, you should use Metal. Linux and Windows users with AMD GPUs should use OpenCL. Linux and Windows users with Nvidia GPUs should use CUDA, but make sure you have the correct drivers for your system, and that you have the latest update to CUDA installed. Additionally, when you manually choose an option from this dropdown menu, the GPU selection mode dropdown also appears.
- **DaVinci Neural Engine Processing:** Lets you choose which hardware to use for the AI tools powered by the DaVinci Neural Engine. Auto chooses what Resolve thinks is the most capable option, but you can manually override it and choose a specific GPU or Neural Engine.

- **GPU selection mode:** Lets you choose between Auto, which lets DaVinci Resolve choose which of the available GPUs on your computer to use for processing, and Manual, which lets you choose which GPUs to enable or disable for processing from a list that appears below. This can be useful in instances where you have multiple GPUs installed on a machine and you want to choose only the most powerful GPUs for processing. This can also be useful in instances where an external eGPU is connected to a laptop or all-in-one with a weaker GPU, so you can choose the more powerful eGPU for processing.
- **GPU selection list:** This list only appears when GPU processing mode is set to either OpenCL, CUDA, or Metal, and when GPU selection mode is set to Manual. A list of every GPU installed in your computer appears, and you can use checkboxes to the left of each GPU to enable or disable specific GPUs from being used for processing.
- **Optimized Viewer Updates:** This only appears on multi-GPU macOS and Windows systems or on single- and multi-GPU Linux systems; enables faster viewer update performance.

Media Storage

This panel lets you define the scratch disk and other media storage locations used by DaVinci Resolve, as well as proxy locations, and the default cache directories locations to be used when creating new projects.

- **Media Storage Locations:** This list lets you define the scratch disk of the system. The first volume in this list is where Gallery stills and cache files are stored, so you want to make sure that you choose the fastest storage volume to which you have access.
- **Mapped Mount:** This column allows you to specify translatable media path mapping between Mac, Linux, and Windows file system conventions.
- **Direct I/O:** This option allows DaVinci Resolve to write directly to the drive using the kernel buffers, bypassing the normal storage cache in RAM. This allows access to the full performance of the drive.
- **Automatically display attached storage locations:** This checkbox lets DaVinci Resolve access media on all temporarily and permanently mounted volumes, including SATA and eSATA, SAS, USB, FireWire, Thunderbolt, Gigabit Ethernet (GbE or GigE), Fibre Channel, and otherwise connected hard drives, without having to add them to this list. This is on by default.
- If you're using the Apple App store version of DaVinci Resolve, turning on "Automatically display attached local and network storage locations" automatically prompts you via a dialog to add "Macintosh HD" as a storage location. Clicking Add Location prompts you to select the Macintosh HD volume with another dialog, and clicking Open then adds that volume to the Media Storage Volumes list. After you click Save to close the Preference windows, Resolve should now auto-mount any volumes attached to your computer in the Media Storage browser of the Media page. Don't do this until after you've added a fast storage volume to the Media Storage Locations list, because you don't want Macintosh HD as the first volume in this list – the very first volume in this list should always be reserved for your fast scratch volume.
- **Proxy Generation Location:** These options let you define where any proxy media you create will be rendered to.

  Proxy subfolders in media file locations: The proxy media is generated inside a subfolder named "Proxy" at the same level in the file hierarchy as the original media file. This means that if your original media is all in the same folder, you will have one "Proxy" folder containing all of the proxy clips. If your original media is all contained in separate folders (i.e., one folder for each video clip), you will have multiple "Proxy" folders, one inside every clip folder and containing one proxy clip each.

  Use project settings: Uses the "Proxy generation location" destination, found in the Working Folders section of the Master Settings of the Project Settings.

  Ask when creating: Opens a filesystem dialog, allowing you to select a specific folder for the proxy generation.

Adding and Removing Storage Locations Manually

Some versions of DaVinci Resolve do not allow automatic display of attached volumes. In this case, you can click the Add button to open a dialog you can use to choose a volume you want to add. You can remove a volume by selecting it in the list then clicking on the Remove button.

Using Path Mapping to Access Volumes From Other Operating Systems

Shared media path mapping support for Mac, Linux and Windows makes it easier for multi-system shops to share Resolve projects among different platforms that use different file path conventions.

To add a mapped mount string:

1. Open the Media Storage panel of the Resolve Preferences window.
2. Add the volume you want to map to the Scratch Disks list.
3. Double-click the Mapped Mount column of the drive you added to edit it.
4. Enter the alternate file path you want that volume to have. For example, if you're on a Windows workstation and you want to access a Linux volume, type the Linux file path into the Mapped Mount column.

NOTE: If the volume you've selected to use for the cache becomes unavailable, DaVinci Resolve will warn you with a dialog.

Decode Options

This panel contains all options available for using the GPU to accelerate the decoding and debayering of various formats.

- **Use GPU for Blackmagic RAW decode:** Lets you use your GPU to accelerate the decoding of Blackmagic RAW (BRAW) media.
- **Decode H.264/HEVC using hardware acceleration:** Allows the use of hardware acceleration for H.264 or HEVC playback, if available on the computer you're using.
- **Use easyDCP decoder:** Since DaVinci Resolve has its own DCP encoder and decoder built in, this checkbox lets you switch over to using easyDCP to do DCP decoding, if you have a license installed on your workstation.
- **Automatically refresh growing files in the media pool:** If you're using a third-party application that records live to a growing video file, you can now begin to edit that file while it's still recording. Simply import the growing file into the Media Pool, and when this box is checked, DaVinci Resolve will continuously refresh to determine if the file has changed, and automatically update its attributes in the Media Pool.
- **Stream files during download from Blackmagic Cloud:** Check this box to be able to use a clip via streaming, before it downloads completely from the Blackmagic Cloud.
- **Use GPU for R3D:** Lets you use your GPU to accelerate debayering of R3D media. The latest RED API enables accelerated 8K debayering using either Metal or Cuda. There are three options:
  - None
  - Debayer
  - Decompression and Debayer

Video & Audio I/O

The preferences in this panel let you choose video and audio interfaces on your workstation.

Video I/O

This section lets you choose which Blackmagic Design video interfaces you want to use for monitoring, capture, playback, and Resolve Live, assuming you have any connected to your workstation. If you have more than one Blackmagic Design video device connected to your computer, you can independently configure them for playback and capture. If no interfaces are connected, no options will be available.

- **Capture Device:** If you have a compatible video capture card for video input, you should choose from the card options that appear here. This setting also sets the selected input device for use in Resolve Live, allowing you to monitor and color correct a live video signal. Any changes to this setting require a restart of the program.
- **Monitor Device:** If you have a compatible video output card, you should choose from the card options that appear here. Leaving this set to “None” disables external video output. Disabling video output can improve real time performance when external monitoring and output is not a priority. You can also choose “None” when you’re using DaVInci Resolve with another application open at the same time that’s using your workstation’s video output interface. When you’ve quit the other application, you can reselect the video output interface for use by DaVinci Resolve. Any changes to this setting require a restart of the program.
- **Release video device when not in focus:** When turned on, DaVinci Resolve releases control of the video output device whenever you switch to another application.
- **Mirror audio I/O engine output:** Audio automatically follows the device set in Audio I/O Engine below.
- **Audio monitoring delay:** Allows you to adjust any latency between the video images and the audio monitoring.

Video input/output options in the System Preferences

Audio I/O

This section lets you define the audio hardware and different sets of speakers with which to monitor audio playback. To access more than the default stereo system output that most workstations default to, you must use whatever software is available for your operating system to choose the desired audio hardware you want to use, and define how many audio outputs are required for the type of monitoring you want to do (stereo, immersive, and so on). For example, on macOS you’ll use the Audio Midi Setup utility to choose output hardware and select a speaker configuration to be made available on your system.

I/O Engine

Lets you choose the audio hardware that DaVinci Resolve uses to process audio. Choices include System Audio, Desktop Video, Fairlight Audio Accelerator, and ASIO (Windows only).

- **System Audio:** System Audio interfaces with your computer's native audio hardware and enables the following parameters.

  Playback processing buffer size: Lets you determine the size of the Playback buffer; to the right a latency display indicates the approximate latency of your choice in milliseconds.

  Record buffer size: Lets you determine the size of the Record buffer; to the right a latency display indicates the approximate latency of your choice in milliseconds.

  Input Device: Lets you chose the audio input device from the hardware attached to your system.

  Output Device: Lets you chose the audio output device from the hardware attached to your system.

  Automatic speaker configuration: Checking this box sets DaVinci Resolve to output audio via your workstation's built-in audio output, even if a compatible video I/O interface is enabled for capture and playback or for Resolve Live. Unchecking this box exposes additional controls with which you can define your own speaker setup.

Assigning different audio I/O devices and required buffer adjustments

About Audio Monitoring and Audio Input

The audio processing throughout DaVinci Resolve, including on the Fairlight page and audio processing using Fairlight FX plugins, is equally compatible with all platforms that DaVinci Resolve runs on, including macOS, Windows, and Linux. In particular, DaVinci Resolve supports audio monitoring and audio input using (i) the audio of a supported Blackmagic Design I/O device such as an UltraStudio or Decklink, (ii) your macOS, Windows, or Linux workstation's on-board audio, (iii) any Core Audio-compatible, Windows-compatible, ASIO, or Advanced Linux Sound Architecture (ALSA)-supported third party audio interface.

Alternately, you can monitor audio with the optional Fairlight Audio Accelerator, which is a PCI card that's designed to handle even more channels of audio I/O monitoring and recording, and that's also capable of accelerating audio processing operations to provide better performance for audio operations.

NOTE: ASIO is a trademark and software of Steinberg Media Technologies GmbH.

Monitor Speaker Configuration

When the Automatic Speaker Configuration box is unchecked it reveals another panel in the Video and Audio I/O Preferences. Here you can assign your monitors to the default Main or Near sets, and you can also create an additional 15 monitor sets specific to your needs.

- **Monitor Set:** Choose the default Main or Near or create up to 15 other user-definable configurations.
- **Rename:** This button allows you to rename any of the monitor sets to something more meaningful for your individual needs.
- **Format:** A dropdown menu allows you to choose the desired format type from Mono up to Dolby Atmos 9.1.6. Below the Format type there are three windows to create the Monitor Set:

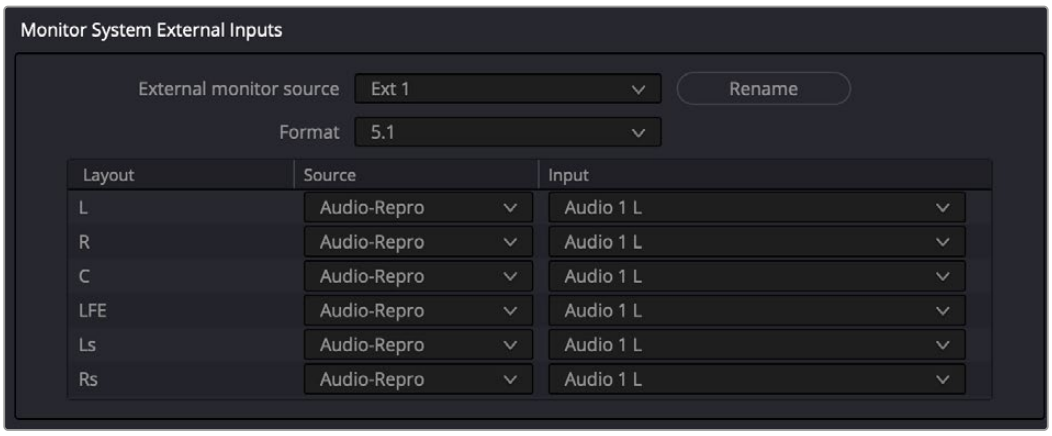
  Layout: Breaks out the channels that correspond to the chosen format.

  Output: Where you can assign the Output channels to your system.

  Trim: Where you can reduce each individual level by up to -24dB of gain or add up to +10dB of gain for fine tuning the speaker calibration required for your particular playback space.

Monitor System External Inputs

You can create multiple sets of monitoring with up to 16 user-definable setups from this panel. This allows flexibility to have different combinations of monitoring speakers that you can switch among for checking, reviewing, and creating different mixes.



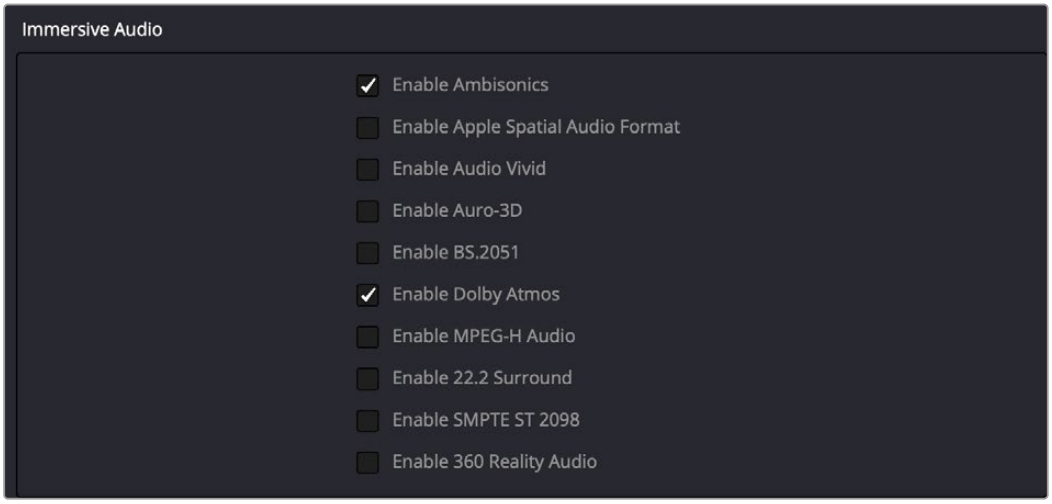
- **External Monitor Source:** Chose None or up to 16 definable configurations.
- **Rename:** Lets you specify a name for an External Monitor Source.
- **Format:** When a Format is chosen, a dropdown menu appears allowing you to choose the desired format type from Mono up to Dolby Atmos 9.1.6. Once a format has been chosen, three more windows appear:

  Layout: Which breaks out the channels that correspond to the chosen format.

  Source: Where you can assign either Input Destination or Audio Repro.

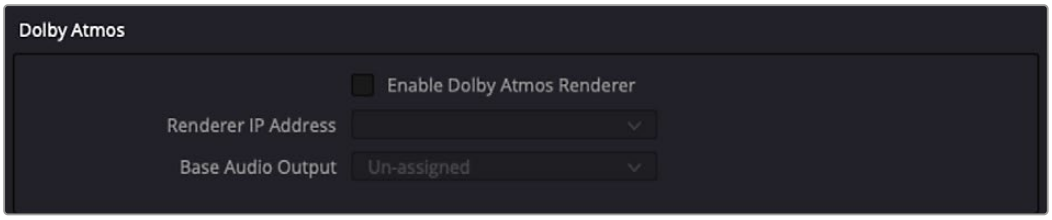
  Input: Where you can assign an individual track when in Audio Repro, or assign the specific channel when in Input Destination.

- **Rename:** This button allows you to rename any of the numerically labeled monitor sets to something more meaningful for your individual needs.



Patching and renaming different external inputs in Video and Audio I/O Preferences

Immersive Audio Controls

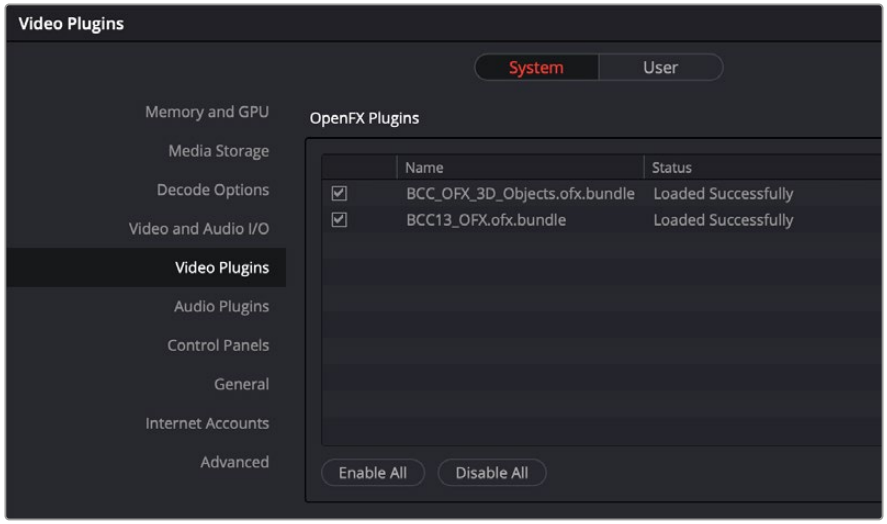


These two Preference panels allow you to configure for the type of immersive audio that you want to have available in your project and also for linking to a Dolby RMU for doing Dolby Atmos mixing.

- **Immersive Audio:** This panel allows you to enable the various types of immersive audio offered within DaVinci Resolve. Those formats are: Ambisonics, Apple Spatial Audio, Audio Vivid, Auro 3D, BS.2051, Dolby Atmos, MPEG-H Audio, 22.2 Surround, SMPTE ST 2098, and 360 Reality Audio.

Immersive Audio Preferences

- **Dolby Atmos:** Checking this box allows the use of an external Dolby Atmos renderer. Once checked you can enter the IP address of the RMU and choose the base audio output.



Dolby Atmos Preferences

Video Plugins

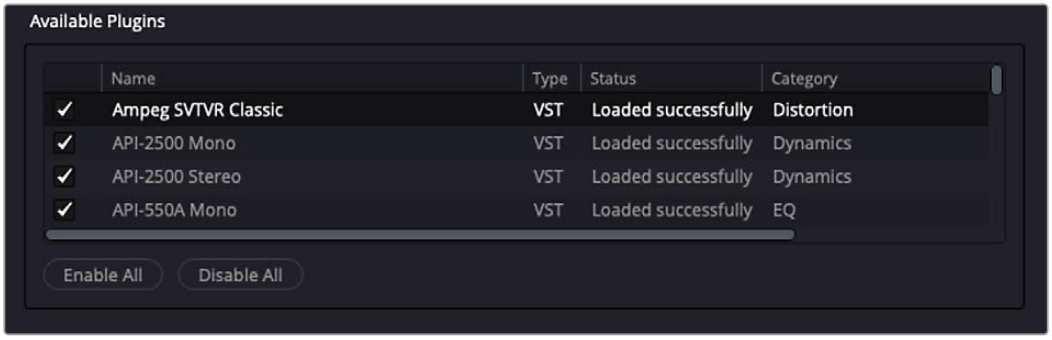
You can selectively enable and disable specific Open FX plugins on startup. You can use this function to streamline and organize the Open FX list to just the plugins you commonly use, or to exclude a problematic plugin that causes instability in the system. Additionally, DaVinci Resolve automatically checks the last plugin loading result on startup, and skips any plugins that previously caused a crash or hang.

Individual Open FX plugins can be manually enabled and disabled in the Video Plugins panel by checking or unchecking the boxes corresponding to the plugins.

The Video Plugins panel allows you to enable or disable specific Open FX plugins at startup.

Audio Plugins

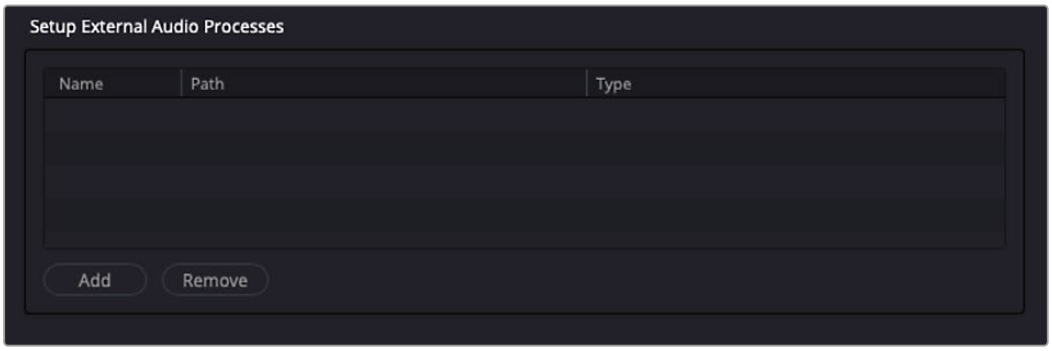
Three sections of parameters let you manage VST effects, enabled plugins, and external audio processes.



- **VST Effects:** A list at top lets you manually add and remove VST plugin effects directories, if necessary. VST effects aren't installed in a standard location, so it may sometimes be necessary to add a newly installed directory of VST plugins that you've just installed on your system.

Audio Plugins Preferences - VST Effects

- **Available Plugins:** Once you've added one or more VST directories to the list, a second list underneath shows all audio plugins that are available within these directories. Each plugin on the list has a checkbox that shows whether or not it's currently enabled. Any VST plugins that cause DaVinci Resolve to crash while loading them during startup will be automatically disabled. You can use this list to see which plugins have been disabled, for troubleshooting purposes, and to reenable such "blacklisted" plugins by turning their checkboxes back on.
- **Category Column:** VST and Audio Units plugins are organized into categories within the Fairlight Mixer. You can move a plugin to a different category by clicking its category name and selecting a new one from the Category popup list.



> **NOTE:** This does not apply to Fairlight FX plugins.

Audio Plugins Preferences - Available Plugins

- **Setup External Audio Processes:** While working in the Fairlight page, you have the ability to process an audio file using a third-party application, if necessary, in the event you need to use another application's capabilities to create an effect or solve an issue that can't be accomplished in the Fairlight page itself. To do this, you must first add one or more applications to the External Audio Process list in the Audio Plugins panel of the System Preferences.

NOTE: VST is a trademark of Steinberg Media Technologies GmbH.

Audio Plugins Preferences - Setup External Audio Processes

To add an External Audio Process:

1. Click the Add button.
2. Double-click the text in the Name column and change the name to that of the application or process you're going to link to.
3. Click once in the Path column, and then use the file dialog to locate and select the application or script you want to use as the external audio process.
4. Open the dropdown menu in the Type column, and choose how you want the selected audio process to work: Reveal (open the application), Command Line (use from Terminal), or Clipboard (copy the audio clip file path to the clipboard to paste into the open command of an application or utility).
5. When you're done, click Save, and restart DaVinci Resolve if you're prompted to.

Control Panels

Two sections let you specify which Color Grading Panel and Audio Console is connected to your workstation.

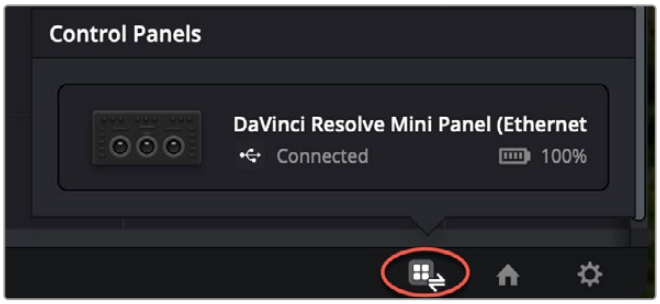
- **Color Grading Panel:** A menu lets you choose which color grading panel you have connected to your workstation. Some panels expose additional controls.

  If you have a DaVinci Resolve Mini or Micro Panel, leave this setting set to None and these panels will be auto-detected by Resolve when you plug them in.

  If you have a control panel that connects via USB, choose your panel from the list.

  If you have a DaVinci Resolve Mini Panel connected over Ethernet, choose “DaVinci Resolve Mini Panel (Ethernet)” and then choose your panel from the dropdown that appears.

  If you’re using a JLCooper Eclipse, choose “JLCooper Eclipse CX” and then enter the IP and Port number into the fields that appear.



- **Audio Console:** A menu lets you choose which Fairlight Audio Console you have connected to your workstation. Some panels expose additional controls.
- **Use MIDI Audio Console:** A checkbox lets you enable the use of a third-party audio console that’s connected to your workstation. Turning this on exposes three additional menus.

  MIDI Protocol: Lets you choose either the HUI or MCU protocol, whichever is compatible with the audio console you want to use.

  MIDI Input: Lets you choose the MIDI input used to connect your console.

  MIDI Output: Lets you choose the MIDI output used to connect your console.

- **Head Tracker:** A menu lets you choose which head tracker profile to use for immersive audio.
- **Display Control Panels Status on Main Footer:** Checking this box displays the status of all connected control panels in an icon in the bottom right footer of the interface. Unchecking the box removes this icon.

The Control Panels Status icon

General

This panel provides various options for scripting, audio processing, monitoring, and sending problem reports.

- **External Scripting Using:** (Resolve Studio only) Options include None, Local, and Network. When set to None, only scripting in the Console window is allowed. When set to Local, external scripts and applications on the same computer can control DaVinci Resolve. When set to Network, external scripts and applications from other computers on the network (or via the internet) can control DaVinci Resolve.
- **Use 10-bit precision in viewers if available:** This checkbox only appears on macOS installations of DaVinci Resolve. Turning this checkbox on lets DaVinci Resolve display 10-bit images in the Viewer.

- **Use Mac Display Color Profile for viewers:** If you're using DaVinci Resolve on macOS, this checkbox enables all viewers in DaVinci Resolve to use whatever display profile is selected in the Displays panel of the System Preferences. This lets DaVinci Resolve use ColorSync on macOS so your Viewer image should better match your output display.

  Viewers match QuickTime Player when using Rec.709 Scene: Check this box to make the viewers match the gamma characteristics of the QuickTime player. This will make the Resolve Viewers and what you see in QuickTime Player match.
- **Optimize project library cloud data traffic:** If you're having difficulty accessing the Blackmagic Cloud through a corporate firewall, check this box to connect without having to set port mapping and firewall exceptions. https://blackmagicdesign.com still needs to be whitelisted for access.
- **Automatically Tag Rec.709 Scene Clips as Rec.709-A:** Turn this checkbox on to automatically tag any Rec. 709 QuickTime files for Rec. 709-A playback. This setting is useful if your final QuickTime video does not match what you see in the Resolve viewers (gamma shift), and you wish to export for the web rather than broadcast.
- **Automatically Scan other project libraries for remote rendering jobs:** Turn this checkbox on to scan all connected project libraries, rather than just the current project library for possible remote rendering jobs.
- **Automatically Check for Updates:** Turn this checkbox on to make it easier to ensure you're using the latest version of DaVinci Resolve. You can also choose DaVinci Resolve > Check For Updates to notify you of new versions and download them when available.
- **Automatically opt-in for new beta program notifications:** Lets you know when public beta versions of DaVinci Resolve become available, in case you're interested in living on the edge.
- **Send report when application quits unexpectedly:** When this checkbox is turned on, this setting enables DaVinci Resolve to automatically prepare a problem report whenever DaVinci Resolve unexpectedly quits. You get to fill out some information (please be as specific as you can about what you were doing when DaVinci Resolve had its issue) and click a button to send the report.
- **Limit Presentations upload speed to X KB/s:** Allows you to set a hard limit on the upload speed while using Presentations to avoid saturating all your network bandwidth.
- **Use Remote Monitoring without Blackmagic Cloud:** Allows you to use remote monitoring on your own network instead of going through Blackmagic Cloud.
- **Use TURN server for Remote Monitoring:** If you are not using Blackmagic Cloud for security reasons and you are using a self-configured or cloud-based TURN servers to route and relay monitoring streams, enter that server here.
- **Prevent sleeping when Blackmagic Cloud sync enabled project is open:** This checkbox is on by default and prevents your computer from entering sleep mode while a Blackmagic Cloud project is active to make sure all online data transfers complete. Uncheck this box to let your computer go to sleep whenever it wants.
- **LUT Locations:** Use this interface to add or remove directories where DaVinci Resolve will look for LUTs to apply throughout the application.

Background Tasks

DaVinci Resolve supports background rendering for certain computationally intensive operations, including background renders, quick exports, and proxy generation. You can also use background analysis for transcription and audio classification. When an operation moves to the background for processing, you can continue working within the Resolve interface without affecting the original operation.

NOTE: Background rendering requires significant computational resources and may slow down your system significantly, depending on your workstation's processor, ram, data throughput and so on. As a result, this operation is disabled by default.

You can monitor the progress of your ongoing background tasks via the pop-up on the bottom toolbar.

Background Tasks preferences.

- **Background Render:** These options control the Background Rendering parameters.

  Enable background renders: Checking this box turns on Background Rendering, while unchecking turns it off.

  Pause background renders on foreground activity: Checking this box will pause your background tasks while you're using the DaVinci Resolve interface, giving you full computer power for your active work.

- **Tasks Options:** These options let you choose which operations to render in the background.

  Transcription: Check this box to move transcription tasks to the background.

  Proxy Generation: Check this box to move proxy generation tasks to the background.

Internet Accounts

The Internet Accounts panel serves as a login manager for the Blackmagic Cloud and other social media sites.

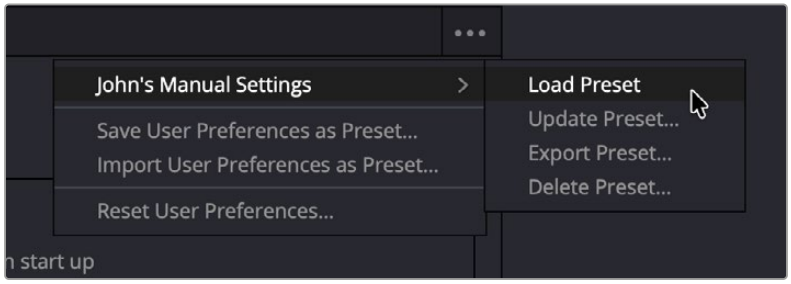
DaVinci Resolve has tight integration with YouTube, Vimeo, TikTok, Dropbox, and Frame.io that allows you to render and upload directly to each service. This panel provides buttons that let you sign into your YouTube, Vimeo, TikTok, Dropbox, and Frame.io accounts, as well as specify a local cache location for media being synced with Frame.io.

For each service you sign into, a floating window presents the interface in which you'll need to enter your login name and password to enable integration, followed by whatever two-factor identification and other required steps are necessary. Once entered, DaVinci Resolve will sign in to each of these services automatically when DaVinci Resolve opens.

The Internet Accounts panel of the System tab of the DaVinci Resolve Preferences window.

Advanced

This tab is used for special Resolve configurations and SAN parameters that are applicable to older file systems.



User

This panel lets you choose user preferences, specific to your workstation, that govern such things as UI behaviors and appearance, auto save settings, editing and color defaults, control panel action, and keyboard shortcut mappings.

TIP: Many of the settings in the User panel used to be found in the Project Settings window prior to version 14, but they were moved here to accommodate collaborative workflows with each user having their own independent general, editing, and color settings, as well as their own keyboard shortcuts.

Saving User Preference Presets

It's possible to save multiple presets for instant recall of different User Preference settings, using the Option menu in the UI Settings window.

The commands for managing User Preference presets in the Option menu of the UI Seμttings window.

Methods of managing User Preference presets:

- **To save a preset:** Choose whatever settings you want to use, then click the UI Settings window Option menu, and choose Save User Preferences as Preset. Enter a name into the dialog, and click OK. That preset will now appear at the top of the Option menu.
- **To load a preset:** Click the UI Settings window Option menu, and choose Load Preset from the submenu of the preset you want to load.
- **To update a preset:** Load a preset you want to edit, then change whatever settings you need to, and choose Update Preset from the submenu of that preset in the Option menu.
- **To export a preset:** Choose Export Preset from the submenu of any preset in the Option menu. A file with the .userprefs extension is saved at the location you chose.
- **To import a preset:** Choose Import User Preferences as Preset in the Option menu, use the dialog to find the exported .userprefs preset file you want to import, and click Open.
- **To delete a preset:** Choose Delete Preset from the submenu of any preset in the Option menu.
- **To reset all presets:** Choose Reset User Preferences from the Option menu to restore all User Preferences to their default settings.

UI Settings

A collection of operational preferences.

- **Language:** A Language dropdown at the top lets you specify which language the DaVinci Resolve user interface displays. DaVinci Resolve currently supports English, Chinese, Japanese, Spanish, Portuguese, French, German, Italian, Russian, Thai, Vietnamese, and Korean.
- **Reload last working project on startup:** Automatically reopens the last project a user had open whenever that user logs back into DaVinci Resolve. This checkbox can only be enabled when editing a preset configuration in the Presets panel, so that it's always on no matter which project you open as long as you're using that particular preset.
- **Use Optimized UI layouts for vertical video:** Checking this box will automatically update the UI to accommodate vertical timelines and video sources. Unchecking this box will maintain the normal UI regardless of video orientation.
- **Show focus indicators in the user interface:** Lets you enable or disable a red line at the top of each panel that indicates which panel currently has focus.
- **Show fonts preview:** Checking this box will display an expanded font selection window with the font name, as well as its corresponding typeface. Selecting a font from this window will insert it into the Font Field in a variety of text tools.
- **Use gray background for user interface:** By default, DaVinci Resolve uses a blue-gray UI background, intended to provide a more attractive experience for users focused on the less color-critical aspects of DaVinci Resolve, namely editing. Turning this checkbox on switches DaVinci Resolve to a totally neutral, desaturated gray UI, which can be valuable as a point of

reference for colorists concerned about the blue-gray UI's potential to bias the eye in the dark environment of the grading suite.

- **Use gray background in viewers:** When turned on, sets the background of all viewers to gray, making it easier to evaluate image blanking or minor sizing adjustments than with the default dark background.
- **Resize image in viewer to square pixels:** This control will select between using a square or non-square pixel aspect ratio within the Viewer. This is important when working with SD images which do not have a square pixel aspect ratio.
- **Delay viewer display by X frames:** When turned on, you can enter a number of frames to delay DaVinci Resolve Viewers as they appear on your computer displays so that the image on your computer display better syncs up with the same image shown on external displays that are delayed due to various signal processing processes.
- **Output single field when paused:** This setting will reduce flicker when grading using a computer monitor or when working with interlaced material. Ordinarily, when viewing interlaced material in Stop or Pause mode, field one is displayed followed by field two. Depending on the image, this can result in a flicker on the display. When this option is enabled, only field one will be shown on the monitor when playback is paused; however both fields will be shown when the clips are played.
- **Stop playback when a dropped frame is detected:** When enabled, sets DaVinci Resolve to stop playback whenever a frame is dropped on output, to warn you that there are performance issues on your workstation. This is particularly useful when you're outputting to tape.
- **Stop renders when a frame or clip cannot be processed:** When enabled, this will halt a render if DaVinci Resolve detects an error in the encoding, rather than continue to try to process it.
- **Show playhead shadow:** Checking this box turns on the playhead shadow, a transparent orange range used for visually measuring that extends a certain number of frames before and after the playhead. The number of frames in the range before or after the playhead can be adjusted in the Editing section of the User Preferences.
- **2D timeline scrolling:** Checking this box will scroll the Timeline vertically through all the Video or Audio tracks when moving the mouse wheel. Unchecking this box will scroll the entire Timeline horizontally when moving the mouse wheel.
- **Timeline sort order:** A user setting that allows you to determine the default sort order of the Timelines that appear in the Viewer dropdown menus throughout DaVinci Resolve.

  Alphabetic: Sorts Timelines alphabetically A-Z.

  Creation Date: Sorts Timelines by oldest creation date first.

  Recently Used (default): Sorts Timelines by the last 10 actively used timelines.

Project Save and Load

The Project Save and Load panel lets you control how projects are opened, and how they're saved.

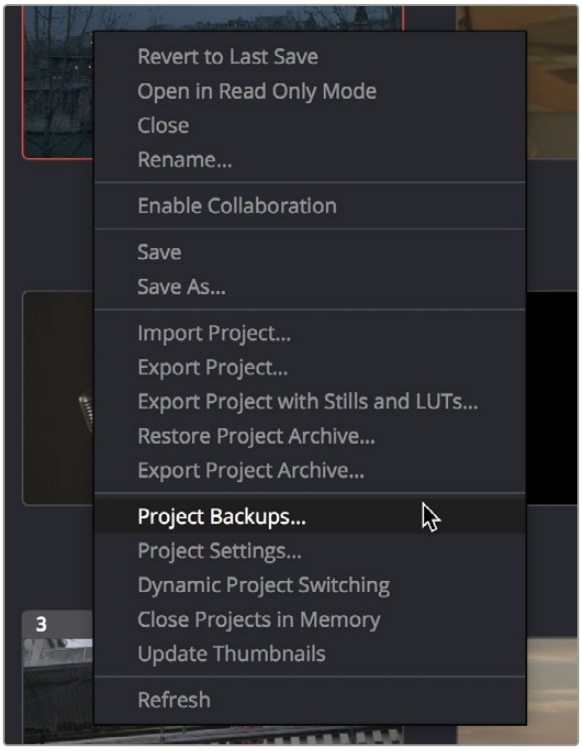
Load Settings

The Load Settings preference lets you control a key aspect of project opening performance, namely whether or not all timelines within a given project are loaded into memory at the time of opening.

- **Load all timelines when opening projects:** To improve the performance of longer projects with multiple timelines, the "Load all timelines when opening projects" checkbox in the Project Save and Load panel of the User Preferences defaults to off.

  When this checkbox is off, opening a project only results in the last timeline you worked on being opened into memory; all other timelines are not loaded into RAM. This speeds up the opening of large projects. However, you may experience brief pauses when you open other timelines within that project, as each new timeline must be loaded into RAM as you open it. If you open

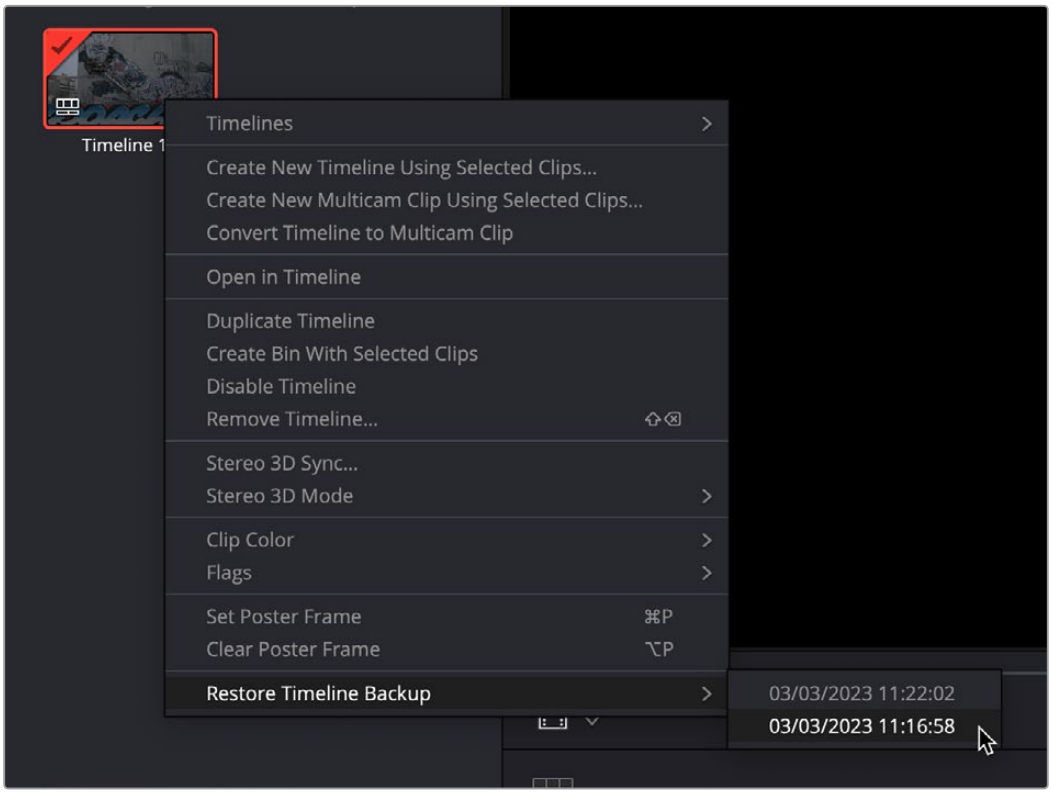
a particularly gigantic timeline, a progress bar will appear letting you know how long it will take to load. Another advantage of this is the reduction of each project's memory footprint, which is particularly valuable when working among multiple projects using Dynamic Project Switching.



If you turn this on, all timelines will be loaded into RAM, and you'll experience no pauses when opening timelines you haven't opened already. However, projects with many timelines may take longer to open and save.

Save Settings

The Save settings allow you to control how DaVinci Resolve handles automated saving and project backups. These features can save you from the heartache of lost work resulting from an unexpected problem.



- **Live Save:** Enabled by default, Live Save is a progressive, fast, always-on autosave mechanism that "saves as you go." All changes in the Cut, Edit, and Fairlight pages are saved as you make them. All changes in the Fusion and Color pages are automatically saved when you switch to another clip, and also periodically and invisibly in the background while you work to ensure that your work is saved even if you haven't switched clips in a while.
- **Project Backups:** Turning on the Project Backups checkbox in the Project Save and Load panel of the User Preferences enables DaVinci Resolve to save multiple backup project files at periodic intervals, using a method that's analogous to a GFS (grandfather father son) backup scheme. This can be done regardless of whether or not Live Save is turned on. Each project backup is a complete project file, excluding stills and LUTs.

  Once you've enabled Project Backups for a long enough time, whatever saved project backups have been created are retrievable in the Project Manager via the contextual menu that appears when you right-click a project, by choosing Project Backups. Opening a project backup does not overwrite the original project; project backups are always opened as independent projects.

Restoring a project backup in the Project Browser

- **Timeline Backups:** Turning on the Timeline Backups checkbox in the Project Save and Load panel of the User Preferences enables DaVinci Resolve to save multiple backups of a timeline at periodic intervals, using a method that's analogous to a GFS (grandfather-father-son) backup scheme. This can be done regardless of whether or not Live Save is turned on.

Restoring a timeline backup in the Media Pool

If you want to revert to a previous backup of a timeline, simply right-click on the timeline in the Media Pool, select Restore Timeline Backup from the contextual menu, and choose the backup from the list of options. Backups are organized by date and time, making it easy to find the specific timeline you want to restore.

Restoring a timeline backup does not overwrite your current timeline. Instead the selected backup will be brought into the Media Pool as a new timeline, with the name "Backup" appended to it.

Project and Timeline backups are only saved when changes have been made to a project. If DaVinci Resolve sits idle for any period of time, such as when your smart watch tells you to go outside and walk around the block, no additional project backups are saved, preventing DaVinci Resolve from overwriting useful backups with unnecessary ones.

Three fields let you specify how often to save a new backup, while the fourth lets you choose where the backups will be saved. These settings apply to both Project and Timeline backups.

Perform backups every X minutes: The first field specifies how often to save a new backup within the last hour you've worked. By default, a new backup is saved every 10 minutes, resulting in six backups within the last hour. Once an hour of working has passed, an hourly backup is saved and the per-minute backups begin to be discarded on a first in, first out basis. By default, this means that you'll only ever have six backups at a time that represent the last hour's worth of work.

Hourly backups for the past X hours: The second field specifies how many hourly project backups you want to save. By default, two hourly backups will be saved for the current day. Past that number, hourly backups will begin to be discarded on a first in, first out basis.

Daily backups for the past X days: The third field specifies for how many days you want to save backups. The very last backup saved on any given day is preserved as the daily backup for that day, and by default daily backups are only saved for two days. Past that number, daily backups will begin to be discarded on a first in, first out basis. If you're working on a project over a longer stretch of time, you can always raise this number.

Backup location: Click the Browse button to choose a location for these backups to be saved. By default they're saved to a "ProjectBackup" directory on your scratch disk, although you could change this to a volume that better fits into your data backup methodology. This folder contains both Project and Timeline backups.

Cache Management

This section allows you to delete your local cache automatically after a certain number of days to keep your drive from filling up with older projects.

Of course, you can always manage these files manually from the Playback > Manage Render Cache menu, but this new preference lets you set and forget a cleanup operation.

Media Cache Settings

Delete Cache files older than xx days: Check the box and select the number of days after which the automatic deletion of the Cache files will occur.

Editing

The settings in this panel affect new timeline settings, editorial default values, trim behaviors, timeline UI appearance, and frame interpolation settings.

New Timeline Settings

These settings define the presets that populate the New Timeline Options window whenever you create a new timeline.

- **Start Timecode:** You can change the Start Timecode if a specific start time is required.
- **No. of Video Tracks:** Enter how many video tracks you want to have. You can also drag within this field to adjust the number of video tracks with a virtual slider.
- **No. of Audio Tracks:** Enter how many audio tracks you want to have. You can also drag within this field to adjust the number of audio tracks with a virtual slider.
- **Audio Track Type:** Choose the channel mapping you want the new audio tracks to use.

Automatic Smart Bins

These settings let DaVinci Resolve automatically create Smart Bins whenever clips with relevant metadata appear in the Media Pool, or whenever such metadata is added to clips that are already in the Media Pool. You can choose which Smart Bins are automatically created via a series of checkboxes.

General Settings

These settings define the timing of resolve-generated effects and editing operations.

- **Standard generator duration:** Defines the default duration of generators you edit into the Timeline, in Seconds or Frames. The default value is 5 seconds.
- **Standard transition duration:** Defines the duration of transitions, in Seconds or Frames, that you add to an edit point in DaVinci Resolve. The default value is 1 second.
- **Standard still duration:** Defines the duration of stills that you import such as TIFF, PNG and other supported graphic file formats, in Seconds or Frames. The default value is 5 seconds.
- **Pre-roll time:** Determines how much of the Timeline before the current position of the playhead to play when using the Play Around command.
- **Post-roll time:** Determines how much of the Timeline after the current position of the playhead to play when using the Play Around command.
- **Audio subframe nudge:** Determines the number of milliseconds or subframes are nudged when you use the Subframe Left/Right controls.
- **Default handles length:** The value used when creating a timeline with handles. The default is one second worth of frames.
- **Default fast nudge length:** The number of frames that are nudged when you use the Shift-Comma (,) and Shift-Period (.) keyboard shortcuts.
- **Pre-playhead shadow length:** The number of frames in the Timeline prior to the playhead covered by the Playhead Shadow, if enabled by checking the “Show playhead shadow box” in the User UI Settings preferences.
- **Post-playhead shadow length:** The number of frames in the Timeline after the playhead covered by the Playhead Shadow, if enabled by checking the “Show playhead shadow box” in the User UI Settings preferences.
- **Automatically switch to single viewer mode when opening trim editor:** Turn this checkbox on if you want DaVinci Resolve to always open the trim editor in a single larger viewer when performing trim operations. Unchecking this box will maintain dual viewer operation even while trimming.
- **Automatically enable dynamic trim when opening trim editor:** Enable this checkbox to make Dynamic Trim Mode the default setting in the Trim Editor.
- **Timeline overlay retains the last performed action:** Turn this checkbox on if you want DaVinci Resolve to always remember the last edit type you used in the Timeline Viewer Overlay, and highlight it on this Overlay whenever you drag another clip over the Timeline Viewer to let you know that the last edit you performed is the new default edit if you drop clips to the left of the overlay.
- **Always highlight current clip in the media pool:** When turned on, any clips at the position of the playhead on the Edit or Color pages will be automatically highlighted in the Media Pool.
- **Limit timecode display to 24 hours:** When this box is checked, timecode will wrap back around to 00:00:00:00 after 23:59:59:xx instead of continuing forward. This makes using time of day timecode more consistent.
- **Prioritize pasting to the in and out range:** Normally, pasted clips appear at the playhead position in the timeline. Check this box if you wish them to be pasted according to the timeline in and out points instead.
- **Sync the Master Timeline to the current frame:** If you turned on “Automatically match master timeline with media pool” in the Color settings, then this option lets you make sure that whenever you open the Master Timeline, the playhead is at the same clip and frame that it was in the previous Timeline you were working on.

- **Show offline reference for timeline gaps:** If there's a missing clip in a conformed timeline that results in a gap in the Timeline Editor, turning this option on sets DaVinci Resolve to show the corresponding frames of an "offline reference movie," if one has been assigned to that timeline, instead of black. This can be helpful in emergency situations when you're missing timeline clips right before a screening or review session; this feature lets you play or output the missing frames using the corresponding media from the offline reference movie, instead of outputting black.

  For more information on using and assigning Offline Reference Movies, jump to this chapter: Importing and Conforming Timelines.

- **Show offline reference for non-conformed edits:** If there's missing media in a project that results in an unlinked clip in the Timeline Editor (represented by a red exclamation point overlay on that clip), turning this option on sets DaVinci Resolve to show the corresponding frames of an "offline reference movie," if one has been assigned to that timeline, instead of black. This can be helpful in emergency situations when you're missing source media right before a screening or review session; this feature lets you play or output the missing frames using the corresponding media from the offline reference movie, instead of outputting black.

  For more information on using and assigning Offline Reference Movies, jump to this chapter: Importing and Conforming Timelines.

- **Use custom safe area overlays:** When turned on, displays Action Area and Title Area fields that let you set a custom percentage for each. The default values are 93% for Action Area and 90% for Title Area.
- **Retain sync and avoid overwrites with ripple edits:** Checking this box will strive to retain sync when ripple trimming by overwriting media on certain tracks if necessary. Unchecking this box will not overwrite any media, but will cause clips to lose sync when ripple trimming.
- **Align audio edits to frame boundaries:** When turned on, the In and Out points of audio clips always align themselves with whole frame boundaries, just like video clips. When turned off, you can perform subframe audio edits to audio-only clips, or to linked audio when you've suspended linked selection.
- **Configure clips as multi-mono on import:** Checking this box allows you to import any multichannel audio in a multiple mono configuration. This lets you take any Stereo, 5.1, or other multichannel sources, and automatically configures them to multiple mono files with the same number of tracks when you add them to the Media Pool.
- **Limit Media Pool audio sync to first timecode match:** When two or more audio clips overlap timecode with a video clip, the default behavior is to sync all overlapping audio clips by making as many new tracks as necessary. Checking this box replaces this behavior by having DaVinci Resolve choose what it thinks is the most likely single audio track, and sync just that single audio clip, ignoring the others.
- **Import Finder tags as Keywords (Mac only):** When turned on, any color tags that are set and defined in Mac OS for a media file will automatically be imported as keyword metadata alongside that media file.

  NOTE: Even when Align audio edits to frame boundaries is turned off, if linked selection is on, you'll be unable to make subframe edits while you're resizing both the audio and video of linked clips.

Text

Check the Display Only Specific Fonts box to explicitly limit the font options shown for your text elements. This lets you set a white list of fonts that you are cleared to use, and hide all other fonts on the system.

To set up an allowed fonts list:

1. Check the box in Preferences > User > Editing > Text > Display Only Specific Fonts.
2. Select a font filter file.

   A font filter file is any UTF-8 text file with a combination of explicit font names or text with asterisk wildcards to match multiple fonts, listed one entry per line.

```
*Gothic* (any font name with Gothic in it)

Arial

Helvetica* (any font name beginning with Helvetica)

Open Sans
```

Default Fades

These settings define the curves of the default audio fades in Fairlight.

- **Fade In/Out:** Define the curve type for fade ins and outs.
- **Crossfades:** Define the curve type for the ins and out of the crossfade.

  Checkboxes for None, Equal Power, and Equal Gain for crossfade type.

Color

The settings in this panel govern different behaviors in the Color page.

General Settings

Affect a variety of behaviors while working in the Color page.

- **Master reset maintains RGB balance:** Defines how the DaVinci control panel trackball/ring reset buttons reset primary color adjustments. When this option is turned off (the default), pressing the ALL Reset button returns the primary correction values to their default values. When this checkbox is turned on, then pressing the ALL Reset button (a) resets the YRGB values so that the overall values are kept and the ratio of YRGB to each other is maintained, and (b) pressing the RGB Reset button sets the three color channels to the average of what they were previously set to.
- **Wipe wraps when viewing reference stills:** Turning this on (the default) lets stills wrap around the edge of the screen while you're adjusting the wipe using the mouse, rather than stopping at the screen's edge. If you find this behavior awkward when trying to quickly create full-frame comparisons with stills to flip on and off, it can be disabled.
- **High-Visibility Power Window Outlines:** Turning this on sets Power Window outlines to be drawn as green (for the center shape) and yellow (for the softness shapes), to make these windows easier to see in certain circumstances, instead of the default white and gray.
- **Mattes display high contrast black and white:** When enabled, the HILITE command, which displays the current key, shows a black and white matte (i.e., high contrast) rather than the standard gray matte.
- **Next scene switches to visible track:** When grading a project with multiple tracks, you can use this option to alter the "next scene" command to work better in projects with multi-clip composites. With this option turned off, pressing NEXT SCENE on the DaVinci control panel, or using the

Down Arrow keyboard shortcut, moves the playhead to the very next clip in the Thumbnail timeline, regardless of whether it's in front of or behind another clip. Turning this option on causes the NEXT SCENE command to move the playhead to the clip in the highest track if the next clip is part of a multi-clip composite with multiple clips stacked over one another.

- **Previous or Next node navigates only to correctors:** Node navigation only selects corrector nodes and bypasses mixer, splitter and combiner nodes, etc.
- **Preserve node numbers when adding nodes:** Checking this box increments the node numbering by the order in which they are created, regardless of its position in the node tree. Unchecked reflows the node numbering automatically based on the node's position in the tree.
- **Always perform copy and paste on selected nodes:** Bypasses the interface focus-based selection for copying and pasting full grades vs. individual nodes. When checked, DaVinci Resolve will only copy and paste between selected nodes regardless of the interface focus.
- **Use Legacy Auto Color:** As of DaVinci Resolve 16, the A button in the Color Wheels palette and the Shot Match command available from the Thumbnail Timeline contextual menu both now use advanced algorithms, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. This checkbox lets you set the A button to use the older algorithm instead.
- **Use Legacy Shot Match:** As of DaVinci Resolve 16, the Shot Match command available from the Thumbnail Timeline contextual menu uses an advanced algorithm, based on the DaVinci Neural Engine, to provide superior results when automatically adjusting color balance and contrast. This checkbox lets you set the Shot Match command to use the older algorithm instead.
- **Histogram Background on Grading Tools:** This dropdown menu lets you turn the histogram that appears in the background of the Curves palette either Off, On based on the node's Input (changes made to the curve do not affect the background histogram), or On based on the node's Output (changes made to the curve do affect the background histogram).
- **Automatically cue x frames into timeline clips:** This setting affects the operation of the NEXT SCENE and PREV SCENE commands in the Color page. The default cue point when moving from one clip to the next is the first frame of each clip. Entering a value, in frames, in this field sets the default cue point to the specified number of frames after the first frame of each clip you move the playhead to. This can be convenient if the source material has black or camera rollup flashes at the beginning of every clip while you're trying to grade dailies.
- **Neighboring Clips in Split Screen:** Lets you choose how many neighboring clips next to the current clips are shown in a grid in the Color page Viewer when you turn on the Neighbor Clips option of the Split-Screen shot comparison control.
- **Switching clips:** (this setting can also be changed from the Option menu in the Node Editor) When switching clips, DaVinci Resolve can switch to the same or another node in the node graph. The four options below determine which node is selected:

  Selects last adjusted node: The default setting, where each clip in the Timeline retains its own independent node selection that's remembered whenever you move back to that clip.

  Selects first node: The first node is always selected when you move to another clip.

  Selects last node: The last node is always selected when you move to another clip.

  Selects same node: If the clip you've moved to has as many or more nodes as the last clip, the node of the same number will be selected. If the clip you've moved to has fewer nodes than the last clip, the next highest node will be selected.

- **Color picker:** Changes the way that colors are selected when using the Secondary color correction controls. DaVinci Resolve is the normal and modern mode, however some colorists who are familiar with the legacy 2K prefer the DaVinci 2K mode.

Ripple Mode

This setting determines the behavior of the Ripple command that's initiated in the Color page.

- **Target clips are set to:** The Ripple mode that's used when you select a Ripple command in the Color page, either using the RIPPLE button on the Advanced Panel, or selected from the Color menu.

  Exact values changed: Changes made to the current clip are rippled to the specified clips using the exact parameters that were changed. For example, if the Master Gain level in the current clip is changed to 0.75 of its range, each clip you ripple will have a Master Gain level of 0.75. Only parameters you adjust are rippled.

  Percent value changed: Changes made to the current clip are rippled to the specified clips by the percentage of change you made to the altered parameters. For example, if the current clip has a Master Gain level of 1.00 and is changed to 0.90 units, then the Master Gain level of each clip you ripple will have a relative reduction of 10% relative to its previous value.

  Unit values changed: Changes made to the current clip are rippled to the specified clips by the same delta of change, using whichever units make sense for the affected parameter. For example, if the current clip had a Master Gain of 0.80 and you increased it to 0.90, each rippled scene's Master Gain level increases by 0.10.

  All values are copied: The current clip's grade is rippled to the specified clips in its entirety. No comparison is made with the original clip's parameters, and all memory parameters are rippled.

Printer Light Step Calibration

For film projects, when you have tight integration with a film lab, it is possible to adjust the printer light calibration sets to match the lab you are using. You should work with your lab technician to set up the Lab Aim settings, the Steps adjustments, which is an incremental value, and the Density Increment adjustment, which is the amount of correction applied within each step. Usually, the Step and Density values will be identical, but this will be up to your lab and your preference.

Fairlight

Video I/O Offset

The two preferences found in this section let you offset overall video playback up to 7 frames earlier than your audio playback, to account for situations where image processing applied to your video output is causing delays that make the video out of sync with your audio. For example, let's say your video output is going through a video convertor that adds a 1 frame delay, and then connects to a video projector that adds another 1 frame of delay. You can set your Video Monitor Offset to 2 frames to compensate, so the audio/video sync is solid.

- **Video Monitor Offset:** This dropdown menu lets you choose an offset from 0 to 7 frames.
- **Apply Offset during Jog and Shuttle:** Turning this checkbox on ensures that the offset you choose is also applied when you use Jog and Shuttle to move through your program.

General Settings

The two preferences found in the General Settings section both let you customize the Loop Jog behavior that's currently available only on the Fairlight page. Choosing Timeline > Loop Jog enables a brief sample preview to be heard while scrubbing the playhead through the Timeline. This can make it easier to recognize bits of dialog or music as you're quickly scrubbing through tracks, in situations where you're trying to locate specific lines or music cues. It also enables this brief sample preview to loop endlessly when you hold the playhead on a frame, so you can pause while scrubbing and hear (by default) the current 80 ms prior to the playhead as it loops. A pair of settings let you customize this behavior.

- **Loop Jog Alignment:** Three options let you choose whether you loop audio Pre the position of the playhead, Centered on the playhead, or Post the position of the playhead.
- **Loop Jog Width:** A field lets you choose how many milliseconds of audio to loop when Loop Jog is enabled. How many milliseconds of audio corresponds to one frame depends on the frame rate of the video. For example, at a frame rate of 25 fps, there are 1000/25 = 40 ms per frame, so the default value of 80 ms equals two frames of looping.
- **Enable auto patching:** Checking this box routes the first of your system audio inputs to the track that has "arm for record" on.
- **Mixer follows selected track:** Checking this box ensures that the selected track appears focused and left-most in the Mixer pane.
- **Include mixer events in Undo history:** Checking this box ensures that you can undo mixer events (such as edits to panning or track mute state).

Automation

The two preferences found in the Automation section let you customize the Glide Time between Automation events and whether or not Automation events are included when recalling a preset or when copying and pasting.

- **Glide Time:** Enter a value in milliseconds to customize the Glide Time for automation.
- **Write on Preset or Clipboard Paste:** Checking this box ensures that Automation events are written to the track when recalling a track preset or copying and pasting. Note that when enabled, the information written is still dependent on the status of what master automation is enabled or disabled. For example, if plugin automation is disabled, no plugin automation will be written.

Playback Settings

These preferences let you improve realtime performance in DaVinci Resolve by disabling specific UI features and optimizing the quality of some operations.

- **Hide UI overlays:** When using a single GPU for both display and CUDA, OpenCL, or Metal processing, or if your display GPU is underpowered, or if you lack the PCIe bandwidth required for the currently specified resolution or frame rate, you may be able to improve real time performance by turning this option on. When enabled, onscreen controls such as the cursor, Power Window outlines, and split-screen views are disabled and hidden during playback. When playback is paused, all onscreen controls reappear.
- **Minimize interface updates during playback:** When enabled, gives priority to real time performance during playback by reducing user-interface updates. This is helpful when you're creating complex grades on systems with low processing power, or when working on projects at high resolutions.
- **Performance Mode Automatic / Manual / Disable:** A trio of radio buttons let you choose between Automatic (default) and Manual (user selectable) behaviors when you turn on Performance Mode in DaVinci Resolve, or you can turn Performance Mode Off altogether. Set to Automatic, Performance mode automatically optimizes a variety of operations in a bid to balance performance with the necessary level of image quality, for fast onscreen performance while always maintaining the highest level of quality for video output. Set to Manual, there are three different settings you can choose to disable for instances where a particular performance tradeoff Resolve is making results in an undesirably noticeable reduction in image quality in Performance Mode:

  Optimized Sizing: Relates to how image resizing is handled.

  Optimized Decode Quality: Relates to how clip resolution vs. timeline resolution is handled.

  Optimized Image Processing: Relates to how image processing operations are handled.

Control Panels

The parameters in this panel let you customize the functionality of the DaVinci Control panels.

Panel Sensitivity

Lets you choose the orientation of red on the trackballs, how sensitive trackballs and rings are, and how sensitive the qualifier knobs are.

- **Classic DaVinci trackball alignment:** When enabled, this checkbox sets all color balance controls in DaVinci Resolve to the traditional orientation they've always used, which is close to, but not exactly the same as, the vectorscope alignment of hues. When disabled, the alignment of color balance controls is exactly the same as the vectorscope alignment of hues, which is similar to how other color grading applications work. You should choose the mode you're most familiar with.
- **Grading style:** Controls the orientation of the trackballs relative to the corrections they make. There are two options:

  DaVinci: Most users will be familiar with the standard DaVinci controls as this mimics the vectorscope (how closely depends on the Classic DaVinci trackball alignment setting).

  Rank: The Rank settings are somewhat different, so this option is for users who are familiar with color controls that the Rank control system offered. In this mode, the orientation of red and green are reversed.
- **Lift RGB balance:** Controls how quickly adjustments made to the Lift trackball (on the left) will adjust the Lift Color Balance parameters in the Color page. This setting affects third-party panels.
- **Lift master:** Controls how quickly adjustments made to the Lift ring (surrounding the leftmost trackball) will adjust the Lift Contrast parameter in the Color page. This setting affects third-party panels.
- **Gamma RGB balance:** Controls how quickly adjustments made to the Gamma trackball (second from the left) will adjust the Gamma Color Balance parameters in the Color page. This setting affects third-party panels.
- **Gamma master:** Controls how quickly adjustments made to the Gamma ring (surrounding the second trackball from the left) adjust the Gamma parameter in the Color page. This setting affects third-party panels.
- **Gain RGB balance:** Controls how quickly adjustments made to the Gain trackball (third from the left) will adjust the Gain Color Balance parameters in the Color page. This setting affects third-party panels.
- **Gain master:** Controls how quickly adjustments made to the Gain ring (surrounding the third trackball from the left) will adjust the Gain Contrast parameter in the Color page. This setting affects third-party panels.
- **Cursor offset:** Controls how quickly adjustments made to the fourth trackball affect the cursor, window position, log-mode offset, and other controls that can be manipulated via this trackball.
- **Cursor master:** Controls how quickly adjustments made to the fourth ring affect log-mode master offset, and other controls that can be manipulated via this ring.
- **Hue/Saturation/Luminance qualifier:** Controls the sensitivity of the HSL panel control knobs.
- **Jog:** Controls the sensitivity of the jog wheel.
- **Shuttle:** Controls the sensitivity of the shuttle dial.

Display Settings

Lets you adjust the display of your Blackmagic Design control panels.

- **LCD brightness:** Controls the overall brightness of the DaVinci control panel displays.
- **Key backlighting:** Depending on which control panel you have selected, two controls let you choose LCD Brightness and Key backlighting of the DaVinci Resolve Mini panel, or three controls let you adjust the color balance of the lit buttons of the DaVinci Resolve Advanced control panel (the default is red).

Metadata

The metadata panel lets you create custom sets of metadata parameters that will be exposed in the Metadata Editor.

> For more information on using this panel, jump to this chapter: jump to this chapter: Using Clip Metadata.

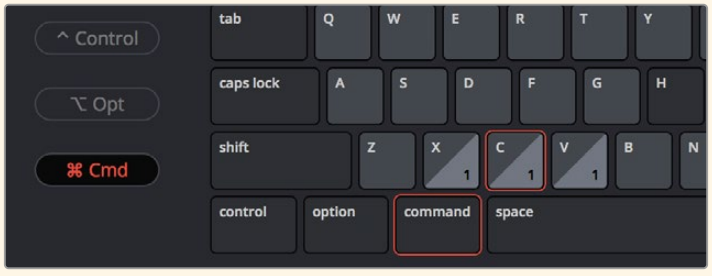
Keyboard Customization

Choosing DaVinci Resolve > Keyboard Customization opens the standalone Keyboard Customization window. This window lets you choose which set of keyboard shortcuts you want to use, discover which keyboard shortcuts are available, or create your own custom keyboard mappings that more closely adhere to the way you like to work, in whichever pages you find yourself working.

The Keyboard Customization window

Choosing Keyboard Shortcut Emulation Presets

Using a dropdown at the top right of this menu, you can choose the default DaVinci Resolve set or any one of the other sets that attempt to mimic other NLEs you might be more familiar with. Please note that keyboard shortcuts can only be remapped to commands that functionally exist within DaVinci Resolve, so if a specific feature of another NLE does not have an equivalent in DaVinci Resolve, that key shortcut may not be mapped in the same way. Fortunately, the editorial feature set of DaVinci Resolve broadly overlaps with common features in other NLEs, so you should find that most features you're used to have a functional equivalent.

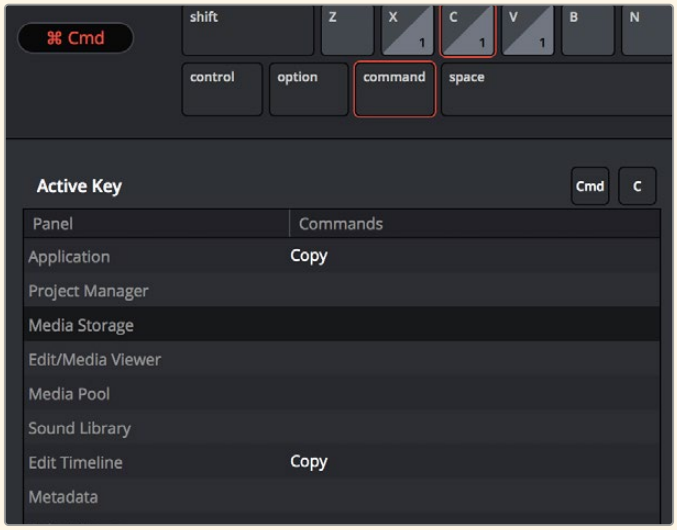


You can choose one of the preset keyboard mappings to emulate another NLE you're familiar with or the default DaVinci Resolve keyboard mapping.

You also have the ability to create your own custom sets of keyboard shortcuts. The Commands list below shows a hierarchical list of commands organized by the menu they appear within. This list lets you select individual commands to remap and can be searched if you're having a hard time finding what you're looking for. This is described in more detail later in this section.

Viewing Commands Assigned to Specific Key Combinations

To see what command a particular key of the keyboard is mapped to, you can click any combination of modifier and other keys on the virtual keyboard at the top of this window. The currently selected keys reveal how they're mapped in the "Active Key" list below.



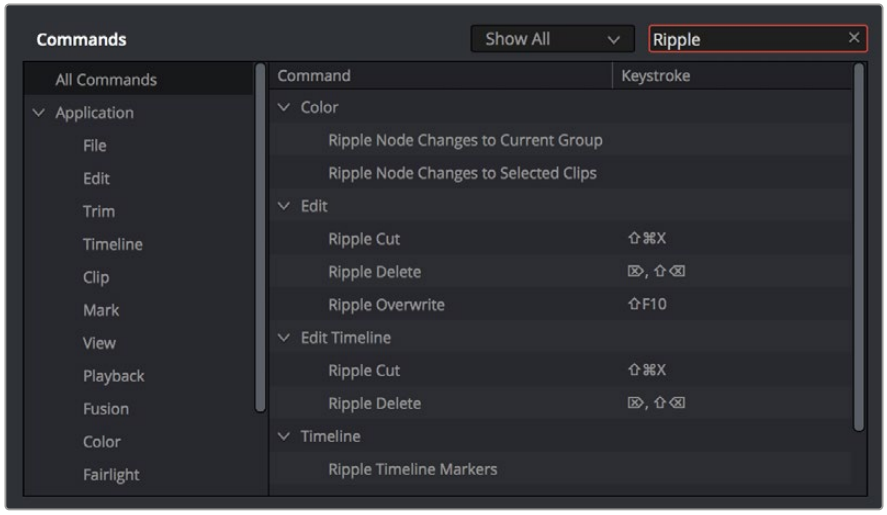
Selecting keys and modifiers on the virtual keyboard displays their command mapping below

TIP: Starting in DaVinci Resolve 15.2, commands can have multiple keys or key combinations assigned to them, and number keys on the numeric keypad of an extended keyboard can be assigned independently from keys at the top of a keyboard.

Panel-Specific Keyboard Mappings

When customizing keyboard shortcuts, they can be assigned to the “Application” so that shortcut works identically within every part of the DaVinci Resolve UI that’s applicable, or you can map a particular keyboard shortcut to do a particular command within a specific panel.

Keyboard shortcuts can now be mapped to specific panels so that different panels can use the same shortcut to accomplish different things



Panel-specific keyboard shortcuts let you use a single key to do different things depending on which panel has focus; for example, one key can do different things in the Media Pool, the Edit Timeline, the Metadata Editor, and the Sound Library, to give a few Edit Page examples. This provides enormous flexibility, but if you go this route, you need to be aware of which panel has focus. Fortunately, starting in DaVinci Resolve 15.2, focus is indicated by a colored highlight at the top of each panel.

Searching for Keyboard Shortcuts

Whether you’re looking to see what keyboard shortcuts are available or looking for a particular command you want to customize, a Search field above the Commands list is available for searching whichever group of commands you want (including All Commands).

To search for specific keyboard shortcuts:

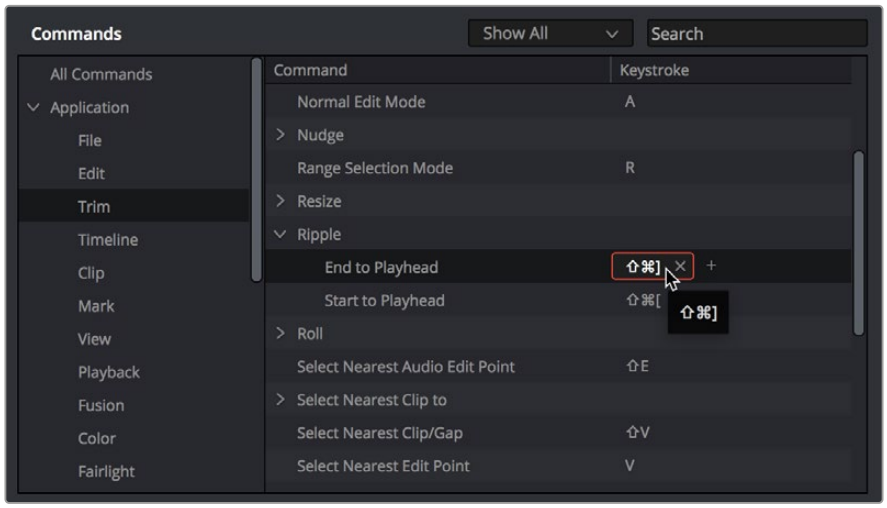
1. Choose DaVinci Resolve > Keyboard Customization.
2. Choose a command group from the Commands list to search within. If you want to search all of DaVinci Resolve, choose “All Commands.”
3. Type a term into the Search field, and the Command/Keystroke list will update to show whatever commands match the search criteria you’ve entered.

Selecting “All Commands” and searching for every keyboard shortcut corresponding to the word “ripple”

Managing Keyboard Mappings

DaVinci Resolve provides the following methods for creating and managing keyboard mappings in the Option menu of the Keyboard Customization menu:

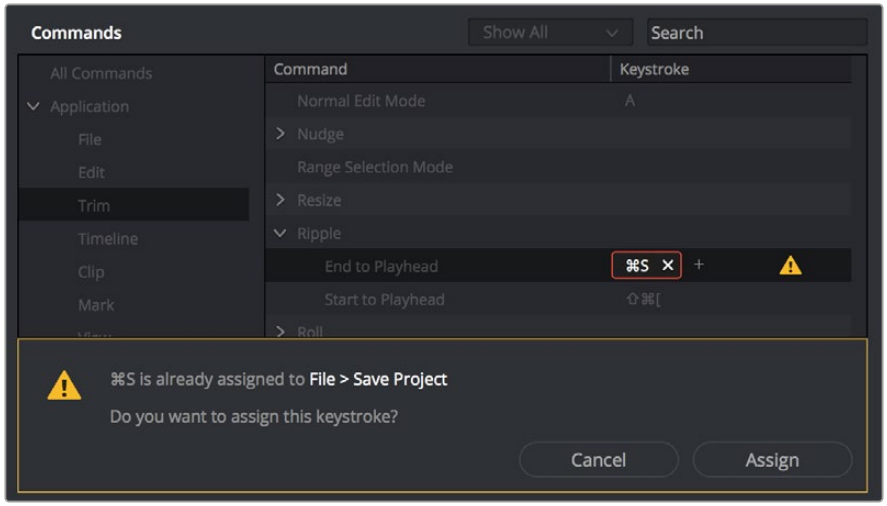
The Option menu of the Keyboard Customization window lets you export, import, and delete keyboard mappings



- **To create a new keyboard mapping:** Choose a keyboard mapping from the dropdown to use as your starting point, choose Save As New Preset from the Keyboard Customization Option menu, then enter a preset name in the dialog, and click OK. That preset will now appear in the preset dropdown menu.
- **To export a keyboard shortcut file for use by another DaVinci Resolve workstation:** Choose a preset from the Export Preset submenu of the Keyboard Customization Option menu, then choose a name and a location for the new file, and click Save.
- **To import a keyboard shortcut file:** Choose Import Preset from the Keyboard Customization Option menu, choose a DaVinci Resolve keyboard shortcut file, and click Open.
- **To delete a keyboard mapping:** Choose a keyboard mapping preset you want to delete, then click the trash can button.

Remapping a Command to One or More Keys

Changing the keyboard mapping for any given command is easy. You can even map a single command to multiple keys, if necessary. In DaVinci Resolve, actions can be application-wide or specific to Media Pool, or Timeline, or other panels. The right column in the key customization dialog shows application-level and panel-level actions. When a panel is in focus, hotkeys prioritize panel-local actions. This allows you to reuse the same key shortcut in the application level and within each panel at the same time.



To change the keyboard shortcut for a particular command:

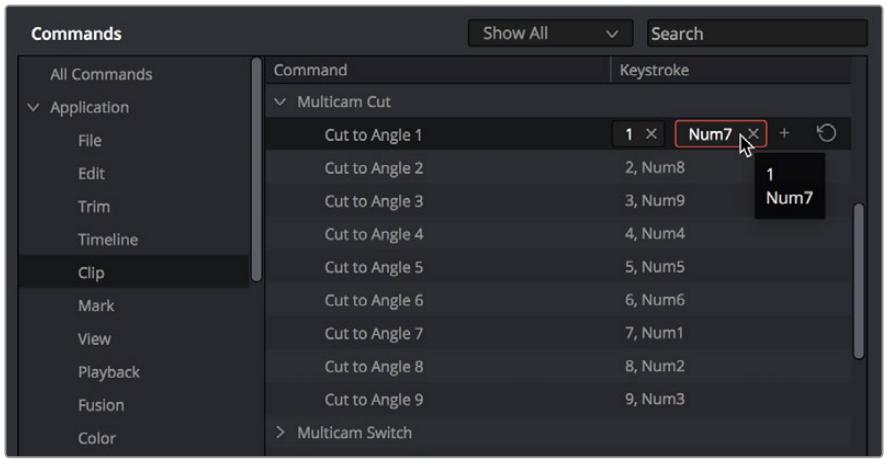
1. Find the command you want to remap in the Commands list by selecting a category. If necessary, use the Search field. Whether a command is mapped generally to the entire application or specifically to a particular panel depends on what you've selected from the list.
   a) If you want the keyboard character you plan to map to work application-wide, choose a menu name from underneath the Application category of the Commands list. Each menu shows all commands associated with it and can be individually searched.
   b) If you want the keyboard character you plan to map to this command to be specific to a particular panel, then choose one from the Panels category underneath. Each panel shows all commands associated with it and can be individually searched.
2. Click within the Keystroke column of the list, to the right of the command, and when a selection appears type a new character using any combination of modifier keys you like.

Clicking to select a keyboard shortcut you want to modify

Please note that if you remap a key that was already assigned to another command, you'll see a warning that the key you're about to remap is already assigned to another command, giving you a chance to cancel and change key assignments if you like.

The warning you see if you try to map the same key to multiple commands

You can override the warning and make the assignment, but having the same character or combination applied to multiple commands can cause problems, so a warning badge appears next to affected commands. Clicking on this badge makes it easy to see where the duplicate is by highlighting the keys on the keyboard, so you can remap one or the other command as necessary.



To resolve a shortcut conflict:

— Click the yellow warning icon next to the action. This shows all actions for that hotkey in the left panel.

— Click on the other conflicting actions at the same level to reveal them in the right pane.

— Change or unset these values so as not to conflict with your new key assignment.

3 (Optional) You also have the option of assigning multiple keyboard shortcuts to a single command. For example, if you want to use keys on the numeric keypad of an extended keyboard in addition to other keys for a particular command, you can now set this up by clicking the “plus” button to the right of a currently assigned keyboard shortcut. This makes another highlight appear, within which you can type any secondary character or combination you like to make the additional assignment. You can do this as many times as you like. When you’re done, all keyboard shortcuts applied to that command appear, separated by commas.

You can map multiple keys to the same command, if necessary

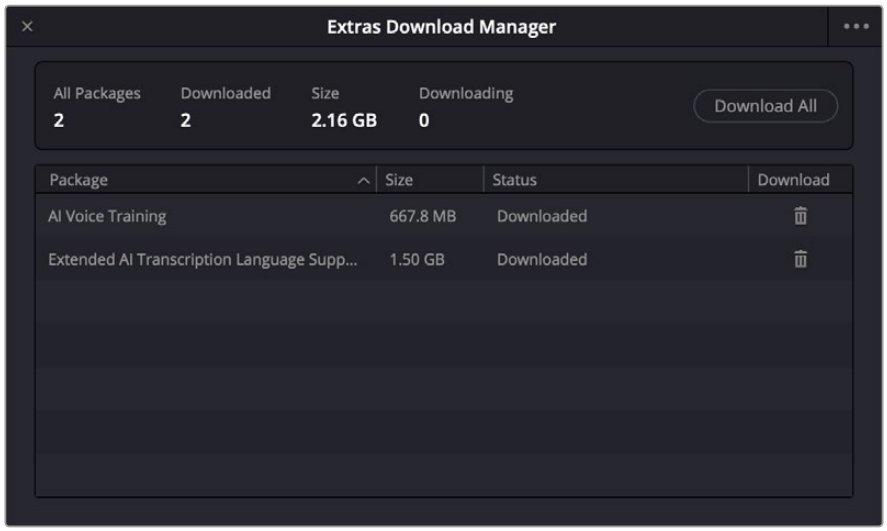
4 When you're finished changing keyboard shortcuts, click the Save button at the bottom right of the Keyboard Mapping list, and then click Close to close the window.

For example, if you set 'Option-G' to:

a) The Media Pool-specific Clip Attributes,

b) The application-wide Mark > Add Flag > Green to 'Option-G'.

When you are focused on the Media Pool, you cannot add green flags with a hotkey. You will need to manually add them via the Mark menu.



In addition, the application-wide Color > Nodes > Add serial node with polygon power window also has the same hotkey (Option-G), so action b will cause the the key customization dialog to show a warning with the conflicting action name and display an icon on both actions.

If you save this state as a preset (with conflicts), DaVinci Resolve will still try to parse your shortcuts logically. For example, on the Edit and Fairlight timelines, Option-G adds a green flag (as color node actions are not applicable). But in the Color page, Option-G can refer to both actions and the user needs to resolve the conflict to make the action work correctly.

DaVinci Resolve Extras Download Manager

As DaVinci Resolve evolves to incorporate more AI-based models, there is a tradeoff in application file size. These AI models tend to be large datasets that not all users will want or need to use. To help with this decision, DaVinci Resolve has the Extras Download Manager, allowing you to pick and choose which optional functionality you want to add to DaVinci Resolve.

The Extras Download Manager can be found at DaVinci Resolve > Extras Download Manager.

The Extras Download Manager

To use the Extras Download Manager, simply view the packages available and select download. You can remove a package in the same interface by clicking on the trashcan icon next to the package name. Downloads will happen in the background while you continue to work. From time to time these packages will be updated, and you will be notified here if your current package is out of date.

Currently, the Download Manager contains packages for AI Voice Training and Extended AI Transcription Support Languages.

Chapter 5

DaVinci Control Panels Setup

There are several hardware control interfaces that are dedicated to more efficient workflows for specific pages in DaVinci Resolve. The DaVinci Control Panels Setup app is where you connect and configure these hardware interfaces.

Contents

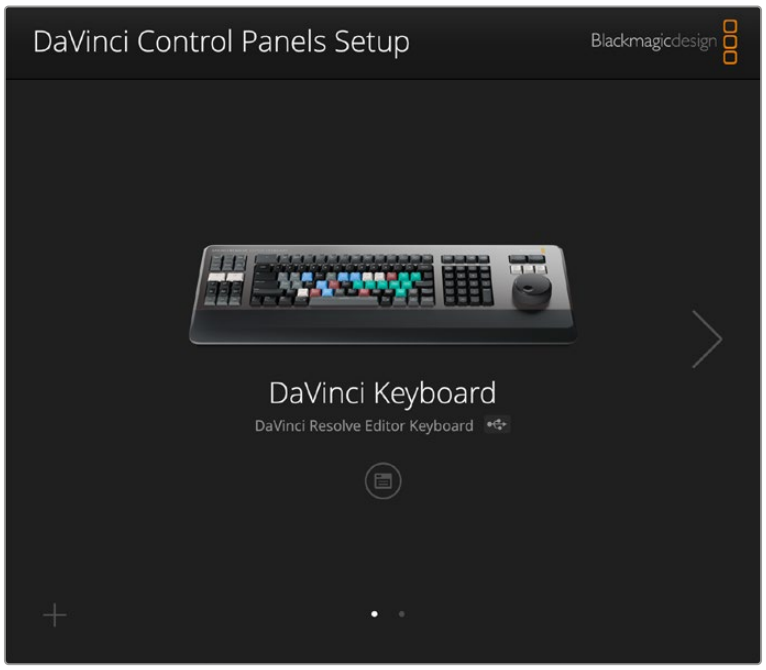
Connected Control Panels Popup 138

DaVinci Control Panels Setup

DaVinci Resolve has many different hardware interfaces designed to increase your efficiency when working within certain pages. Specialized keyboards, color control surfaces, and audio mixing panels can be connected to your system, and the DaVinci Control Panels Setup is where you configure these devices.

The DaVinci Control Panels Setup utility is a separate application automatically installed alongside DaVinci Resolve. You can access this program directly from within DaVinci Resolve by choosing Help > DaVinci Control Panels Setup, or you can launch the program from the DaVinci Resolve folder in your OS.

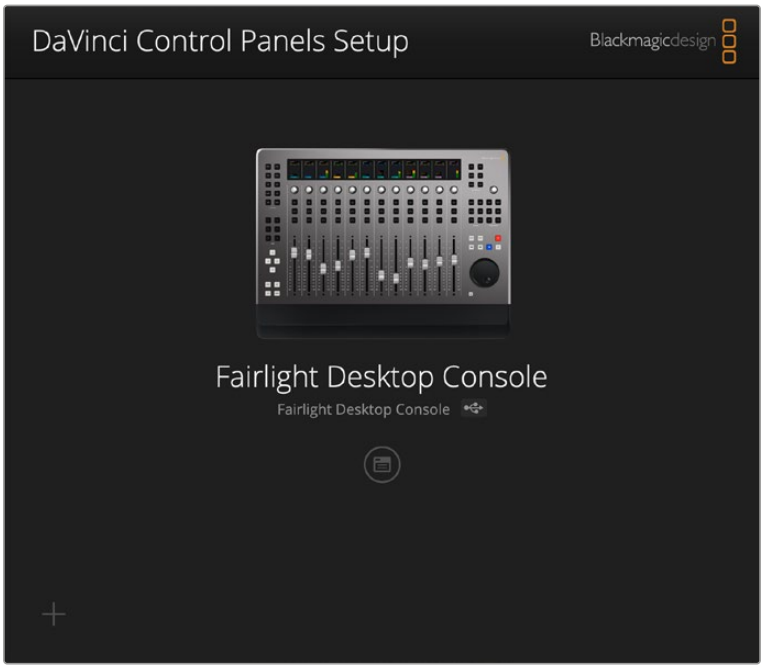


Make sure your hardware is connected and powered on before launching the application.

The DaVinci Control Panels Setup icon

DaVinci Control Panels Setup Layout

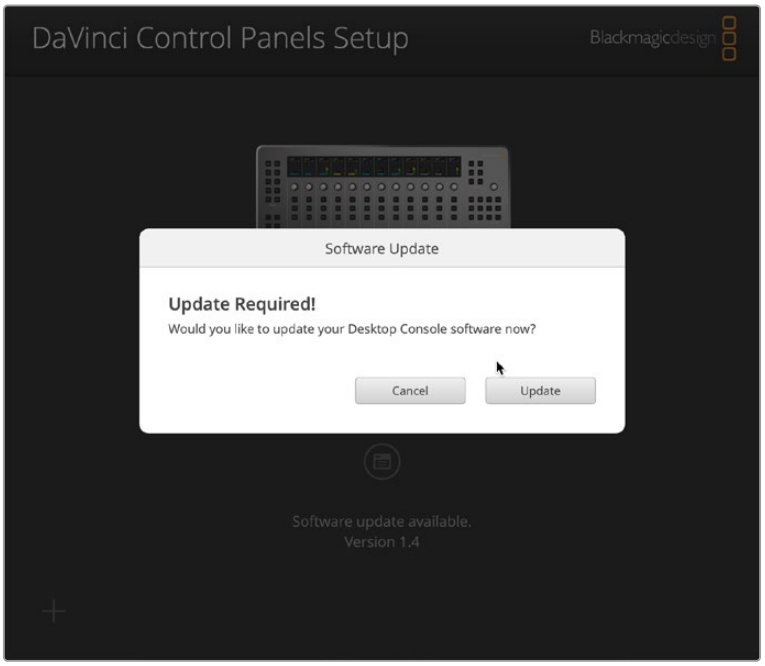
When you launch DaVinci Control Panels Setup, you will be presented with an interface showing you the detected hardware device on your system. If you have multiple hardware devices, you can scroll through them by clicking on the Left and Right Arrows on the sides of the window. If no devices are detected, the interface will tell you “No DaVinci control panels found.”



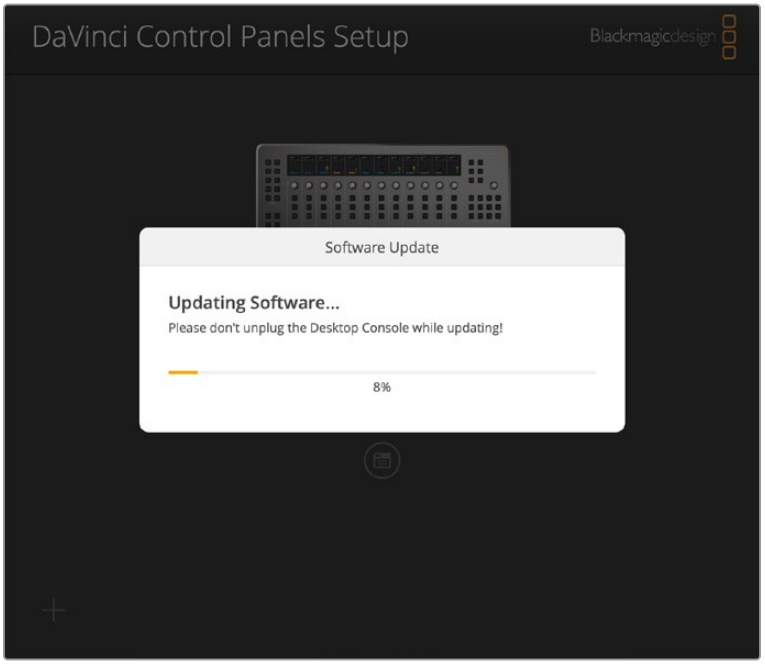
The DaVinci Control Panels Setup window showing a DaVinci Editor Keyboard attached. The two dots below and the triangle to the right show another device connected as well.

The DaVinci Control Panels Setup showing no detected hardware

Using DaVinci Control Panels Setup



The DaVinci Control Panels Setup presents a simple interface to connect to your devices, update their firmware, and modify their settings.



The DaVinci Control Panels Setup showing the Fairlight Desktop Console attached

Firmware

On startup, the DaVinci Control Panels Setup application will automatically check for any possible firmware updates for your device from the Blackmagic Design servers. If the application finds a newer firmware version it will ask you if you wish to update your device, or cancel and remain on your current firmware version. When updating it's important not to unplug or power-down the device during the process as that can cause firmware corruption. Firmware updates include bug fixes and are required, in some cases, to use your device with new features in DaVinci Resolve. It is recommended to always update your device to the latest firmware unless you have a specific reason not to.

The firmware update dialog box

The firmware updating

Ethernet Connection

If you are connecting your device via Ethernet, you may need to enter its IP address before it can be configured in DaVinci Control Panels Setup. To do so, click on the “+” icon in the lower left corner of the interface. An Add DaVinci Control Panel window will appear, allowing you to type in the device’s IP address. The device must be on the same Ethernet network as the computer you’re connecting it to.

You can manually add an Ethernet-connected device by typing in its IP address.

Settings

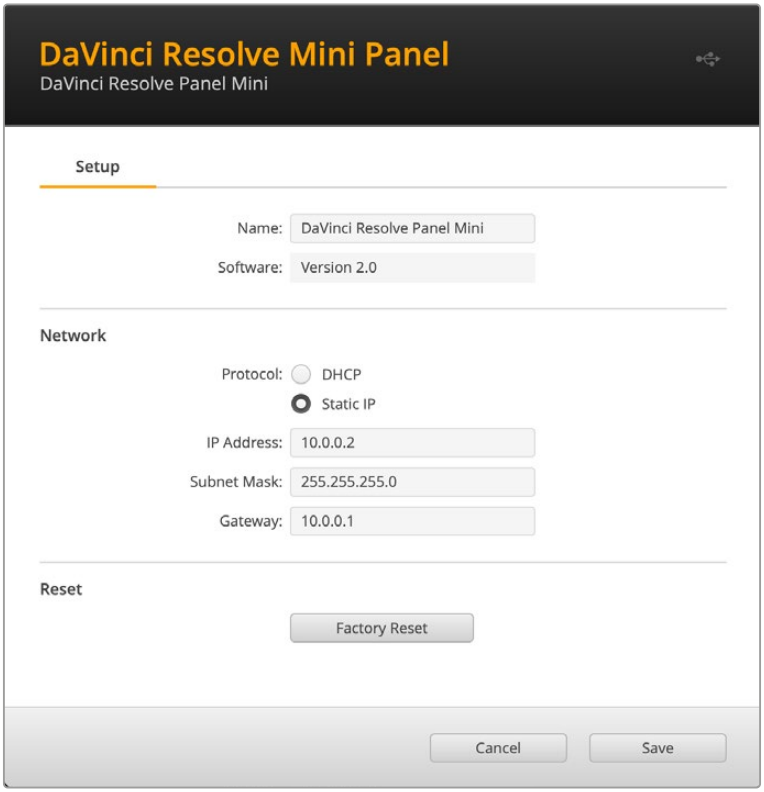
You can access your device’s settings by clicking on the setup icon directly below your device. Different hardware devices will have different settings, but generally they will be broken down into the following categories:

Setup

- **Name:** You can set a specific name for your hardware device to differentiate it in the interface and bluetooth selection preferences.
- **Software:** The current firmware version of the device.

Network

If your device has an ethernet connection, you can set up its networking settings. If you are new to networking, it is suggested that you leave the Protocol setting to DHCP, and let the computer figure it out. If you are part of a larger facility, you may want to consult with your IT department for the appropriate manual settings instead.



- **Protocol:** Choose whether you want the device’s IP address to be set automatically by DHCP or to provide your own manual static IP address below.
- **P Address:** You can manually assign the IP address for the device.
- **Subnet Mask:** You can manually assign the Subnet Mask for the device.
- **Gateway:** You can manually assign the Gateway address for the device.

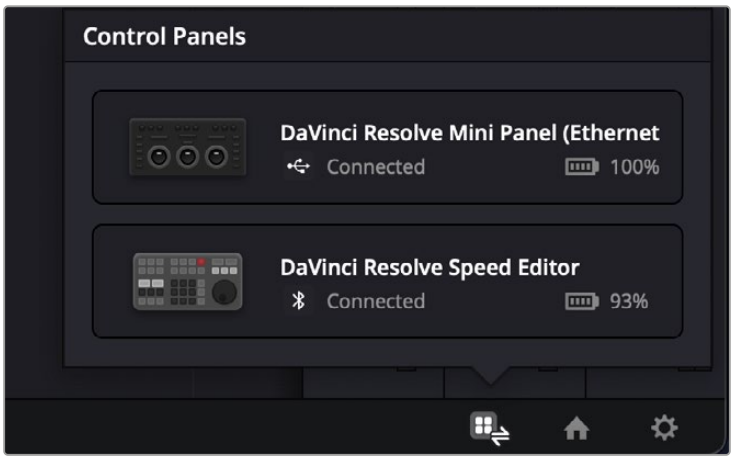
Reset

- **Factory Reset:** Resets your device back to the factory defaults. This maybe useful in some troubleshooting situations.

The DaVinci Control Panels Setup showing the DaVinci Resolve Mini Panel attached

The Settings for the DaVinci Resolve Mini Panel

Customizing Display Brightness Settings



You can adjust the display of your Blackmagic Design control panels by going to DaVinci Resolve > Preferences > User > Control Panels.

— **LCD brightness:** Controls the overall brightness of the DaVinci control panel displays.

— **Key backlighting:** Depending on which control panel you have selected, two controls let you choose LCD Brightness and Key backlighting of the DaVinci Resolve Mini panel, or three controls let you adjust the color balance of the lit buttons of the DaVinci Resolve Advanced control panel (the default is red).

Connected Control Panels Popup

In the lower-right corner of the DaVinci Resolve interface, you will find a Control Panels popup box. Clicking on this icon shows you all currently connected control panels, how they are connected, and their battery status.

The Control Panels popup

Chapter 6

Project Settings

This chapter covers the settings used for defining the properties of each individual project. It's a good idea to familiarize yourself with the information in this chapter prior to setting up your first project.

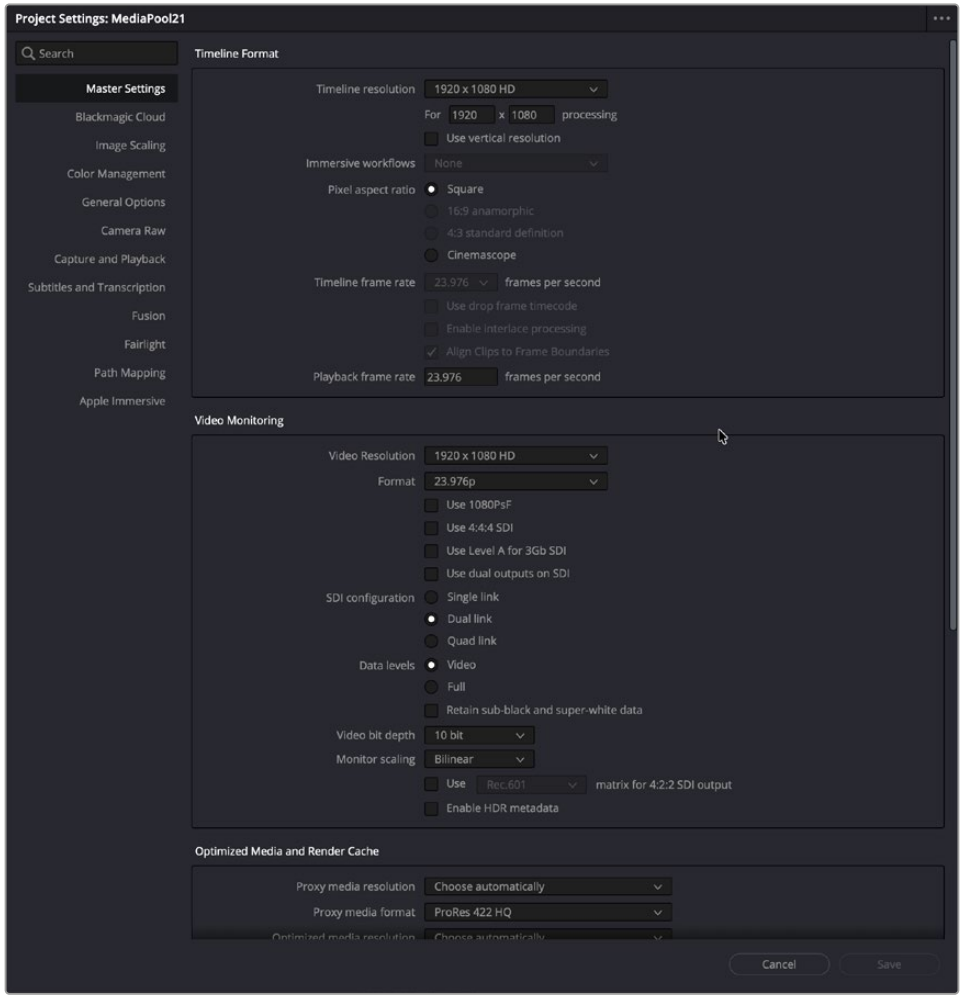
What Are the Project Settings?

The Project Settings window contains all project-specific parameters that are saved along with that project. These include essential project properties such as the timeline format, video monitoring settings, how to optimize media, and where to save cache files. It also includes image scaling properties, color management settings, and many other properties that affect projects in fundamental ways.



Opening and Editing Project Settings

All of these project-specific settings are easily accessed from anywhere in DaVinci Resolve by clicking the gear button at the bottom right of the page bar.

Project Manager and Project Settings buttons

The Project Settings window opens in the middle of the screen.

The Project Settings window.

The Project Settings window is divided into a series of panels which can be selected from a sidebar at the left. Each panel contains a collection of related settings that affects some category of DaVinci Resolve functionality.

To alter project settings:

1. Click on the name of any group of settings in the sidebar at the left to open that panel.
2. Change whatever settings you need to change.
3. Do one of the following to apply your changes:

   Click Save to apply the changes you've made and close the Project Settings.

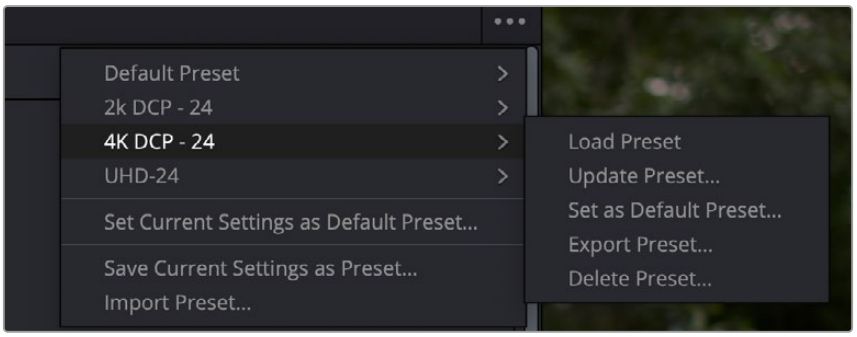
   Option-click Save to apply the changes you've made and keep the Project Settings window open, so you can make other changes. This option is available because it's sometimes necessary to keep the Project Settings window open as you continue making changes that may visibly affect the clips and timelines in your project.

Searchable Preferences and Project Settings

DaVinci Resolve has search bars in both the Preferences and Project Settings so you can easily locate a particular setting.

To search, type the setting name in the search bar. A list of possible matches will appear as you type. You can then click on a setting name, which takes you to its corresponding page. It will also briefly highlight the setting name, making it easier to locate.

Type the name of a setting in the search bar, then click on your chosen result from the list. This brings you to that setting's page and highlights it, making it easy to locate.



Presets

The Presets menu lets you save customized collections of Project Settings for future recall. Presets can save the state of nearly every parameter and setting in every panel of the Project Settings window, and make it easy to switch among different setups for different tasks, or to accommodate different types of projects.

The Presets menu is accessed by clicking on the option menu (three dots) in the upper-right corner of the Project Settings window. The Presets menu shows the following items:

- **Project Settings Presets:** The list of all current Project Presets is shown here, headed by the Default Preset.
- **Set Current Settings as Default Preset:** This option saves the current Project Settings as the new Default Preset.
- **Save Current Settings as Preset:** This option allows you to save the current Project Settings as a new preset that will show up in the menu list above.
- **Import Preset:** This option will open a file browser to let you import a DaVinci Resolve Project Settings Preset file. The extension for these files is .preset.

  You can use this menu to create, import, and export your own presets, adding as many as you need to accommodate the types of projects you work on.

The Presets Menu is accessed by clicking on the option menu of the Project Settings window

To create a new preset:

1. Do one of the following:
   - — Right-click a project in the Project Manager, and choose Project Settings from the contextual menu.
   - — Open any project, then open the Project Settings.
2. Use the different panels of the Project Settings window to alter whichever settings you need to. There's no need to save your changes as you go; you'll save them all at once later.
3. Click on the option menu (three dots) in the upper right-hand corner of the Project Settings window.
4. Select Save Current Settings as Preset.
5. Enter a descriptive name for your new preset in the dialog box, and press the OK button.
6. Your new preset name will now appear in the Project Settings Preset menu.

   Once you've created one or more custom presets, you can load them into a project at any time.

To load a preset's settings into a project:

1. Open a project with a preset you want to update.
2. Open the Project Settings window.
3. Click on the option menu in the Project Settings window.
4. Click on the Project Preset name you want to use for the open project.
5. Select Load Preset from the dropdown menu.

   The Project Settings will be updated to the new preset immediately. There is no undo for this function.

To update a preset:

1. Open the Project Settings window.
2. Use the different panels of the Project Settings window to alter whichever settings you need to update.
3. Click on the option menu in the Project Settings window.
4. Click on the Project Preset name you want to update.
5. Select Update Preset from the dropdown menu, and select Update from the dialog box.

   The preset will be replaced with your current settings. There is no undo for this function.

To set the default preset:

1. Select the preset from the Project Settings Presets list you want to be loaded each time you make a new project.
2. Click on the preset and select Set As Default Preset.

   or

1. Select "Set Current Settings as Default Preset" from the option menu of the Project Settings window to make whatever your project settings are currently the new default preset.
2. Select Update from the dialog box.

   The preset will be replaced with your current settings. There is no undo for this function.

To export a preset:

1. Click on the preset from the Project Settings Presets list you want to export.
2. Choose Export Preset from the dropdown menu.
3. Enter a name for the preset and where you want to save it in the file browser, and press Save.

   The DaVinci Resolve Project Settings Preset file will export to that destination with a ".preset" extension.

To import a preset:

1. Click on the option menu in the Project Settings window.
2. Select Import Preset.
3. Navigate the file browser to the DaVinci Resolve Project Settings Preset file you wish to import. The file will have a ".preset" extension. Press Open.

To delete a preset:

1. Click on the preset from the Project Settings Presets list you want to delete.
2. Choose Delete Preset from the dropdown menu.
3. Press Delete in the dialog box.

   The Project Settings will be deleted immediately. There is no undo for this function.

Master Settings

This panel is project specific and lets you set up and adjust the most essential properties of the timelines in your project, including the timeline format, video monitoring method, and conform options. In many workflows, you'll want to adjust these settings before getting started with your project.

By default, all timelines use these project-wide settings. However, beginning with DaVinci Resolve 16, you can optionally create timelines with individual Format, Monitoring, and Output Sizing settings. However, if you change a timeline to use "Basic Settings," then that timeline will mirror the project-wide options that are selected in the Project Settings.

Timeline Format

This group of settings affects the geometry and image processing of the current project.

- **Timeline resolution:** A dropdown menu that lets you choose a frame resolution preset to use for image processing while grading. DaVinci Resolve is resolution independent, so you can change the resolution at any time and all windows, tracks, sizing changes, and keyframe data will be automatically recalculated to fit the new size. For example, you can work on a 4K project while monitoring at HD resolutions if your room is only set up with an HD monitor, and then render the finished project at 4K resolution for final delivery. Alternately, you can downsize an HD project to an SD resolution to create another set of deliverables.

  For more information on Resolve's resolution independence, jump to this chapter: Sizing and Image Stabilization".

- **Frame size (Labeled "For X x Y processing"):** Lets you set resolutions not found in the "Timeline resolution" dropdown menu.
- **Use vertical resolution:** This checkbox swaps the horizontal and vertical pixels of the Timeline resolution. This lets you format your timeline vertically for display on smart phones, tablets, or televisions that are in an upright configuration for digital signage.
- **Pixel aspect ratio:** Used to select PAR settings for image formats that don't use the default square pixel format. You can apply a 16:9 anamorphic PAR, a 4:3 PAR for SD projects, or a Cinemascope ratio.
- **Timeline frame rate:** Determines the primary frame rate used by the project. A variety of standard and high frame rate (HFR) settings are available. If you're importing an AAF or XML file, this setting is automatically set via an option in the Project Import dialog. Ideally, you should choose a frame rate before importing media into the Media Pool. However, the first time you import media into an empty Media Pool, you're prompted if the incoming media frame rate doesn't match the Timeline frame rate set here, and you have the option of automatically updating this setting to match that of the media you're importing. Once one or more files have been added to the Media Pool, this setting cannot be changed.
- **Use drop frame timecode:** Enables or disables drop frame timecode for the current project. Off by default.
- **Enable interlace processing:** Interlaced media is supported throughout DaVinci Resolve. The "Enable interlace processing" checkbox forces DaVinci Resolve to process all operations internally using separated fields, in order to properly maintain the field integrity of interlaced clips in your program. In addition, each clip in the Media Pool has a Field Dominance dropdown menu in the Video panel of the Clip Attributes window that lets you specify whether clips are upper- or lower-field dominant; an Auto setting makes this choice by default.

There is also a corresponding checkbox in the Render Settings panel of the Deliver page, named “Field rendering,” that lets you enable and disable field rendering when you’re rendering file-based output.

There are two instances where you want to leave this setting turned off:

— If you’re working with progressive-frame media, it is not necessary to turn this checkbox on. Doing so will unnecessarily increase processing time.

— If you’re using interlaced clips in a progressive-frame project and you’re intending to deinterlace those clips using the Enable Deinterlacing checkbox in the Clip Attributes window, then you must keep “Enable video field processing” off. Otherwise, the Enable Deinterlacing checkbox will be disabled for all clips.

For more information about deinterlacing clips, jump to this chapter: Modifying Clips and Clip Attributes.

If you’re working on a project with interlaced media that you intend to keep interlaced, then whether or not it’s necessary to turn field processing on depends on what types of corrections you’re applying to your clips. If you’re mastering your program to an interlaced format, and you’re applying any adjustments that would cause pixels from one field to move or bleed into adjacent fields, then field processing should be enabled; effects requiring field processing include filtering operations such as blur, sharpen, and OpenFX operations, as well as sizing transforms that include pan, tilt, zoom, rotate, pitch, and yaw.

On the other hand, regardless of whether you’re outputting interlaced or progressive-frame media, if you’re not filtering or resizing your clips, and you’re only applying adjustments to color and contrast, it’s not necessary to turn on field processing for interlaced material, and in fact, leaving it off may somewhat shorten your project’s rendering time.

- **Align Clips to Frame Boundaries:** When working with interlaced material, you can chose whether to perform edits at the field or frame boundaries. When checked this means all editing actions and playhead stepping will occur at full frame boundaries. This works independently of the audio subframe controls, so it’s still possible to get perfect audio sync while working with video at the frame level. When unchecked, all editing actions and playhead stepping will be performed at the field boundary instead.
- **Playback frame rate:** Usually mirrors the frame rate selected in the “Video format” setting (in the Video Monitoring section below), which is typically based on the frame rate of the external display that’s connected to your video interface, given the “Timeline Frame Rate” setting. For example, a 50Hz monitor requires a 25 fps playback frame rate for synchronous display without dropped frames. If you want to monitor playback at a slower frame rate, type the frame rate of your choice in this field and DaVinci Resolve will make the appropriate calculations to drop or repeat frames as necessary to match it. This can be useful for temporarily seeing how clips look in slow motion.

Video Monitoring

The settings available in this group control the signal that’s output by the video output interface that’s connected to your workstation, and let you specify what standard of signal is output, and via which signal path.

By default the frame size and frame rate match those in the Timeline resolution and Playback frame rate options. However, if necessary you can change these settings to match those of the external display you’re using to monitor your work. For example, if you’re working with 2K files for 2K output, but you’re color correcting using a high definition monitor set to 1080 resolution, you can select the appropriate HD standard for that monitor without changing the Timeline Resolution settings.

- **Video Resolution:** Lets you choose a standard video frame size to be output via your connected video output interface.
- **Format:** Lets you choose a standard video frame rate to be output via your connected video output interface.
- **Video connection checkboxes:** Lets you choose the signal standard to output from your connected video output interface to the video monitor. Make sure to choose a standard that's supported by both your video interface and your monitor.

  The options are:

  Use 1080PsF: Output progressive video in 1080i format for older HDTV sets.

  Use 4:4:4 SDI: A signal path for monitoring image data to monitors that supports 4:4:4 chroma sampling, typically over SDI connections.

  Use Level A for 3Gb SDI output: A signal path for monitoring image data via a single 3 Gb/s SDI connection.

  Use dual outputs on SDI output: All DaVinci Resolve systems can generate a side-by-side display that can be sent to a Stereoscopic monitor via the HD-SDI output of an UltraStudio 4K or DeckLink card. When dual SDI 3D monitoring is enabled, each eye is output separately at full resolution. In this mode, split-screen wipes and cursors will not be visible on the grading monitor.
- **SDI Configuration:** Lets you choose from among Single Link, Dual Link, and Quad Link SDI, depending on what your display supports.
- **Data Levels:** This setting only affects the data levels being output via the video interface that connects the DaVinci Resolve workstation to your external display. It has no effect on the data that's processed internally by DaVinci Resolve, or on the files written when you render in the Deliver page. It is imperative that the option you choose in DaVinci Resolve matches the data range to which your external display is set. Otherwise, the video signal will appear to be incorrect, even though the internal data is being processed accurately by DaVinci Resolve.

  There are two options:

  Video: This is the correct option to use when using a broadcast display set to the Rec. 709 video standard.

  Full: If your monitor or projector is capable of displaying "full range" video signals, and you wish to monitor the full 10-bit data range (0–1023) while you work, this is the correct option to use.

  For more information about data levels, jump to this chapter: Data Levels, Color Management, and ACES.
- **Retain sub-black and super-white data:** Turning this checkbox on lets DaVinci Resolve output the undershoots (sub-black) and overshoots (super-white) within the headroom of video encoded data levels to video. When this is turned off, these out-of-bounds values are clipped in video output.
- **Video bit depth:** Choose the bit depth that corresponds to the capability of your display. You can choose between 8-bit and 10-bit. Monitoring in 10-bit is more processor intensive, but preferable to avoid the appearance of banding that may not in fact be in the image data being processed by DaVinci Resolve.
- **Monitor scaling:** Defaults to basic, and is only enabled to smooth the edges of video being viewed on a projector with very large screens. These settings minimize high frequency artifacts that may be seen. This may also be noticeable if you have a 2K or HD project but are monitoring on an SD monitor. The other option, Bilinear, has different effects on the monitored image depending on your display device, so you may need to check to verify that it's appropriate for your environment.

- **Use Rec601 Matrix for 4:2:2 SDI output:** Don't use this checkbox unless you know what it does. You know who you are.
- **Enable HDR metadata:** (only available in Studio version) Turning on this checkbox outputs the metadata necessary to send High Dynamic Range signals over HDMI 2.0a and have it be correctly decoded by an HDR-aware video display. When this checkbox is enabled, it's recommended to also enable the "HDR mastering is for X nits" checkbox in the Color Management page, and set the "nit" level (slang for cd/m2) to whatever peak luminance level your HDMI connected HDR display is capable of.

Optimized Media and Render Cache

These settings govern the resolution and codec of optimized media that DaVinci Resolve can generate in order to facilitate greater real time performance, as well as cached media that's generated by the Smart and User Cache.

- **Proxy media resolution:** A dropdown list lets you choose whether to generate proxy media at each clip's Original size, or at Half, Quarter, One-Eighth, or One-Sixteenth the resolution of the original media, or allow DaVinci Resolve to choose this automatically for you based on your timeline settings.
- **Proxy media format:** Specifies the format in which proxy media files will be written. You can choose from among a variety of Uncompressed, ProRes, and DNxHD formats, depending on your requirements.
- **Optimized media resolution:** A dropdown list lets you choose whether to generate optimized media at each clip's Original size, or at Half, Quarter, One-Eighth, or One-Sixteenth the resolution of the original media, or allow DaVinci Resolve to choose this automatically for you based on your timeline settings.
- **Optimized media format:** Specifies the format in which optimized media files will be written. You can choose from among a variety of Uncompressed, ProRes, and DNxHD formats, depending on your requirements.
- **Render cache format:** Specifies the format in which render cache files will be written. You can choose from among a variety of Uncompressed, ProRes, and DNxHD formats, depending on your requirements.
- **Enable background caching after X seconds:** Specifies the duration of inactivity after which automatic background caching will begin.

  A series of checkboxes let you force specific types of effects to be cached when you use the User Cache, which is a more selective manner of caching than the Smart Cache. These include:

  Automatically cache transitions in user mode: If you're using User mode and you find that your workstation does not have adequate performance to play transition effects in real time, you can force these categories of effects to be automatically included in the Sequence Cache and cached when you're using the User mode of caching.

  Automatically cache composites in user mode: If you're using User mode and you find that your workstation does not have adequate performance to play composite mode or opacity effects in real time, you can force these categories of effects to be automatically included in the Sequence Cache and cached when you're using the User mode of caching.

  Automatically cache Fusion effects in user mode: If you've created effects for a clip in the Fusion page and you find that your workstation does not have adequate performance to play that clip in real time, you can force these categories of effects to be automatically included in the Sequence Cache and cached when you're using the User mode of caching.

Working Folders

These fields let you specify to which folders cache and gallery files are written.

- **Project media location:** Lets you choose a specific folder on your system to hold all generated media created for that project. Generated media includes things like new audio files created from the Voiceover tool and Voice Convert, or essentially any type of new media created by DaVinci Resolve itself. This allows you to make sure all the media for a project is in one common location, making it easier to hand off, move or relink media, rather than have some media in DaVinci Resolve's internal file structure and some on a media drive. DaVinci Resolve will automatically create new subfolders at your chosen media location based on media type, which makes it easy to send some or all generated media to another location.

  You can also set this location in the Create New Project dialog when creating a new project.

Inside the project media location, DaVinci Resolve will create subfolders automatically to organize any media generated from within the program.

- **Proxy generation location:** All proxy media files that you create are saved in the directory path specified by this field.
- **Cache files location:** All render cache files that you create are saved in the directory path specified by this field. This path defaults to a hidden "CacheClip" directory that's created at the location of the first Media Storage Volume you specify in the DaVinci Resolve Preferences window.
- **Gallery stills location:** By default, all stills you save are saved in the DPX format, and are placed in the directory path specified by this field. This path defaults to a hidden ".gallery" directory that's created at the location of the first Media Storage Volume you specify in the DaVinci Resolve Preferences window.

> **NOTE:** If the volume you've selected to use for the cache becomes unavailable, DaVinci Resolve will warn you with a dialog.

Frame Interpolation

These settings determine the default state for all retiming and speed change effects, including when clips are in mixed frame rate timelines.

- **Retime Process:** This dropdown menu lets you choose a default method of processing clips that don't match the project frame rate in mixed frame rate timelines and clips with speed effects (fast forward or slow motion) applied to them, throughout the project. Since each clip in every timeline defaults to "Project Settings," changing this setting will change the way most mixed frame rate and speed effected clips will be processed, except for those with custom settings selected.

  There are three options:

  Nearest: The most processor efficient and least sophisticated method of processing; frames are either dropped for fast motion, or duplicated for slow motion.

Frame Blend: Also processor efficient, but can produce smoother results; adjacent duplicated frames are dissolved together to smooth out slow or fast motion effects. This option can provide better results when Optical Flow displays unwanted artifacts.

Optical Flow: The most processor intensive, but highest quality method of speed effect processing. Using motion estimation, new frames are generated from the original source frames to create slow or fast motion effects. The result can be exceptionally smooth when motion in a clip is linear. However, two moving elements crossing in different directions or unpredictable camera movement can cause unwanted artifacts.

- **Motion estimation mode:** When using mixed frame rate clips in a timeline that has Optical Flow retiming enabled, when using Optical Flow to process speed change effects, or when using Image Stabilization or Temporal Noise Reduction controls in the Color page, the Motion Estimation dropdown of the Master Settings (in the Project Settings window) lets you choose options that control the trade-off between speed and quality.

  There are additional "Enhanced" Optical Flow settings available in the "Motion estimation mode" dropdown in the Master Settings panel of the Project Settings. The "Standard Faster" and "Standard Better" settings are the same options that have been available in previous versions of DaVinci Resolve. They're more processor-efficient and yield good quality that are suitable for most situations. However, "Enhanced Faster" and "Enhanced Better" should yield superior results in nearly every case where the standard options exhibit artifacts, at the expense of being more computationally intensive, and thus slower on most systems.

  "Speed Warp Faster" and "Speed Warp Better" are available for even higher-quality slow motion effects using the DaVinci Neural Engine. Your results with this setting will vary according to the content of the clip, but in ideal circumstances this will yield higher visual quality with fewer artifacts than even the Enhanced Better setting.

  "AI Speed Warp Metal" (macOS only) is a specifically enhanced version of Speed Warp that takes advantage of Mac hardware. It should dramatically speed up the DaVinci Neural Engine Speed Warp operations.

- **Motion range:** When using mixed frame rate clips in a timeline that has Optical Flow retiming selected, or when using Optical Flow to process speed change effects, this dropdown menu lets you choose the default setting to use, small, medium or large motion, for all speed and motion related calculations so you can try and improve the result by matching the type of motion in the source media.

  This setting can also be changed on a clip by clip basis in the Edit page Inspector.

New improved Motion estimation mode settings in the Master Settings panel of the Project Settings

Blackmagic Cloud

The Blackmagic Cloud panel contains settings that control how your project interfaces with the Blackmagic Cloud service.

Project Media Location

Chooses where you want to store media for use with Blackmagic Cloud projects.

- **Folder Location:** Shows the file path for where the Blackmagic Cloud media is stored on your computer. You can update this by pressing the Change location button and choosing a new location in the file browser.

Multi User Collaboration

Chooses whether you want multiple users to be able to work on this project.

- **Allow multiple users to simultaneously access and work on this project:** Check this box to enable the collaborative workflow tools for this cloud project. Deselect if you are working on a cloud project as a single user.

Blackmagic Cloud Storage Syncing

These tools allow you to control the syncing behavior of Blackmagic Cloud Storage.

- **For Media Files:** These options let you choose what media to upload and sync to your Blackmagic Cloud Storage account for other users' access.

  Don't Sync media: Does not upload any media to Blackmagic Cloud Storage.

  Sync proxies only: Uploads only proxy media to Blackmagic Cloud Storage.

  Sync proxies and originals: Uploads both proxies and the original media to Blackmagic Cloud Storage. This can use an extremely large amount of storage depending on the amount and size of the original media.

  Generate proxies automatically: Check this box to have DaVinci Resolve automatically generate proxy media for your master clips.

- **Proxies are created as:** These options let you set the codec that proxy files will use.
- **Display synced media in:** Lets you set the timeframe parameter for displaying any synced media.

Remote Cameras

Sets permissions for users of the Blackmagic Cameras and the Camera app.

- **Allow remote cameras to see this project and to load media directly into the media pool:** Allows Blackmagic Camera and Camera app users that are members of this project to upload camera media to the Blackmagic Storage account and will add it to the project's Media Pool directly.

Blackmagic Cloud

Press the Blackmagic Cloud Website button to go to the Blackmagic Cloud web interface, where you can setup, access and pay for various Blackmagic Cloud services.

Image Scaling

The Image Scaling panel contains settings that determine how and when clips are resized for various reasons.

Image Scaling

These settings affect the methods used to resize clips in various situations.

- **Resize Filter:** The first group of settings lets you choose the filter method used to interpolate image pixels when resizing clips:

  Smoother: May provide higher quality for projects using clips that must be scaled down to fit an SD resolution frame size.

  Bicubic: While the Sharper and Smoother options are slightly higher quality, Bicubic is still an exceptionally good resizing filter and is less processor intensive than either of those options.

  Bilinear: A lower quality setting that is less processor intensive. Useful for previewing your work on a low-performance computer before rendering, when you can switch to one of the higher quality options.

  Sharper: Usually provides the best quality in projects using clips that must be scaled up to fill a larger frame size or scaled down to HD resolutions.

  Custom: This setting lets you take control of the exact algorithm used in all resizing operations. The custom Resize Filter options available are: Bessel, Box, Catmul-Rom, Cubic, Gaussian, Lanczos, Mitchell, Nearest Neighbor, Quadratic, and Sinc. In practice, the difference between these methods can be quite subjective. However, if you need to match a specific resizing method used from another application, you can do it here. For everyday use, the normal resizing filters in DaVinci Resolve should be sufficient.

- **Override input scaling:** Checking this box lets you choose an Input Sizing preset to apply to the project.
- **Override output scaling:** Checking this box lets you choose an Output Sizing preset to apply to the project.
- **Deinterlace quality:** (only available in Studio version) A fourth group of settings lets you choose the quality/processing time tradeoff when deinterlacing Media Pool clips using the Enable Deinterlacing checkbox in the Clip Attributes window. There are three settings:

  Normal: A high-quality deinterlacing method that is suitable for most clips. For many clips, Normal is indistinguishable from High. Normal is always used automatically during playback in Resolve.

  High: A more processor-intensive method that can sometimes yield better results, depending on the footage, at the expense of slower rendering times.

  DaVinci Neural Engine: This option uses the advanced machine learning algorithms of the DaVinci Neural Engine to analyze motion between the fields of interlaced material and reconstructs them into a single frame. This option is very computationally intensive but, ideally, will deliver an even more aesthetically pleasing result than the “high” setting.

Input Scaling

Contains one setting, Mismatched resolution files, that lets you choose how clips that don't match the current project resolution are handled. There are four options:

- **Center crop with no resizing:** Clips of differing resolution are not scaled at all. Clips that are smaller than the current frame size are surrounded by blanking, and clips that are larger than the current frame size are cropped.
- **Scale full frame with crop:** Clips of differing resolution are scaled so that the clip's shortest dimension is fit to match the frame. Excess pixels are cropped.
- **Scale entire image to fit:** The default setting. Clips of differing resolution are scaled so that the clip's longest dimension is fit to match the frame. The shorter dimension has blanking inserted (letterboxing or pillarboxing).
- **Stretch frame to all corners:** Useful for projects using anamorphic media. Clips of differing resolutions are squished or stretched to match the frame size in all dimensions. This way, anamorphic media can be stretched to match full raster, or full raster media can be squished to fit into an anamorphic frame. An added benefit of this setting is that it makes it easy to mix anamorphic and non-anamorphic clips in the same project.

Output Scaling

These settings let you optionally choose a different resolution to be output via your video output interface, for monitoring, outputting to tape, or rendering. In particular, if you set the resolution in the Render Settings list of the Deliver page to something other than the Timeline Resolution, these settings are used to make the change (for example, if you're rendering a downconversion of the current timeline). This can be used in situations where you're working on a high resolution 4K project, but you want to monitor using an HD display and output HD resolution media for approval.

- **Match timeline settings:** Turned on by default, so that these settings mirror the Timeline Resolution, Image Scaling, and Input Image Scaling settings described above. Turning this checkbox off lets you choose different settings for monitoring, outputting to tape, or rendering, using the other settings in this group.
- **Output resolution:** Lets you choose an alternate resolution.
- **For:** Lets you specify a different custom alternate resolution.
- **Pixel aspect ratio:** Lets you specify an alternate pixel aspect ratio to match the alternate timeline format.
- **Mismatched resolution files:** Lets you choose an alternate way of handling mismatched resolution files given the alternate resolution you've chosen. These options work identically to those of the "Input Image Scaling" group.
- **Super Scale:** Sets a very processor-intensive and high quality upscaling algorithm that actually creates new pixels for the resized image. The possible values are: None, 2-3-4x, 2-3-4x Enhanced, and Auto.

For more information on Super Scale, jump to this chapter: Image Sizing and Resolution Independence.

Color Management

The various options found in the Color Management panel let you configure DaVinci Color Management (RCM) or ACES if you have either enabled, and they also allow you to pre- or post-process the DaVinci Resolve image processing pipeline using LUTs and Broadcast Safe settings, in order to accommodate a wide range of different color workflows.

Color Space and Transforms

If you choose DaVinci YRGB Color Managed or ACES in the Color Science menu at the top, then the other dropdown menus in this section become enabled.

> For more information on DaVinci Resolve Color Management and ACES, jump to this chapter: Data Levels, Color Management, and ACES.

If you're new to color or color management, you're strongly recommended to read this chapter.

If you choose to use Resolve Color Management (RCM), ACEScc, or ACEScct, the settings in this panel give you extensive control over how color is transformed, starting with choosing the default color settings for the source media in your project (via the Input Color Space), through choosing how you want your grading controls in DaVinci Resolve to behave (via the Timeline Color Space), and then specifying how the final color will look on your monitor and output device (via the Output Color Space).

- **Color science:** There are four options that let you choose whether to work with manual or automated color management.

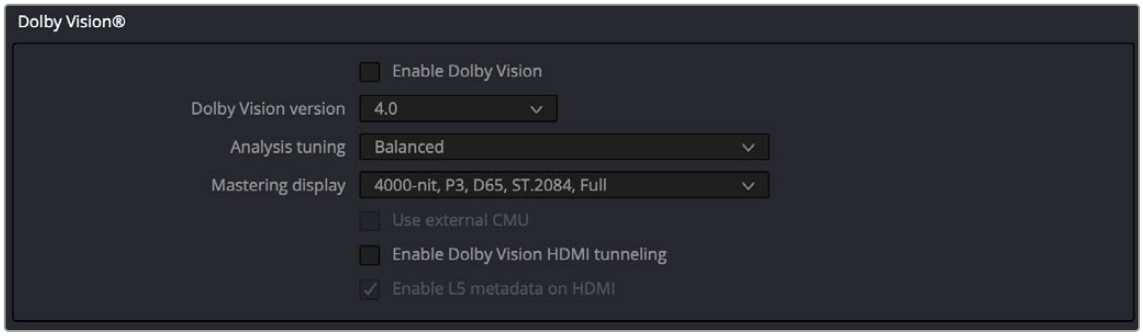
  DaVinci YRGB color science: DaVinci Resolve's original color science, in which you manage all and any color transforms from one color space to another manually, using either LUTs or manual adjustments.

  DaVinci YRGB Color Managed: Enables the Resolve color-managed workflow (RCM) for grading.

  DaVinci YRGB Color Managed (Legacy): Enables the legacy Resolve color-managed workflow for compatibility with legacy projects.

  ACEScc or ACEScct: Both of these are standardized color management schemes that are available for facilities using ACES workflows. Of the available settings, ACEScct is the most intuitive way of working for most colorists, as it handles the lifting of shadows in a creatively useful way.

  > For more information on Color Management and ACES, jump to this chapter: Data Levels, Color Management, and ACES.



- **ACES version:** This dropdown only appears if you choose one of the DaVinci ACES options from the Color science dropdown menu. Lets you switch between different versions of the ACES specification. This lets you choose the appropriate older version of ACES whenever you open an older project.
- **Use Separate Color Space and Gamma:** If this checkbox is turned off (the default), the Color Management panel of the Project Settings exposes one dropdown each for the Input, Timeline, and Output Color Space settings, and each setting simultaneously transforms the gamut and gamma, depending on which option you choose. If you turn this checkbox on, then the Color Management panel changes so that the Input, Timeline, and Output Color Space settings each display two pop-ups. The first dropdown lets you explicitly set the gamut, while the second dropdown lets you explicitly set the gamma.

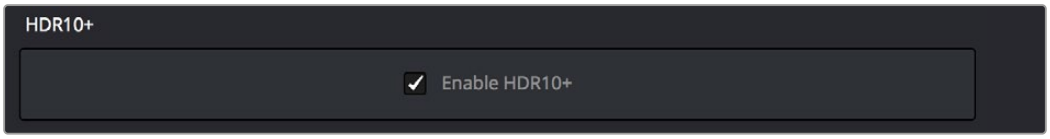
To provide more detailed information, the simple and advanced global controls available for Resolve Color Management (RCM) are covered in a dedicated chapter.

For more information, jump to this chapter: Data Levels, Color Management, and ACES.

Dolby Vision™

DaVinci Resolve includes a GPU-accelerated software version of the Dolby Vision CMU (Content Mapping Unit) for doing Dolby Vision grading and finishing workflows right in either the free version of DaVinci Resolve or in DaVinci Resolve Studio. This is enabled and set up in the Color Management panel of the Project Settings with the Enable Dolby Vision checkbox.

Dolby Vision settings in the Color Management panel of the Project Settings



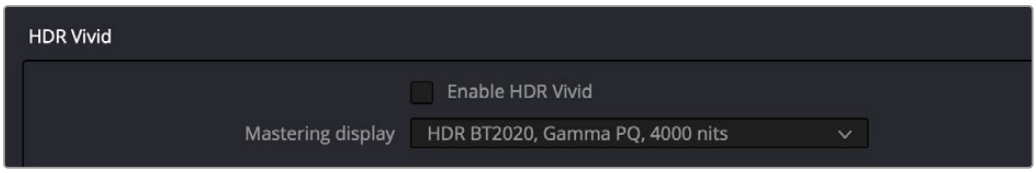
There are five controls available:

- **Enable Dolby Vision:** Turns Dolby Vision on and off. When on, this checkbox enables the Dolby Vision palette in the Color page.
- **Dolby Vision version dropdown:** Lets you choose which version of the Dolby Vision algorithms to use. Options at the time of this writing include 2.9 and 4.0.
- **Analysis tuning:** Choose from a variety of options for how Dolby Vision will analyze and control highlight retention.
- **Master Display dropdown:** Lets you choose the nit level and gamut of the master HDR display you're grading on.
- **Use External CMU:** A checkbox lets you choose whether to use the built-in software CMU or a hardware CMU that you have connected to your DaVinci Resolve workstation.
- **Enable Dolby Vision HDMI tunneling:** If you are using a Blackmagic Decklink 8K Pro G2 device for monitoring, you can check this box to enable HDMI tunneling. This lets you view Dolby Vision content directly on a consumer display in real time.
- **Enable L5 metadata on HDMI:** If HDMI tunneling is activated, enables the L5 metadata. This should be checked if HDMI tunneling is on.

NOTE: Dolby Vision controls are available to all DaVinci Resolve users for monitoring and automatically generating Dolby Vision metadata for creating other HDR and SDR deliverables from the HDR grade you've made. However, if you want to be able to make manual trims on top of this automatic analysis, you must email dolbyvisionmastering@dolby.com for more information on obtaining a license.

HDR10+

DaVinci Resolve supports the new HDR10+ HDR format by Samsung. Please note that this support is a work in progress as this is a new standard. When enabled, an HDR10+ palette exposes trimming parameters that let you trim an automated downconversion of HDR to SDR, creating metadata to control how HDR-strength highlights look on a variety of supported televisions and displays. This is enabled and set up in the Color Management panel of the Project Settings with the Enable HDR10+ checkbox. Turning HDR10+ on enables the Dolby Vision palette in the Color page.

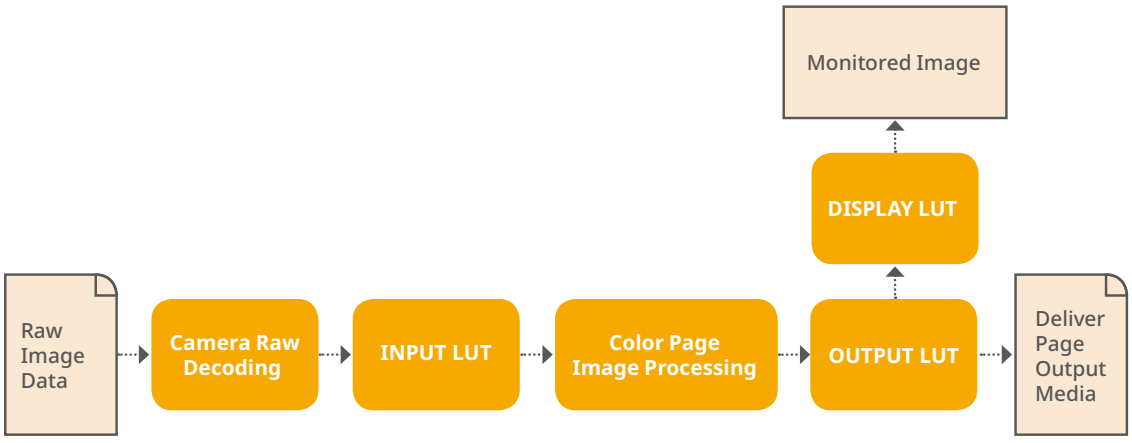


HDR10+ settings in the Color Management panel of the Project Settings

HDR Vivid

HDR Vivid is the HDR video technology standard released by the China UHD Video Industry Alliance (CUVA). Mastering in this format assures wide compatibility with HDR televisions, phones, computers, and other devices in China.

- **Mastering Display dropdown:** Lets you choose the nit level of the master HDR display you're grading on.



HDR Vivid settings in the Color Management panel of the Project Settings

Lookup Tables

This group of controls lets you add LUTs to the Resolve image processing pipeline that affect every timeline in the entire project all at once. These LUTs can be used for a wide variety of functions, such as to trim Timeline grades, apply Log to Linear conversions, simulate film output, and limit the signal to accommodate Broadcast Safe requirements.

Different options let you insert image processing to different stages of the pipeline as seen in the following diagram:

Keep in mind that since you can apply both 1D and 3D LUTs simultaneously, 1D LUTs at each step are always applied before 3D LUTs.

- **Input Lookup Table:** Two dropdown menus let you add 1D and/or 3D LUTs that process the current Timeline before every other image processing operation in DaVinci Resolve.
- **Output Lookup Table:** Two dropdown menus let you add 1D and/or 3D LUTs that process the current Timeline after the operations applied in the Color page, but before the temporarily applied Display LUT.
- **Video Monitor Lookup Table:** Two dropdown menus let you add 1D and/or 3D LUTs that process the current Timeline after every other image processing operation in DaVinci Resolve. However, Display LUTs are only temporarily applied for purposes of monitoring; they're never applied to rendered media, or to the signal that is output to tape using the controls in the Deliver page. Display LUTs are particularly valuable for applying a film print emulation LUT in a Log workflow, or for applying a monitor calibration LUT if you're outputting to a single display and you don't have dedicated outboard calibration hardware.
- Here's an example. It's common, when grading for film output using a Log workflow, that you'll use the Display LUT dropdown menu to apply a film emulation LUT that simulates the image as it will be output from the film recorder, taking into account the film lab and print stock used, in order to make sure that the image you're grading will appear as close as possible to what the eventual release print will look like in the cinema.
- **Color Viewer Lookup Table:** Two dropdown menus let you add 1D and/or 3D LUTs that process the image shown in the Viewer on your computer display, independently of the Display LUT that's used to output to your broadcast display. By default, this follows the Video Monitor LUT setting, but you can also use this option to apply a specific calibration transform for your computer monitor. Alternately, you could use it to desaturate the GUI Viewer to be able to specifically evaluate image contrast, or if you don't want to have to argue with your client over which display looks correct.
- **Scopes Lookup Table:** Ordinarily, DaVinci Resolve's internal software video scopes provide an unbiased analysis of the actual video data levels within the Resolve image processing pipeline. However, you can choose to have the software scopes use the Video Monitor LUT selection, or any other LUT installed on your system, to transform this analysis to reflect the monitored output.
- **3D Lookup Table Interpolation:** Lets you choose the processing quality of both LUT and DCTL operations in DaVinci Resolve. 3D Lookup tables (LUTs) are 3D tables of red, green, and blue values that specify an output color value for each input color value, thereby providing a method of making color transformations using pre-calculated data. While powerful, 3D LUTs have finite detail; for example, one might have a 17x17x17 LUT that specifies 4913 individual color transforms. When applied to a floating point image that contains more data than the LUT specifies transforms for, color values falling between the 17x17x17 color transforms specified by the LUT need to be interpolated. You can choose from two methods that trade off processing efficiency for higher quality:

  Trilinear: (Default) Trilinear is backward compatible with grades that use LUTs from previous versions of DaVinci Resolve and matches the look of LUTs being applied in other applications.

  Tetrahedral: Tetrahedral is slightly more processor-intensive, but results in higher image quality LUT and DCTL processing, with reduced color-banding. Tetrahedral is recommended for projects that don't need backward compatibility with previous versions of DaVinci Resolve or LUTs created in other applications.
- **Update Lists button:** Refreshes the LUT dropdown menus if you've added new LUTs to your system since DaVinci Resolve has been opened.
- **Open LUT Folder button:** This selection opens the master folder in your file system, as described in the list of DaVinci Resolve LUT paths shown above.

Adding Lookup Tables to Your DaVinci Resolve Installation

The dropdown menus in the Color Management panel include a series of factory preset LUTs that were installed with DaVinci Resolve, along with any LUTs that have been generated by DaVinci Resolve, or that you've imported into the proper directory for your operating system.

- **On macOS:** Library/Application Support/Blackmagic Design/DaVinci Resolve/LUT/
- **On Windows:** C:\ProgramData\Blackmagic Design\DaVinci Resolve\Support\LUT
- **On Linux:** /opt/resolve/LUT

If you downloaded the non-studio version of DaVinci Resolve from the Apple App Store, LUTs are saved in a different location in order for DaVinci Resolve to remain totally self-contained. In this case, you can click the "Open LUT Folder" button in the Lookup Tables panel of the Project Settings, to open up a Finder window at the location these LUTs are stored. You can use this window to copy LUTs that you want Resolve to have access to, or delete LUTs that you no longer need.

If you add a LUT to one of these directories after DaVinci Resolve has been opened, you can click the Update Lists button to refresh the contents of the dropdown menus.

DaVinci Resolve uses both 1D and 3D LUTs. 3D LUTs that are created by DaVinci Resolve are in the .cube format, configured as 33x33x33 cubes with 32-bit floating point processing. DaVinci Resolve can also read and use LUTs in the Shaperlut format.

Broadcast Safe

Broadcast Safe settings can be enabled while you grade to limit both the luma and chroma of the video signal to one of three levels of acceptable overshoots and undershoots.

- **Broadcast safe IRE (mV) levels:** A dropdown menu for choosing one of three levels of aggressiveness when limiting the signal. Choose the range that corresponds to your QC requirements.
- **Make Broadcast Safe:** A checkbox that turns broadcast safe limiting on and off.

NOTE: The clipping imposed by Broadcast Safe itself does not have an inherently soft roll-off. For best results, Broadcast Safe should be used in conjunction with the Soft Clip controls in the Color page.

General Options

This panel presents a selection of general preferences that affect the interface and operation of DaVinci Resolve.

Conform Options

The settings in this group determine how clips are conformed to match imported project files with source media on disk by extracting timecode, reel names, file names, file paths, and so on.

> For more information on conforming and relinking, jump to this section: Conforming and Relinking Media.

- **Use Timecode:** Determines how DaVinci Resolve extracts timecode from referenced media files. There are two options:

  Embedded in the source clip: The preferred setting for most projects to conform automatically and apply grades to the resulting clips. As long as DaVinci Resolve can reference the timecode in either a media file's timecode track, or in the header metadata of the frames in a DPX sequence, you can use timecode to reconform clips, or even completely change the media file to which a clip refers.

  From the source clip frame count: This setting is useful if the source media lacks timecode metadata, and all that's available is a frame count that identifies frames via sequentially numbered integer values.

- **Conform partial clips with black gaps:** Inserts black frames whenever you conform a clip that doesn't contain all the required frames. When this option is selected, partial clips are flagged in the Edit page with a P in the thumbnail of the clip that it is lacking frames.
- **Automatically conform missing clips added to Media Pool:** Enabled by default, must be disabled to use collaborative workflow. When this checkbox is turned on, DaVinci Resolve maintains a dynamic relationship between clips in the Media Pool and those in a project's various timelines. When this checkbox is on and you import clips with matching timecode/file names/reel names to clips in a timeline, DaVinci Resolve will automatically reconform all matching missing clips, and all other timeline clips that have force conform turned off.
- **Assist using reel names from the:** When this checkbox is turned on, DaVinci Resolve uses reel numbers when conforming clips to match any imported project. This setting must also be turned on if you want to choose different reel name extraction methods for individually selected clips using the Clip Attributes window. Turning this checkbox off forces DaVinci Resolve to identify clips using file names when conforming XML and AAF projects. File names can only be used for conforming XML or AAF files, or when importing a DaVinci Resolve project.

  There are four options:

  Source clip file pathname: Obtains the reel number by extracting it from each media file's path. This makes it possible to extract a reel number from all or part of the file name, or from all or part of the name of any folder in the path that encloses that file. This extraction is defined using the Pattern field.

  Pattern: A code that defines how a reel number should be extracted from the source clip path name.

> For more information about creating patterns, jump to this section: Conforming and Relinking Media.

Media Pool folder name: The reel number is obtained from the name of the bin in the Media Pool that encloses that clip. This option is often used for stereo projects, deriving the reel number from "Left" and "Right" named directories. It's also useful for projects that are inheriting new VFX clips on a daily basis.

Embedding in source clip file: Useful for file formats where the reel number is embedded within the media file itself. QuickTime files created by Final Cut Pro, DPX frame files, and CinemaDNG files are all formats that are capable of containing reel number header data.

Source clip filename: If there is no defined reel number, often it's easy to just use the source clip filename. This is a safe option to use in situations where you want to manually choose different reel name extraction methods for individual clips using the Clip Attributes window.

- **Limit reel name matching to X characters:** For situations where you've been provided with media files with extra characters in the reel name that don't correspond to the names used in the project file you've been given, "Limit reel name matching to X characters" lets you omit a specific number of characters from the end of a reel name. This works in conjunction with the following setting.
- **Ignore the first X characters of the reel name:** For situations where you've been provided with media files with extra characters in the reel name that don't correspond to the names used in the project file you've been given, "Ignore the first X characters of the reel name" lets you omit a specific number of characters from the beginning of the reel name. Combined with the previous setting, you can trim any reel name to a conformable subset of characters.
- **Extract reel names from EDL comments:** Media file formats such as R3D have reel names, obtained from the file names, that are longer than the eight characters that are allowable in a standard EDL. This option allows DaVinci Resolve to extract reel names from appropriately formatted EDL comments, such as those output from Final Cut Pro 7.
- **Sort timeline using reel number and timecode:** Lets you change the behavior of C mode sorting in the Timeline. With this checkbox turned on (the default), all clips in the Timeline are sorted by reel number first, and then by source timecode. This way, clips with similar timecode from the same reel will appear next to one another in C mode. If you turn this checkbox off, reel number is ignored, and all clips in the Timeline are sorted only by source timecode. This may result in clips from multiple sources being mixed together, but it is useful in specific situations.
- **Mixed frame rate format:** (Only available prior to importing media into a project) This dropdown menu lets you choose the method used to conform mixed frame rates for rendering and playback. Which option you choose dictates the accuracy with which retimed clips in DaVinci Resolve match the same clips that were retimed in other editing applications when you import those timelines into DaVinci Resolve via XML or AAF. This dropdown menu also appears in the Load AAF or XML dialogs.

  If you're editing from scratch in DaVinci Resolve: You should leave this setting set to "Resolve."

  When importing timelines via XML from Apple software: Choose the "Final Cut Pro 7" or "Final Cut Pro X" methods of conform.

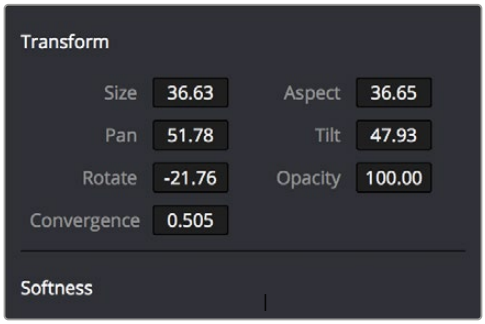
  When importing timelines via XML or AAF from Premiere Pro, Media Composer, Smoke, or other NLEs: You should choose "Resolve."

  When none is selected: DaVinci Resolve conforms and processes all clips in the Timeline to play at the frame rate that's selected in the "Timeline frame rate" dropdown menu. For example, 23.98, 29.97, 30, 50, 59.94 and 60 fps clips will all play at 24 fps if that's what "Timeline frame rate" is set to in the Master Project Settings, and clips will play slower or faster accordingly.

  How clips in mixed frame rate timelines are rendered out depends on whether the Render Settings are set to render individual source clips or one single clip. When you render the Timeline as individual source clips, all clips are rendered individually at their original frame rate. If you select "single clip," all clips are converted to the "Timeline frame rate" frame rate and rendered as a single media file.

Color

These settings affect clip versions and timeline interactions when working in the Color page.



- **Automatically label gallery stills using:** When enabled, DaVinci Resolve automatically generates labels for all gallery stills you take based on the following controls:

  Naming dropdown: Lets you choose what name to use for new stills. Options include: Clip Name, Clip Version Name, Source Timecode, Timeline Timecode, Timeline Name, Display LUT Name, Custom Label Using Tags (using metadata variables).

  Append still number on export checkbox: When enabled, each new still has an appended still number. Where the number appears depends on the following radio buttons.

  As Suffix/As Prefix buttons: Lets you choose to place still numbers at the end of an auto generated gallery label or at the beginning.

- **Luminance mixer defaults to zero:** Selecting this option sets the Y channel of the YRGB parameters for all grades to zero. This is required to be able to export a compliant ASC-CDL, and will impact all grades that use the Lum Mix control.
- **Use legacy Log grading ranges and curve:** DaVinci Resolve 12.5 introduced a modification to the Log grading controls that provides smoother, more pleasing results using the same controls. To maintain backward compatibility with older projects, a “Use legacy Log grading ranges and curve” checkbox in the Color panel of the Project Settings lets you switch your project between the older Log control behavior and the newer one. Older projects that are opened in DaVinci Resolve have this checkbox turned on by default, while new projects have this turned off by default.
- **Use S-curve for contrast:** On by default, this checkbox sets the contrast control in the Color Wheels palette to apply an “S-curve” to the image, such that the shadows and highlights of a signal will not be clipped when you increase the value. If you would prefer for these contrast adjustments to be made linearly, and for the signal to be allowed to clip when you reach the upper and lower boundaries of the video signal, you can turn this checkbox off.
- **Use legacy sizing interactions for windows and effects:** DaVinci Resolve 14.1.1 improved how window tracking applies transformations, to correctly handle things like pixel aspect ratio (par). New projects should leave this setting disabled, however older projects should leave this checkbox enabled to ensure tracking and transforms remain applied the way they were before.
- **Apply stereoscopic convergence to windows and effects:** When enabled, DaVinci Resolve correctly maintains the position of a window that’s been properly placed over each eye as convergence is adjusted in the 3D palette. Enabling this checkbox also enables an additional Convergence parameter in the Window palette that lets you create properly aligned convergence for a window that’s placed onto a stereoscopic 3D clip, as seen in the following screenshot.

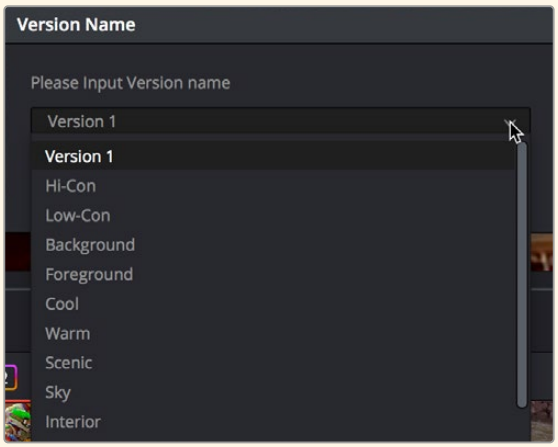
The Convergence control in the Transform section of the Window palette appears when you enable “Apply stereoscopic convergence to windows and effects”

- **Use local version for new clips in timeline:** Automatically sets all new clips that are added to existing timelines, or all clips that are added to new timelines that are imported via AAF, EDL, or XML, to use local grades by default. If you want all clips added to new timelines to use remote grades instead, as with DaVinci Resolve version 9 and earlier, you can turn this checkbox off.
- **Automatically match master timeline with media pool:** If you turn on this option before importing any media into the Media Pool, or importing any timelines that will in turn import media into the Media Pool, you can create projects with a Master Timeline. When enabled, clips are added to and removed from the Master Timeline as they're added to and removed from the Media Pool, so that the Master Timeline always contains all media in the Media Pool. Once media has been imported into a project, this setting cannot be changed.
- **Save timeline thumbnails with project:** To minimize project size, and maximize the speed of saving and loading projects, you should leave this checkbox unchecked. If you select the checkbox, all of your Timeline thumbnails will be stored inside every project, instead of in the default directory that's ordinarily dedicated to stills, during both Save and Auto Save operations. This provides a good history of the project but takes much longer to complete and uses more hard disk space.
- **Use BGR pixel order for DPX v2:** Lets you choose a different pixel order for projects using DPX version 2 media.
- **Embed timecode in audio output:** When turned on, directs DaVinci Resolve to output LTC timecode that's embedded in channel 16 of the SDI stream and channel 2 of the analog audio output from your video interface.
- **Use Timelines Bin:** This option is only available to be changed before you add clips to the Media Pool; after you've added clips, it's no longer available. Turning Use Timelines Bin on creates a dedicated Timelines bin in the Media Pool, at the top of the Bin List. When enabled, the Timelines bin contains all timelines in a project, and you're prevented from putting timelines into any other bin in the Media Pool. Whenever you create or import a new timeline, it automatically appears in the Timelines bin. You can add subfolders to the Timelines bin for more specific organization.
- **Node Stack Layers:** Lets you set the number of node stack layers you wish to use in the Color page.

  Post Group Node Stack Layer: Adds a final Stack Layer after all the others, letting you dedicate the last node stack layer for post group grades and transforms.

Dynamics Profile

Defines the default transition from one dynamic keyframe to the next for keyframed effects in the Color page. By default this transition is linear, with the "Dynamic profile start" and "Dynamic profile end" parameters set to 1. However, if you need to alter the acceleration of the interpolation of values from one dynamic keyframe to the next, then you can change that keyframe's Dissolve Type in order to "ease" the effect transition you're creating. The values in these settings correspond to the graph curves found in the Dynamic Attributes dialog when editing keyframes in the Color page.



For more information, jump to this chapter: Keyframing in the Color Page.

Versions

Ten text fields provide a way for you to designate automatic names for the versions of grades that you select in the Color page. To the right of each text field, a dropdown menu lets you add a name from a handy list of predefined terms that's been provided. Alternately, you can simply click any field and type your own custom name.

When you change the name of a version in the Color page, the names you define in this list are available from a dropdown menu in the Version Name dialog.

Using a predefined list of names for your different versions avoids typos that can later create folder naming issues when you use the “Commercial Workflow” options for rendering your media in the Deliver page.

Using the named dropdown
when editing the name of a version

Camera Raw

This panel contains groups of parameters that correspond to every camera raw media format that’s supported by DaVinci Resolve. Using these parameters in the Camera Raw panel, you can override the original camera metadata that was written at the time of recording, and make simultaneous adjustments to all camera raw clips using the “project” raw settings.

To provide more detail, these settings are covered in detail in a dedicated chapter.
For more information, jump to this chapter: Camera Raw Settings.

Capture and Playback

All settings in this panel let you define the functionality of capture and playout to tape using device controlled VTRs connected to your Resolve workstation via the connected video capture and output interface.

For more information on deck capture, jump to this chapter: Ingesting From Tape.
For more information on video output to tape, jump to this chapter: Delivering to Tape.

Deck Settings

These settings affect both capture and playback when using the tape ingest options of the Media page, or the tape output options of the Deliver page.

- **Video capture and playback:** You can choose the video format (frame size and frame rate) with which to output to tape from this dropdown menu. HD timelines can be downconverted to SD, and SD timelines can be upconverted to HD using the format conversion of your DeckLink card.
- **Use left and right eye SDI:** A checkbox that enables supported video interfaces to ingest and output muxed stereoscopic video when used with supported VTRs, such as HDCAM SR decks with 4:2:2 x 2 mode. (When muxed stereoscopic signals are ingested, each eye is separated into individual left-eye and right-eye image files.) This parameter only appears when your hardware is set up appropriately.
- **Video connection operates as:** Selects between the available signal options: Use 4:4:4 SDI and Enable Single Link. Which options are available depend on which video capture card you are using.
- **Data Levels:** Lets you specify the data range (normally Video or Full) that's used when ingesting from or outputting to tape. This option switches the data range of the signal output by your video capture card, but only during capture from tape in the Media page, or output to tape in the Deliver page. When capture or output is not currently occurring, your video capture card goes back to using the identically named data range setting in the Master Project Settings pane, which governs how you monitor the signal being output on an external broadcast display or projector.
- **Video bit depth:** Choose the bit depth that corresponds to the capability of your deck. Depending on your workstation's configuration, you can choose between 8-bit and 10-bit. Outputting to 10-bit is more processor intensive, but higher quality for compatible devices, and is the default setting.
- **Use deck autoedit:** If supported by your video deck, this is the best method to record video to the deck, as it enables the deck to roll the edit using the specified preroll, and control the edits via serial device control. If this checkbox is turned off, a basic edit On/Off mode is used by the deck, with the potential for frame inaccuracies if the "Non auto edit timing" setting is not properly adjusted.
- **Non auto edit timing:** Adjusts the edit synchronization of the connected deck when auto edit is turned off.
- **Deck preroll:** Sets the number of seconds for preroll. How much is appropriate depends on the performance of your deck.
- **Video output sync source:** When using a DeckLink card this is set to Auto. Other capture cards may require you to set the sync source to "Reference" for playout and "Input" for ingest. This setting is only available if you have a DVS card installed on your system.
- **Add 3:2 pulldown:** Inserts or removes the 3:2 pulldown required to record or play 23.98 fps media to or from a 29.97 tape format.

Capture

These settings are used when you use the Capture mode in the Media page to capture clips from tape into the Media Pool.

- **Capture:** Lets you choose whether to capture both Video and Audio, or Video Only.
- **Video Format:** The format that scanned film frames are saved as. When capturing from tape, the available options are DPX and QuickTime. When capturing from the Cintel film scanner, this is restricted to Cintel Raw Image (CRI), which is a raw data format that DaVinci Resolve automatically debayers as a Cineon log-encoded image for grading.

- **Codec:** The codec used to write captured media. When capturing from tape, these include the various type of Apple ProRes, 8- and 10-bit YUV 422, 10-bit RGB, and the various types of DNxHD. Cintel Raw Image files default to rgb.
- **Save in folder path:** A series of checkboxes let you specify what other information to use to define the directory hierarchy that will hold the captured media. Every checkbox you turn on adds an additional directory with a name defined by that checkbox's metadata. You can choose any or all of the following: Program name, Clip number, Reel number, and Roll/Card.
- **Apply reel number to:** Lets you choose how to write the reel name. Two checkboxes let you write the reel number to the file's name, and/or to the Header data.
- **Use prefix:** A field lets you type in a prefix to be used in the media file's name. This lets you add text identification that will make the media more easily identifiable and searchable.
- **Apply prefix to:** Two checkboxes let you choose to use the prefix you typed in the file name, and/or in the folder name.
- **Use frame number with:** When capturing to image sequences, you can choose how many digits to use when writing the frame number into the name of each frame file.
- **Set batch ingest handles to:** When capturing to image sequences from a batch list, defines how many frames of additional handles to ingest along with each logged clip.
- **Input:** Lets you choose how many tracks of audio to capture, from 2 to 16.

Playout

These settings only affect the video signal that's output when you use the Edit to Tape mode of the Deliver page.

- **Output:** Lets you choose whether to output both Video and Audio, Video Only, or Audio Only if you're doing an audio layback.
- **Output Source Timecode:** Turn this checkbox on to output each individual clip's source timecode. This option is only applicable when assemble editing to tape.
- **Output LTC:** With a Blackmagic Design DeckLink or UltraStudio device using HD-SDI, longitudinal timecode (LTC) is available on track 16 of the HD-SDI video signal, making it easy to use a Mini Converter de-embedder to extract this analog timecode audio signal and feed it directly to a recording device. This is particularly helpful if you have outboard video processing equipment such as a noise reducer or format converter that passes through the VITC timecode.
- **Delay LTC by x frames:** When outputting LTC to bypass outboard processing gear, such as a noise reducer or format converter, you can compensate for the processing delay by delaying the timecode by a matter of frames to ensure that the processed image and timecode reach the deck at the same time. With a DVS card there is a separate timecode output.
- **Offset audio by x frames:** Lets you specify an offset between the audio track and video to achieve proper A/V sync in cases where the video is being delayed by outboard processing hardware.
- **Output x channels of audio:** Choose the number of audio tracks to output to tape.
- **Set batch playout head handle to x seconds:** When batch outputting multiple clips, you can specify a number of frames before the In point of each clip to be output as well.
- **Set batch playout tail handle to x seconds:** When batch outputting multiple clips, you can specify a number of frames after the Out point of each clip to be output as well.

Subtitles and Transcription

The Subtitles panel lets you adjust presets that govern subtitles being created in subtitle tracks of the timeline.

- **Max Character Per Line:** Defaults to 60. Lets you choose the maximum number of characters allowed on one line in a subtitle.
- **Minimum Caption Duration:** Defaults to 3 seconds. Lets you choose the minimum duration allowed for subtitles in the timeline.
- **Maximum Characters Per Second:** Defaults to 30. Automatically calculates the maximum allowable characters per second based on a subtitle clip's duration.

The Transcription setup panel lets you select the language that DaVinci Resolve uses to analyze audio clips for transcription.

Language: Select one of the supported languages here. Selecting Auto lets DaVinci Resolve analyze the audio clip and choose the language spoken.

Enable Extended Language Support: If your language isn't on the language list, enable this box to activate the extended language set. This feature is currently in beta.

Fusion

Fusion allows consistent frame numbering for all compositions, including trimmed clips. This means that any composition created in Fusion can start with the same start frame number. In new projects you can change the default start frame for Fusion compositions in the project settings.

- **Legacy Fusion Composition Frame Count:** Sets the Fusion composition at zero frames to the first frame of the source media for the composition.
- **Default Start Frame:** Lets you type in a default frame number to start your fusion comps in this project.

This helps with Visual FX workflows in three ways:

- Matching existing keyframes to the right frame offsets—when replacing an asset with mismatched frame offsets (e.g., a sub clip, different format or round trip, or VFX connect workflows with mismatching handles).
- Rendering to specific frame ranges—when aligning to delivery standards for commercial workflows (e.g., compositions should start at sequence frame 1000).
- Consistent Referenced Comp behavior—essential when applying a referenced composition to different clips with different trims.

- **Downscale to Timeline Resolution for Timeline Clip Compositions:** To increase playback performance for complex fusion projects, you can check this box to automatically downscale all media to the timeline resolution before fusion operations happen. This does not work with .exr media however.

Fairlight

The Fairlight panel lets you set up your project's audio sample rate, as well as setting up various audio-specific tools in the Fairlight page.

General

Audio Sample Rate

This setting can only be changed prior to creation of your first timeline. Once one or more timelines have been created in a project, the Audio Sample Rate is locked to whatever was chosen.

The Audio Sample Rate, measured in kilohertz, is the number of samples per second used for audio processing in DaVinci Resolve. This setting defaults to 48000 (or 48 kHz), which is typical for broadcast and cinema work. However, you can change this to 96000 or 192000 if you want to mix and process audio at higher precision.

Be aware that using a higher sample rate, such as 96 kHz instead of 48 kHz, will use twice as much processing power and result in media that's twice the size.

NOTE: Regardless of the Timeline Sample Rate you select, when you import audio files at different sample rates, they will be automatically re-sampled to the Timeline Sample Rate so they play correctly.

Use Fixed Bus Mapping

If you want to work using the previous method of fixed-bus mapping, you can do so for new projects by opening the Fairlight panel of the Project Settings and turning on the "Use fixed bus mapping" checkbox.

If your project has fixed busing enabled and you want to change to FlexBus, then uncheck the "Use fixed bus mapping" checkbox. Note that once you have made the change, it will not allow you to change it back to legacy busing. The advantages to changing from legacy busing to FlexBus are enormous, so you will not regret making the change.

Use 32-Bit Float Recording

Filling in this checkbox gives you the ability to record 32-bit floating point audio. This setting can only be changed prior to creation of your first timeline.

Enable Soft Fades

Since version 14.0, Fairlight has automatically added a 1.5ms (72 samples) crossfade between adjacent timeline clips, allowing you to quickly edit your audio without having to manually add crossfades to prevent clicks or pops during playback.

This feature is still active by default, but you can switch off Soft Fades by removing the checkmark, which can be helpful when you need to hear the audio clips in their entirety.

Enable Ramp Up on Play

When this feature is active, your mix will fade in to prevent clicks whenever playback starts. The default faded-in (ramp-up) time is 2.1ms, but it can be adjusted up to 100ms.

Ramp Up on Play is especially useful when working on mixes with high track counts.

Audio Metering

The options in this section of the Fairlight Project Settings let you customize the Loudness Meters on the Fairlight page, while the others affect all other audio meters in DaVinci Resolve.

- **Meter Type:** Lets you select the desired Meter Type. Selecting Custom from this dropdown menu activates the following options:

  Level detector: This lets you select Sample Program, VU, or RMS for audio level metering detection.

  Scale: This setting lets you select either IEC 60268-18 or Quasi Linear for audio level metering scaling.

  Decay: This determines the time in seconds for level metering decay in 20 dB increments, following peak levels registering on the meters.

  Peak Indicator: This sets the hold time for peak level indication in the meters.

  — Off
  — Short hold + fall
  — Medium hold + fall
  — Medium hold
  — Long hold
  — Infinite hold

- **Pre fader metering on tracks:** This checkbox lets you choose how meters in the Fairlight page display their audio analysis. There are two options:

  Post Fader (unchecked): Meters always display the level of each clip's signal after whatever fader adjustments have taken place. Fading a track's level down diminishes the visible level of that audio signal in the meter. This setting is good if you prefer a visual indication of the relative levels you've set your various audio tracks to, which is a very NLE-oriented behavior.

  Pre Fader (checked): Meters always use the volume levels of the audio clips in that track, even if you've lowered the level using the sliders. If you've keyframed a clip's volume, that change will be reflected by the audio meters, even though fader changes are not. Viewing meters this way means you can always see how much level is available to clips in your mix, regardless of what the current fader levels are set to, in the event you want to keep track of audio you want to bring back into the mix later on. This is a very DAW-oriented behavior.

- **Target Loudness level:** Lets you set the LUFS value that's used as a reference level for loudness metering. Defaults to –23 LUFS, which conveniently makes the display of these meters scale similarly to traditional audio meters that you're already used to.
- **Loudness Scale:** Lets you choose which scale you want to use with which to measure the meters. Options currently include the default of EBU +9 Scale (–18 to +9), and EBU +18 Scale (–36 to +18).
- **Bus Meter Alignment Level:** Sets the peak of the bus meter.
- **Bus Meter High Level:** Sets the dB level at which the meter starts showing red.
- **Bus Meter Low Level:** Sets the dB level at which the meter starts showing yellow.

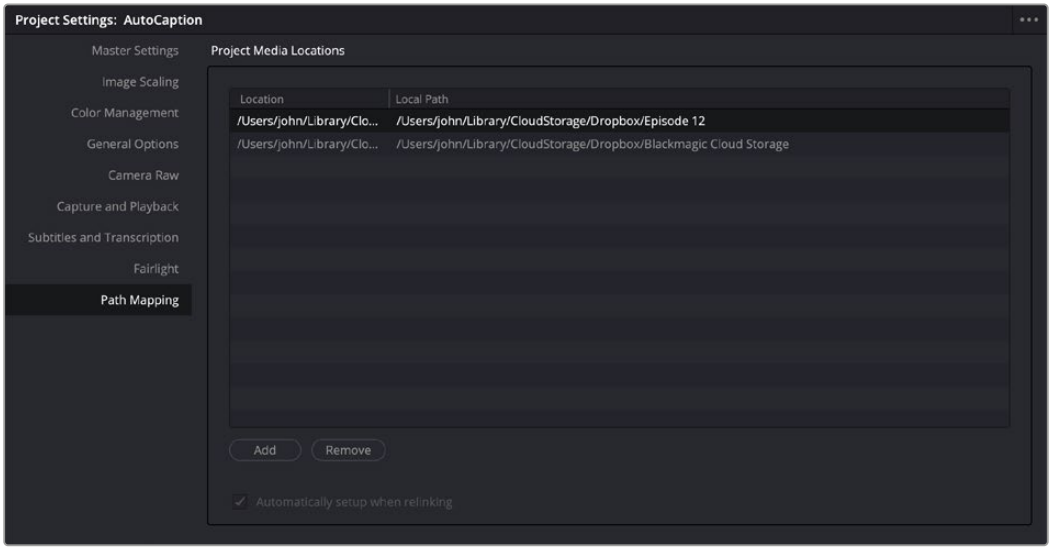
Path Mapping

The Path Mapping panel lets you configure your system's file paths, allowing you to seamlessly link and share media clips while collaborating with other users on their own systems. For example, Editor A and Colorist B are collaborating on the same project. Editor A is working on a Mac in L.A., where Colorist B is working on a PC in Bangkok. They are both sharing media in a cloud service's folder, but the file paths to that cloud folder are different for both of them locally.

- The Editor's Mac folder is at /Users/editor/cloudfolder/Episode 12
- The Colorist's Windows folder is at D:\Projects\Episodes\cloudfolder\Episode 12

Normally if they were collaborating, each one would constantly have to re-link the files from the other before they could continue as the path names would not match. By both of them adding the "Episode 12" location, and mapping their local paths in this section, DaVinci Resolve will automatically convert the file paths on the fly as they work. There would be no need for re-linking the clips as long as all the media they used was in the same hierarchy in the Episode 12 folder.

You can use Path Mapping to make things easier for non-collaborative workflows as well. For example, for a single user on a laptop, they could setup a link from their local media folder to their NAS. This removes the need to relink the media each time they leave and return to the office.



NOTE: Path Mapping differs from using the older Mapped Mount option in the Media Storage preferences. Mapped mount requires each user knowing the file path of all the other users. Path Mapping lets the user just present their own file path, and DaVinci Resolve takes care of the translation for all the other users instead.

Project Media Locations

This setting lets you set up your project's media locations so that they can easily be shared and translated with other DaVinci Resolve users. The idea is to have a media folder in common with all the other users (i.e., all connected to the same shared cloud storage folder), and set up the path to your own individual folder here.

- **Location:** Shows you the name of the shared folder.
- **Local Path:** Shows the path to this folder on your filesystem.
- **Add:** Opens a filesystem dialog to let you select the shared folder.

  Once the location is selected, press the Browse button and use the file system to set the local path to that folder on your computer.
- **Remove:** Removes a shared folder from the Path Mapping settings. It does not delete the folder from your system.
- **Automatically setup when relinking:** With this setting enabled, when relinking offline media, DaVinci Resolve automatically creates a mapping. It compares the path in the project file and the user selected path and creates a relative path between the two. It checks if other offline media in this project is available in those relative paths and relinks them as appropriate. It also does the same check with proxies in proxy subfolders.

The Path Mapping Project Settings

Apple Immersive

These controls let you set parameters for creating Apple Immersive content for the Vision Pro VR headset.

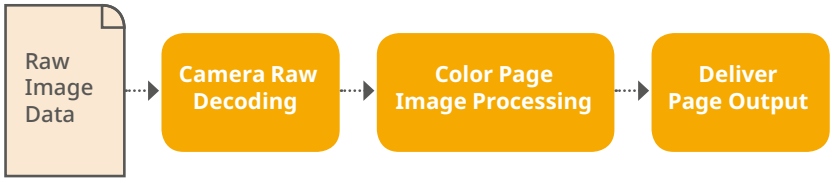
Apple Immersive Processing

This section allows you to set custom ILPD (Immersive Lens Profile Data) to modify how the immersive content is calibrated and projected.

- **Apple immersive calibration:** Shows you the name of the calibration file. Selecting the option menu lets you choose from a list of previously used calibration files.
- **Projection format:** Choose the projection format for the media files.
- **Update Lists:** Click this button to refresh the ILPD content accessible in the Media Pool.
- **Open Calibration Folder:** Click this button to open the calibration folder on your local system, to choose an ILPD file.

Chapter 7

Camera Raw Settings



This chapter discusses in detail each of the settings available for every camera raw format that is supported in DaVinci Resolve. These settings are available in the Camera Raw panel of the Project Settings, via the Inspector in the Media, Cut, and Edit pages, or in the Camera Raw palette of the Color page.

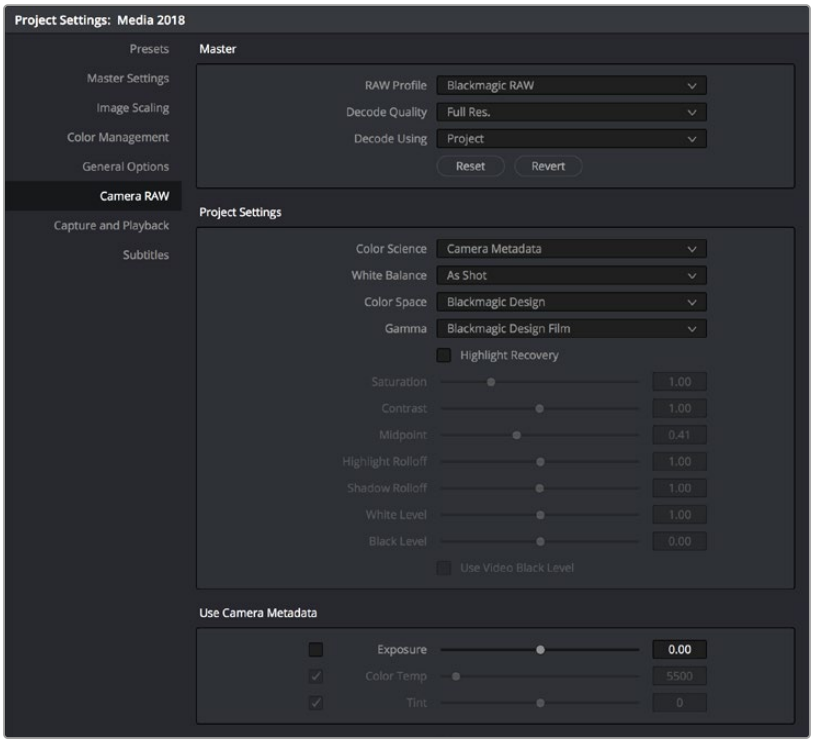
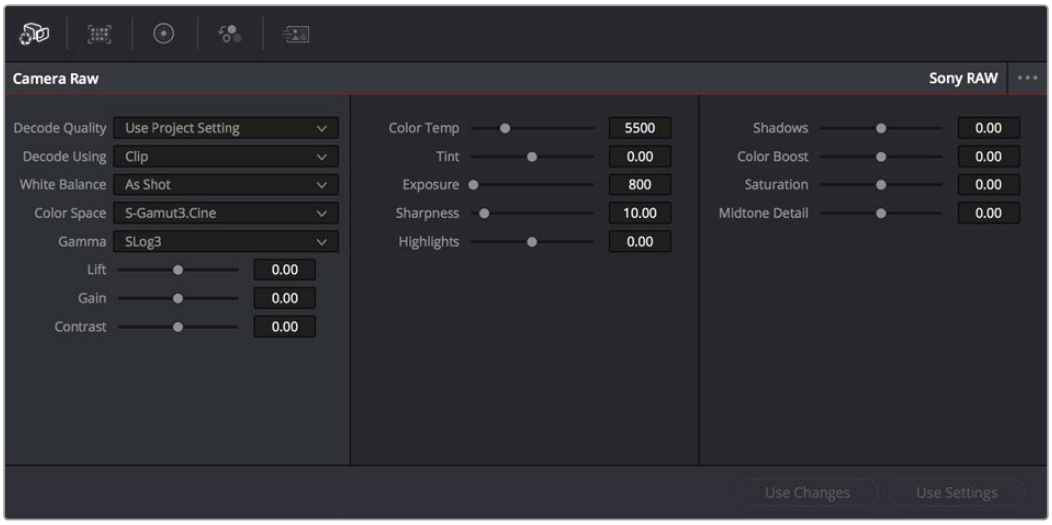
Camera Raw Decoding Explained

Camera raw media formats are so named because they capture raw color space data directly from the sensor of whatever digital cinema camera did the recording. Raw image data is not human readable, and must be debayered or demosaiced to convert the original raw data into image data that can be handed off to DaVinci Resolve's image processing pipeline.



Raw decoding is the very first image processing operation that takes place, and it takes place before all other operations in the Color page, before even the Source bar in the Node Editor. For this reason, it's important to understand that the ideal transformation of raw image data to DaVinci Resolve-friendly image data is one that preserves the maximum amount of image data for continued processing. Since the 32-bit floating point accuracy of DaVinci Resolve's image processing pipeline preserves all transformed raw data with exceptional fidelity, the Camera Raw parameters are primarily useful for making whatever initial adjustments will produce the most optimum starting point for grading.

Each group of Camera Raw settings is available from the Raw Profile menu. This description covers the settings that are available for each of the camera raw media formats supported by DaVinci Resolve.



Camera Raw Project Settings

The Camera Raw panel of the Project Settings contain groups of parameters that correspond to every camera raw media format that's supported by DaVinci Resolve. Using these parameters in the Camera Raw panel, you can override the original camera metadata that was written at the time of recording, and make simultaneous adjustments to all camera raw media throughout your project.

Camera Raw project settings

Each supported camera format has different controls that are specific to that format. These controls are also mirrored in the Camera Raw palette in the Color page, which lets you individually adjust the Camera Raw parameters for individual clips in a Timeline when you set Decode Using to Clip.

Camera Raw project palette in the Color page

Camera Raw Image Inspector

The Image panel in the Inspector exposes the Camera Raw parameters. If the video clip is in a Raw format, the specific camera's Raw controls will be exposed for user manipulation. Raw still images from Nikon (NEF) and Canon (CR2) cameras can also be adjusted in this panel.

The Image Inspector for a Blackmagic RAW file

ARRI

The ARRI ALEXA can record ProRes, DNxHD, or raw image data. When shooting raw, image data is recorded straight from the Bayer sensor, and must be debayered by DaVinci Resolve.

Master Settings

ARRI ALEXA media is extremely simple to debayer. There are only three Master settings.

- **Decode Quality:** Lets you debayer ARRI ALEXA raw files at Full, Half, or Quarter resolution to improve performance on slower systems. Lower resolution media is lower quality, but faster to work with and process. If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.
- **Decode Using:** The option you select determines whether all ARRI ALEXA media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the ARRI default settings.
- **Import Media at Open Gate Resolution:** Enables DaVinci Resolve to access the "open gate" area of clips from ALEXA cameras capable of shooting in this mode, which produces a 3.4K image with extra area for stabilization and repositioning.

Project Settings

The following decoder settings let you adjust the color and exposure of ALEXA clips.

- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Tint:** Adjusts color balance to push the image between magenta and green; useful for balancing images with a green or magenta color cast, such as fluorescent or sodium vapor bulbs. 0 is unity. The range is –150 to +150.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 0 is unity, and 10 is the default. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).

- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Decode as monochrome:** When this box is checked the ArriRaw footage will be decoded in black and white only. This setting is designed to work with the Alexa Monochrome range of cameras. If applied to normal ARRI Raw, it will simply discard the color information. RAW controls that affect color, such as saturation and color temp, will have no effect.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **Color Temp:** Adjusts color balance to alter the "warmth" of the image. Adjustable in Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. +2000 is unity. The range is +2000 to +11,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image, for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –12 to +12.
- **Exposure:** Increases or lowers image lightness in units relative to ASA values. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. 160 is unity. The range is +160 to +3200.
- **Finetune Red:** Advanced debayer setting.
- **Finetune Green:** Advanced debayer setting.
- **Finetune Blue:** Advanced debayer setting.

ARRI Media and Log-C

ALEXA media is usually recorded using Log-C gamma and color processing, which is very similar to the Cineon Log gamma curve, developed by Kodak to produce flat-contrast, wide-gamut image data that preserves image detail with a wide latitude for adjustment. There is no ALEXA raw parameter to adjust this, so for Rec. 709 monitoring and deliverables you need to "normalize" Log-C clips in one of three ways.

You can use Resolve Color Management (RCM) to automatically normalize log-encoded media according to the type of media it is.

You can create your own adjustment to normalize Log-C clips as part of the grading process, using the parameters of the Color page. This approach gives you the most flexibility, as you'll be making custom settings that maximize the image data that's available in every scene.

Alternately, you can use a LUT to normalize Log-C clips to obtain a fast starting point for additional grading. Used in this way, LUTs can be applied either as an output LUT, if the entire Timeline is nothing but ALEXA raw media, or as a LUT that's applied to an individual node of a grade, if you're mixing ALEXA raw media with other formats. This provides a fast and easy solution to linearizing ALEXA media that can be useful for creating dailies for offline editing. However, one LUT may not be suitable for all clips. If you're applying individual LUTs to each

clip, you can create multiple LUTs, each with differing contrast settings, in order to gain the speed benefits of using LUTs, while taking into account the individual differences among clips.

ARRI has a LUT generator available online that you can use to create custom LUTs for use with a variety of color correction applications at: https://www.arri.com/en/learn-help/learn-help-camera-system/tools/lut-generator

Blackmagic RAW

A raw format developed by Blackmagic Design and used by a variety of Blackmagic cameras. This format relies on the increased processing capabilities of modern cameras to perform a certain amount of in-camera pre-processing (including noise management, sensor profiling, and edge reconstruction) to partially de-mosaic the image and then re-encode the result, factoring in the characteristics of the originating image sensor. The image is encoded in such a way as to later enable typical raw controls but with efficiently compressed files (using a custom non-linear 12-bit space) that are not computationally challenging to decode and use. BRAW media can be encoded at either a Constant Bitrate (with variable compression of 3:1, 5:1, 8:1, and 12:1) or at Constant Quality (with a variable bitrate).

BRAW Sidecar Metadata Files

BRAW files have been designed to accommodate descriptive metadata that enables look management from on-set through post. This metadata is both embedded in the .braw files and included within .sidecar files that are saved alongside the media. Metadata .sidecar files that are present always takes precedence over the embedded metadata for purposes of decoding. However, if there's no .sidecar file, decoding of the .braw file falls back on the embedded metadata.

Modifying Sidecar Files

You can use the Camera Raw palette of the Color page to Update a BRAW clip's sidecar file with changes made to the Camera Raw settings. Click Update Sidecar to save changes, and click Export Frame to export a one-frame image for reference.

Master Settings

These parameters let you choose the decode quality and method that raw clips will be transformed to use when debayered.

- **Decode Quality:** Lets you debayer .braw files at Full, Half, Quarter, or Eighth resolution to improve performance on slower systems. Lower resolution media is lower quality but faster to work with and process. If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.
- **Decode Using:** The option you select determines whether all .braw media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the Blackmagic Raw default settings.

Project Settings

These parameters let you choose the color science, white balance color space, gamma, and other visual settings guiding how the image will be transformed to suit your program and RCM.

- **Color Science:** Lets you choose what version of camera color science you want to use to decode .braw media.

  Camera Metadata: Chooses whichever version of color science was selected by the camera at the time of shooting.

  Gen 4: The original version of color science available for recording and decoding .braw media.

  Gen 5: A newer more film-like curve designed for better skin tones and high contrast/saturation color response.

- **White Balance:** The first seven options offer White Balance presets, which automatically adjust the Color Temp and Tint parameters. These options include: Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash. An eighth option, Custom, makes the Color Temp and Tint parameters user-adjustable. The default is As Shot.
- **Color Space:** Debayering .braw data requires choosing a color space to convert the raw signal into. Bear in mind that the color space you choose is merely a starting point for further correction. There is no requirement that you choose one or the other color space for any given workflow, and all settings will yield high-quality image data suitable for further color correction. You should choose the color space that provides the most pleasing starting point for your particular project.

  Blackmagic Design: A wide gamut color space designed for digital cinema workflows on Blackmagic Design cameras.

  Rec. 709: Decodes into the standard color space specified by the Rec. 709 standard for high definition video. While you may find this option useful as a starting point, it is not required for programs being output to video.

  Rec. 2020: Decodes into the standard color space specified by the Rec. 2020 standard for high definition video, UHD video, and beyond. While you may find this option useful as a starting point, it is not required for programs being output to video.

  DCI-P3 D65: Decodes RGB-encoded image data with a D65 white point, intended for monitoring with a P3-compatible display.

  DCI-P3 Theater: A setting designed for adaptive viewing of DCI-P3 in a theater with a projector using a D60 white point.

  CIE 1931 XYZ D65: A specialty setting for outputting to an XYZ color space with a D65 adaptive white point.

  CIE 1931 XYZ D50 (PCS): A specialty setting for outputting to an XYZ color space with a D50 adaptive white point, as used by the profile connection space of the DNG image format.

- **Gamma:** There are several options available for choosing a gamma profile to be used when debayering .braw media. Which one is best really depends on how you like to work, as all will yield high-quality image data without clipping the signal internally within DaVinci Resolve's image processing pipeline. Even though some of these options will produce a range of image data that will clip on output, all of that image data is preserved "under the hood" and can be used and retrieved in your grade.

  Blackmagic Design Film: A log-encoded "film workflow" oriented option that's specifically designed for version 4 of the Blackmagic Design color science. This option is designed to fit the maximum amount of information from wide latitude BMD cameras into the data range of 0–1023. Using this setting provides all the dynamic range from the source media into a signal that can be transcoded to other formats with no compromise. However, this is not a viewable image and requires grading to normalize it into an image that can be delivered to audiences.

Blackmagic Design Video: The standardized gamma curve for standard-dynamic-range HD and UHD display. For wide-latitude images, highlights will be clipped, but all image data will be preserved internally for retrieval via grading as necessary.

Blackmagic Design Extended Video: An SDR-compatible gamma curve similar to the above but with compressed highlights that preserve more highlight detail in the visible range of the image. Intended to be a fast starting point for grading SDR images. Fewer highlights are clipped, but nonetheless all image data is preserved internally for retrieval via grading as necessary.

Blackmagic Design Custom: For specialty workflows.

Linear: A scene linear setting, suitable for visual effects and specialty workflows.

Rec. 2100 Hybrid Log Gamma: The standardized gamma curve for the HLG standard of high-dynamic-range (HDR) video jointly developed by the BBC and NHK.

Rec. 2100 ST2084 (PQ): The standardized gamma curve for high-dynamic-range (HDR) video as encoded by Dolby Vision and HDR10+. Also referred to as the PQ curve.

- **Highlight Recovery:** A checkbox that lets you include additional highlight sensor data that's usually clipped by the standard decoding matrix. In cases where you have extremely clipped peak highlights, you may obtain additional image detail this way, although it may contain unusual color artifacts.
- **Gamut compression:** Prevents monochromatic highly saturated light sources (LEDs, neon signs, etc.) from clipping the gamut.
- **Apply LUT:** Applies color metadata to the BRAW file from the selected LUT source.
- **LUT source:** Choose the color metadata from the sidecar file, or the metadata embedded in the clip.
- **Saturation:** Adjusts the color intensity of the image. 1 is unity. The range is 0 (desaturated) through +4 (extremely high).
- **Contrast:** Increases contrast by raising the top of the signal and lowering the bottom of the signal about the Midpoint slider (described below). Raising this value increases contrast, while lowering this value lowers contrast. 1 is unity. The range is 0 (minimum contrast) to +2 (maximum contrast).
- **Midpoint:** The level about which contrast is either expanded or contracted. 0.41 is unity. The range is 0 (black) to +1 (maximum white).
- **Highlight Rolloff:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 1 is unity. The range is 0 (minimum) through +2 (maximum).
- **Shadow Rolloff:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent while leaving the midtones alone. 1 is unity. The range is 0 (minimum) through +2 (very high).
- **White Level:** A gain setting for adjusting the highlights.
- **Black Level:** A lift setting for adjusting the shadows.
- **Use Video Black Level:** A legacy video setting that adds pedestal to the video signal. For people using video equipment dating from when shoulder pads were cool.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available. Deselect the Use Camera Metadata checkboxes to activate the controls.

- **Exposure:** Increases or lowers image lightness in units relative to *f*-stops. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –5 to +5.
- **Color Temp:** Only available when White Balance is set to something other than As Shot. Designed to alter the "warmth" of the image. Adjustable in Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. +5500 is unity. The range is +2000 to +50,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image, for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –150 to +150.

BRAW Files and Blackmagic Design Film

Blackmagic Design's logarithmically encoded Blackmagic Design Film gamma setting, which produces flat-contrast, wide-gamut image data that preserves image detail with a wide latitude for adjustment, is a modified version of the standard Cineon curve. However, the modifications are designed to emphasize the strengths of the sensors used by the Blackmagic Design cameras. Similarly to working with clips using Cineon, the ARRI ALEXA's Log-C gamma, or Sony's proprietary S-Log or S-Log2 formats, you need to normalize clips using Blackmagic Design Film by using Resolve Color Management (RCM), by making a manual adjustment to color and contrast, or by applying a LUT, using techniques discussed previously.

Canon RAW

Canon RAW (CRW) is produced by a variety of Canon cameras.

Master Settings

These parameters let you choose the decode quality and method that raw clips will be transformed to use when debayered.

- **Decode Quality:** Lets you debayer Canon RAW files at Full, Half, or Quarter resolution to improve performance on slower systems. Lower resolution media is lower quality but faster to work with and process. If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.
- **Decode Using:** The option you select determines whether all Canon RAW media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the Canon RAW default settings.

Project Settings

Canon RAW has a variety of settings that can be adjusted to alter the image quality of the debayered result. The Color Temp and Tint parameters are only available if the White Balance dropdown menu is set to Custom.

- **White Balance:** The first seven options offer White Balance presets, which automatically adjust the Color Temp and Tint parameters. These options include Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash. An eighth option, Custom, makes the Color Temp and Tint parameters user-adjustable.
- **Color Space:** Choose Canon Cinema Gamut or other common colorspaces.
- **Gamma:** Choose a Canon Log version or Rec 709.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **Exposure:** Increases or lowers image lightness in units relative to *f*-stops. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –5 to +5.
- **Color Temp:** Only available when White Balance is set to something other than As Shot. Designed to alter the "warmth" of the image. Adjustable in Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. +6500 is unity. The range is +2000 to +50,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image, for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –150 to +150.

CinemaDNG

CinemaDNG is an open format capable of high-resolution raw image data with a wide dynamic range and is one of the formats recorded by the Blackmagic Design Camera when you shoot in raw mode. CinemaDNG images are decoded with full dynamic range when the Highlight Recovery checkbox is selected.

DaVinci Resolve version 11.2.1 introduced improved debayering for raw CinemaDNG media acquired using any of the Blackmagic Design cameras. The "Apply Pre Tone Curve" setting controls whether you're using the older debayering method (when turned on) or the newer, visually improved debayering method (when turned off).

Master Settings

These parameters let you choose the decode quality, white balance, color space, and gamma that raw CinemaDNG clips will be transformed to use when debayered.

- **Decode Quality:** Lets you debayer CinemaDNG raw files at Full, Half, or Quarter resolution to improve performance on slower systems. Lower resolution media is lower quality but faster to work with and process. If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.
- **Decode Using:** The option you select determines whether all CinemaDNG media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the CinemaDNG default settings.
- **Apply Pre Tone Curve:** When this checkbox is turned off (the default for new projects created in DaVinci Resolve 11.2.1 or later), DaVinci Resolve debayers CinemaDNG raw media using an improved method that delivers better-looking results, specifically for media acquired using any of the Blackmagic Design cameras. When this checkbox is turned on (the default for projects created in earlier versions of DaVinci Resolve), the older debayering method is reenabled for backward compatibility. However, turning Pre Tone Curve on may also provide better results for CinemaDNG raw files coming from other sources. If you're importing .dng media from cameras other than those from Blackmagic Design, you should try both settings to see which type of debayering you prefer.
- **Apply Soft Clip:** This checkbox is only available when Apply Pre Tone Curve is turned off. When turned on, high dynamic range parts of the signal (super-white highlights) are brought back into the picture as visible image detail you can adjust, similar to using the Highlights control to retrieve these otherwise clipped parts of the signal.

Project Settings

CinemaDNG has a variety of settings that can be adjusted to alter the image quality of the debayered result. The Color Temp and Tint parameters are only available if the White Balance dropdown menu is set to Custom.

- **Color Science:** Lets you choose what version of camera color science you want to use to decode CinemaDNG media.

  Camera Metadata: Chooses whichever version of color science was selected by the camera at the time of shooting.

  Gen 4: The original version of color science available for recording and decoding CinemaDNG media.

- **White Balance:** The first seven options offer White Balance presets, which automatically adjust the Color Temp and Tint parameters. These options include: Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash. An eighth option, Custom, makes the Color Temp and Tint parameters user-adjustable.
- **Color Space:** Multiple color spaces are adjustable, depending on your intended workflow:

  Rec. 709: Decodes into the standard color space specified by the Rec. 709 standard for high definition video.

  P3 D60: Decodes into the standard P3 color space specified by the DCI standard for digital cinema projection.

  Blackmagic Design: Decodes into a log-encoded color space that remaps the raw data into an approximation of the Log-C standard. Choosing Blackmagic Design Film also forces the Gamma setting to Blackmagic Design Film. This setting produces flat-contrast image data that preserves image detail with a wide latitude for adjustment, which is suitable as a starting point for detailed grading and is also compatible with log workflows intended for film output.

- **Gamma:** Five gamma settings are available, depending on what starting point you want to use for further grading.

  2.4: A simple power-function gamma setting commonly used for broadcast.

  2.6: A simple power-function gamma setting commonly used for digital cinema projection.

  Rec. 709: A gamma of 2.35, with a linear segment near black, approximating the EBU recommended gamma for broadcast.

  sRGB: A gamma of 2.2, with a linear segment near black, intended for reproduction on computer displays alongside the sRGB color space.

  Linear: A simple linear gamma setting.

  Blackmagic Design Film: A log-encoded gamma setting that approximates Cineon encoding, the main difference being that more data is encoded in the darkest portion of the Blackmagic Design Film signal. When you choose this setting, the appropriate variation of gamma will be applied based on your particular sensor, be it 4K or 4.6K.

  Blackmagic Design Video: A normalized gamma setting that provides a fast starting point for grading if you don't want to begin with a log-encoded image.

- **Highlight Recovery:** A checkbox that lets you include additional highlight sensor data that's usually clipped by the standard decoding matrix. In cases where you have extremely clipped highlights, you may obtain additional image detail this way, although it may contain unusual color artifacts.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter and achieves a smooth blend between the retrieved highlights

and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).

- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **Exposure:** Increases or lowers image lightness in units relative to *f*-stops. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –5 to +5.
- **Color Temp:** Only available when White Balance is set to something other than As Shot. Designed to alter the "warmth" of the image. Adjustable in Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. +6500 is unity. The range is +2000 to +50,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image, for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –150 to +150.

CinemaDNG Files and Blackmagic Design Film

Blackmagic Design's logarithmically encoded Blackmagic Design Film gamma setting, which produces flat-contrast, wide-gamut image data that preserves image detail with a wide latitude for adjustment, is a modified version of the standard Cineon curve. However, the modifications are designed to emphasize the strengths of the sensors used by the Blackmagic Design cameras. Similarly to working with clips using Cineon, the ARRI ALEXA's Log-C gamma, or Sony's proprietary S-Log or S-Log2 formats, you need to normalize clips using Blackmagic Design Film by using Resolve Color Management (RCM), by making a manual adjustment to color and contrast, or by applying a LUT, using the same techniques discussed previously.

Nikon RAW

Nikon RAW (NEF) is produced by a variety of Nikon cameras.

Master Settings

These parameters let you choose the decode quality and method that raw clips will be transformed to use when debayered.

- **Decode Quality:** Lets you debayer Nikon RAW files at Full, Half, or Quarter resolution to improve performance on slower systems. Lower resolution media is lower quality but faster to work with and process. If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.
- **Decode Using:** The option you select determines whether all Nikon RAW media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the Nikon RAW default settings.

Project Settings

Nikon RAW has a variety of settings that can be adjusted to alter the image quality of the debayered result. The Color Temp and Tint parameters are only available if the White Balance dropdown menu is set to Custom.

- **White Balance:** The first seven options offer White Balance presets, which automatically adjust the Color Temp and Tint parameters. These options include Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash. An eighth option, Custom, makes the Color Temp and Tint parameters user adjustable.
- **Color Space:** Choose one of the common video colorspaces.
- **Gamma:** Choose N-Log or one of the common video colorspaces.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).
- **Shadows:** Lets you selectively l°ighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened, while areas of high detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).

- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **Lens Distortion:** Check this box to apply automatic Lens Distortion Correction.
- **Lens Vignette:** Adjusts the correction strength to control vignetting.
- **Exposure:** Increases or lowers image lightness in units relative to *f*-stops. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –5 to +5.
- **Color Temp:** Only available when White Balance is set to something other than As Shot. Designed to alter the "warmth" of the image. Adjustable in Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. +6500 is unity. The range is +2000 to +50,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –150 to +150.

Panasonic Varicam RAW

Panasonic Varicam RAW (CRW) is produced by a variety of Panasonic cameras (such as the VariCam 35 and VariCam Pure 4K) recording to Codex VRAW recorders.

Master Settings

These parameters let you choose the decode quality, white balance, color space, and gamma that raw clips will be transformed to use when debayered.

- **Decode Quality:** Lets you debayer Varicam RAW files at Full, Half, or Quarter resolution to improve performance on slower systems. Lower resolution media is lower quality but faster to work with and process. If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.
- **Decode Using:** The option you select determines whether all Varicam RAW media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the Varicam RAW default settings.

Project Settings

Panasonic Varicam RAW has a variety of settings that can be adjusted to alter the image quality of the debayered result. The Color Temp and Tint parameters are only available if the White Balance dropdown menu is set to Custom.

- **White Balance:** The first seven options offer White Balance presets, which automatically adjust the Color Temp and Tint parameters. These options include: Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash. An eighth option, Custom, makes the Color Temp and Tint parameters user-adjustable.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **Color Temp:** Only available when White Balance is set to something other than As Shot. Designed to alter the “warmth” of the image. Adjustable in Kelvin. Lower values correct for “warmer” lighting, while higher values correct for “cool” lighting. +6500 is unity. The range is +2000 to +50,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image, for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –150 to +150.

Phantom Cine

The Phantom line of high-speed digital cinema cameras record wide latitude, high-gamut media using the Cine Raw format.

Master Settings

These parameters let you choose the decode quality, white balance, color space, and gamma that raw Phantom Cine clips will be transformed to use when debayered.

- **Decode Using:** The option you select determines whether all Phantom Cine media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the Cine default settings.
- **Timecode:** There are four types of timecode that Phantom Cine files can be set to use:

  Set to zero: Camera timecode is ignored, instead using a simple frame count with the first frame considered 0.

  Time of day (Local): Time of day timecode recording.

  Time of day (GMT): Time of day timecode recording based on Greenwich Mean Time.

  SMPTE: Standard SMPTE timecode.

Project Settings

The following settings for exposure, color, and sharpness are available.

- **Gamma:** Three options are available for setting the gamma of the debayered output:
  - Rec. 709
  - Log 1
  - Log 2
- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowing it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).

- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).

RED

R3D source media, recorded by the various models of RED DIGITAL CINEMA cameras, contains one of the most elaborate sets of raw parameters of any of the camera formats. These settings are divided into four different groups.

Master RED Settings

The Master RED settings are the most important, handling decode quality and the control governing whether the original camera metadata is used, or if you're overriding the camera metadata project-wide with custom settings.

These settings also contain the dropdown menus that let you choose the color space and gamma curve used to transform the raw image data into image data for processing in DaVinci Resolve when debayering R3D clips. Which Color Space and Gamma Curve settings you use are solely a matter of preference; there is no absolute requirement to use one or the other for any given type of workflow. You're simply looking for settings that provide the best starting point for the media you have, given the type of grading you're looking to do.

For example, in many cases combining the REDcolor3 Color Space setting and REDlog Film gamma curve will offer a starting point that retains the most image detail with the greatest latitude for adjustment. On the other hand, if you're working in a hurry, for example to generate dailies for offline editing, using one of the REDcolor Color Space settings with one of the REDgamma settings can offer an image that's more immediately pleasing and that requires fewer adjustments to achieve an acceptable result. These are not recommendations, they're only examples. As always, the ideal settings for your project depend heavily on the quality of the source media, so you should experiment with media from your own projects to find the most suitable results to your eye.

Master

These top settings determine the image quality that you're choosing to extract from the R3D source media. The tradeoff is that higher quality media at higher resolution will be more processor-intensive to debayer, depending on your workstation's capabilities.

- **Decode Quality:** Determines the image quality of the decoded R3D data that's handed off to the DaVinci Resolve image processing pipeline. The Decode Quality you select has a direct impact on real time performance. Decoding performance depends entirely on the hardware capabilities of your system.

  On the most modern systems, R3D files can be decoded using accelerated GPU-based debayering if you set the Use GPU for R3D dropdown menu to Debayer in the Decode Options panel of the DaVinci Resolve System Settings. DaVinci Resolve 16.1.2 introduced the latest RED API-enabling 8K-accelerated debayering using Cuda. Otherwise, R3D files can be decoded with high performance using multi-core CPU processing if your workstation has fast enough CPUs.

If necessary, you can also choose a lower quality setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when rendering the final output. A “Force debayer res to highest quality” checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.

- **Bit Depth:** DaVinci Resolve can decode R3D files with 8-, 10-, or 16-bit image data for processing. Choosing 16-bit for maximum quality may impact playback performance on some hardware.
- **Timecode:** The timecode recorded for R3D media depends on the camera setting in use when it was shot. There are three choices:

  Camera: This setting automatically selects between Absolute and Edge depending on what was chosen as the default timecode mode on the camera. This setting needs to be selected before you add R3D media to the Media Pool. If you’re browsing R3D media when you change this setting, you should refresh the folder in the Library of the Media Pool before adding media to the Media Pool.

  Absolute: The default. Records “time of day” timecode. If an external timecode source was connected and the camera was put into Jam Sync mode, the external timecode would have been recorded instead.

  Edge: The first recorded clip for each magazine starts at 01:00:00:00, and the timecode of each subsequent clip is recorded sequentially and continuously.

- **Decode Using:** The option you select determines whether all R3D media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the RED default settings.

Project Settings

These settings control the fundamental methods used to debayer R3D media. The selections you make to these settings determine the basic color and contrast that you’re choosing to extract from the camera raw image data.

- **Color Science:** The options are Original, which was the color science used by early builds of the REDone camera, Version 2, and IPP2, which is the current version of color science used by the entire RED camera line. Unless you need to match the look of older projects using the older color science, the newest color science is generally preferable.
- **Color Space:** Because RED cameras record R3D data which uses a raw color space, debayering the native R3D data requires choosing a color space to convert the raw signal into. Bear in mind that the color space you choose is merely a starting point for further correction. There is no requirement that you choose one or the other color space for any given workflow. You should choose the color space that provides the most pleasing starting point for your particular project.

  DragonColor2: A further optimized version of DragonColor that is especially recommended for underwater footage.

  REDcolor4: A further optimized version of REDcolor3 that is especially recommended for underwater footage.

  REDWideGamutRGB: Part of RED’s IPP2 (image processing pipeline 2) initiative; this is a camera color space designed to encompass all colors that can be recorded by RED cameras without clipping, and is meant to provide a single common starting point for all models of RED cameras, for convenient grading to HDR or SDR workflows.

  Rec. 2020: Decodes into the standard color space specified by the Rec. 2020 standard for high definition video, UHD video, and beyond. While you may find this option useful, it is not required for programs being output to video.

Rec. 709: Decodes into the standard color space specified by the Rec. 709 standard for high definition video. While you may find this option useful, it is not required for programs being output to video.

sRGB: Decodes into the standard color space defined by the sRGB standard, typically used for computer display.

Adobe1998: Decodes into Adobe's unique version of the sRGB standard.

DCI-P3: Decodes to an RGB-encoded image data with a D61 white point, intended for use when outputting media for DCI mastering.

DCI-P3 D65: Decodes RGB-encoded image data with a D65 white point, intended for monitoring with a P3-compatible display.

ProPhoto RGB: A color space developed by Kodak that offers a large gamut intended for photography. An idiosyncrasy of this color space is that the green and blue primary points are outside the boundaries of visible color, meaning this gamut encompasses "imaginary" colors in order to achieve an extremely large gamut.

CameraRGB: Outputs the original, unmodified sensor data. Not a recommended setting.

REDspace: Fits the raw R3D image data into a color space that's larger than that of Rec. 709. Appropriate for digital cinema mastering and film output. REDspace was the predecessor to the REDcolor setting.

REDcolor: A color space that's similar to the Rec. 709 option, but modified to balance accuracy with pleasing color rendition, emphasizing accurate skin tones.

REDcolor2: Similar, but less saturated than, REDcolor.

REDcolor3: Similar saturation to REDcolor, but with additional modifications to improve the color rendition of skin tone. Introduced as the optimum color space for Epic cameras, but also appropriate for previous generations of RED cameras.

DragonColor: A color space optimized for cameras with the RED Dragon sensor, although this color space can be used for previous generations of RED cameras as well.

- **Gamma Curve:** There are several options available for choosing a gamma profile to be used when debayering the raw R3D data:

REDgamma4: The latest iteration of the REDgamma curve, designed to give a good in-camera look without the need for grading, while retaining great dynamic range and highlight handling. REDgamma4 is suitable for all RED cameras.

REDlog Film: An improved logarithmic gamma setting that's designed to remap the original 12-bit R3D data to the standard Cineon gamma curve. This setting produces flat-contrast image data that preserves image detail with a wide latitude for adjustment, and is compatible with log workflows, including those intended for film output.

Linear: No gamma adjustment is made, this is a linear-to-light representation of data from the RED camera's sensor.

Rec. 709: A gamma curve typical for Rec. 709 display. Does not provide an abundance of latitude for grading.

Gamma 2.4: A simple power-function gamma setting commonly used for broadcast.

Gamma 2.6: A simple power-function gamma setting commonly used for digital cinema projection.

sRGB: Similar gamma setting to that employed by Rec. 709.

HDR ST.2084: The standardized gamma curve for high-dynamic-range (HDR) video. Also referred to as the PQ curve.

Hybrid Log Gamma: The standardized gamma curve for the HLG standard of high-dynamic-range (HDR) video jointly developed by the BBC and NHK.

BT.1886: The standardized gamma curve for standard-dynamic-range HD and UHD display. Does not provide an abundance of latitude for grading.

Log3G12: An expanded option for RED's IPP2 (image processing pipeline 2) initiative, this is a wide dynamic range log space designed to encode camera data from all RED models to a common starting point in RWG color space for convenient grading to HDR or SDR workflows. Log3G12 provides 12 stops of dynamic range above mid gray, 2 more stops than Log3G10. However, this is at the expense of a slight loss of precision.

Log3G10: Part of RED's IPP2 (image processing pipeline 2) initiative, this is a wide dynamic range log space designed to encode camera data from all RED models to a common starting point in RWG color space for convenient grading to HDR or SDR workflows. 3G represents the mapping of 18% mid gray to 1/3, and 10 represents the 10 stops of dynamic range above mid gray this supports.

PDlog 685: A logarithmic gamma setting that maps the native 12-bit RED image data into the linear portion of a Cineon or film transfer curve.

PDlog 985: A logarithmic gamma setting with different mappings.

Custom PDlog: A logarithmic gamma setting that exposes user adjustable Black Point, White Point, and Gamma PDlog parameters so you can customize your own log gamma curve.

REDspace: Similar to Rec. 709, but slightly altered to be more appealing, primarily through higher contrast and lighter midtones. The predecessor to the REDgamma curve.

REDlog: A logarithmic gamma setting that maps the original 12-bit R3D image data to a 10-bit curve. The blacks and midtones occupying the lowest 8 bits of the video signal maintain the same precision as in the original 12-bit data, while the highlights that occupy the highest 4 bits are compressed. While reducing the precision of highlight detail, the tradeoff is that there's an abundance of precision throughout the rest of the signal. This is a good setting for maintaining maximum latitude.

REDgamma: An improved gamma curve designed to be perceptually appealing on displays calibrated for Rec. 709, with an improved soft roll-off in the highlights to maintain highlight detail while grading.

REDgamma2: Similar to REDgamma, with higher contrast.

REDgamma3: The most recent iteration of the REDgamma curve. Based on a log starting point, but with a pleasing "ready to view" contrast curve applied, designed to be a visually pleasing starting point that maintains excellent dynamic range. REDgamma3 is also designed to work with REDcolor3.

- **Blend Type:** Works to control how RED HDRX media is used. When using either Simple or Magic Motion to blend HDRX exposures, there's no need to use the second output in the Node Editor. You can choose from three options:

  None: Only the regular exposure is used.

  Simple: Blends the two HDRX exposures to achieve a pleasing middle ground.

  Magic Motion: Uses a proprietary algorithm to combine the dual exposures to combine overexposed and well-exposed regions of the picture in a more targeted fashion, while blending the sharpness of the regularly exposed source with the motion blur of the underexposed source.

- **Blend Bias:** Lets you adjust how much of the regular exposure and how much of the underexposure are combined.
- **Apply Metadata Curves:** If the R3D media files were preprocessed in REDCINE X Pro, and saved with color curve metadata, you can use this setting to either use or discard that metadata.
- **D.E.B. (Dragon Enhanced Blacks):** A checkbox that enables the elimination of red noise in RED cameras using the Dragon sensor.
- **Embedded Audio:** Enables embedded audio in R3D media.

Decoder Settings

This second group of settings contains additional controls for finessing the debayering of RED raw image data. Which controls are exposed depends on which Color Science setting is selected above. Many of the settings in this group are color correction adjustments, some of which resemble analogous controls in the Color page. However, the FLUT and DRX controls manage the exposure of the debayered media being fed to the DaVinci Resolve image processing pipeline, and so can be used to retrieve image detail from R3D source media in cases where the default settings are clipping or crushing detail in the highlights or shadows that would be unavailable to DaVinci Resolve as a result.

- **De-noise:** Applies image-wide noise reduction. There are seven settings available, from mild to maximum, that you can use to balance noise reduction against any possible image degradation.
- **OLPF Compensation:** (color science versions 1 and 2) OLPF compensation applies a low pass filter to reduce color moiré. There are four options: Off (the default), Low, Medium, and High.
- **Image Detail:** (color science versions 1 and 2) Controls the demosaicing algorithm that's used for the software decoding of R3D media. You can choose a level of sensor detail extraction: Low, Medium, and High (recommended). If you're using a RED ROCKET card, this setting is ignored as there is a fixed algorithm that's used.
- **FLUT:** (color science versions 1 and 2) A gain operation that lets you boost or attenuate the ISO in smaller increments. 0 is unity. The range is –8 to +8.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. The image is compressed rather than clipped at the limits of 100 and 0 percent. 0 is unity. The range is –1 to +1.
- **Saturation:** (color science versions 1 and 2) Adjusts the color intensity of the image. 1 is unity. The range is 0 (minimum) through 5.0 (very high).
- **DRX:** (color science versions 1 and 2) A Dynamic Range control (X) that lets you recover highlights while taking into account Color Temperature (degrees Kelvin) and Tint. 0 is unity, and 1.0 is the maximum value.
- **Shadow:** (color science version 1 and 2) Provides control over the toe (low range) of the FLUT adjustment. 0 is unity. The range is –2 to +2.
- **Brightness:** Adjusts image lightness. Image data is compressed rather then clipped at 100 and 0 percent. 0 is unity. The range is –10 to +10.
- **Flashing pixel adjust:** A setting to apply noise reduction for removing or minimizing any flashing pixels recorded from the sensor. Levels are: None, Low, Medium, and High.

Three additional parameters are available for IPP2 workflows, but they only function when DaVinci Resolve is set to use DaVinci YRGB Color Managed color science and the Timeline to Output Gamut Mapping in the Color Management panel of the Project Settings is set to RED IPP2 Gamut Mapping. These controls (which are also mirrored in the Color Management panel when enabled) are designed to let you tone map wide gamut media that's being graded to a smaller gamut, such as Rec. 709.

The RED IPP2 Gamut Mapping controls that appear in the Color Management tab of the Project Settings

- **Output Tone Map:** (color science IPP2) Provides an easy setting for setting the resulting contract when tone mapping wide dynamic range images to standard dynamic range (SDR) output. Settings are: None, Low, Medium, and High. Low results in less contrast; High results in more contrast.
- **Highlight Roll Off:** (color science IPP2) Five settings let you adjust how much to roll off the highlights to fit within the current gamut. These are: None, Hard, Medium, Soft, and Very Soft. Hard provides a minimum of roll-off; Very Soft provides a maximum of roll-off. This setting interacts with the HDR Peak Nits slider below.
- **HDR Peak Nits:** (color science IPP2) Adjusts the amount of highlight compression that's done by Highlight Roll Off.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **ISO:** A gain operation that keeps the black point at 0 while raising or lowering the white point of the image, linearly scaling everything in between. Raising the ISO results only in boosted highlights being more compressed; no clipping will occur. 320 is unity. The range is 50–6400.
- **Exposure Adjust:** Increases or lowers image lightness in units relative to *f*-stops. Using exposure to boost the image beyond 100 or to lower it below 0 will clip, not compress, the image data that's passed along to the DaVinci Resolve image processing pipeline. 0 is unity. The range is –7 to +7.
- **Color Temp:** Designed to alter the "warmth" of the image while keeping white elements of the scene looking neutral. Adjustable in degrees Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. This parameter is designed specifically to adjust RED linear light image data to make the most photometrically accurate correction. 5600 is unity. The range is 1700 to 10,000.
- **Tint:** Color balance correction for images with a green or magenta color cast, such as fluorescent or sodium vapor bulbs. This parameter is designed specifically to adjust RED linear light image data to make the most photometrically accurate correction. 0 is unity. The range is –100 to +100.

Sony RAW

Sony makes several digital cinema cameras, such as the F65 and F55, that record wide latitude, high-gamut media either using Sony's 12-bit SR codec, or as 16-bit raw media files. Since Sony's cameras do not use a traditional Bayer pattern, special debayering is necessary when working with F65 raw media, and the image data is demosaiced using the following raw controls and parameters.

Master Settings

These parameters let you choose the decode quality, white balance, color space, and gamma that Sony raw clips will be transformed to use when debayered.

- **Decode Quality:** Determines the image quality of the decoded Sony raw data that's handed off to the DaVinci Resolve image processing pipeline regardless of the Play Quality setting. The Decode Resolution you select has a direct impact on real time performance, and decoding performance depends entirely on the hardware capabilities of your system.

  If necessary, you can choose a lower resolution setting that provides better real time playback on systems with limited performance while you work, and then switch to a higher quality when

rendering the final output. A “Force debayer res to highest quality” checkbox in the Render Settings list of the Deliver page makes it easy to follow this workflow.

- **Decode Using:** The option you select determines whether all F65 media throughout the project is decoded using the original Camera Metadata settings (the default selection), using Project settings in which you choose custom settings to be applied to all clips, or using the Sony default settings.

Project Settings

These settings control the fundamental methods used to debayer Sony raw media. The selections you make to these settings determine the basic color and contrast that you’re choosing to extract from the camera raw image data.

- **White Balance:** The first seven options offer White Balance presets, which automatically adjust the Color Temp and Tint parameters. These options include: Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash. An eighth option, Custom, makes the Color Temp and Tint parameters user-adjustable.
- **Color Space:** Multiple color spaces are adjustable, depending on your intended workflow:

  Rec. 709: Decodes into the standard color space specified by the Rec. 709 standard for high definition video.

  P3 D60: Decodes RGB-encoded image data with a D60 white point, intended for monitoring with a P3-compatible display.

  SGamut: Decodes into Sony’s wider S-gamut color space, designed to provide the widest range of image data for adjustment.

  SGamut3: The gamut is identical to SGamut, but color reproduction is more accurate, according to Sony’s “Technical Summary for S-Gamut3Cine/S-Log3 and S-Gamut3/S-Log3” whitepaper.

  SGamut3.Cine: According to Sony’s “Technical Summary for S-Gamut3Cine/S-Log3 and S-Gamut3/S-Log3” whitepaper, S-Gamut3.Cine is designed to provide a more traditionally log-encoded workflow with color reproduction that is slightly wider than the P3 gamut.

  P3: Decodes to an RGB-encoded image data with a D61 white point, intended for use when outputting media for DCI mastering.

  ACES: Decodes to image data that maps to the ACES profile for the camera that was used.

- **Gamma:** Five gamma settings are available, depending on what starting point you want to use for further grading.

  Gamma 2.4: A simple power-function gamma setting commonly used for broadcast.

  Gamma 2.6: A simple power-function gamma setting commonly used for digital cinema projection.

  Rec. 709: A gamma curve typical for Rec. 709 display.

  SLog: Not designed for viewing, Sony’s SLog gammas are designed to provide a wide latitude for grading; 14-stops according to Sony. 18% gray is at 38%.

  SLog2: This version has a half stop offset from SLog to allow for a higher dynamic range. 18% gray is at 32%.

  SLog3: An “easier to grade” version of SLog. 18% gray is at 40%. According to Sony’s “Technical Summary for S-Gamut3Cine/S-Log3 and S-Gamut3/S-Log3,” SLog3 is designed to provide a more traditionally log-encoded workflow, with a gamma curve that is similar, but not identical, to Cineon workflows.

  Linear: A simple linear gamma setting.

- **Lift:** Adjusts the black point of the media, raising it or lowering it while scaling all midtone values between it and the white point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.

- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of how you adjust this control, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 20 is unity. The range is 0 to 100.
- **Highlights:** Makes it easy to selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a naturalistic result. 0 is unity. The range is –100 (minimum) through +100 (maximum).
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Color Boost:** Lets you naturalistically raise the saturation of regions of low saturation, sometimes referred to as a vibrance operation. Can be used also to lower the saturation of regions of low saturation. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened while areas of high-detail are left alone. 0 is unity. The range is –100 (minimum) through +100 (very high).
- **Enable ICVFX:** While VFX shooting in a virtual production workflow, the LED wall lighting in the background is mixed with normal lighting for people in the foreground. Checking this box lets you correct for that mixed lighting.

  LED Wall Kelvin: Dial in the color temperature of the LED wall.

  Light Blend: Specifies the mixing ratio of the normal lighting and LED wall lighting. A value of 100 is normal lighting only (equivalent to ICVFX mode disabled). A value of 0 is the LED wall lighting only.

Use Camera Metadata

The most elemental camera metadata settings for exposure and color that are available.

- **Exposure:** Increases or lowers image lightness in units relative to ASA values. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. +800 is unity. The range is +1 to +65,535.
- **Color Temp:** Designed to alter the "warmth" of the image. Adjustable in degrees Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting. +6500 is unity. The range is +2000 to +50,000.
- **Tint:** Only available when White Balance is set to something other than As Shot. Designed to alter the green to magenta balance of the image, for images with fluorescent tinting. Lower values add green to compensate for magenta lighting, while higher values add magenta to compensate for green lighting. 0 is unity. The range is –150 to +150.

Sony Media and SLog

Sony's proprietary SLog gamma setting, which produces flat-contrast, wide-gamut image data that preserves image detail with a wide latitude for adjustment, is also available on some other Sony cameras. Similarly to working with clips using the ARRI ALEXA's Log-C gamma, you need to normalize SLog clips by using Resolve Color Management (RCM), by making a manual adjustment to color and contrast, or by applying a LUT, using the same techniques discussed previously.

When applying a LUT, there are two methods that Sony recommends. A 1D LUT can be used to transform SLog clips into the standard Cineon (or Log-C) curve if your ultimate goal is to output Log media for film printing. If you're planning to output to a normalized format, you can use a dedicated LUT to make this transformation.

For more information, search the web for Sony's document "SLog: A new LUT for digital production mastering and interchange applications."

Chapter 8

Improving Performance, Proxies, and the Render Cache

DaVinci Resolve is a high-performance piece of software designed to enable real time effects on a variety of workstations.

This section describes the various ways you can monitor your performance to make sure you're maintaining real time playback, along with different methods of optimizing real time performance, including using on-the-fly proxies and the background Render Cache.

Background Rendering

DaVinci Resolve supports background rendering for certain computationally intensive operations, including background renders, quick exports, and proxy generation. You can also use background analysis for transcription and audio classification. When an operation moves to the background for processing, you can continue working within the Resolve interface without affecting the original operation.

NOTE: Background rendering requires significant computational resources and may slow down your system significantly, depending on your workstation's processor, ram, data throughput and so on. As a result, this operation is disabled by default.

You can monitor the progress of your ongoing background tasks via the pop-up on the bottom toolbar.

Background Tasks preferences.

- **Background Render:** These options control the Background Rendering parameters.

  Enable background renders: Checking this box turns on Background Rendering, while unchecking turns it off.

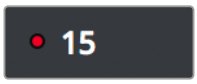
  Pause background renders on foreground activity: Checking this box will pause your background tasks while you're using the DaVinci Resolve interface, giving you full computer power for your active work.

- **Tasks Options:** These options let you choose which operations to render in the background.

  Transcription: Check this box to move transcription tasks to the background.

  Proxy Generation: Check this box to move proxy generation tasks to the background.

The Background Tasks pop-up.



Understanding the GPU Status Display

Every viewer in DaVInci Resolve exposes a GPU status indicator and a frame-per-second (FPS) meter, which appears in the Viewer's title bar, which shows you your workstation's performance whenever playback is initiated. Since DaVinci Resolve uses one or more GPUs (graphics processing units) to handle all image processing and effects, the GPU status display shows you how much processing power is being used by whichever clip is playing.

Frame rate and GPU indication, green is good

A green status indicator shows there is plenty of GPU processing headroom available. As the GPU resources is increasingly taxed, this green graph eventually turns red to show that the available GPU power is insufficient for consistent real time playback.

Red indicates that playback is at slower than real time

Eventually, as you add more and more effects and corrections, you'll reach the limits of available performance, forcing DaVinci Resolve to either drop frames, or play video at a slower speed in order to maintain high image quality, shown by the red FPS indicator.

When real time performance falls short, DaVinci Resolve provides a variety of controls and options that let you enhance real time playback and effects. Each is useful for different situations, and all can work together so you can choose the best trade-off between image quality and performance while you work. All of these methods can be set up to have no effect on your delivered output.

Prioritizing Audio or Video Playback in the Edit Page

When available processing power is insufficient to play the clip or clips at the position of the playhead due to the grade, transforms, or effects that are applied at that moment in the Timeline, you have the ability to choose exactly how performance in DaVinci Resolve degrades, by turning the "Show All Video Frames" on or off in the Option menu of the Edit page Viewers.

- **Show All Video Frames off:** The default setting, ideal for video editing. Prioritizes audio playback at the expense of dropping video frames when processing power is tight, resulting in a more conventional playback experience.
- **Show All Video Frames on:** An alternate setting that's ideal when you're doing effects work, for which you need to see every single frame play back, sequentially. Audio quality is compromised while every frame of video plays in slower-than-real-time, if necessary, to maintain playback.

Keep in mind that this setting only affects playback when GPU performance is lacking. In areas of the Timeline where performance is adequate, playback remains uncompromised.

Performance Mode Improves Overall Performance

Performance Mode, which is found in the Playback Settings of the User Preferences, analyzes your computer's configuration, the CPU, GPU, connected video interface, and so on, and automatically tunes DaVinci Resolve's under-the-hood image processing settings to provide the best interactivity on your machine. It's set to Automatic by default, although you can choose to adjust its effect manually, or disable it altogether. When enabled, Performance Mode dramatically improves the experience of editing, mixing, and grading on less powerful computers.

While Performance Mode is turned on, DaVinci Resolve still outputs to video, renders in the Delivery page, and processes via the Media Management command at the highest quality. As a result, using Performance Mode makes no compromise in the quality of your output, so creative editors and audio mixers can leave this setting on always.

Finishing editors and colorists might notice subtle differences between the image on your computer monitor on less powerful computers when Performance Mode is on versus when it's off, which is why this setting can be disabled, either entirely or in part using checkboxes in the Playback Settings panel of the User Preferences for instances where GUI interactivity is less important than your onscreen display.

Adjusting Performance Mode

A pair of radio buttons in the Playback Settings panel of the User Preferences let you choose between Automatic (default) and Manual behaviors when you turn on Performance Mode in DaVinci Resolve. Set to Automatic, Performance mode automatically optimizes a variety of operations in a bid to balance performance with the necessary level of image quality, for fast onscreen performance while always maintaining the highest level of quality for video output.

Set to Manual, there are three different settings you can choose to disable for instances where a particular performance tradeoff results in an undesirably noticeable reduction in image quality in Performance Mode:

- **Optimized Sizing:** Relates to how image resizing is handled.
- **Optimized Decode Quality:** Relates to how clip resolution vs. timeline resolution is handled.
- **Optimized Image Processing:** Relates to how image processing operations are handled.

Timeline Proxy Mode Improves Effects Performance

If you don't want to either drop frames or play at slower than real time speed whenever the GPU Status indicator is in the red, an immediate way of improving performance is to turn on the Use Timeline Proxies option in the Playback menu. Using timeline proxies reduces processing demands by taking advantage of the resolution independence of DaVinci Resolve to lower the resolution of your clips on-the-fly, thereby increasing real time playback performance without the need to spend time caching part or all of the timeline, or create optimized media (both discussed later).

To turn Use Timeline Proxies on and off:

- Choose Playback > Timeline Proxy Resolution > Half Resolution, Quarter Resolution, or None.

  Turning on one of the proxy resolutions reduces the working resolution by either half or a quarter of whatever the current Timeline resolution is for your project. Working at a temporarily reduced resolution increases your workstation's real time performance, while the resolution independence of Resolve guarantees that every window you draw and sizing operation you make scales correctly to the actual resolution of your project.

Proxy Resolution	Width	Height
Full 8K UHD	7680	4320
Full UHD/Half 8K UHD	3840	2160
Full-HD/Half UHD/Quarter 8K UHD	1920	1080
Half-HD/Quarter UHD/Eighth 8K UHD	960	540
Quarter-HD/Eighth UHD/Sixteenth 8K UHD	480	270

Table of half and quarter proxy resolutions for different television frame sizes

IMPORTANT: Timeline Proxy Mode is entirely different and independent of the creation of Proxy Media as described later in this chapter. The two functions, Timeline Proxy Mode and Proxy Media, have no relation to each other.

Reducing Decode Quality Improves Raw Media Performance

The Use Proxy command will improve performance when grades and effects are responsible for your project's slower than real time playback, but Use Proxy won't help when real time performance is being used up by the need to debayer raw media. While you could improve playback performance by taking the time to either generate optimized media (see below) or render to the Fusion Output Cache by enabling the Smart Cache (see later in this chapter), the fastest solution is to open the Camera Raw panel of the Project Settings and reduce the Decode Quality of the raw media formats you're using:

- **Decode Quality:** Camera raw formats such as R3D and F65 can be debayered at different levels of quality. For higher real time performance, you can choose a lower quality setting while you work, and then switch to a higher quality when rendering the final output.

  Options for reducing resolution vary by each raw format's differing capabilities, but at the very least include full, half, and quarter resolution (R3D and Sony Raw have options for full, half, quarter, eighth, and sixteenth). Exceptions include the Canon RAW, Panasonic Varicam RAW, and Phantom Cine formats, which only decode to full resolution.

  If you reduce the decode quality of raw media formats in your project to improve performance, you can use the "Force debayer res to highest quality" checkbox in the Render Settings list of the Deliver page to ensure that DaVinci Resolve renders all raw formats at the highest quality available, so you don't have to worry about forgetting to change the decode quality back when it's time to render your deliverables.

Optimized Media Improves Overall Performance

If you're editing processor-intensive source formats such as camera raw, H.264, or 8K media, and your computer isn't fast enough to work with it easily in real time, you can create pre-rendered, low-overhead duplicate media to use instead, that's automatically managed alongside the original media. This is called "Optimized Media." Optimized Media lets you work more quickly by allowing you to edit with a more processor-efficient media format and resolution, while providing the ability to easily switch your project back to the original source media whenever you want. So, you can use Optimized media to edit, and switch back to the original source media when it's time to finish and output. Switching is as easy as choosing Playback > Use Optimized Media if Available to toggle Optimized media on and off.

The advantage of using optimized media to help you work faster is that it's pre-generated, meaning you can render it once and then use the files for the duration of your work in that project (unless you change the debayering settings of the raw media). Also, optimized media improves the playback performance of clips throughout DaVinci Resolve, including in the Media page and in the Media Pool and Source Viewer of the Edit page, whereas the similar but different Fusion Output Cache component of the Smart Cache only improves the performance of clips that are already in the Timeline by caching them at the Timeline resolution. This makes optimized media ideal for editing workflows of all kinds.

Choosing the Appropriate Optimized Media Format for Your Project

You have the option of choosing the Format of the optimized media you create, using controls in the Master Settings panel of the Project Settings. Be aware that the format you choose via the "Optimized Media Format" menu will determine whether out-of-bounds image data (also known as "overshoots") and Alpha Channels are preserved when the clip is cached.

- **Preventing Clipping:** You should use 16-bit float, ProRes 4444, ProRes 4444 XQ, or DNxHR 444 if you plan on grading using optimized media. This is particularly true for HDR grading.
- **Preserving Alpha Channels:** Also be aware that the format you choose will determine whether Alpha Channels will be preserved if they're present in the clips being optimized. Currently, the Uncompressed 10-bit, Uncompressed 16-bit Float, ProRes 4444, ProRes 4444 XQ, and DNxHR 444 formats preserve alpha channels.

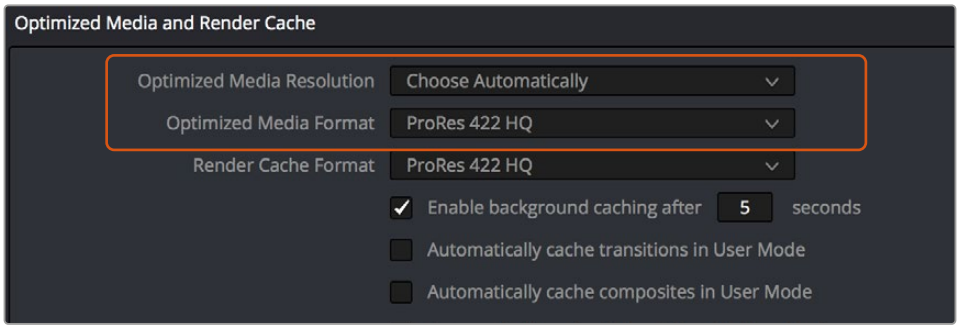
Creating Optimized Media

Creating optimized media to work with is easy. Resolve automatically manages the relationship between source clips and the optimized media you create, so all you need to do is choose which clips to make optimized media for. You can manually choose which clips to optimize, or you can use a Smart Bin to collect all of the media corresponding to one or more formats you need to optimize to gather it procedurally. In either case, this gives you the option of only optimizing clips in formats that require optimization, saving you time.

For example, if you're editing a project that consists half of camera raw media, and half of DNxHD media, you probably only need to optimize the camera raw media, so you can create a Smart Bin that gathers all of it, based on Resolution, Codec, File Name, or whatever other metadata is appropriate. Once gathered, it's an easy thing to select all of these clips in preparation for the next step.

To create optimized media for one or more selected clips:

Right-click one of the selected clips, and choose Generate Optimized Media from the contextual menu.



All optimized media is written to the same directory as the Cache files are written, which defaults to the first scratch disk listed in the Preference dialog's Media Storage panel. The location of Cache and Optimized files is also selectable via the "Cache files location" setting in the Master Settings panel of the Project Settings.

Optimized Media for Raw Source Clips

In general, once you create optimized media, DaVinci Resolve keeps track of it and continues using it regardless of whatever changes you make to your project, including changing the Timeline resolution. However, any change to the camera raw settings of optimized clips will automatically discard the optimized media, requiring you to re-generate optimized media for them.

Customizing the Type of Optimized Media You Create

The Master Settings panel of the Project Settings has a set of controls that govern what kind of media files are created when you create optimized media.

Options available for creating optimized media in the Master Settings panel of the Project Settings

There are two settings affecting Optimized Media in the Optimized Media and Render Cache section:

- **Resolution:** Lets you choose whether to create optimized media at the same size as your original media files (by choosing Original), or to reduce the bandwidth of your optimized media further by reducing its resolution by a Half, Quarter, Eighth, or Sixteenth. The "Choose automatically" option tries to balance visual quality with efficiency by only reducing the resolution of media files that are larger than the currently selected Timeline resolution, using whatever reduction ratio best matches the Timeline resolution.
- **Optimized Media Format:** Lets you choose the format and codec with which to generate optimized media. Options include Uncompressed 10-bit, and Uncompressed 16-bit float for maximum quality. Other options include ProRes Proxy through 4444 XQ, and DNxHR LB through 444. All options will store image data in the optimized and proprietary .dvcc image format. While smaller formats take less room on your scratch disk, there are two good reasons to use higher-quality formats for creating Optimized Media.

  Preventing Clipping: Be aware that the format you choose will determine whether out-of-bounds image data is preserved when the signal is optimized. If you find that image data (typically super-white levels) are clipped after optimization, you should switch to 16-bit float, ProRes 4444, or ProRes 4444 XQ; in particular, any of these three codecs are appropriate optimized formats for HDR grading.

  Preserving Alpha Channels: Also be aware that the format you choose will determine whether Alpha Channels will be preserved, if they're present in the clips being Optimized. Currently, the Uncompressed 10-bit, Uncompressed 16-bit Float, ProRes 4444, ProRes 4444 XQ, and DNxHR 444 formats preserve alpha channels.

Choosing Resolution Automatically

The “Choose automatically” option of the Resolution setting bears a bit more explanation. When selected, only source media with a higher resolution than the selected Timeline resolution will generate downsized optimized media. How much each clip will be downsized depends on how much larger each clip is than the Timeline resolution. For example, if you’re working within a 1080 resolution project, then 8K clips will generate quarter-resolution optimized media, and 4K clips will generate half-resolution optimized media, such that all optimized media is somewhere around 1080 resolution. All clips that are 1080 and smaller generate optimized media at the same resolution as the source clips.

In the example of a 4K project, 8K clips will generate half-resolution optimized media, and all other clips that are 4K and smaller will generate optimized media at the same resolution as the source clips.

Proxy Resolution	Width	Height
Full 8K UHD	7680	4320
Full UHD/Half 8K UHD	3840	2160
Full-HD/Half UHD/Quarter 8K UHD	1920	1080
Half-HD/Quarter UHD/Eighth 8K UHD	960	540
Quarter-HD/Eighth UHD/Sixteenth 8K UHD	480	270
Eighth-HD/Sixteenth UHD	240	135

Table of optimized resolutions for different television frame sizes

Switching Between Optimized and Original Media

Choosing whether or not you’re using optimized media is easy. Simply choose Playback > Use Optimized Media if Available to switch your entire project between using optimized media (if it’s been generated), or the original media. Furthermore, a checkbox in the Render Settings of the Deliver page lets you choose whether you want to use optimized media to speed up rendering, or render using the original media only.

NOTE: Optimized media is not included in Media Management operations, nor is it included as part of Archive operations in the Project Manager.

Sharing Optimized Media Between Projects

Optimized Media is shared across projects in the same project library (previously optimized media was confined to a single project). This means that if you create optimized media for a clip in one project, that same optimized media will be used for that clip in any other project that’s in the same project library. This happens automatically and requires no user input. This will dramatically cut down the space requirements for working with the same media across different projects.

Rediscovering Lost Optimized Media

It's difficult, but it is possible to lose track of optimized media you've generated in certain rare circumstances. For example, if you generate optimized media on another workstation, but failed to save the project, DaVinci Resolve may lose the relationship between the clips in the Media Pool and the optimized media files you created. In these cases, it's possible to rediscover the optimized media so you don't have to regenerate it.

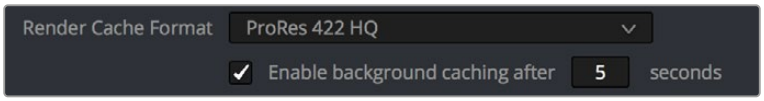
To rediscover lost optimized media:

Select the clips in the Media Pool for which you know you have optimized media, then right-click one of the selected clips and choose Rediscover Optimized Media from the contextual menu.

Deleting Optimized Media

The optimized media you generate within a project is persistent; it's saved for future use even when the project is closed and later reopened. If you need to delete optimized media to free up space on your scratch volume (or wherever you've decided to locate your project's cache files), you must delete the optimized media manually in your OS. By default, the Optimized Media is stored in the first volume in the Media Storage tab of the System Preferences.

Using Optimized Media for Delivery



An option in the More options section of the Render Settings in the Deliver page, "Use Optimized Media," lets you output using Optimized Media, rather than the original media, in order to save rendering time. If you're planning on using this option, it's advisable to set the Optimized media format to a suitably high-quality HDR-capable format to guarantee the best results.

Using the Smart or User Cache Improves Effects Performance

Another option for achieving real time performance when the GPU Status indicator is in the red due either to Timeline effects, Color page grading, or processor-intensive media in the Timeline, is to use the Smart Cache or User Cache modes of the Render Cache. What DaVinci Resolve calls "caching" is sometimes referred to by other applications as "rendering." Both terms refer to the behind-the-scenes creation of new media, with all effects "baked in," which DaVinci Resolve plays back in real time in place of the original source media containing processor-intensive effects at the same time. This results in smooth playback without the risk of dropped frames.

The DaVinci Resolve Smart Cache and User Cache automatically render and cache clips, including simple video clips, compound clips, Fusion clips, and nested timelines that have processor-intensive grades and effects applied to them, or that you manually flag for caching by right-clicking any clip in the Color page or Edit page timeline and enabling the Render Cache Clip Output option. When the Smart or User Caches are enabled, frames of each automatically or manually flagged clip are cached either during playback in the Timeline, or automatically whenever you pause work, to the "Cache files location" specified in the Master Settings panel of the Project Settings.

Once you've cached clips in the Timeline, they play back in real time until they're modified, which automatically flushes the now out-of-date cache files for those modified clips and triggers the need to re-cache.

The settings governing caching in the Master Settings panel of the Project Settings

To use clip caching on any page, do one of the following:

- Choose Playback > Render Cache > Smart to set DaVinci Resolve to automatically cache computationally intensive effects and timeline clips in formats judged too processor-intensive to play in real time.
- Choose Playback > Render Cache > User to set DaVinci Resolve to cache clips and effects that you manually choose to cache, as well as automatically caching processor-intensive effects (transitions, composites, and Fusion Effects) you specify in the Master Settings of the Project Settings.
- Choose Playback > Render Cache > Off to disable all render caching.
- In the Color and Edit pages, press Option-R to cycle among Off, Smart, and User.

Choosing the Appropriate Cache Media Format for Your Project

You have the option of choosing the Format of the cached media you create, using controls in the Master Settings panel of the Project Settings. Be aware that the format you choose via the "Render Cache Format" menu will determine whether out-of-bounds image data (also known as "overshoots") and Alpha Channels are preserved when the clip is cached.

- **Preventing Clipping:** You should use 16-bit float, ProRes 4444, ProRes 4444 XQ, or DNxHR 444 if you plan on grading using cached media. This is particularly true for HDR grading.
- **Preserving Alpha Channels:** Also be aware that the format you choose will determine whether Alpha channels will be preserved, if they're present in the clips being cached. Currently, the Uncompressed 10-bit, Uncompressed 16-bit Float, ProRes 4444, ProRes 4444 XQ, and DNxHR 444 formats preserve Alpha channels.

How Cached Media Is Organized

The cache mechanism in DaVinci Resolve actually comprises three independently managed media caches that interact with one another. This is done to keep you working quickly by ensuring that changes you make to your timeline don't require a grade to be re-cached, and that changes you make to a grade don't require the timeline to be re-cached. The three levels of caching are:

First, Fusion Output Caching

Formerly called the "Source Cache" in previous versions of DaVinci Resolve. When enabled by turning on the Smart Cache, by individually turning on Render Cache Fusion Output for a particular clip, or by enabling the automatic caching of clips with Fusion Effects applied in the Project Settings, this caches the portion of each source media file that appears in the Timeline in its pre-graded state for clips that have the following characteristics:

- Clips in media formats DaVinci Resolve considers to be processor-intensive to decode, such as H.264, HEVC, and various raw camera formats
- Clips with Fusion Effects that have been added in the Fusion page

Effectively, this is a "pre-Color page" cache. By caching all processor-intensive clips in the Timeline, you'll experience vastly improved trimming and grading performance. However, you also have the option to turn the Fusion Output Cache on or off for individual clips, or for multiple selected clips all at once. This lets you switch between using the native source of each clip with live effects, or the cached clip in the cache format you've chosen.

The advantage of the Fusion Output Cache over Optimized Media is that you only cache clips that are used in a timeline, which is ideal for finishing workflows. However, the Smart and User caches aren't useful for speeding up work done with source media in the Media Pool and Source Viewer when you're at the very beginning of an edit; that's what Optimized Media is for (as described in the previous section).

If Optimized media exists for a given clip, and "Use Optimized Media if available" is turned on, then Optimized media will be used instead of the Fusion Output Cache if there are no Speed effects or Fusion Effects applied to a particular clip.

Second, Node Caching

The Node Cache, which is a separate level of caching from the Fusion Output Cache, can be triggered in several different ways, corresponding to the three different purposes it serves.

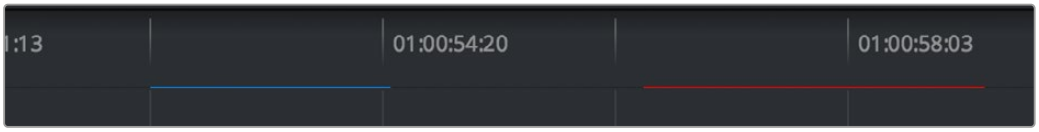
- When enabled by turning on the Smart Cache, nodes with processor-intensive operations (along with all nodes appearing upstream in that grade's node tree) are automatically cached, meaning that, for example, if Nodes 1 and 2 are cached, you can continue adjusting Nodes 3, 4, and 5 to your heart's content without needing to re-render your grade to the cache. Operations that trigger caching include Noise Reduction, Motion Blur, and any Resolve FX or OFX plugin that's added to a node. If you've added a Resolve FX to a node that's capable of playing in real time but that node is being flagged for caching anyway, you can force caching off for that node by right-clicking it and choosing Node Cache > Off from the contextual menu.
- You can manually force any node to cache if it and its upstream nodes are compromising performance but somehow not being automatically flagged, by right-clicking a node and choosing Node Cache > On from the contextual menu.
- You can also turn on the "Render Cache Color Output" option for a clip in the Timeline of either the Edit or Color pages. This forces that clip's entire grade to be cached via the Node Cache, all the way through the Node tree's output. This can result in higher real time performance in the Edit page, at the expense of needing to completely re-cache that clip whenever you adjust any part of its grade.
- If you apply Resolve FX or OFX filters to clips in the Edit page, these will also be cached via the Node Cache. You can choose which OFX to cache via the Render Cache OFX Filter submenu in the contextual menu for clips in the Timeline. This is useful when you have a combination of realtime and non-realtime filters applied to a clip; caching the non-realtime filters only enables you to continue adjusting realtime filters without the need to re-cache. However, be aware that making changes to a filter being cached in the Edit page timeline will force that clip's grade to be re-cached in the Color page, and vice versa.

If multiple nodes are flagged for caching in a particular node tree, then each node will be individually cached. That way, you can turn a cached node off and on to get a before-and-after look without needing to re-cache the entire node tree. If a clip is part of a group in the Color page, you can enable a Group Cache in the Group Pre-Clip and Group Post-Clip Node Editor modes, which cache these parts of a group grade as part of the Node Cache.

Third, the Sequence Cache

The Sequence Cache is a separate cache for effects that are specifically applied within the Timeline in the Edit page. These include transitions, opacity adjustments, adjustment layers and composite mode superimpositions, as well as clips with Speed or Retime effects. Sequence Cache effects can be auto-cached in both the Smart and User caches.

Choosing a Cache Format and Location



The cache format is user selectable by opening the Master Settings panel of the Project Settings, and using the “Render Cache Format” dropdown menu to choose one of the ProRes, DNxHR, or uncompressed 10- or 16-bit float uncompressed .dvcc formats. Selecting a higher quality cache format guarantees high quality image playback, but makes more demands on the throughput and size of your available disk storage. On the other hand, choosing a more highly compressed cache format makes real time playback possible on less capable computers with slower and smaller storage, at the expense of slightly compromised image quality. Ideally, you should choose the highest quality cache format that your workstation’s storage can accommodate.

The format you choose via the “Render Cache Format” menu will determine whether out-of-bounds image data (including “super white” or HDR strength highlights) is preserved when the signal is cached. Formats in this menu that end in “– HDR” preserve out-of-bounds image data, while formats that don’t, wont. If you find that image data (typically bright highlights) is clipped after caching or optimizing, you should switch to 16-bit float, ProRes 4444, ProRes 4444 XQ, or DNxHR 444; in particular, any of these codecs are appropriate for HDR grading.

The Cache files location defaults to the first volume you add to the Scratch Disks list of the Media Storage panel of the System Preferences. If no scratch disk is specified, your System disk will be used, which may pose problems with capacity and/or performance depending on the size and type of System disk you’re using, and on the media format you choose to cache to. For this reason, it’s nearly always advisable to set your first scratch disk to the largest, fastest storage volume available to your workstation.

When Caching Happens

When caching is enabled, cache indicators along the bottom of the Timeline Ruler of the Edit page timeline shows the status of the cache. Red means “to be cached,” while blue means “has been cached.”

Source, Clip, and Sequence Cache bars seen in the Timeline of the Edit page; red bars show areas of the Timeline that need caching, blue shows areas that have been cached

In the Color page, cache indicators are node specific, showing the node in your grading node tree (including all upstream nodes) at which caching will take place.

Node Cache indicator seen as a red colored node number on node two of the Node Editor of the Color page

Caching happens in two ways. First, when either Smart or User caching is enabled, caching always happens whenever you play clips with red caching indicators.

Second, if background caching is enabled in the Project settings (it's turned on by default), and you don't make any changes to your project for a user-definable number of seconds (this is adjustable in the Master Settings panel of the Project Settings), caching will automatically begin during periods of user inactivity. So feel free to use this as an excuse to take those coffee, mate, or tea breaks; DaVinci Resolve will keep on working for you.

The Difference Between the Smart Cache and User Cache Modes

The Smart Cache option of the Render Cache submenu provides the easiest user experience when you want to "set it and forget it." Choosing Smart triggers a variety of automatic caching behaviors designed to optimize playback in DaVinci Resolve by rendering clip formats, grading operations, and timeline effects that are known to be performance-intensive, while also letting you manually flag clips that you'd like to cache that the Smart Cache hasn't.

The User Cache, on the other hand, does not automatically cache clips in processor-intensive formats, so this is a good option to choose when your workstation is capable of playing all media formats you're using in real time. Ordinarily, the User cache relies on you to control what is cached and what is not by manually flagging specific clips and effects. However, the Master Settings panel of the Project Settings has three options you can enable for automatically caching transitions, composites, and Fusion Effects while in User Cache mode (these options are found in the Optimized Media and Render Cache group). Of these settings, only "Automatically cache Fusion Effects in User Mode" is turned on by default.

Here are the differences between the Smart and User cache modes for each type of caching DaVinci Resolve does.

Fusion Output Caching

- **In Smart mode:** For all clips with "Render Cache Fusion Output" set to either Auto (by default) or On, three types of effects are rendered. First, H.264, H.265, DCP, JPEG2K, or camera raw clips that have been edited into a timeline are cached. Camera Raw clips are cached using the currently selected project or clip debayer settings. Second, Speed effects are cached at the source level, which makes it possible to move cached speed effects clips on the Timeline without needing to re-cache them. Finally, Fusion Clips or clips with Fusion Effects applied to them are also cached, and manually flagged clips are also cached in Smart mode.
- **In User mode:** Clips with Render Cache Fusion Output set to On are cached, while clips set to Auto are ignored, except for clips with Fusion Effects, which are automatically cached in Auto mode when the "Automatically cache Fusion Effects in User Mode" Project Setting is on.

Caching Specific Nodes in the Color Page

- **In Smart mode:** DaVinci Resolve automatically caches all nodes that use Motion Blur, Noise Reduction, or Resolve FX and OFX plugins. Manually flagged nodes are also cached in Smart mode.
- **In User mode:** DaVinci Resolve only caches nodes that have been manually flagged by right-clicking them and choosing Node Cache > On to force that node to cache in User mode, along with all upstream nodes to the left of them.

Cache Color Output Is Actually Node Caching for the Whole Grade

- **In Smart mode:** Manually flagged clips with Render Cache Color Output turned on cache the entire output of the Color page node graph, effectively caching that clip's entire grade. This is most useful when you want to improve trimming and playback performance in the Edit page. Flagging a clip for caching also causes EVERY SINGLE VERSION associated with that clip to be cached as well.
- **In User mode:** Manually flagged clips with Render Cache Color Output turned on also cache the entire output of the Color page node graph.

Caching of Resolve FX and OFX in the Edit Page Is Also Node Caching

Caching of Resolve FX and OFX filters applied to clips in the Edit page can only be set manually, whether you're in Smart or User mode. Only filters that you have flagged to cache by right-clicking the clip they're applied to and choosing them in the Render Cache OFX Filter submenu are cached.

Sequence Caching

- **In Smart mode:** DaVinci Resolve automatically caches all superimposed clips that use composite modes other than "Normal," any clips with opacity or speed effects, and any transitions. Clips cannot be manually flagged for Sequence caching.
- **In User mode:** If you've enabled User mode and you find that your workstation does not have adequate performance to play composite and opacity effects in the Edit page, you can force these categories of effects to be automatically cached in User mode via a set checkboxes in the Optimized Media and Render Cache section of the Master Settings of the Project Settings. When these options are enabled, you also gain the ability to exclude specific tracks from being cached, by right-clicking the track header of any video track you want to exclude from caching, and choosing Exclude track from caching. Excluding an entire track from caching is a convenient way of keeping a track full of effects that are capable of playing in real time on your workstation, such as a track of titles, from wasting time and storage by being cached when it's not necessary.

Manually Controlling the Cache

This section describes how to manually control each type of caching that is manually controllable in DaVinci Resolve.

Controlling Fusion Output Caching

You can manually control which clips in the Timeline are cached, and which are not. You can select one or more clips in the Timeline of the Edit page, or in the Thumbnail Timeline of the Color page, right-click one of the selected clips or thumbnails, and choose an option from the Render Cache Fusion Output submenu. There are three options:

- **Auto:** The clip will only be cached in Smart mode if it's a format designated for caching or if there's a speed effect applied. The clip will only be cached in User Mode if "Automatically cache transitions in User Mode" is enabled.
- **On:** The clip will be cached in either Smart or User mode, no matter what format or effects are applied.
- **Off:** The clip will not be cached at all, in either Smart or User modes.

Controlling Node Caching

You can manually control which nodes in a grade are cached, and which are not. Right-click any node in a node tree, and choose an option from the Node Cache submenu. There are three options:

- **Auto:** The flagged node and all upstream nodes will only be cached in Smart mode if it contains an operation that's designated for caching.
- **On:** The node will always be cached in either Smart or User mode, no matter what operations it performs.
- **Off:** The node will not be cached, in either Smart or User modes. This lets you exclude nodes from caching in Smart mode if they're capable of real time operation on your system.

Controlling Color Output Caching

Each clip in the Timeline (including Adjustment clips) has a Color Output setting that you can turn on or off by right-clicking that clip in the Timeline of the Edit page, and choosing Render Cache Color Output from the contextual menu. A check mark indicates when this setting is turned on.

Controlling Edit Page Filter Caching

You can choose which of the Resolve FX or OFX filters applied to a particular clip should be cached by right-clicking that clip in the Timeline of the Edit page, and choosing which of the filters in the Render Cache OFX Filter submenu you want to cache.

Each filter applied to that clip appears in this submenu in the order in which it's applied to the clip, and you can turn the caching of specific filters on and off (selected filters appear with a check mark to the left of their menu item).

Using Cached Media When Rendering in the Deliver Page

The "Use Render Cached Images" option in the "More options" section of the Video panel of the Render Settings in the Deliver page lets you write media directly from the cache, rather than re-rendering the effects from scratch, in order to save rendering time when you output your project. If you're planning on using this option, it's advisable to set the cache format to a suitably high-quality format to guarantee the best results.

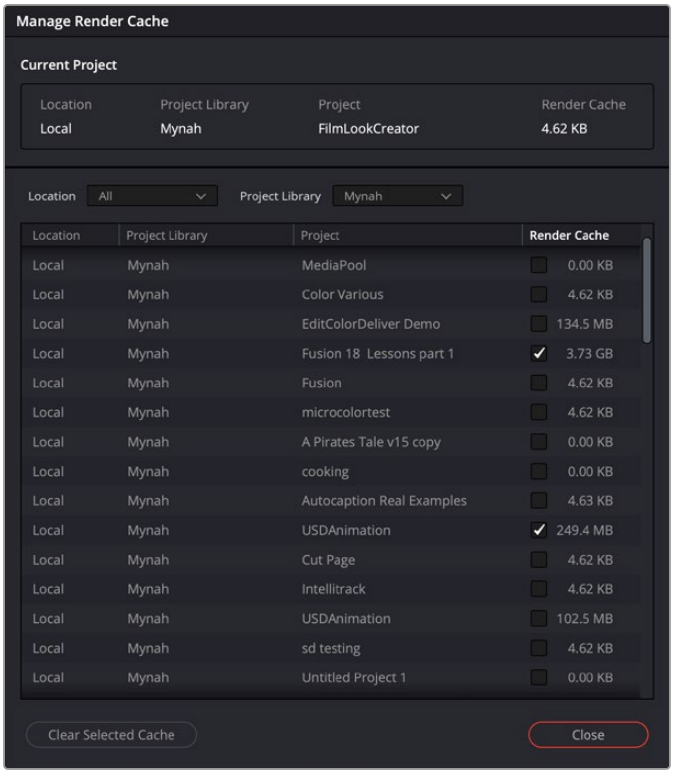
Clearing Cached Media

Each project's cache is persistent; the cache is saved for future use even when the project is closed and later reopened. If you need to delete a project's cache to free up space on a storage volume, there are three options in the Delete Render Cache submenu:

- **All:** You can delete all media in the cache to reset every single cached clip.
- **Unused:** You can choose to delete only Unused cache clips that no longer correspond to clips or effects in the Timeline.
- **Selected clips:** You can make a manual selection of clips in the Timeline, and delete the cache corresponding to just those clips.

To clear a project's cache:

Open the project, and choose Playback > Delete Render Cache > All, Unused, or Selected Clips.



The Cache Manager

There is an advanced render cache management window to help you easily see the size and manage your cache data for various projects across all your project libraries. This cache manager can be accessed from Playback > Manage Render Cache.

The Cache Manager window ties in with the Project Manager, letting you select cached media from any library accessible from your system, not just the current project library.

The functions of the Cache Manager are:

- **Location:** This dropdown menu lets you choose the type of project library to connect to. Options are: Local, Network, Cloud, and All.
- **Project Library:** This dropdown menus lets you choose the project library whose projects you want to manage. This lists all the project libraries in the selected Location, and you can select one for management. You can also select All to reveal all project libraries in that location.
- **Project:** The main window shows all the projects in the Project Libraries selected above. It is categorized into sortable columns by Location, Project Library, Project Name, and Render Cache. Check the box in the Render Cache column to select any projects you want to delete the cache of.
- **Clear Selected Cache:** Click this button to delete the Cache for all the selected projects. As of this writing there is no warning dialog or undo for this function, so double check that you've selected the correct caches for deletion.
- **Close:** Closes the Cache Manager.

The Cache Manager

Automatic Cache Deletion

A User Preference allows you to delete your local cache automatically after a certain number of days to keep your drive from filling up with older projects.

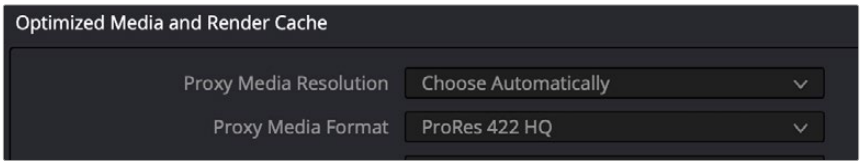
It is found in DaVinci Resolve > Preferences > User > Cache Management > Delete cache older than xx days.

Check the box to automatically delete any cache files older than the number of days set in the field.

You can always manage these files manually from the Playback > Manage Render Cache menu, but this new preference lets you set and forget a cleanup operation.

Using Proxy Media

DaVinci Resolve includes a Proxy Media workflow to provide a playback optimization option that makes it easier to exchange projects online, work on projects remotely, and work with external media asset management systems. It creates a simple and flexible system for editing collaboration that can be custom configured to your specific requirements.



Creating and Using Proxy Media

Proxy Media is essentially more highly compressed (and potentially lower resolution) versions of your source media that are linked to your source media in DaVinci Resolve via metadata. This is done in such a way as to make it easy to switch back and forth between the original and proxy media as your needs require.

Typically, this lets you use lower bandwidth proxy media for increased real-time effects performance and full speed playback while editing, while easily reverting back to more bandwidth and processor-intensive source media for color correction, finishing, and final output. In addition to enabling better performance, these proxy files are fully portable, which lets you move your whole project easily from workstation to workstation, and even across the internet, accompanied by much more compact proxy media.

You set the resolution and format of your proxies in the Optimized Media and Render Cache section of the Master Settings panel in the Project Settings. There are two settings that control the actual media files created by the Generate Proxy Media command.

- **Proxy Media Resolution:** Choose “Original” to keep proxies the same resolution as the source media. If you prefer, reduce the resolution of the proxy media files by choosing Half, Quarter, Eighth, or Sixteenth to save bandwidth. The “Choose Automatically” option balances visual quality with efficiency by only reducing the resolution of media files that are larger than the currently selected Timeline resolution, using whatever reduction ratio best matches the Timeline resolution.
- **Proxy Media Format:** Lets you choose the specific QuickTime format and codec that the proxy files will be created with. There are several ProRes and DNxHR varieties to chose from, as well as H.264 and H.265 options. Which format you chose will be determined by the bandwidth and quality tradeoffs that you need for a particular project. For example, if you simply want better playback speed from RAW media while preserving image quality, you may want to pick a high-quality codec like ProRes 422 HQ, or DNxHR HQX. If your goal is to send your media across the internet to another editor, you may want to chose a more compressed format, such as ProRes Proxy, or even H.264 or H.265, to keep file sizes small.

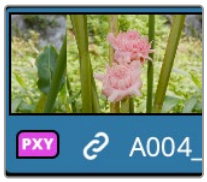
The Proxy Media Resolution and Format settings

To generate proxy media in DaVinci Resolve:

1. Select all of the clips you wish to generate proxies for in the Media Pool.
2. Right-Click any selected clip and choose “Generate Proxy Media” from the contextual menu.

   DaVinci Resolve will display a progress bar and give you a time estimate for completion as it renders out your selected clips to the format and codec determined by the Proxy Media Resolution and Format settings.

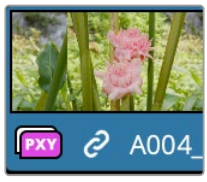
NOTE: If your source clip has a separate audio file synced to it in the Media Pool, any proxies generated from that clip will include the synced audio, but that audio will be embedded in the video clip instead of being created as a separate file.



Where is Proxy Media Saved?

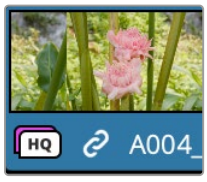
Proxy media is created in the “Proxy generation location” destination, found in the Working Folders section of the Master Settings of the Project Settings. The proxies are further organized into subfolders by original source clip location. It is important to have enough free space on this drive to contain the proxies. Once created, these proxy files can then be moved to any other drive location on the system, if you wish, and then re-linked to their source files.

This location can be overridden by adjusting the Proxy Generation Location options in the Media Storage settings in the DaVinci Resolve Preferences.



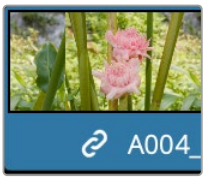
Proxy Handling Display

In both the Media Pool and on the Timeline in the lower left corner of a clip, there can be found a proxy status icon. This icon changes to let you know exactly which type of media DaVinci Resolve is currently using.



The Proxy Only icon

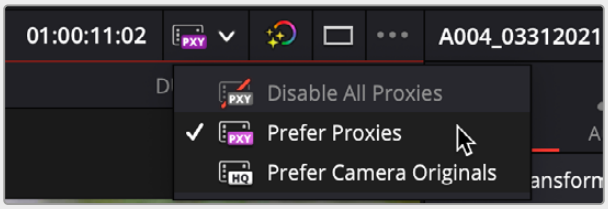
Purple PXY Only: This icon indicates that only proxy media is available; the camera original media is missing.



The Proxy Preferred icon

Purple PXY over a White Background: This icon indicates that both camera originals and proxy media for this clip exist, and that proxy media is being used.

The Camera Original Preferred icon



White HQ over a Purple Background: This icon indicates that both camera originals and proxy media for this clip exist, and that original media is being used.

The Camera Original with no icon

No Icon: No icon means that proxy workflow has been disabled, and all media is Camera Original.

You can select which media you prefer to use in the Proxy Handling selector in the top right of the Viewer. This is a global setting that changes proxy handling for all the viewers across DaVinci Resolve.

The Proxy Handling Selector in the Viewer lets you choose which type of media to use.

Creating Proxy Files with the Blackmagic Proxy Generator

The Blackmagic Proxy Generator is a separate program that can automatically generate proxy media from master video files placed in a watch folder. This is a small, lightweight application that can be left to run in the background while importing media. This frees up your DaVinci Resolve program to do more creative tasks while the proxies are generated.

Using Watch Folders

Watch folders are simply specific folders in your OS that are constantly monitored by the Blackmagic Proxy Generator. When new files are added to the watch folder, the Blackmagic Proxy Generator is notified, and it automatically transcodes those new files into proxy media, without any additional human interaction needed. You can have as many different watch folders as you want; the only requirement is that the storage media the watch folder is on has enough space to hold both the original media files and the new proxy media.

IMPORTANT: The proxy media is generated inside a subfolder named “Proxy” at the same level in the file hierarchy as the original media file. This means that if your original media is all in the same folder, you will have one “Proxy” folder containing all of the proxy clips. If your original media is all contained in separate folders (i.e., one folder for each video clip), you will have multiple “Proxy” folders, one inside every clip folder and containing one proxy clip each.

NOTE: You can not name a watch folder “proxy.” That name is reserved for the Proxy Generator.

To Add a New Watch Folder

You need to create at least one watch folder and can have as many different watch folders as you need. For example, you could have separate watch folders for each card, or scene, or date, or whatever makes the most sense for your workflow.

1. Select the Add button.
2. Create a new folder, or select an existing folder in the file system window.
3. Click on the open button.

The new watch folder will appear in the Watch Folders pane of the Blackmagic Proxy Generator and will display its location and current status.

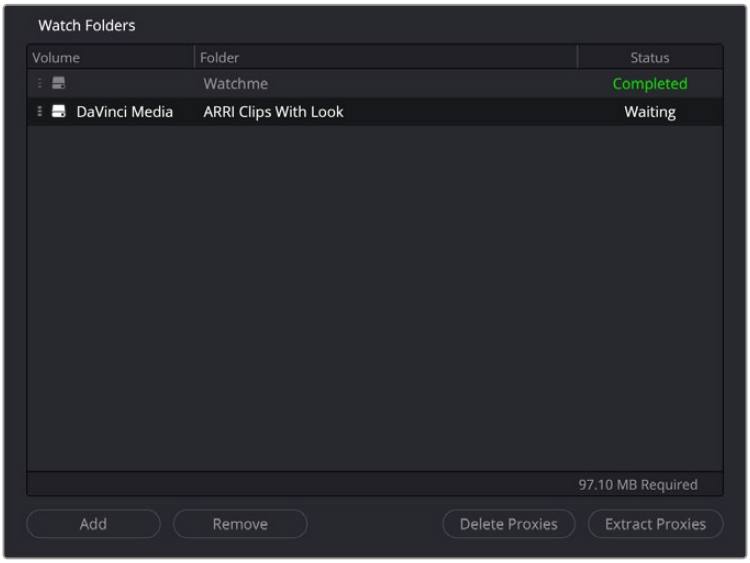
To Remove an Existing Watch Folder

When you're finished using a specific watch folder, you can remove it from the Blackmagic Proxy Generator's watch list. Removing a folder does not delete it or its files from your drive; it only stops the Blackmagic Proxy Generator from monitoring it.

1. Select the watch folder from the Watch Folders list.
2. Select the Remove button.

If you've accidentally removed the wrong watch folder, you can simply add it back again using the steps above.

Monitoring Watch Folders



You can see the status of all your watch folders in the Watch Folders section of the Blackmagic Proxy Generator. You can manually change the order that they appear in the list by dragging an entry up or down in the list. The estimated disk space required for the proxies can be found below, and there are three columns that contain information about each folder.

- **Volume:** This is the logical volume (disk, network storage, usb drive, etc.) that the watch folder is on. This lets you know which physical device needs to be attached to the computer for the Blackmagic Proxy Generator to function.
- **Folder:** This is the name of the Watch Folder. It does not show the folder's path, only the name of the watch folder itself.
- **Status:** This column shows the current status of the files in the watch folder.

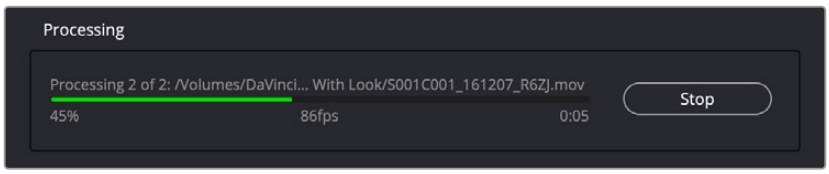
  Waiting: This folder has clips in it that have not been transcoded yet into proxies. It is waiting for the Blackmagic Proxy Generator to be started or for a folder ahead of it in the queue to be finished.

  Processing (x/x): This folder has clips that are currently being transcoded. The number to the left of the slash is the current clip number, the number to the right is the total number of clips to be transcoded.

  Completed: This folder has finished transcoding all proxy files for the media in the folder.

The Watch Folders section of the Blackmagic Proxy Generator

Setting the Proxy Format



You can select the proxy codec you wish to use by selecting the format from this list.

The Proxy Media Format section of the Blackmagic Proxy Generator

Starting and Stopping the Blackmagic Proxy Generator

Once you've set up a watch folder and selected a proxy format, all you need to do is select the Start button in the Processing pane to automatically transcode and monitor your watch folders. If you want to stop the process at any time, just select the Stop button. You can also toggle Start/Stop by pressing the space bar.

The Processing pane of the Blackmagic Proxy Generator

In the Processing pane, you can also see the status of the current job. The pane displays the progress of the job in terms of number of clips rendered (x of x), a progress bar, and a percentage indicator. It also displays the name of the current clip, the frames-per-second (fps) that the render is happening at, and an estimated time left to complete.

Managing Proxies from the Blackmagic Proxy Generator

There are two options to help manage your proxy files once they've been created. The Processing mode must be stopped for them to be available.

Delete Proxies: This option deletes all proxy files (and the Proxy folder) from the selected watch folders.

Extract Proxies: This option copies all proxy files from the selected watch folders to a new destination in the file system dialog. This is useful to create a separate proxy-only folder that you can hand over to another person on a portable hard drive or upload onto cloud storage.

Linking Proxies from the Blackmagic Proxy Generator in DaVinci Resolve

Once your proxies are created they are linked automatically to their original source media in DaVinci Resolve when you import the original clips in the watch folder into the Media Pool. You can also link and unlink them manually as explained in the Managing Proxy Media section later in this chapter.

Generating Proxy Media in Other Applications

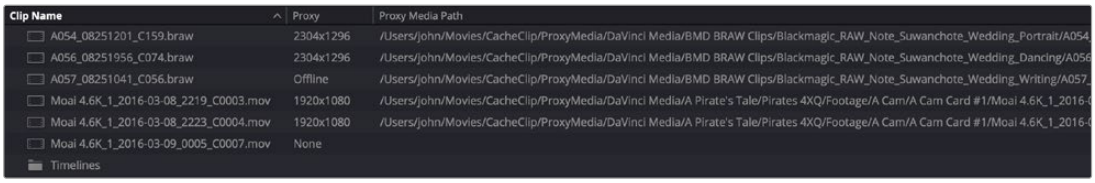
Proxy files can also be generated in applications outside of DaVinci Resolve, such as other NLEs or various media asset management systems. To properly link the proxy to its source media in DaVinci Resolve, the proxy file must meet the following criteria:

- Proxy files must have identical timecode to the source file.
- Proxy files must have the same file name as the source file (excluding extensions).
- Proxy files must have the same frame rate as the source file.
- The format and codec used for proxy files must be supported in DaVinci Resolve.

  If your proxy file meets these criteria, you'll be able to manually link proxy media created in other applications to source clips in the Media Pool as described below.

Managing Proxy Media

You can check the status and location of all your proxy media in the List view of the Media Pool. Right-click on any column heading and click the checkboxes of "Proxy" and "Proxy Media Path."



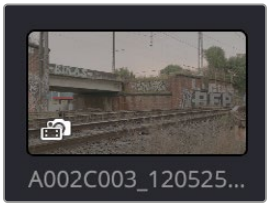
- **Proxy:** This column shows the current proxy status.

  None: Indicates no proxy media has been created.

  Offline: Indicates a proxy has been created but cannot be found in the Proxy Media path.

  (Resolution): A number indicating the resolution of the created proxy and that it is online.

- **Proxy Media Path:** The location of where DaVinci Resolve is looking for the proxy file. If this location is incorrect, you can relink the proxy to a new path manually.



The proxy columns in List view, showing Proxy Media status and location

Linking Clips to Proxy Media

If you've created proxy media in another application, or moved the internally created proxy media out of its default location in "ProxyMedia," you'll need to manually link the proxies to their source media files in your Media Pool.

To link proxy media to a source clip:

1. Select one or more clips in the Media Pool you wish to link proxy media to.
2. Right-click one of the selected clips, and choose "Link Proxy Media" from the contextual menu.
3. Use the file browser to find the specific proxy file or directory (in the case of multiple clips) to set a new Proxy Media path, and click Open. If you select an incorrect file or directory, a warning dialog box will appear and no linking will occur.
4. If the linking was successful, the proxy media icon will show up on the clip's thumbnail in the Media Pool.

The Proxy Icon showing in the lower left corner of the thumbnail, indicating proxy media is linked for this clip

To unlink proxy media from a source clip:

1. Select a clip or clips in the Media Pool you wish to unlink proxy media from.
2. Right-click on any clip and select “Unlink Proxy Media” from the contextual menu. This will remove the metadata link from proxy to source and will set the status in the Proxy column to “None.”

NOTE: Unlinking a proxy file does not delete it. The proxy file remains on the hard drive where it was created. As of this writing, proxy files must be deleted manually using your OS file system outside of DaVinci Resolve.

Re-generating Proxy Media

You can generate more than one proxy file per clip. This can be useful if you want to set multiple Camera Raw parameters and choose between them, or to create proxy files of different resolutions.

To generate a new proxy:

1. Make your desired changes to the current clip’s settings.
2. Right-click on the same clip and select “Generate Proxy Media” from the contextual menu.

A new proxy file is created in the same directory as the previously linked proxy file, and its file name is appended with “_s00x” to differentiate it. The latest proxy generated is automatically linked to the source file, but previous proxy versions are retained on disk, so you can then manually relink the different versions as needed.

Switching Between Proxy Media and Original Media

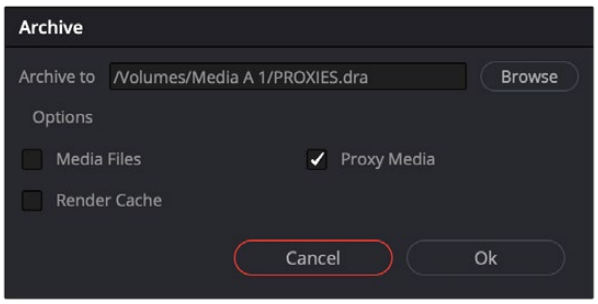
You can switch between using your original source media and the proxy media for playback in the Cut page by using the Proxy Handling icon in the Viewer, or in the Edit page, by selecting Playback > Proxy Handling and selecting one of the following options.

- **Disable All Proxies:** This option disables the proxies altogether and forces the original media playback only. If the original media is not available, the clip is replaced with a Media Offline graphic.
- **Prefer Proxies:** This option will use proxy files for playback, and if there is no proxy file for a clip, the original media will automatically be used instead. If the original media is not available, the proxies will be used, and the timeline will have a purple line across it for the duration that the original clips are missing.
- **Prefer Camera Originals:** This option will use the original media files for playback, and if there is no original media file for a clip, the proxy media will automatically be used instead, and the timeline will have a purple line across it for the duration that the original clips are missing.

TIP: Regardless of the proxy mode, a purple line on your timeline indicates the original media is missing and gives you a visual indicator to help identify those missing clips.

Using Proxy Files for Delivery

By default, the Deliver page always reverts proxies to the original source media for final output to ensure the highest quality render. Checking the “Use proxy media” box in the Advanced Settings of the Video Render settings in the Deliver page overrides this so DaVinci Resolve uses proxy media for final output instead. This can be useful if you need to save rendering time while making dailies, or to quickly create outputs of your timeline for producers or audio engineers where master quality is not necessarily needed. You will also need to check the “Use proxy media” box if you are editing with proxies and do not have access to the original source media.



Moving Proxies Using a DaVinci Resolve Archive (.dra)

When moving proxies from one DaVinci Resolve system to another, it can be time consuming and problematic to manually copy many individual assets (proxies, graphics, source files, etc.) from different folders and locations. By far the easiest way to move complete projects from system to system is by letting DaVinci Resolve do all that file management for you, by creating a DaVinci Resolve Archive (.dra). An archive file contains not only your project, but all its media as well, maintaining the file paths and organization of the original project.

To create a DaVinci Resolve Archive file, right-click on any project in the Project Manager, and choose “Export Project Archive” from the dropdown menu. Within this mechanism, a new Archive setting in DaVinci Resolve makes working with proxies simple and elegant.

Creating a Proxy-Only Archive to Share

In the Archive Options dialog, if you check Proxy Media, and uncheck Media Files and Render Cache, DaVinci Resolve will make an Archive using only the proxy media. This allows you to create a compact and easily transported version of your project to either move to another computer, or to give to an editor working remotely. If proxy media is not available for a clip (say a graphic or a media file you didn’t create a proxy for in the first place), the original media is automatically exported to ensure that nothing goes offline.

Archive Setting options for exporting only Proxy Media

The resulting .dra is a folder that is a fully self-contained version of your project and proxy media. This folder can easily be moved from drive to drive, or zipped up and sent across the internet.

Working Remotely Using Proxy Media

The proxy workflow in DaVinci Resolve opens up many new possibilities for editing collaboration and media management. For example, one common workflow is to use the RAW camera master source clips in the editing suite but to then generate low resolution proxies to take home to edit on a laptop.

To create a portable set of proxies for editing on a laptop:

1. Set up the Resolution and Format settings for the proxies in the Project Settings. In this case, you may want to use "Choose Automatically" and a low-bandwidth, easily editable codec like ProRes LT or DNxHR LB.
2. Select all source media in the Media Pool and Generate Proxy.
3. Export a DaVinci Resolve Archive (.dra) onto an external drive, with only Proxy Media checked.
4. Go away. Once at home, connect that drive to your home laptop, and use the Restore Project Archive command in the Project Manager to import the archive.
5. When you've finished working at home, export a timeline, bin, or project from your laptop when finished, and bring just that file back into the edit suite to continue working with the original source media.

Another common scenario might involve sending proxies over the internet to an editor in another city or country.

To send a project to another editor over the internet:

1. Set up the Resolution and Format settings for the proxies in the Project Settings. In this case, you may want to use a low resolution like "quarter" or "one-eighth," and a low-bandwidth, highly-compressed codec like H.265 for the smallest file sizes possible.
2. Select all of the source media in the Media Pool and Generate Proxy.
3. Export a DaVinci Resolve Archive (.dra), with only Proxy Media checked.
4. Using the file compression tools in your OS, zip the archive folder so it becomes one large file.
5. Upload the resulting .zip to the online file sharing service you prefer, and send the download link to the remote editor.
6. Once the other editor unzips and imports the archive, you and they can then simply send timelines, bins, and/or project files back and forth to collaborate. These files are small enough to transfer over email or an instant messaging service.

   Additionally, you may have your editing computer connected via ethernet to a Media Asset Management system that can create its own proxies. In order to edit smoothly via the network, you need to use low bandwidth proxies instead of the source media.

To create proxy media externally to edit over a local network:

1. Import the original source media files to your Media Pool from the network storage system you're using.
2. Set up the proxy generation settings in your Media Asset Management software to accommodate the amount of network bandwidth you expect to have access to.
3. Make sure the timecode and frame rate of the proxies match the original source media, and render the proxies to a network location.
4. Select all of your original source media in the Media Pool, and choose "Link Proxy Media."
5. Choose the proxy media at the network location where they've been rendered.

Proxy Media vs. Other Playback Optimizations in DaVinci Resolve

There continue to be other methods of optimizing real time performance in DaVinci Resolve, so it's natural that one might wonder how this is different from Optimized media, Timeline Proxy Mode, and other performance optimization techniques available in DaVinci Resolve. The key aspect of proxy media that differentiates it is that proxy media is independent, portable, and can be created by applications outside of DaVinci Resolve, if desired.

Proxy Media vs. Timeline Proxy Mode

One of the oldest performance optimization options, originally named "Proxy Mode" in previous versions of DaVinci Resolve, has been renamed "Timeline Proxy Mode" in DaVinci Resolve 17 to differentiate it from Proxy Media. While the new Proxy Media feature creates actual media files on disk, "Timeline Proxy Mode" simply reduces the resolution of the timeline on-the-fly, allowing for increased real time playback performance. To be clear, Proxy Media and Timeline Proxy Mode are two entirely different features, which are wholly independent of one another.

Proxy Media vs. the Render Cache

Proxy Media is designed to create easy-to-edit primary source material on the Timeline, for improved performance before you start editing. The Render Cache is designed to improve the real time performance of clips that have enough computationally intensive effects (such as Resolve FX, color corrections, noise reduction, compound clips, fusion compositions, etc.) to slow playback, even at the current Timeline resolution. Proxy Media is independent and portable (you can move clips wherever you want; you just have to relink them afterward), while the Render Cache media is not designed to be moved or interacted with externally and only works with the project it was made for.

Proxy Media vs. Optimized Media

On the surface, Proxy Media and Optimized Media appear similar in function. Both options are designed to create lower bandwidth, easier to edit versions of source media. However, Optimized Media is managed internally by DaVinci Resolve, cannot be exported, and is not user accessible. In contrast, Proxy Media creates fully portable and independent media that can be easily managed by the user.

Using Optimized Media, Proxy Media, and Caching Together

How you use DaVinci Resolve's various performance-enhancing features together is entirely up to you, but you should know that they're not an either/or proposition. For example, you can create optimized media from the camera raw original clips in your project, then enable Timeline Proxy Mode playback to enhance the performance of your 4K timeline, and turn on Smart Cache to speed up your work in the Color page as you add Fusion effects, noise reduction, and Resolve FX or OFX to every clip. All of these optimization methods work happily and seamlessly together to improve your performance while keeping the image quality of your project as high as the Optimized, Proxy, and Cache formats you've selected in the Master Settings panel of the Project Settings.

Which Playback Optimization Method Should I Use?

DaVinci Resolve's various playback optimization features are designed to specifically increase performance to make up for hardware, storage, and bandwidth deficiencies, but knowing when to use each method is essential to proper functionality. Included below is a quick reference.

- **Timeline Proxy Mode:** My timeline is playing back, just a little bit too slowly.
- **Cache Clip:** I need help playing back a few clips in real time that have heavy effects applied.
- **Optimized Media:** I need help playing back all my source media in real time, and I will only be editing on this computer.
- **Proxy Media:** I need help playing back all my source media in real time, and I need to collaborate and share this media with other users, programs, or outside storage locations.

Other Project Settings That Improve Performance

In addition to working with proxies, using reduced raw decoding quality, generating optimized media, and enabling the Smart and User caches, there are five additional options in the Project Settings window and one setting in the UI Settings panel of the User Preferences that you can use to further improve real time performance if you're working on an underpowered computer, at the expense of lower image quality while you work. These settings can then be changed back to higher quality modes prior to rendering.

- **Set timeline resolution to:** (Master Project Settings, Timeline Format) DaVinci Resolve is resolution independent, so you can change the resolution at any time and all windows, tracks, sizing changes, and keyframe data will be automatically recalculated to fit the new size. Lowering the Timeline resolution while you're grading will improve real time performance by reducing the amount of data being processed, but you'll want to increase Timeline resolution to the desired size prior to rendering. This is effectively the same as using the Proxy command, but you get to choose exactly what resolution you want to work at.
- **Enable video field processing:** (Master Project Settings, Timeline Format) You can leave this option turned off even if you're working on interlaced material to improve real time performance. When you're finished, you can turn this setting back on prior to rendering. However, whether or not it's necessary to turn field processing on depends on what kinds of corrections you're making. If you're applying any filtering or sizing operations such as blur, sharpen, pan, tilt, zoom, or rotate, then field processing should be on for rendering. If you're only applying adjustments to color and contrast, field processing is not necessary.
- **Video bit depth:** (Master Project Settings, Video Monitoring) Monitoring at 8-bit improves real time performance, at the expense of possibly introducing banding to the monitored image.
- **Monitor scaling:** (Master Project Settings, Video Monitoring) Lets you choose which transform filter to use when scaling video to fit into the Video format resolution you've specified. Options are Bilinear and Basic.
- **Resize Filter:** (Image Scaling) A dropdown menu that lets you choose an alternate image transform filter (such as Bilinear) that is lower quality but less processor intensive. A "Force sizing highest quality" checkbox in the Render Settings list of the Deliver page helps make sure you don't accidentally render your final media at this lower quality setting, however.

- **Hide UI overlays:** (User Preferences, Playback Settings) Off by default. When using a single GPU for both display and CUDA or OpenCL processing, or if your display GPU is underpowered, or if you lack the PCIe bandwidth required for the currently specified resolution or frame rate, you may be able to improve real time performance by turning this option on. When enabled, onscreen controls such as the cursor, Power Window outlines, and split-screen views are disabled and hidden during playback. When playback is paused, all onscreen controls reappear.
- **Minimize interface updates during playback:** (User Preferences, Playback Settings) On by default. While enabled, this setting improves real time performance by hiding on-screen controls that appear in the Viewer, such as the cursor, Power Window outlines, and split-screen views during playback. When playback is stopped, onscreen controls reappear.

Chapter 9

Data Levels, Color Management, and ACES

This chapter covers operational details that affect how color is managed for media that is imported into and exported from DaVinci Resolve. If color accuracy is important to you, then it's a good idea to learn more about how Resolve handles the data levels of each clip, how DaVinci Resolve Color Management helps you to work with different formats, and how to use ACES.

Data Levels Settings and Conversions

Different media formats use different ranges of values to represent image data. Since these data formats often correspond to different output workflows (cinema vs. broadcast), it helps to know where your project's media files are coming from, and where they're going, in order to define the various data range settings in DaVinci Resolve and preserve your program's data integrity.

To generalize, with 10-bit image values (with a numeric range of 0–1023), there are two different data levels (or ranges) that can be used to store image data when writing to media file formats such as QuickTime, MXF, or DPX. These ranges are:

- **Video:** Typically used by Y'CBCR video data. All image data from 0 to 100 percent must fit into the numeric range of 64–940. Specifically, the Y' component's range is 64–940, while the numeric range of the CB and CR components is 64–960. The lower range of 4–63 is reserved for "blacker-than-black," and the higher ranges of 941/961–1019 are reserved for "super-white." These "out of bounds" ranges are recorded in source media as undershoots and overshoots, but they're not acceptable for broadcast output.
- **Full:** Typical for RGB 444 data acquired from digital cinema cameras, or film scanned to DPX image sequences. All image data from 0 to 100 percent is simply fit into the full numeric range of 4 to 1023.

Keep in mind that every digital image, no matter what its format, has absolute minimum and maximum levels, referred to in this section as 0–100 percent. Whenever media using one data range is converted into another data range, each color component's minimum and maximum data levels are remapped so that the old minimum value is scaled to the new data level minimum, and the old maximum value is scaled to the new data level maximum;

- (minimum Video Level) 64 = 4 (Data Level minimum)
- (maximum Video Level) 940 or 960 = 1023 (Data Level maximum)

Converting Between Ranges and Clipping

Simply converting an image from one data range to another should result in a seamless change. All "legal" data from 0–100 percent is always preserved and is linearly scaled from the previous data range to fit into the new data range.

The exceptions to this are undershoots and overshoots that you've deliberately set, also referred to as out-of-bounds levels. The overshoots and undershoots that are allowable in "Video Levels" media (known as sub-black or super-black and super-white) are usually clipped when converted to full-range "Full Levels." However, DaVinci Resolve preserves this data internally, and these clipped pixels of detail in the undershoots and overshoots are still retrievable by making suitable adjustments in the Color page to bring them back into the "legal" range.

The out-of-bounds image data that's preserved within the headroom of Video Levels by DaVinci Resolve while working is usually clipped, however, when you either output to video or render your output. There are two settings that let you get around this for instances where you want to preserve these levels:

A checkbox in the Video Monitoring group of the Master settings, “Retain sub-black and super-white data,” lets DaVinci Resolve output undershoots (sub-black) and overshoots (super-white) to video when Data Level is set to Video. When this is turned off, these out-of-bounds values are clipped on output.

A checkbox in the Advanced settings of the Render settings in the Deliver page, “Retain sub-black and super-white data,” lets DaVinci Resolve render undershoots (sub-black) and overshoots (super-white) to exported media when Data Level is set to Video.

Internal Image Processing and Clip Data Levels

It’s useful to know that, internally to DaVinci Resolve, all image data is processed as full range, uncompressed, 32-bit floating point data. What this means is that each clip in the Media Pool, whatever its original bit-depth or data range, is scaled into full-range 32-bit data. How each clip is scaled depends on its Levels setting in the Clip Attributes window, available from the Media Pool contextual menu.

Selecting Auto, Video, or Full levels

By converting all clips to uncompressed, full-range, 32-bit floating point data, Resolve guarantees the highest quality image processing that’s possible. As always, the quality of your output is dependent on the quality of the source media you’re using, but you can be sure that Resolve is preserving all the data that was present in the original media.

Assigning Clip Levels in the Media Pool

When you first import media into the Media Pool, either manually in the Media page or automatically by importing an AAF or XML project in the Edit page, Resolve automatically assigns the “Auto” Levels setting. When a clip is set to Auto, the Levels setting used is determined based on the codec of the source media.

DaVinci Resolve generally does a good job of figuring out the appropriate Levels setting of each clip on its own. However, in certain circumstances, such as when you’re working with media that was originated in one format but transcoded into another, you may find that you need to manually choose the appropriate settings so that the levels of each clip are interpreted correctly. This can be done using each clip’s Levels setting in the Clip Attributes window, available from the Media Pool contextual menu in either the Media or Edit pages.

To change a clip’s Data Level setting:

1. Open the Media or Edit page.
2. Select one or more clips, then right-click one of them and choose Clip Attributes.
3. Click the Levels ratio button corresponding to the data level setting you want to assign, then click OK.

TIP: If you need to change the Levels setting of a range of clips that share a unique property such as reel name, resolution, frame rate, or file path, you can view the Media Pool by column, and sort by the particular column that will best isolate the range of media to which you need to make a data level assignment.

Once you change a clip's Levels setting, that clip will automatically be reconverted based on the new assignment. If it appears to be correct, then you're ready to work. If it doesn't, then you may want to reconsider the Levels assignment you've made, and you should check with the person who provided the media to find out how it was generated, captured, and exported.

So long as the Levels settings used by your clips are accurate, you should be ready to work. However, problems can still occur based on what external video hardware you're using with your workstation, and how you need to deliver the finished media to your client. For this reason, there are three additional data level settings that you can use to maintain data integrity, while at the same time seeing the proper image as you work.

Video Monitoring Data Levels

Superficial problems may result if the settings used by your external display differ from the settings you're using to process data levels in Resolve. Accordingly, there is a Video/Full Level setting in the Master Settings panel of the Project Settings (in the Video Monitoring section).

When you change this setting, the image being output to your external display should change, but the image you see in your Viewer will not. That's because this setting only affects the data levels being output via the video interface connecting the Resolve workstation to your external display. It has no effect on the data that's processed internally by Resolve, or on the files written when you render in the Deliver page.

There are two options:

- **Video:** This is the correct option to use when using a broadcast display set to the Rec. 709 video standard (10-bit 64–940).
- **Full:** If your monitor or projector is capable of displaying "full range" video signals, and you wish to monitor the full 10-bit data range (4–1023) while you work, then this is the correct option to use.

It is imperative that the option you choose in DaVinci Resolve matches the data range the external display is set to. Otherwise, the video signal will appear to be incorrect, even though the internal data is being processed accurately by DaVinci Resolve.

Auto/Video/Full Level selection for monitoring

Deck Capture and Playback Data Level

There is a separate “Video/Data Level” setting that is specific to when you’re capturing from or outputting to VTRs. This setting also affects the video signal that is output via the video interface connecting the Resolve workstation to your VTR (which is usually also in the signal chain used for monitoring). However, it only takes effect when you’re capturing from tape in the Media page, or editing to tape in the Deliver page. If you never capture or output to tape, this setting will never take effect.

This setting is found in the Deck Capture and Playback panel of the Project Settings.

The reason for a separate option for tape capture and output is that often you’d want to monitor in one format (normally scaled Rec. 709), but output to tape in another (full range RGB 444). This way, you can set up Resolve to accommodate this workflow, and then not have to worry about manually switching your video interface back and forth.

There are two options:

- **Video:** This is the correct option to use when you want to output conventional Rec. 709 video to a compatible tape format.
- **Full:** This is the correct option to use when you want to output “full range” RGB 444 video to a compatible tape format.

Once tape ingest or output has finished, your video interface goes back to outputting using the setting specified by the “Colorspace conversion uses” setting in the Master Settings panel of the Project Settings (in the Video Monitoring section).

Output Data Level Settings in the Deliver Page

Finally, there’s one last set of data level settings, available in the Render Settings list, within the Format group. It’s the “Set to video or data level” dropdown menu. It’s there to give you the ability to convert the data level of your rendered output, if necessary.

All media is output using a single data level, depending on your selection.
There are three options:

- **Automatic:** The output data level of all clips is set automatically based on the codec you select to render to in the “Render to” dropdown menu.
- **Video:** All clips are rendered as normally scaled for video (10-bit 64–940).
- **Full:** All clips are rendered as full range (10-bit 4–1019).

For most projects, leaving this setting on “Automatic” will yield the appropriate results. However, if you’re rendering media for use by another image processing application (such as a compositing application) that is capable of handling “full range” data, then full range output is preferable for media exchange as it provides the greatest data fidelity. For example, when outputting media for VFX work as a DPX image sequence, or as a ProRes 4444 encoded QuickTime file, choosing “Unscaled full range data” guarantees the maximum available image quality. However, it is essential that the application you use to process this media is set to read it as “full range” data, otherwise the images will not look correct.

So, What's the "Proper" Data Range for Output?

Strictly speaking, there is no absolutely "proper" data range to use when outputting image data. As long as the Levels setting of each clip in the Media Pool is set to reflect how each clip was created, your primary consideration is which data range is compatible with the media format or application you're delivering to. If the media format you're exporting to supports either normally scaled or full range, and the application that media will be imported into supports either normally scaled or full range, then it's really your choice, as long as everyone involved with the project understands how the data range of the media is meant to be interpreted once they receive it.

Outputting to hardware is a bit trickier, in that you need to make sure that the external display or VTR you're outputting to is set up to receive a signal using the data range you've chosen. If the device is limited to only one data range, then you need to be sure that you're outputting to it using that data range, or the levels of the image will appear to be incorrect, even though the image data being processed by Resolve is actually fine.

Introduction to DaVinci Resolve Color Management

How color is managed in DaVinci Resolve depends on the "Color Science" setting at the top of the Color Management panel of the Project Settings. There are four options: DaVinci YRGB, DaVinci YRGB Color Managed, DaVinci ACEScc, and DaVinci ACEScct. This section discusses the second setting, DaVinci YRGB Color Managed. ACEScc and ACEScct is discussed in the following section in this chapter.

Display Referred vs. Scene Referred Color Management

The default DaVinci YRGB color science setting, which is what DaVinci Resolve has always used, relies on what is called "Display Referred" color management. This means that Resolve has no information about how the source media used in the Timeline is supposed to look; you can only judge color accuracy via the calibrated broadcast display you're outputting to. Essentially, you are the color management, in conjunction with a trustworthy broadcast display that's been calibrated to ensure accuracy.

DaVinci Resolve 12 introduced a color science option called "DaVinci YRGB Color Managed," or more simply "Resolve Color Management" (RCM). This introduced a so-called "Scene Referred" color management scheme, in which you have the option of matching each type of media you've imported into your project with a color profile that informs DaVinci Resolve how to represent each specific color from each clip's native color space within the common working color space of the timeline in which you're editing, grading, and finishing.

This is important, because two clips that contain the same RGB value for a given pixel may in actuality be representing different colors at that pixel, depending on the color space that was originally associated with each captured clip. This is the case when you compare raw clips shot with different cameras made by different manufacturers, and it's especially true if you compare clips recorded using the differing log-encoded color spaces that are unique to each camera.

This Scene Referred component of color management via RCM doesn't do your grading for you, but it does try to ensure that the color and contrast from each different media format you've imported into your project are represented accurately in your timeline. For example, if you use two different manufacturer's cameras to shoot green trees, recording Blackmagic Film color space on one, and recording to the Sony SGamut3.Cine/SLog3 color space on the other, you can now use RCM to make sure that the green of the trees in one set of clips match the green of the trees in the other, within the shared color space of the Timeline.

It should be mentioned that this sort of thing can also be done manually in a more conventional Display Referred workflow, by assigning LUTs that are specific to each type of media, or using Color Space Transform Resolve FX in order to transform each clip from the source color space to the destination color space that you require. However, RCM's automation can make this process faster by freeing you from the need to locate and maintain a large number of LUTs to accommodate your various workflows. Also, the matrix math used by RCM (as well as the Color Space Transform operation) extracts high-precision, wide-latitude image data from each supported camera format, preserving high-quality image data from acquisition, through editing, color grading, and output. These are all advantages when compared to lookup tables, which can have plenty of precision, but can clip out-of-bounds image data and introduce issues when differing lookup table interpolation methods cause minor inconsistencies with color space transformations from application to application.

The preservation of wide-latitude image data deserves elaboration. LUTs clip image detail that goes outside of the numeric range they're designed to handle, so this often requires the colorist to make a pre-LUT adjustment to "pull back" image data in the highlights that you want to retrieve. Using RCM eliminates this two-step process, since the input color space matrix operations used to transform the source preserves all wide-latitude image data, making highlights easily retrievable without any extra steps.

Updated RCM In DaVinci Resolve 17

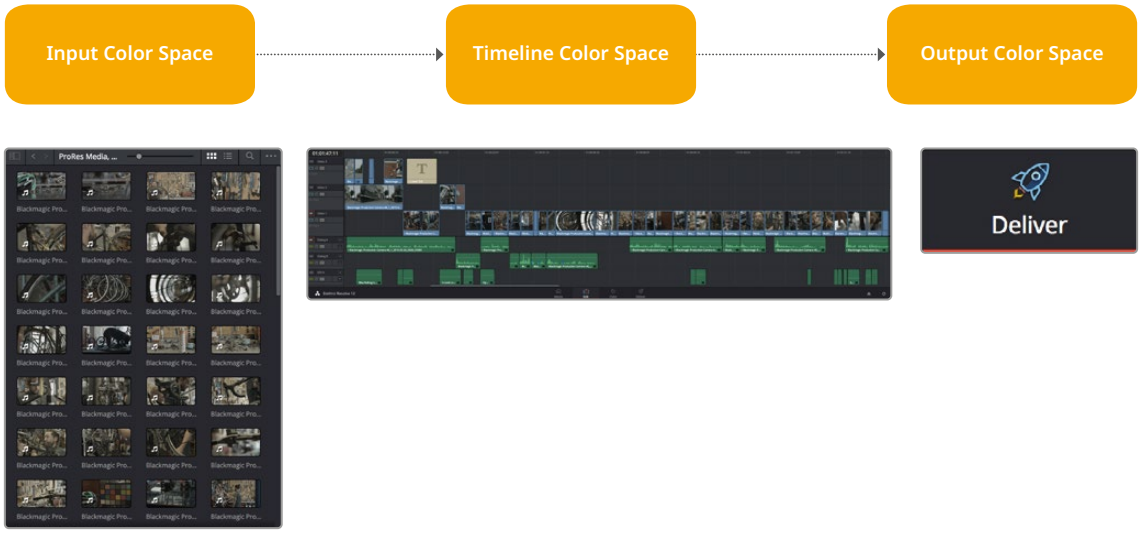
In version 17, DaVinci Resolve introduced the biggest improvements to Resolve Color Management (RCM) since it was originally introduced, adding numerous features to simplify setup, improve image quality, and make the "feel" of your grading controls more consistent. Specific improvements include improved metadata management for incoming media files that support color metadata, a new wide gamut color space suitable for using as your default Timeline working color space for any program, a new Input Tone Mapping option (Input DRT) that makes it easier to mix media formats for SDR and HDR grading, improved Timeline to Output Tone Mapping (Output DRT) that offers improved shadow and highlight handling, and select color space-aware grading palettes that make controls feel and perform well no matter what you're grading.

This updated Resolve Color Management has the same name as the previous version. However, older projects using the previous version of RCM will have Color science set to Legacy, to preserve the older color management settings and color transformations effect on your work. For more information on how the previous generation of RCM works, refer to the September 2020 version of the DaVinci Resolve 16 Manual.

How Is DaVinci Resolve Color Management Different from ACES?

This is a common question, but the answer is pretty simple. Resolve Color Management (RCM) and ACES are both Scene Referred color management schemes designed to solve the same problem. However, if you're not in a specific ACES-driven cinema workflow, DaVinci Resolve Color Management can be simpler to use, and will give you all of the benefits of color management, while approximating the "feel" that the DaVinci Resolve Color page controls have always had.

Resolve Color Management for Editors



RCM isn't just for Colorists. RCM can be easier for editors to use in situations where the source material is log-encoded. Log-encoded media preserves highlight and shadow detail, which is great for grading and finishing, but it looks flat and unpleasant, which is terrible for editing.

Even if you have no idea how to do color correction, it's simple to turn RCM on in the Color Management panel of the Project Settings, and then use the Media Pool to assign the particular Input Color Space that corresponds to the source clips from each camera. Once that's done, each log-encoded clip is automatically normalized to the default Timeline Color Space of Rec. 709 Gamma 2.4. So, without even having to open the Color page, editors can be working with pleasantly normalized clips in the Edit page.

The Input, Timeline, and Output Color Space

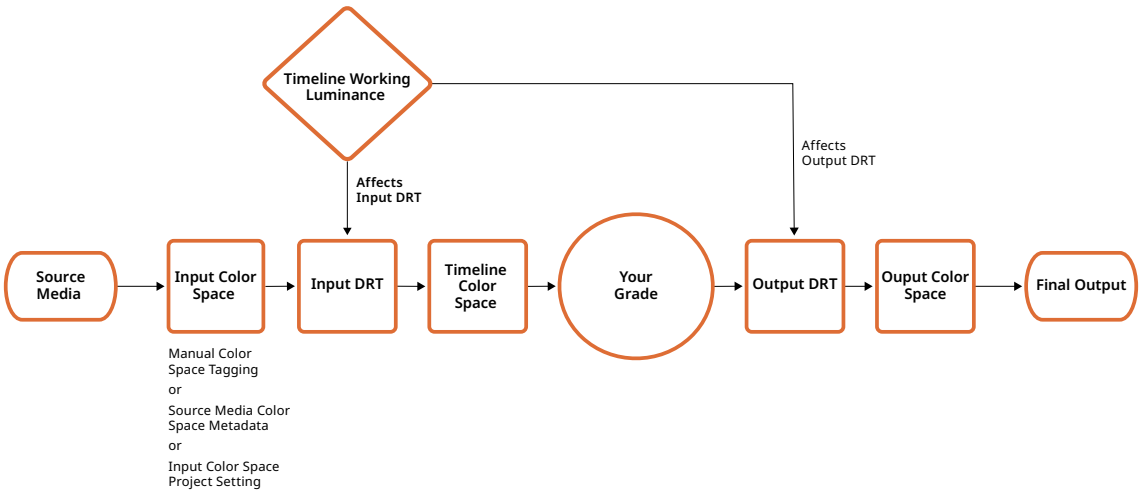
The foundation of Resolve Color Management rests on three core settings. Not only do you have the ability to either automatically or manually identify the color science of each individual source clip (the Input Color Space), but you also have explicit control over the working color space within which all color adjustments and operations are made (the Timeline Color Space), and you have separate control over the Output Color Space that defines how your graded image will be monitored and output.

This means that, basically, Resolve Color Management consists of two color transforms working together, converting each source clip via its Input Color Space definition into the Timeline Color Space in which you work, and then converting the adjusted image from the Timeline Color Space to whatever Output Color Space you require to deliver the project.

Resolve Color Management consists of three color transforms working together.

This means that, as a colorist, you can set the Timeline Color Space that you're working in to whatever you prefer. If you prefer grading wide-gamut log media because you like the way the grading controls behave in that color space, you can set the Timeline Color Space in the Color Management panel of the Project Settings to DaVinci Wide Gamut (more on this below), or any of the available log formats, including ARRI Log C, REDWideGamutRGB/Log3G10, and Cineon Film Log. If you instead prefer grading in the Rec. 709 color space because you're mastering a standard dynamic range (SDR) program to Rec. 709 and you're more comfortable with how the controls in DaVinci Resolve have always felt in that color space, you can choose that instead. Whatever Timeline Color Space you assign is what all source clips will be transformed to for purposes of making grading adjustments in the Color page, so you can make this choice using a single setting.

A key benefit of the color space conversions that RCM applies is that no image data is ever clipped during the Input to Timeline color space conversion. For example, even if your source is log-encoded or in a camera raw format, grading with a Rec. 709 Timeline Color Space does nothing to clip or otherwise limit the image data available to the RCM image processing pipeline. All image values greater than 1.0 or less than 0.0 are preserved and made available to the next stage of RCM processing, the Timeline to Output color space conversion.



Consequently, if you're grading in a color space other than the one you need to output to, you don't have to worry about data loss during the color transformation back to the color space you actually want to output to. The Output Color Space setting gives you the freedom to work using whatever Timeline Color Space you like while grading, with Resolve automatically converting your output to the specific color space you want to monitor with and deliver to. And thanks to the precision of the image processing in DaVinci Resolve, you can convert from a larger color space to a smaller one and back again without clipping or a loss of quality. Of course, if you apply a LUT or use Soft Clip within a grade, then clipping will occur, but that's a consequence of using those particular operations.

TIP: If you want to use Resolve Color Management, but you want the Input and Output Color Spaces to match whatever you set the Timeline Color Space to, you can choose "Bypass" in the "Input Colorspace" and "Output Colorspace" dropdown menus.

Finally, it is the Output Color Space that determines the final color space of your rendered result. While no image data is clipped during the Source to Timeline color space conversion, image data will be clipped during the Timeline to Output color space conversion in order for the final image to conform to the color space being rendered and output, unless you use the Gamut Mapping options to compress image data during the Timeline to Output Color Space conversion.

The RCM Image Processing Pipeline

The previous explanation is, of course, simplified. To clarify the inner workings of Resolve Color Management for advanced users, the following flowchart presents a rudimentary overview of how every parameter works together to automatically manage the color of clips in your program.

Resolve Color Management's image processing pipeline, illustrated

Identifying the Input Color Space of Different Clips

Central to the process of automated color management is knowing the color space and transfer function used by every clip of source media in your project. There are a variety of ways DaVinci Resolve can figure this out, in a cascading decision-tree that can be manually overridden if necessary. Deriving the Input Color Space involved the following stages of automated decision making:

1. If the source media is a camera raw format like .braw, .R3D, .ari, etc., DaVinci Resolve uses manufacturer-supplied colorimetry to automatically debayer the clip and identify its Input Color Space.
2. Otherwise, if the source media has embedded color space metadata (QuickTime or .MXF make this possible), then use that to identify the Input Color Space.
3. Otherwise, if there is no embedded color space metadata, use the default Input Color Space setting of the Project Settings to assign an Input Color Space to all otherwise unidentified clips.
4. If necessary, you can manually set the Input Color Space of clips in the Media Pool, which overrides both embedded color space metadata (in case it's wrong), or the default Input Color Space setting (if you're dealing with multiple color spaces). You cannot override the Input Color Space of camera raw media.

The following sections discuss each of these steps in more detail.

Using Camera Raw Formats

When you use RCM in a project that uses Camera Raw formats, color science data from each camera manufacturer is used to debayer each camera raw file to specific color primaries with linear gamma, so that all image data from the source is preserved and made available to DaVinci Resolve's color managed image processing pipeline. As a result, the Camera Raw project settings and Camera Raw palette of the Color page are disabled, because RCM now controls the debayering of all camera raw clips, and all image data from the raw file is available no matter which Timeline Color Space you choose to work within.

Using Source Media Color Space Metadata

When enabled, RCM automatically identifies the color space information of imported media that's been either transcoded or recorded directly to supported non-raw media formats, reading the NCLC metadata of QuickTime-wrapped files, the color space metadata of .mxf-wrapped files, and the XML sidecar files that track color management in ACES workflows. This behavior is automatic; there are no visible controls governing this behavior aside from the individual Input Color Space and Input Gamma settings associated with each clip in the Media Pool.

Color Space Metadata in QuickTime

DaVinci Resolve is capable of reading the NCLC metadata found within media files wrapped within a QuickTime container for proper color management. This metadata consists of three values formatted as (for example) 1-1-1. From left to right, these three digits specify the Color Primary (or color space), Transfer Function (or gamma), and Color Matrix used by that media file.

These values are standardized in the SMPTE Registered Disclosure Document RDD 36:2015. For your information, the different codes are listed in the following table. In the previous example, the code of 1-1-1 indicates a standard dynamic range clip that uses the BT.709 primaries, transfer function, and color matrix.

Color Primary		Transfer Function		Color Matrix	
0	Reserved	0	Reserved	0	GBR
1	ITU-R BT.709	1	ITU-R BT.709	1	BT709
2	Unspecified	2	Unspecified	2	Unspecified
3	Reserved	3	Reserved	3	Reserved
4	ITU-R BT.470M	4	Gamma 2.2 curve	4	FCC
5	ITU-R BT.470BG	5	Gamma 2.8 curve	5	BT470BG
6	SMPTE 170M	6	SMPTE 170M	6	SMPTE 170M
7	SMPTE 240M	7	SMPTE 240M	7	SMPTE 240M
8	FILM	8	Linear	8	YCOCG
9	ITU-R BT.2020	9	Log	9	BT2020 Non-constant Luminance
10	SMPTE ST 428-1	10	Log Sqrt	10	BT2020 Constant Luminance

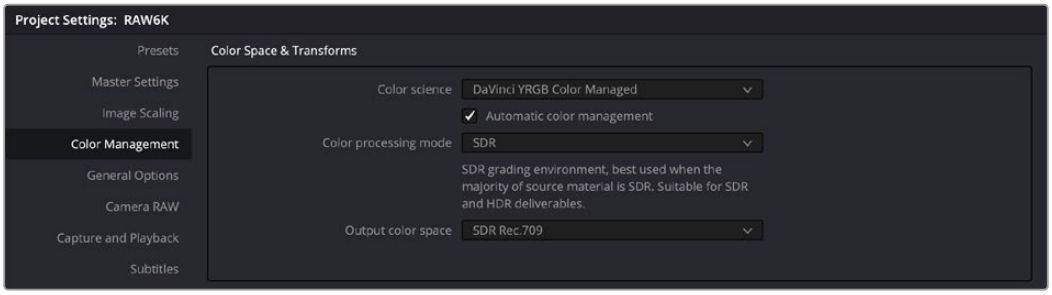
The Default Input Color Space

The default Input Color Space can only be set if the “Resolve color management preset” dropdown menu is set to Custom. Otherwise, it defaults to “Rec. 709 Gamma 2.4” for all presets. Or else, this setting is the default color space that all otherwise unidentified clips in the Media Pool will default to.

Manually Tagging Clip Color Space

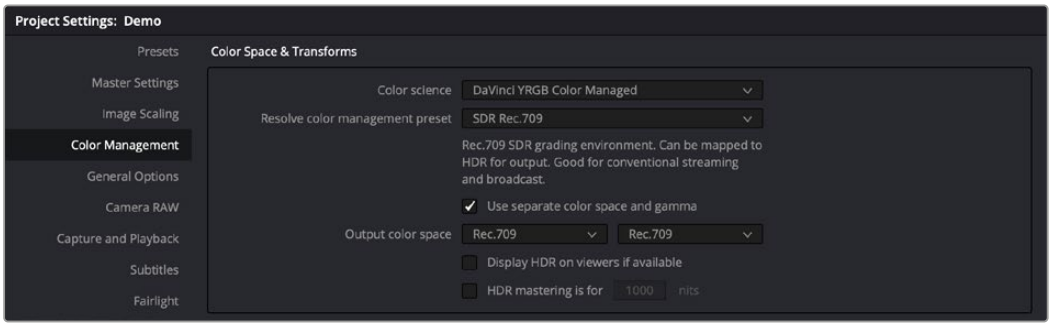


If necessary, you can manually identify the color space of one or more selected clips in the Media Pool by right-clicking them and choosing the Input Color Space (and optionally the Input Gamma) from the contextual menu.

Simple RCM Setup

When you first choose DaVinci YRGB Color Managed from the Color science dropdown menu of the Color Management panel in the Project Settings, you're presented with a simple pair of menus for setting up how you want to work with Resolve Color Management: the "Resolve color management preset," and the "Output Color Space."

Automatic Color Management



The first option when using RCM is to decide to use either Automatic Color Management or the Manual Presets. When the Automatic Color Management box is checked, DaVinci Resolve presents you with a simplified set of options for the most common use cases. For the Color Processing Mode, you choose SDR or HDR, and based on the file types and codecs in the Media Pool, DaVinci Resolve will automatically choose the appropriate input color space. Then, select from a list of common Output color spaces for delivery. If you want specific control of these parameters, uncheck Automatic Color Management box and select from the Color Management Presets below.

Automatic Color Management presets for fast, simple color management set up

Resolve Color Management Presets

The Resolve Color Management preset menu lets you choose how you want to use RCM to grade your program. Each of these presets fully configures your project's use of color management, and the setting you select directly impacts how you'll grade your program. Because of this, once you choose a method of working and you grade every clip in your program, those grades rely on the preset you used being selected in order to appear as they should.

Resolve Color Management presets for manual color management set up

When it comes to choosing a preset, a good way to think about which to use is to choose an SDR or HDR preset that corresponds to the primary deliverable you plan on outputting. Both SDR and HDR presets have several variations that you can choose among.

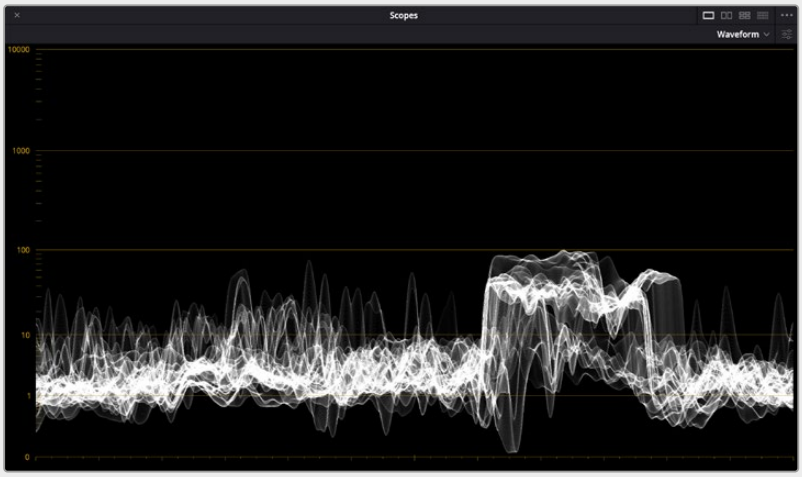
While these presets correlate to how you plan on outputting your program, they don't lock you in, since you can always change the Output Color Space (described below). This makes it possible to export multiple versions of your program, each intended for different venues, no matter which color management preset you're using.

Whenever you choose a preset, a brief description explains the workflow that preset is intended to facilitate. Here's a list of the available presets, with slightly more detailed explanations.

- **SDR Rec.709:** (default) Sets up a Rec. 709 SDR grading environment. Your work can be converted to HDR on output, if specified, but is limited to a Rec. 709 gamut with out-of-bounds colors being clipped. Gamma 2.4 is not mentioned in the name because scene versus display OOTF is managed automatically. Suitable for conventional streaming and broadcast.
- **SDR P3 Broadcast:** Sets up a P3-D65 SDR grading environment. Your work can be mapped to HDR for output, if specified, but it is limited to a P3-D65 gamut with out-of-bounds colors being clipped. Gamma 2.4 is not mentioned in the name because scene versus display OOTF is managed automatically. Suitable for wider gamut streaming and broadcast at SDR levels.
- **SDR P3 Cinema:** Sets up a P3-D60 SDR grading environment. Your work can be mapped to HDR for output, if specified, but it is limited to a P3-D60 gamut with out-of-bounds colors being clipped. Suitable for conventional Cinema projection.
- **SDR Rec.2020:** Sets up a Rec. 2020 SDR grading environment. Your work can be mapped to HDR for output, if specified. Good for wide gamut streaming and broadcast.
- **DaVinci Wide Gamut:** Sets up an extra wide gamut grading environment that's suitable for grading either SDR or HDR. Capable of exporting with maximum image fidelity, preserving highlight details of up to 10,000 nits. This is a log-encoded grading space for colorists wishing to work that way. Suitable for creating mezzanine intermediates or final deliverables, or for grading HDR with high nit levels.
- **HDR P3 Broadcast:** Sets up a P3-D65 HDR grading environment. Output gamut is limited to P3-D65, with out-of-bounds colors being clipped. Suitable for grading wide gamut SDR or HDR up to 1000 nits.
- **HDR Rec.2020:** Sets up a Rec. 2020 HDR grading environment. Suitable for wide gamut SDR or HDR deliverables up to 1000 nits.
- **Custom:** If none of the available presets suits how you need to work, you can choose Custom, which exposes the full set of RCM settings for you to set up to suit your needs.

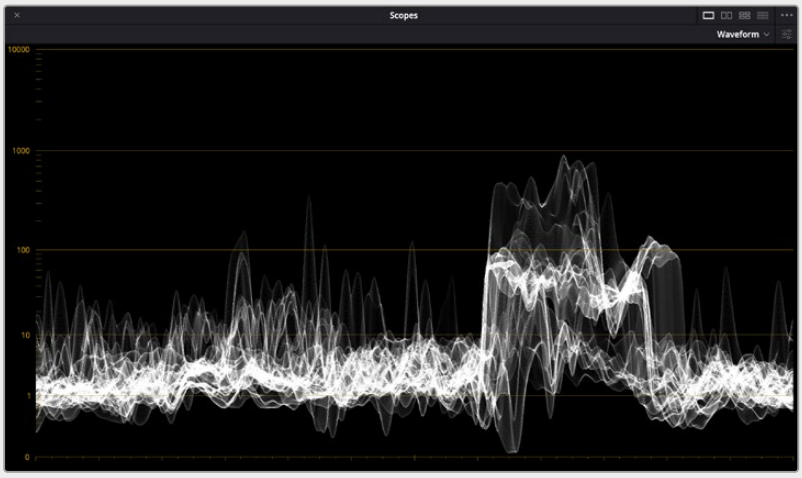
IMPORTANT: For all presets, importing media that's in an identical or smaller gamut maps the image data into the larger color space of the preset without transforming it. Importing media with a wider gamut than the color space of the preset remaps the image data to fit into the smaller color space, while preserving as much image detail as possible.

Output Color Space



For most DaVinci Resolve installations and projects, you'll set your Output Color Space to match the needs of your program, according to your display's capabilities (or the capabilities your display is set to use for the project at hand). You'll also typically use a Resolve Color Management preset that matches those capabilities.

However, RCM gives you the flexibility of grading in one color space and then outputting to others, when necessary. For example, it's easy to grade an SDR Rec. 709 version of a program for streaming or broadcast, and then switch the Output Color Space to SDR P3 Cinema to output an additional deliverable for theatrical exhibition.



To facilitate this, you can set the Output Color Space to any setting, independent of the Resolve Color Management preset you've selected, and DaVinci Resolve will automatically convert from your Color Management Preset to the Output Color Space of your choice. When you do so, here are the rules that govern the resulting image transform.

When going SDR to HDR:

- 0-50 nits (18% mid-gray) in your program is mapped to 0-50 nits on output (no change).
- Everything from 51-90 nits in your program is remapped from 51 to 100 nits (slightly expanded).
- Everything from 91-100 nits in your program is remapped from 101 to 1000 nits (greatly expanded).

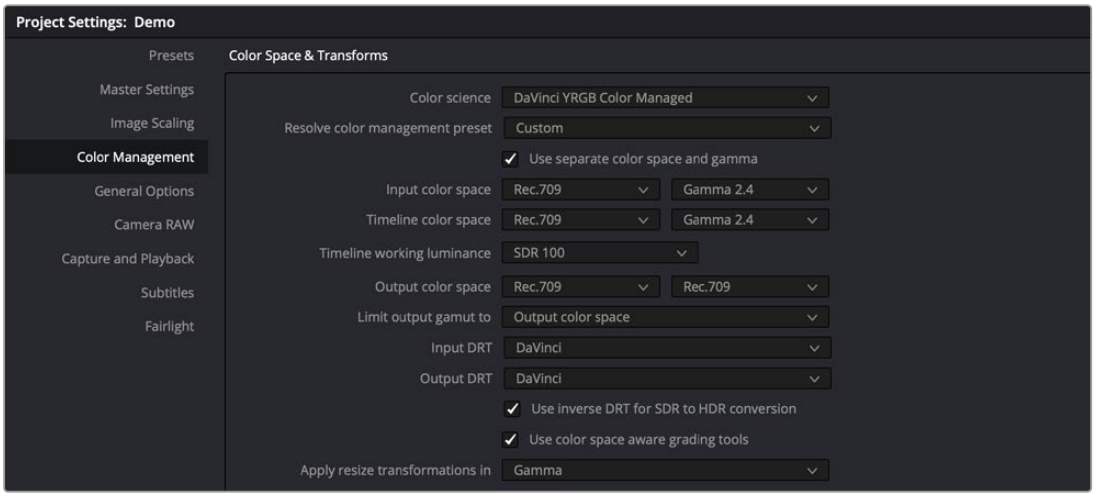
Original SDR grade seen within an HDR scale,

After an automatic SDR to HDR conversion

When going from HDR to SDR, the reverse is done:

- 0-50 nits (18% mid-gray) in your program is mapped to 0-50 nits on output (no change).
- Everything from 51 to 100 nits in your program is remapped from 51-90 nits (slightly compressed).
- Everything from 101 to 1000 nits in your program is remapped from 91-100 nits (greatly compressed).

While these methods of converting between SDR and HDR provide an effective starting point for conversion, they're not meant to be an automatic solution. It's critical that you do a trim pass whenever outputting a deliverable in a new color space and EOTF, so you can check every clip and make adjustments to improve the result when necessary.

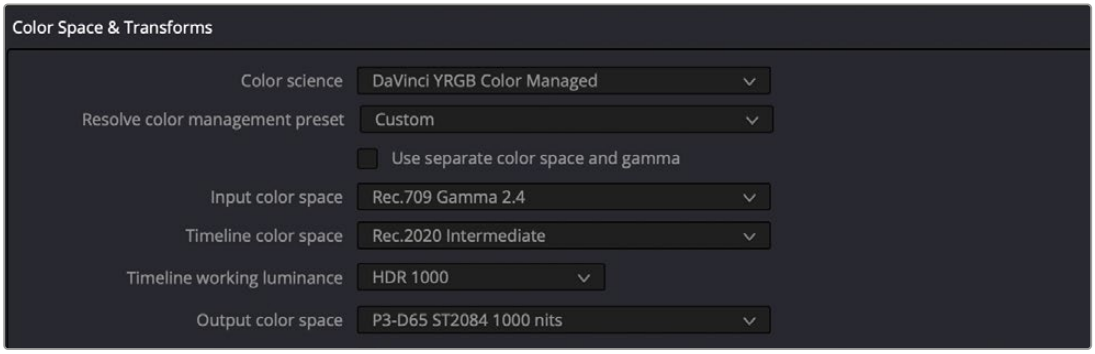


NOTE: When converting SDR to HDR, this behavior may exaggerate noise in imported SDR media that happens to have large flat expanses of bright colors. If you see particular clips that show this issue, you can disable this behavior on a clip by clip basis in the Media Pool clip contextual menu, or the Thumbnail Timeline contextual menu in the Color page, by toggling "Inverse DRT for SDR to HDR Conversion."

Advanced RCM Setup

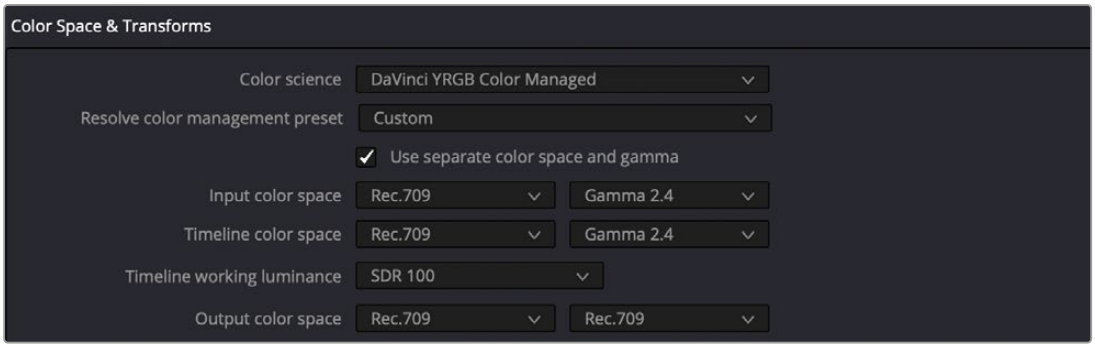
Advanced users who need more detailed control over every aspect of RCM can choose Custom from the Resolve Color Management preset menu. This exposes every control that's available, which opens a world of workflow possibilities for advanced users and post production facilities.

Because each of the settings encompasses a significant amount of functionality, the following sections cover each particular parameter in detail.



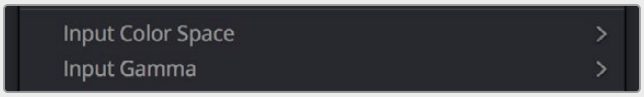
NOTE: Older projects using RCM will have Color science set to Legacy, to preserve the older color management settings and color transformations effect on your work. For more information on how the previous generation of RCM works, see the September 2020 version of the DaVinci Resolve 16 Manual.

Custom Color Management settings of Resolve Color Management, as updated in DaVinci Resolve 17



Single Setting vs. Dual Setting RCM

There are two ways you can set up RCM. When the "Use Separate Color Space and Gamma" checkbox is turned off, the Color Management panel of the Project Settings exposes one dropdown each for the Input, Timeline, and Output Color Space settings. Each setting lets you simultaneously transform the gamut and gamma, depending on which option you choose. This makes it a bit simpler to set up the transform you need.



Single setting Resolve Color Management

If you turn the “Use Separate Color Space and Gamma” checkbox on, then the Color Management panel changes so that the Input, Timeline, and Output Color Space settings each display two pop-ups. The first dropdown lets you explicitly set the gamut, while the second dropdown lets you explicitly set the gamma. This makes it easier to see exactly which pair of transforms is being used at each stage of RCM.

Dual setting Resolve Color Management

Additionally, Dual Setting RCM enables you to assign separate gamut and gamma transforms to clips in the Media Pool.

Dual setting Resolve Color Management assignments for Media Pool clips

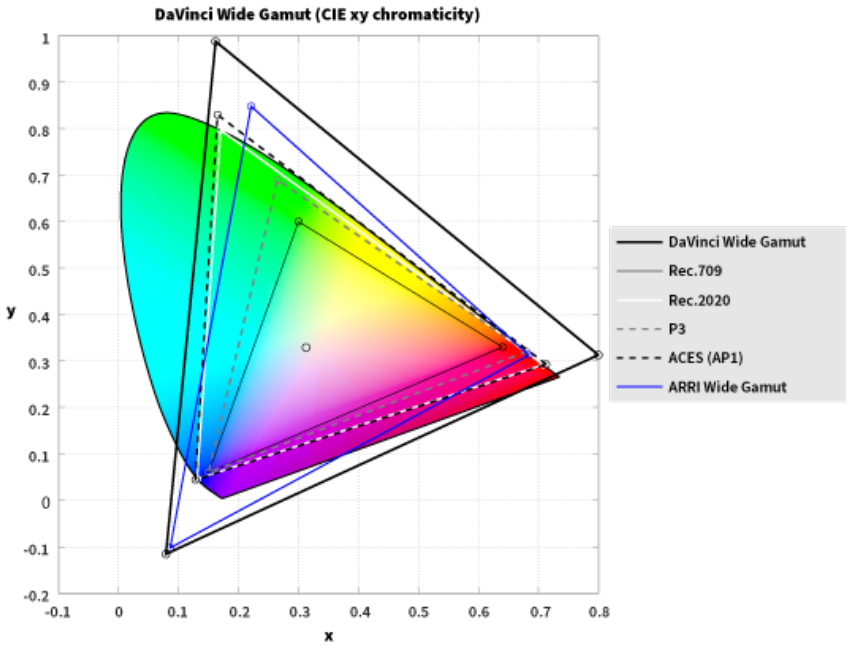
Setting the Input Color Space

This setting is the default color space that all otherwise unidentified clips in the Media Pool will default to, unless you manually identify the color space of these clips by right-clicking them and choosing an Input Color Space (and optionally Input Gamma) from the contextual menu.

This setting does not affect media in camera raw formats, or media with embedded color space metadata.

Choosing a Timeline Color Space

The Timeline Color Space is the “working” color space that determines how each clip’s contrast and color are mapped for adjustment, which in turn has an impact on how sensitive the effects and grading controls are as you work. Some colorists prefer to work in the classic “video” color space of Rec. 709, since the controls feel comfortable and familiar, particularly if you’re mastering SDR content. On the other hand, colorists who are used to working with log-encoded media (likely using the Log controls) often prefer to work in a more film-oriented workflow using Cineon, LogC, or other wide gamut, logarithmically encoded formats.

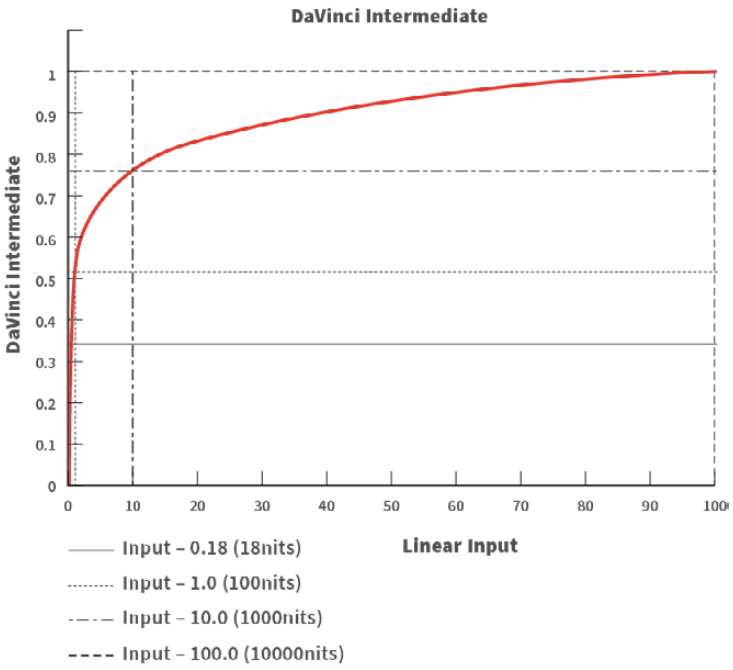


If you’re outputting an SDR deliverable, any color space that you’re comfortable will produce good results. However, if you’re outputting an HDR deliverable, it’s in your best interest to choose a wide gamut Color Space (and Gamma) to obtain the best results on output. In this instance, DaVinci Wide Gamut is a great choice (see below for more information).

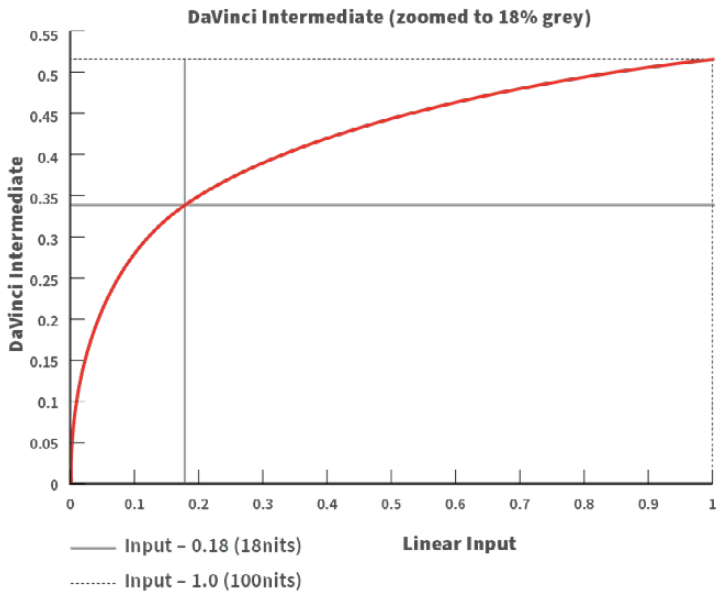
No matter which Timeline Color Space you choose to work in, all clips in an edit are transformed from the Input Color Space that’s either automatically or manually assigned to them, to the Timeline Color Space setting to provide the final output. This is how you can grade within a Log-encoded timeline color space and yet view a normalized or de-logged image.

IMPORTANT: Once you choose a Timeline Color Space and begin grading, do not change your Timeline Color Space, or you’ll end up changing all of the grades that are built using the mathematics it defines. You can always change the Output Color Space to create a new deliverable, but all of your grades depend on the Timeline Color Space to render correctly.

DaVinci Wide Gamut Color Space and DaVinci Intermediate Gamma



DaVinci Wide Gamut (DaVinci WG) and DaVinci Intermediate are Timeline Color Space and Gamma settings developed by Blackmagic Design that provide a reliable universal internal working color space, which encompasses a practical maximum of what image data any given camera can capture. The DaVinci Wide Gamut color space is greater than BT.2020, ARRI Wide Gamut, and even ACES, so you don’t ever lose image data, no matter where your media is coming from.



The DaVinci Wide Gamut color space

Furthermore, the primary color values of the DaVinci WG color space are set such that the process of automatically mapping source media from different cameras into this gamut is extremely accurate as part of the Input to Timeline Color Space conversion, and tone and saturation mapping from one color space to another can be done more accurately in the Timeline to Output Color Space conversion. This also helps to produce greater consistency among media from different cameras when making manual grading adjustments (though some variations due to differences in camera and lens systems will remain).

The DaVinci Intermediate OETF gamma setting has been designed to work with DaVinci Wide Gamut to provide a suitable internal luminance mapping of high precision image data, in preparation for mastering to either HDR or SDR standards, as your needs require, without losing image data.

The DaVinci Intermediate OETF seen encoding HDR levels

The DaVinci Intermediate OETF encoding SDR levels

Resolve Color Management is extremely flexible, so you don't have to use DaVinci Wide Gamut/DaVinci Intermediate as your Timeline color space if you don't want. However, it presents many advantages and is worth trying out to see if it can improve your workflow.

For more information, refer to the "DaVinci Resolve Wide Gamut Intermediate" document at https://www.blackmagicdesign.com/support/family/davinci-resolve-and-fusion.

Timeline Working Luminance

This control is only visible while the Resolve Color Management presets menu is set to Custom Settings. The Timeline Working Luminance dropdown menu lets you choose how the Input DRT (described below) maps the maximum level of a source image to the currently selected Timeline Color Space. This setting also defines the maximum highlight level that's possible to output into the currently selected Output Color Space using the Output DRT.

While it's typical to set this according to the mastering standard you're grading to via a collection of SDR and HDR labeled settings, there are additional settings available that make it possible to add more automatic compression of highlights as you grade.

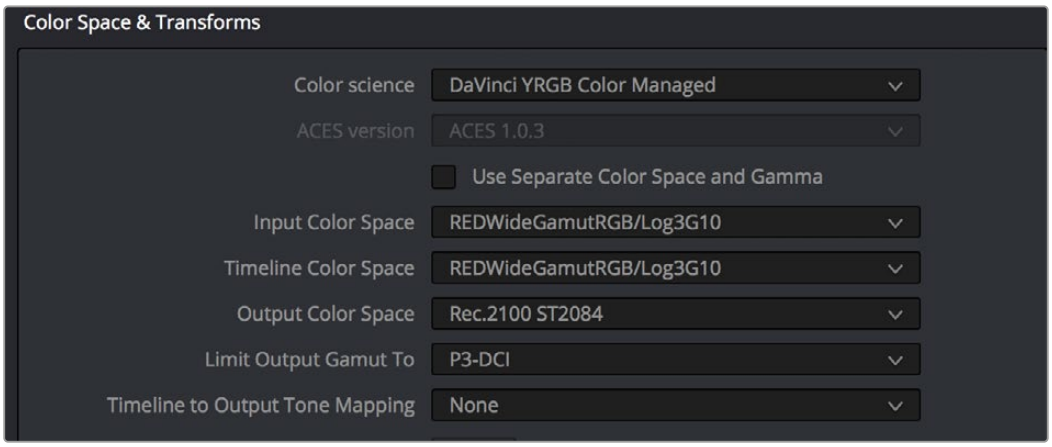
- **SDR 100:** The conventional setting for grading SDR material with a maximum level of 100 nits.
- **HDR 500-4000:** Conventional settings for grading HDR material at a variety of maximum mastering levels. So long as output DRT isn't set to None, there will be some manner of rolloff in the highlights, unless inverse DRT is enabled, in which case there will be no rolloff.
- **SDR and HDR ER settings:** These "extended range" settings each specify two values and provide more headroom for aggressive grading of highlights by enabling DaVinci Resolve to compress a greater range of out-of-bounds image data without clipping, which can result in a smoother look.

  Here's how it works. Suppose you choose the setting "HDR ER 1000/2000." In this case, the Input DRT is used to map the maximum brightness of each source image to the range specified by the first value, which is 1000 nits. Then, when you grade, the signal isn't clipped until it reaches the maximum range specified by the second value, which is 2000 nits. This provides an additional 1000 nits of out-of-bounds headroom before the image data is hard clipped by RCM's image processing pipeline. The Output DRT is then used to map from the maximum brightness specified by the second number (2000 nits) to the output value defined by the currently selected Output Color Space, in the process compressing this out-of-bounds headroom to preserve as much highlight detail as is possible given the range you've selected.
- **Custom:** Exposes a field where you can enter a specific nit value.

203 Nit Support for SDR to HDR

This control is only visible while the Resolve Color Management presets menu is set to Custom Settings. Resolve Color Management has support for remapping SDR content to HDR by mapping 100 nits to 203 nits (defined as the diffuse white level) according to the BT.2100 recommendation. This enables the peak highlights of SDR material to compete more favorably against the significantly brighter highlights of HDR content in programs that combine both (such as documentaries), so that SDR whites continue to appear white, rather than gray, when compared to diffuse white in HDR.

The checkbox that enables this is hidden by default. Whenever you set the Output to an HDR standard while the Timeline is set to an SDR standard, the “Use 203 nits reference for Rec.2100 HDR” checkbox for remapping SDR highlights to HDR appears in both the RCM settings of the Color Management panel of the Project Settings and in the Color Space Transform Resolve FX plugin.



The “Use 203 nits reference for Rec.2100 HDR” checkbox in Resolve Color Management for scaling SDR levels appropriately into HDR color space

Gamut Limiting, Restricting Values Within a Larger Gamut

This control is only visible while the Resolve Color Management presets menu is set to Custom Settings. In the emerging world of larger gamuts for distribution, it’s increasingly common for delivery specifications to specify output to a large gamut, such as Rec. 2020, yet require that image values be restricted to a smaller gamut, such as P3. This is to allow delivery to “future-proofed” delivery standards, while preventing saturation values that are too high to be displayed on consumer displays that aren’t capable of implementing the full scope of those standards.

In this case, you’ll choose a larger gamut in Output Color Space, but you’ll then choose a smaller gamut in “Limit Output Gamut To.” When you do this, all image values falling outside the “Limit Output Gamut To” standard specified will be hard clipped. This setting defaults to None.

Choose a setting from the Limit Output Gamut To menu to limit image values within a larger gamut

Input DRT Tone Mapping

This control is only visible while the Resolve Color Management presets menu is set to Custom Settings. RCM has always transformed the color primaries of different media formats to match one another within the shared Timeline Color Space. In this updated version, the Input DRT (Display Rendering Transform) dropdown menu provides a variety of different options to enable DaVinci Resolve to automatically tone map the image data of SDR and HDR clips to better match one another when they’re fit into the currently selected Timeline Color Space. While each option varies in the details, they are all automated input-to-timeline color transforms that do the following:

- Log-encoded media, or media using a 2.4 gamma transfer function, is mapped so the black point, midtones at 18% gray, and white levels match those of HDR media. Highlight data will be carefully stretched as necessary so that the highlights of all clips in the Timeline, whether SDR or HDR, are treated similarly.
- Raw formats such as BRAW, RED, and ARRI RAW, and media using HDR transfer functions are minimally mapped along an HDR range of tonality.
- All color transforms into the Timeline Color Space are done without clipping.

The idea is to distribute the image data of each clip in the Timeline, be it SDR or HDR media, along a similar histogram, with shadows, midtones, and highlights spread out in such a way as to create an easier starting point for grading. One result of this is that grades made for one type of media mostly work well with other types of media.

Different options are provided governing the details of how this Input to Timeline Color Space transform is achieved. They all do the same thing but have different advantages.

- **None:** This setting disables Input DRT Tone Mapping. No tone mapping is applied to the Input to Timeline Color Space conversion at all, resulting in a simple 1:1 mapping to the Timeline Color Space.
- **Simple:** A good mapping for color transforms from HDR to SDR.
- **Luminance Mapping:** Same as DaVinci, but more accurate when the Input Color Space of all your media is in a single standards-based color space, such as Rec. 709 or Rec. 2020.
- **DaVinci:** This option tone maps the transform with a smooth luminance roll-off in the shadows and highlights, and controlled desaturation of image values in the very brightest and darkest parts of the image. This setting is particularly useful for wide-gamut camera media and is a good setting to use when mixing media from different cameras.
- **Saturation Preserving:** This option has a smooth luminance roll-off in the shadows and highlights, but does so without desaturating dark shadows and bright highlights, so this is an effective option for colorists who like to push color harder. However, because over-saturation in the highlights of the image can look unnatural, two parameters are exposed to provide some user-adjustable automated desaturation.

  Sat. Rolloff Start: Lets you set a threshold, in nits (cd/m^2), at which saturation will roll off along with highlight luminance. Beginning of the rolloff.

  Sat. Rolloff Limit: Lets you set a threshold, in nits (cd/m^2), at which the image will be totally desaturated. End of the rolloff.

Output DRT Tone Mapping

This control is only visible while the Resolve Color Management presets menu is set to Custom Settings. To accommodate workflows where you need to transform one color space into another that has a dramatically larger or smaller gamut, an additional group of settings have been added that can help to automate the expansion or contraction of image data necessary to give a pleasing result.

Using the available options in the Output DRT dropdown menu will compress or expand your image data as necessary during the Timeline to Output Color Space transformation that RCM performs when monitoring or rendering a timeline, in order to make sure that the final result is either not clipping, or to ensure that it's taking better advantage of the new color space. This is not meant to provide your final grade. Rather, it's meant to give you a faster starting point, when you need it, for proceeding with your own more detailed grade of the result.

Here are some examples of what the Gamut Mapping controls of RCM can be used for:

1. If you're working with high-dynamic-range log-encoded media and you're outputting to Rec. 709 as you work, turning on Gamut Mapping lets RCM use saturation and tone mapping to give you a more immediately pleasing image with highlight detail that's not clipped.
2. If you're working with standard-dynamic-range log-encoded media and you're outputting to an HDR format as you work, turning on Gamut Mapping lets RCM use saturation and tone mapping to expand the highlights of the image to HDR strength to give you an image with more immediate visual impact on HDR screens.

(Before/After) Gamut Mapping used to automatically fit high-dynamic-range media into the Rec. 709 color space

The Output DRT (Display Rendering Transform) dropdown menu provides the following options.

- **None:** No tone mapping is applied to the Timeline to Output Color Space conversion at all, resulting in a simple 1:1 output with no softness or rolloff applied. All image data outside of gamut will be clipped.
- **Simple:** A good mapping for color transforms from HDR to SDR.
- **Luminance Mapping:** Same as DaVinci, but more accurate when all your media is in a single standards-based color space, such as Rec. 709 or Rec. 2020, set to the Timeline and Output.
- **DaVinci:** This option tone maps your output with a smooth luminance roll-off in the shadows and highlights, and controlled desaturation of image values in the very brightest and darkest parts of the image. It's been designed to give smooth, naturalistic highlights and shadows as you push and pull the values of your images, without the need for additional settings. This setting is particularly useful for wide-gamut camera media and is a good setting to use when mixing media from different cameras.

- **Saturation Preserving:** This option has a smooth luminance roll-off in the shadows and highlights to prevent clipping. It does so without desaturating dark shadows and bright highlights, so this is an effective option for colorists who like to push color a bit harder. However, because over saturation in the highlights of the image can look unnatural, two parameters are exposed to provide some user-adjustable automated desaturation.

  Sat. Rolloff Start: Lets you set a threshold, in nits (cd/m^2), at which saturation will roll off along with highlight luminance. Beginning of the rolloff.

  Sat. Rolloff Limit: Lets you set a threshold, in nits (cd/m^2), at which the image will be totally desaturated. End of the rolloff.

- **RED IPP2:** This setting lets you use RED IPP2 tone mapping to output to an SDR format, such as Rec. 709; two settings are exposed with which to choose how your output will be shaped.

  Output Tone Map: Lets you choose what kind of tone mapping you want to use for your output. Options include: None, Low, Medium, and High.

  Highlight Roll Off: Lets you choose what kind of highlight rolloff you want to use to prevent clipping. Options include: None, Hard, Medium, Soft, and Very Soft.

  HDR peak nits: A slider lets you choose the peak nit level you want to tone map to. Defaults to 10,000 nits.

Use Inverse DRT for SDR to HDR Conversion

This control is only visible while the Resolve Color Management presets menu is set to Custom Settings. A device rendering transform (DRT) is typically used when converting high dynamic range media to a lower dynamic range color space/mastering standard. Thus, setting up a color transform from SDR to HDR is an "inverse" operation to expand the dynamic range of SDR media to HDR standards. The way this works is that levels at 100 nits are mapped to the maximum value set for the Timeline Working Luminance parameter, and all other image levels are strategically tone mapped in order to give yourself a good starting point for grading SDR media into an HDR program.

This setting also has a secondary use. With this setting turned on, you can output Rec. 709 clips with color that's identical to the input, with no compression in the highlights.

NOTE: Turning on "Use Inverse DRT for SDR to HDR Conversion" may exaggerate noise in imported SDR media with large flat expanses of bright colors.

Use White Point Adaptation

This control applies a chromatic adaptation transform to account for different white points between color spaces.

- Uncheck this box if you simply want to view the input color space's white point unaltered in the output color space. For example, wanting to use a P3-D60 mastered clip inside a P3-D65 timeline for reference purposes.
- Check this box to apply the chromatic adaptation transform to convert the input white point to match the output color space's white point. For example, wanting a P3-D60 mastered clip to cut in with other clips mastered in a P3-D65 timeline.

NOTE: This control is only visible while the Resolve Color Management presets menu is set to Custom Settings.

Color Space Aware Grading Tools

In DaVinci Resolve version 17, both Resolve Color Management and ACES enables “color space aware” palettes, such as the new HDR palette, to have controls that feel consistent, no matter what color space the original media is from, or what Timeline Color Space you’re using.

Other palettes, such as the Qualifier and Curves palettes, become color space aware when you turn on the “Use Color Space Aware Grading Tools” checkbox in the Color Management panel of the Project Settings (this is turned on by default). When you’re using color space aware grading tools, you should not turn on HDR Mode for the node you’re working on.

- In the case of the Qualifier palette, this enables Qualifiers to create high-quality keys as you would expect, no matter what the color space of the original media is, or what Timeline Color Space you’re using.
- In the case of the Curves palette, this makes the overall range of each curve better fit the overall data range of the current clip, making curves adjustments easier and more specific.

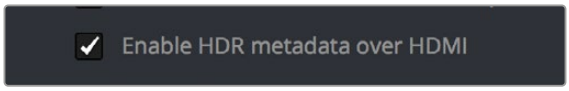
NOTE: This control is only visible while the Resolve Color Management presets menu is set to Custom Settings.

Apply Resize Transformations In

When you’re using Resolve Color Management, a new “Apply Resize Transformations In” Project Setting is available in the Color Management panel while the Resolve Color Management presets menu is set to Custom Settings. This setting lets you choose which color space is used for resizing operations. Ordinarily, resizing is done in Linear, but certain specialty workflows benefit from doing resizing in other color spaces, so this option lets you choose which is best. The available options are:

- **Timeline:** Uses the Timeline Color Space to perform all resizing operations.
- **Log:** Uses a Log Color Space for resizing. Good for avoiding artifacts in certain high-contrast images, such as titles and star fields.
- **Linear:** Usually provides the best results with most SDR media.
- **Linear Mapped:** Usually provides the best results with most HDR media.
- **Gamma:** Provided in case you find a need for this option.
- **Gamma Mapped:** Usually provides best results when mixing SDR media with wide gamut and log-encoded media on the same timeline.

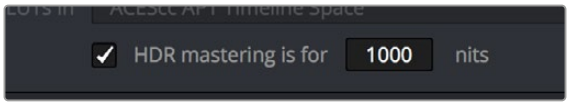
Graphics White Level



The “Graphics white level” setting lets you define a shared maximum level in nits (cd/m^2) for titles, generators, and selected effects that generate color. Changing this setting lets you change the maximum level of all DaVinci Resolve-generated titles, generator graphics, and effects at once to accommodate different mastering and output requirements.

Display HDR On Viewers If Available

Turn this checkbox on if your computer monitors and operating system are capable of accommodating HDR display. This allows the Viewers to show true HDR, according to the capabilities of your computer monitor.



HDR Mastering Is For (Studio Version Only)

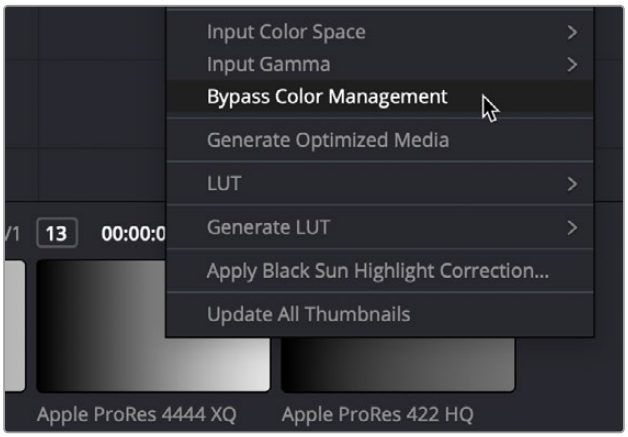
If you have a DeckLink 4K Extreme 12G or an UltraStudio 4K Extreme video interface, then DaVinci Resolve 12.5 and above can output the metadata necessary to correctly display HDR video signals to display devices using HDMI 2.0a when you turn on the "Enable HDR metadata over HDMI" checkbox in the Master Project Settings.

The Enable HDR metadata over HDMI option in the Master Project Settings lets you output HDR via HDMI 2.0a.

When you do so, a setting in the Color Management panel of the Project Settings, "HDR mastering is for X" lets you specify the output, in nits, to be inserted as metadata into the HDMI stream being output, so that the display you're connecting to correctly interprets it. The output you specify should match what your display is expecting.

The "HDR mastering is for" setting lets you insert metadata for HDR output via HDMI 2.0a.

Resolve Color Management and the Fusion Page

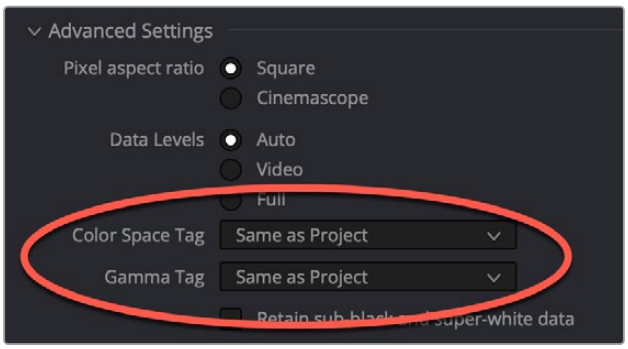


Enabling RCM also allows the Fusion page to handle the color of clips automatically. Images output by MediaIn nodes are automatically converted to Linear color space, which is the preferred color space with which to perform high-quality compositing operations. Setting the LUT menu of each Viewer in the Fusion page to Managed ensures that you're looking at the image in Rec. 709, so that the image looks correct to the artist even though they're really working in the Linear color space. Each MediaOut node then converts the image back to the timeline color space for handoff to the Color page.

With RCM off, you must manage color in the Fusion page manually, either using the Source Color Space and Source Gamma Space settings of each MediaIn node, or using the CineonLog or FileLUT nodes in your node tree.

For more information on how color management affects the Fusion page, and why the Linear color space is preferable for compositing, jump to this chapter: Controlling Image Processing and Resolution.

Ability to Bypass Color Management Per Clip

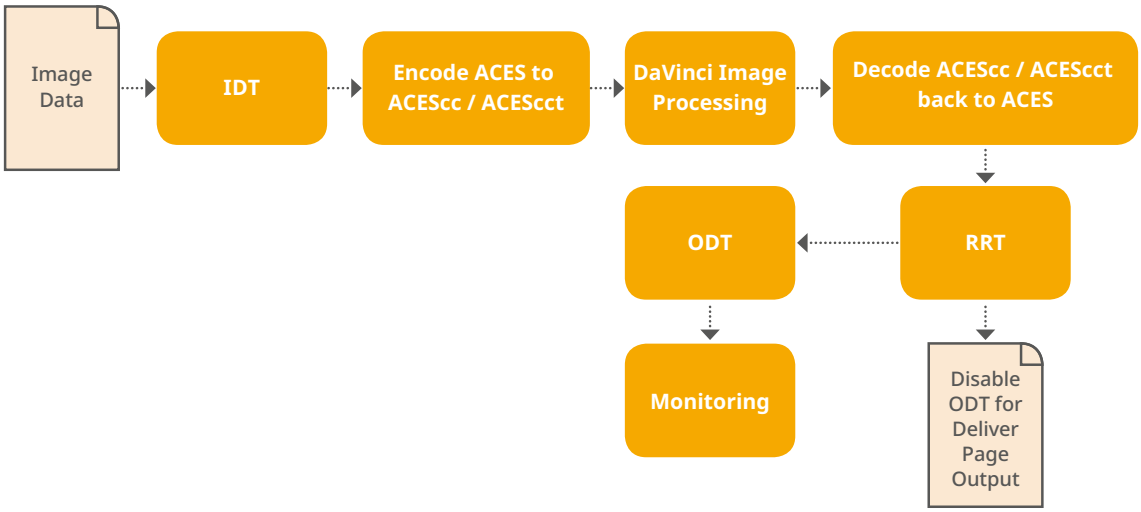


When you right-click a clip in the Thumbnail Timeline of the Color page, a “Bypass Color Management” setting appears underneath the Input Color Space and Input Gamma submenus that let you identify a clip’s color characteristics. Choosing this option so that it appears checked lets you exclude that clip from color management altogether, in the event you want to manually manage that clip using LUTs, the Color Space Transform node, or simply by doing manual grading.

The Bypass Color Management option for clips in the contextual menu of the Thumbnail Timeline

Exporting Color Space Information to QuickTime Files

If you render QuickTime files from the Deliver page, then color space tags will be embedded into each file based on either the Timeline Color Space (if Resolve Color Management is disabled) or the Output Color Space (if Resolve Color Management is enabled). Two settings in the Advanced Settings of the Render Settings let you choose how color space metadata will be embedded into your output for supported media formats, “Color Space Tag,” and “Gamma Tag.” These default to “Same as Project,” which will match the Output Color Space currently selected in the Project Settings.



The Color Space Tag and Gamma Tag settings in the Render Settings

Color Management Using ACES

The ACES (Academy Color Encoding Specification) color space has been designed to make scene-referred color management a reality for high-end digital cinema workflows. ACES also makes it easier to extract high-precision, wide-latitude image data from raw camera formats, in order to preserve high-quality image data from acquisition through the color grading process, and to output high-quality data for broadcast viewing, film printing, or digital cinema encoding.

An oversimplification of the way ACES works is that every camera and acquisition device is characterized to create an IDT (Input Device Transform) that specifies how media from that device is converted into the ACES color space. The ACES gamut has been designed to be large enough to encompass all visible light, with more than 25 stops of exposure latitude. In this way ACES has been designed to be future-proof, taking into consideration advances in image capture and distribution.

Meanwhile, an RRT (Reference Rendering Transform) is used to transform the data provided by each image format's IDT into standardized, high-precision, wide-latitude image data that in turn is processed via an ODT (Output Device Transform). Different ODT settings correspond to each standard of monitoring and output, and describe how to accurately convert the data within the ACES color space into the gamut of that display in order to most accurately represent the image in every situation. The RRT and ODT always work together.

ACES signal and processing flow

By using the ACES color space and specifying an IDT and an ODT, you can ingest media from any capture device, grade it using a calibrated display, output it to any destination, and preserve the color fidelity of the graded image.

For more information on ACES refer to the ACES Central Website.

Setting Up ACES in the Project Settings Window

There are four parameters available in the Color Science dropdown of the Color Management panel of the Project Settings that let you set up DaVinci Resolve to use the ACES workflow:

- **Color science is:** Using this dropdown menu, you can choose either DaVinci ACES, or DaVinci ACEScc color science, which enables ACES processing throughout DaVinci Resolve.

  ACEScc: Choose DaVinci ACEScc color science to apply a standard Cineon-style log encoding to the ACES data before it is processed by DaVinci Resolve. This well defined common encoding makes it possible for ASC CDL values to be used across systems using the same ACEScc encoding. After processing, a reverse encoding is applied in order to output ACES linear data.

  ACEScct: A variation of ACEScc that adds a roll-off at the toe of the image that's different from the encoding of ACEScc, in order to make color correction lift operations "feel" more like they do with film scans and LogC encoded images, which makes it easier to raise the darkest values of the image and get milky shadows, something that can be difficult with ACEScc. After processing, a reverse encoding is applied in order to output ACES linear data.

- **ACES Version:** When you've chosen one of the ACES color science options, this dropdown becomes available to let you choose which version of ACES you want to use. You can choose from ACES 1.0.3, ACES 1.1, ACES 1.2, ACES 1.3, or ACES 2.0 (the latest version).
- **ACES AMF:** For Aces 1.3 or above, you can select an ACES AMF file to be applied. More details can be found in the ACES AMF section below.
- **ACES Input Device Transform:** This dropdown menu lets you choose which IDT (Input Device Transform) to use for the dominant media format in use. DaVinci Resolve currently supports the following IDTs:

  ACEScc/ACEScct/ACEScg: Standardized transforms for each of these ACES standards.

  ADX (10 or 16): 10-bit or 16-bit integer film-density encoding transforms meant for use if you're working with film scans that were initially encoded in an ACES workflow. This transform is designed to maintain the variation in look between different film stocks.

  ALEXA: Color management settings for all ARRI ALEXA cameras.

  BMD Film/4K/4.6K: Color management settings for Blackmagic Design cameras.

  Canon 1D/5D/7D/C200/C300/C300MkII/C500/C700: Color management settings for Canon cameras.

  DCDM: This IDT transforms X'Y'Z'-encoded media with a gamma of 2.6.

  DCDM (P3D65 Limited): This IDT transforms X'Y'Z'-encoded media with a gamma of 2.6, specifically hard clipped to a P3 gamut with a D65 white point.

  DRAGONcolor/2 and REDgamma3/4/REDlogFilm combinations: Different combinations of the DRAGONcolor, REDgamma, and REDlogFilm settings are provided for legacy RED workflows.

  P3-D60: Transforms RGB-encoded image data with a D60 white point, intended for monitoring with a P3-compatible display using a D60 white point.

  P3-D65: Transforms RGB-encoded image data with a D65 white point; intended for monitoring with a P3-compatible display using a D65 white point.

  P3-D65 (D60 sim.): Transforms RGB-encoded image data with a D65 white point; intended to simulate monitoring with a P3-compatible display using a D60 white point on a display with D65.

  P3-D65 ST2084 (108/1000/2000/4000 nits): Transforms an image that's compatible with the P3 color gamut, using the SMPTE standard PQ (ST.2084) tone curve for High Dynamic Range (HDR) post-production. Three settings for four different peak luminance ranges are provided; which one is appropriate to use depends on the maximum white level of the display used to create the media. Preliminary standards exist for HDR displays with peak luminance at 1000 nits, 2000 nits, and 4000 nits. A setting of 108 nits is provided for Kodak laser projection.

P3-D65: Transforms RGB-encoded image data with a D65 white point, intended for monitoring with a P3-compatible display using a D65 white point.

P3-D65 ST2084 (1000/2000/4000 nits): Transforms an image that's compatible with the P3 color gamut, using the SMPTE standard PQ (ST.2084) tone curve for High Dynamic Range (HDR) post-production. Three settings for three different peak luminance ranges are provided; which one is appropriate to use depends on the maximum white level of the display used to create the media. Preliminary standards exist for HDR displays with peak luminance at 1000 nits, 2000 nits, and 4000 nits.

P3-DCI (D60 sim.): Produces output that's specifically for output on a DCI projector with a D60 white point. This output may look magenta on other display devices that aren't set up for DCI display.

P3-DCI (D65 sim.): Produces output that's specifically for output on a DCI projector with a D65 white point. This output may look magenta on other display devices that aren't set up for DCI display.

Panasonic V35: Color management settings for each listed camera.

Rec.2020: This IDT transforms media created with the wide-gamut standard for consumer and broadcast television.

Rec.2020 ST2084 (1000/2000/4000 nits): This IDT transforms media created within the wide-gamut standard for consumer and broadcast television, using the SMPTE standard PQ (ST.2084) tone curve for High Dynamic Range (HDR) post-production. Three settings provided for HDR televisions with different peak luminance capabilities.

Rec.2020 HLG (1000 nits): This IDT transforms media within the wide-gamut standard for consumer and broadcast television and uses the Hybrid Log-Gamma (HLG) standard tone curve for High Dynamic Range (HDR) post-production. A single setting is provided for HDR televisions with peak luminance at 1000 nits.

Rec.709 (Camera): A deprecated legacy IDT for Rec. 709 that's included for backward compatibility. Converts the source data to linear based on Rec. 709 and transforms the result to ACES, but while this transformation is technically correct, it's not necessarily pleasing after conversion through the matching ODT. For this reason, the academy updated to the following Rec. 709 IDT, which is the inverse of the Rec. 709 ODT.

Rec.709: A standard transform designed to move media in the Rec. 709 color space into the ACES color space. This option is used for any other file type that might be imported, such as ProRes from Final Cut Pro, DNxHD from Media Composer, and any media file captured from tape.

Rec.709 (D60 sim.): A standard transform designed to move media in the Rec. 709 color space with a white point of D60 into the ACES color space.

REDColor2/3/4/REDGamma3/4/REDLogFilm combinations: Different combinations of the REDcolor, REDgamma, and REDlogFilm settings are provided for legacy RED workflows.

RWGLog3G10: The standardized RED IPP2 color pipeline transform for all RED camera media.

If you're working on a project that mixes media formats that require different IDTs, then you can assign different IDTs to clips using the Media Pool's contextual menu, or using the Clip Attributes window, which is also accessible via the Media Pool's contextual menu.

- **ACES Output Device Transform:** This dropdown menu lets you choose an ODT (Output Device Transform) with which to transform the image data for monitoring on your calibrated display, and when exporting a timeline in the Deliver page. You can choose from the following options:

  ADX (10 and 16): A standardized ODT designed for media destined for film output. Two settings accommodate 10-bit and 16-bit output. This ODT is not meant to be used for monitoring.

  DCDM: This ODT exports X'Y'Z'-encoded media with a gamma of 2.6 intended for handoff to applications that will be re-encoding this data to create a DCP (Digital Cinema Package) for digital cinema distribution. This can be displayed via an XYZ-capable projector.

DCDM (P3D60 Limited): Outputs a P3 hard-limited signal with a D60 white point.

DCDM (P3D65 Limited): Outputs a P3 hard-limited signal with a D65 white point.

P3 D60: Outputs RGB-encoded image data with a D60 white point; intended for monitoring with a P3-compatible display using a D60 white point.

P3 D65: Outputs RGB-encoded image data with a D66 white point; intended for monitoring with a P3-compatible display using a D66 white point.

P3 D65 (D60 sim.): Outputs RGB-encoded image data to simulate monitoring with a P3-compatible display using a D60 white point on a display with a D65 white point.

P3 D65 (Rec.709 Limited): Outputs RGB-encoded image data with a D65 white point within a P3 gamut that's hard-limited to the color range of Rec. 709.

P3 D65 ST2084 (108/1000/2000/4000 nits): Outputs an image that's compatible with the P3 color gamut, using the SMPTE standard PQ tone curve for High Dynamic Range (HDR) post-production. Three settings for three different peak luminance ranges are provided; which one is appropriate to use depends on the maximum white level of your display. Preliminary standards exist for HDR displays with peak luminance at 1000 nits, 2000 nits, and 4000 nits. A setting of 108 nits is provided to simulate an HDR signal clipped to an SDR range.

P3 DCI (D60 sim.): Outputs RGB-encoded P3 image data that appears as if with a D60 white point on a DCI projector with a DCI white point.

P3 DCI (D65 sim.): Transforms RGB-encoded image data with a D61 white point (the DCI mastering standard) that appears as if with a D65 white point.

P3-D65 ST2084 (1000/2000/4000 nits): Transforms an image that's compatible with the P3 color gamut, using the SMPTE standard PQ (ST.2084) tone curve for High Dynamic Range (HDR) post-production. Three settings for three different peak luminance ranges are provided; which one is appropriate to use depends on the maximum white level of the display used to create the media. Preliminary standards exist for HDR displays with peak luminance at 1000 nits, 2000 nits, and 4000 nits.

Rec.2020: This ODT is for compatibility with the full range of this wide-gamut standard for consumer and broadcast television.

Rec.2020 (P3D65 Limited): Outputs a P3D65 hard-limited signal within this wide-gamut standard for consumer and broadcast television.

Rec.2020 (Rec.709 Limited): Outputs a Rec. 709 hard-limited signal within this wide-gamut standard for consumer and broadcast television.

Rec.2020 HLG: Outputs the full Rec. 2020 gamut to the Hybrid Log-Gamma standard for HDR.

Rec.2020 HLG (1000 nits, P3D65 Limited): Outputs a 1000 nit, P3D65 hard-limited signal within the Rec. 2020 gamut and the Hybrid Log-Gamma standard for HDR.

Rec.2020 ST2084 (1000/2000/4000 nits): This ODT transforms media created within the wide-gamut standard for consumer and broadcast television, using the SMPTE standard PQ (ST.2084) tone curve for High Dynamic Range (HDR) postproduction. Three settings are provided for HDR televisions with different peak luminance capabilities.

Rec.2020 ST2084 (1000/2000/4000 nits, P3D65 Limited): This ODT transforms media within the wide-gamut standard for consumer and broadcast television but with hard clipping at the boundary of the P3 gamut for televisions that are limited to the smaller P3 gamut for digital cinema; also uses the SMPTE standard PQ (ST.2084) tone curve for High Dynamic Range (HDR) post-production. Three settings are provided for HDR televisions with different peak luminance capabilities.

Rec.709: This ODT is used for standard monitoring and deliverables for TV.

Rec.709 (D60 Sim): A standard transform designed to move media in the Rec. 709 color space with a white point of D60 into the ACES color space.

sRGB: A standardized transform designed for media created for computer display in a consumer environment.

sRGB (D60 Sim): A standardized ODT designed for media destined for computer display in a consumer environment. Suitable for monitoring when grading programs destined for the web.

ACEScc/ACEScct/ACEScg: Standardized transforms for each of these ACES standards.

You must manually select an ODT that matches your workflow and room setup when working in ACES.

- **Process Node LUTs in:** This dropdown menu lets you choose how you want to process CLF LUTs that are added to nodes in your grades while working in ACES, such as Look LUTs in on-set or VFX workflows. There are two choices: ACEScc AP1 Timeline Space (the default), and ACES AP0 Linear.

  ACEScc AP1: For LUTs that have been designed to take the specific range of ACEScc data using the AP1 primary coordinates.

  ACES AP0: For LUTs that have been designed for normal ACES data from 65504 to -65504 floating point values.

NOTE: ACES grades require CLF LUTs that have been specifically created for ACES workflows. If you want to apply a regular LUT within a grade, you must do a color space transform to convert the image from ACES to whatever space the LUT was designed to work within, and then another color space transform to convert the image back to ACES; however, this workflow does not alway provide ideal results.

The Initial State of Clips When Working in ACES

Don't worry if the initial state of each image file appears differently than what was monitored originally on set. What's important is that if the camera original media was well exposed, the IDT used in ACES mode will retain the maximum amount of image data, and provide the maximum available latitude for grading, regardless of how the image initially appears on the Timeline.

ACES AMF 2.0

DaVinci Resolve supports ACES AMF 2.0 files for import and export. ACES AMF is a sidecar file written in XML that defines the input and output transforms of the clip. This makes sure that the correct input and output transforms are applied throughout the post production pipeline. These files can either be loaded at a project level or a clip level. Clips with the "applied" attribute set to true are tagged appropriately with no transforms applied. However, if they are set as false, the transform is applied within DaVinci Resolve.

NOTE: You must use version 1.3 or above of the ACEScc or ACEScct Color Science to use AMF files.

Working with AMF Files

- **Project level AMF:** These will have all transforms applied. (i.e., any defined input, look, or output transforms which have their “applied” attribute set to false will be applied.) The input and output transforms are applied via the project settings “ACES Input Transform” and “ACES Output Transform” menus, and these menus will display “From AMF” if they are using a transform from the loaded AMF file.
- **Clip level AMF:** An AMF can be loaded from the Color page clip thumbnail context menu from the Clip AMF menu. This list is also populated from the ACES Transforms AMF subfolder. A clip-level AMF will not apply the output transform; that can only be applied from project settings. Any input or look transforms will have their “applied” attribute set to false. The look transforms are applied within a compound node labeled AMF LMTs.
- **ACES Gamut Compression:** If the ACES reference gamut compress algorithm is specified in a look transform within the AMF, it will set the “Apply ACES reference gamut compress” checkbox to checked. The user can see what input, gamut compress, look and output transforms are applied by clicking the “View Transforms” button at the bottom of the “Color Space & Transforms” section of the Settings > Color Management section.

To Import an AMF

1. Place your AMF files in the ACES Transforms/AMF directory on your computer. This is folder is found:

   MacOS: the users Library/Application Support/Blackmagic Design/DaVinci Resolve/Aces Transforms/AMF

   Windows: the users AppData\Roaming\Blackmagic Design\DaVinci Resolve\Support\ACES Transforms\AMF

   Linux: opt/resolve/Developer/DaVinciCTL/AcesTransforms/AMF

2. In the Project Settings, set the Color Management > Color Science setting to ACEScc or ACEScct.
3. Select the ACES version to be 1.3 or above.
4. Click on the ACES AMF dropdown menu, and select the AMF from the list.

Exporting AMF Files

There are three choices to select from when you export an AMF file.

Source Master mode:

- All the applied attributes will be set to false.
- A source master is not associated with any clips or images.

Dailies Request mode:

- You can select the folder to store the output AMFs.
- A dailies AMF is created for and associated with each clip, and the applied attribute will be set to false.

VFX Request mode:

- A VFX AMF will only have the input transform with the applied attribute set to false.

AMF Delivery Behaviors

- For AMF delivery, the Export AMF option can be chosen in the Deliver page render settings.
- When using Source Master, the images are rendered to ACES AP0 or Linear masters with only the input transforms applied; all other transforms are set to applied false.
- The resulting AMF is not associated with any clips or images with an aim to define and transmit a color pipeline with its post production look alongside ACES AP0 or Linear data.
- In Dailies Request, all transforms are applied on the rendered images and all transforms are set to applied true.
- The resulting AMF is associated with each clip in the project.
- In VFX Request, the clips are rendered to ACES AP0 or Linear with only the input transform applied and all other transformed are set to false.
- Displays the AMF transform name.
- Custom ACES AMF folder support in Project Settings.
- AMF tree selection from the project settings ACES AMF option menu.
- Support for project-level Look transforms.
- Indicator for the current working location.

To Export an AMF

1. Right-click on your timeline in the Media Pool.
2. Select Timelines > Export > AMF in the contextual menu.
3. Choose the type of AMF file to export: Source Master, Dailies Request, or VFX Request.
4. Enter the name of the AMF file and its save location in the file browser.
5. Click on the Save button.

The Timeline Color Space in ACES Workflows is Fixed

When you're working in ACES, you do not get to change the Timeline Color Space as you do in Resolve Color Management. The ACES working color space is a log-encoded color space, which encourages a more traditional, film-oriented approach to grading.

Tips for Rendering Out of an ACES Project

When choosing an output format in the Deliver page, keep the following in mind:

- If you've delivering graded media for broadcast, set the ACES Output Device Transform to be Rec. 709, then you can output to whatever media format is convenient for your workflow.
- When you're delivering graded media files to another ACES-capable facility using the DCDM or ADX ODCs, you should choose the OpenEXR RGB Half (uncompressed) format in the Render Settings, and set the ACES Output Device Transform to "No Output Device Transform."
- When you're rendering media for long-term archival, you should choose the OpenEXR RGB Half (uncompressed) format in the Render Settings, and set the ACES Output Device Transform to "No Output Device Transform."

Chapter 10

HDR Setup and Grading

High Dynamic Range (HDR) grading for cinema, television, and streaming is the latest evolution of the consumer media experience.While HDR workflows in high-end cinema and television aren't new, this way of mastering media has been slow to expand to less expensive programming.

However, new developments and an expanding array of affordable HDR-capable consumer devices are poised to make HDR mastering of visual content increasingly ubiquitous.

This chapter describes what HDR is for the uninitiated and covers the operational details that will let you set up DaVinci Resolve to do HDR grading.

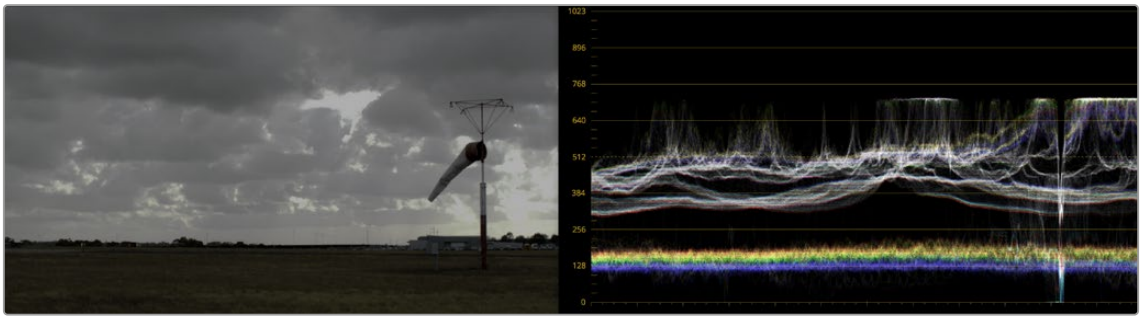
High Dynamic Range (HDR) Grading in DaVinci Resolve

The HDR features found in DaVinci Resolve are only available in DaVinci Resolve Studio.

High Dynamic Range (HDR) video describes an emerging family of video encoding and distribution technologies designed to enable a new generation of television displays to play video capable of intensely bright highlights and increased saturation. The general idea is that the majority of an HDR image will be graded similarly to how a Standard Dynamic Range (SDR) image is graded now, with the shadows and midtones being mostly the same between traditionally SDR and HDR-graded images. This is mostly because shadows are shadows and are meant to be dark; however this philosophy also maintains a comfortable viewing experience and easier backward compatibility when you need to master both SDR and HDR versions of a program.

The difference is that HDR provides abundant additional headroom for very bright highlights and color saturation that far exceed what has been previously visible in SDR television and cinema. This enables the colorist to create more vivid and life-like highlights in images, such as sunsets, lit clouds, firelight, explosions, sparkles, and other intensely bright and colorful imagery. In short, you can now "open up" the highlights in an image just as you've always been able to open up, or expand, the detail of the shadows. This not only provides more life-like lighting intensity and saturation, but it also dramatically expands the contrast available in the scene. For example, a calibrated SDR display should have a peak luminance level of 100 nits (cd/m^2), but existing HDR displays can provide peak luminance levels of 700, 1000, or even 4000 nits.



> However, because it's an evolving technology, the technical standards that have been developed far exceed what current consumer televisions, projectors, phones, and tablets are capable of. At the time of this writing, consumer televisions are capable of outputting 700 to 1600 nits. Furthermore, consumer displays are often saddled with automatic brightness limiting (ABL) circuits that limit power consumption to acceptable levels for home use, which means that only a certain percentage of the picture may reach these peak values at any one time. This is fine, because the point of HDR is not that you're making the entire image brighter, it's that you have more headroom for specific bright highlights and additional saturation.
>
> For all of these reasons, HDR standards focus on describing what displays should be capable of, not how these levels are to be used. That is a creative decision.

HDR Isn't Just for Televisions

Lest you think that living room televisions and projectors are the only way to watch HDR content, certain flagship iOS and Android phones and tablets have implemented HDR viewing capabilities that are capable of meeting or even exceeding the UltraHD requirements for HDR content on an OLED display. This makes HDR, surprisingly, a widely available mobile experience.

The Different Ways of Mastering HDR

While different HDR technologies use different methods to map the video levels of your program to an HDR display's capabilities, they all output a "near-logarithmically" encoded signal that requires a compatible television that's capable of correctly stretching this signal into its "normalized" form for viewing. This means if you look at an HDR signal that's output from the video interface of your grading workstation on an SDR display, it will look flat, desaturated, and unappealing until it's plugged into your HDR display of choice.

A graded HDR image being output looks similar to a log-encoded image

At the time of this writing, there are five principal approaches to mastering HDR that DaVinci Resolve is capable of supporting, including:

- Dolby Vision®
- HDR10
- HDR10+
- HDR Vivid
- Hybrid Log-Gamma (HLG)

Each of these HDR standards define how an HDR signal is encoded for export and later mapped to the visible output of an HDR or SDR display. Grading to each of these standards requires some degree of color management, and DaVinci Resolve gives you three main ways to handle this:

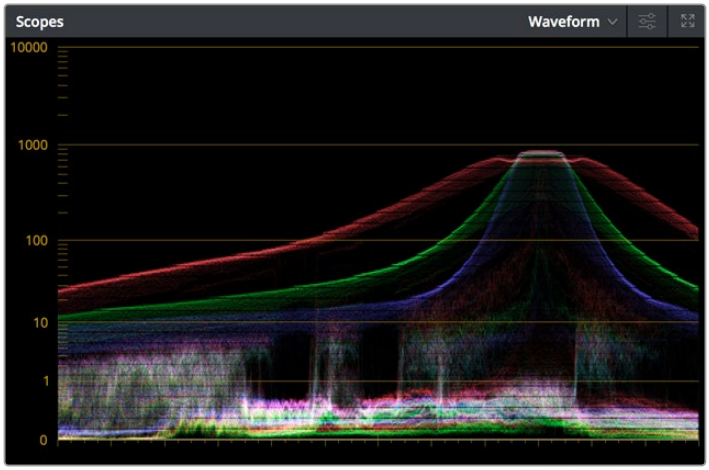
- The easiest way is to enable Resolve Color Management (RCM) or ACES in the Color Management panel of the Project Settings, and use the Color Space conversion options that are available. There are options there for each supported type of HDR.
- The transforms that are available in RCM are also available as Resolve FX operations, if you want to organize your grading pipeline more manually using the Color Transform Resolve FX adjustment.
- LUTs are also available to accomplish each of these color space conversions if you want to develop your own specific image processing pipeline based on custom-made LUT or DCTL transforms.

Overall, Resolve Color Management and ACES are reliable and recommended approaches to handling HDR grading in DaVinci Resolve in most instances.

For more information on Resolve Color Management, jump to this chapter: Data Levels, Color Management, and ACES.

What Do I Do With HDR?

While these standards make HDR mastering and distribution possible, they have nothing to say about how these HDR-strength levels should be used creatively. That's up to you, because the question of how to utilize the expansive headroom for brightness and saturation that HDR enables is fully within the domain of the colorist, as a series of creative decisions that must be made regarding how to assign the range of highlights that are available in your source media to the above-100 nit HDR levels you're mastering to as you grade, given the peak luminance level that you're assigned to master with. Which HDR peak luminance level you use (1000 nit, 3000 nit, 4000 nit) probably depends on which display you have access to and who's distributing the resulting program.



Analyzing HDR Signals Using Video Scopes

When you're using waveform scopes of any kind, including parade and overlay scopes, the signal will fit within the 10-bit scale used to analyze the signal much differently owing to the way HDR is encoded. The following chart of values will make it easier to understand how each level in "nits" (i.e., cd/m^2) corresponds to a code value within the 10-bit image scale:

10-Bit Code	Nearest Value in cd/m^2	HDR Display Peak Luminance Capability
1019[†]	10,000	No commercially available display
948	5000	Outdoor LED Displays
920	4000	Professional HDR Displays from Sony, Dolby, Flanders Scientific, EIZO, etc.
889	3000	Professional HDR Displays from Sony, Dolby, Flanders Scientific, EIZO, etc.
844	2000	Professional HDR Displays from Sony, Dolby, Flanders Scientific, EIZO, etc.
824	1600	Virtual Production Wall Panels
767	1000	Professional HDR Displays from Sony, Dolby, Flanders Scientific, EIZO, etc.
728	700	OLED mobile phone brightness
691	500	Minimum standard for an "UltraHD" OLED display
635	300	Professional SDR displays in "HDR preview mode"
593	203	BT.2408 recommendation for diffuse white of SDR content being intercut with 1000 nit max HDR content
528	108	Dolby Cinema projector
520	100	Standard peak luminance for SDR displays
447	48	Standard peak luminance for SDR DCI projection, Dolby Cinema 3D peak luminance
4[†]	0	Absolute black

[†] 0–3 and 1020–1023 are reserved values

While this table of values is useful for understanding where HDR nit levels fall on legacy external scopes, if you're monitoring with the built-in video scopes in DaVinci Resolve, you can turn on "HDR (ST.2084/HLG)" in the Waveform Scale Style settings in the Scopes option menu, which replaces the 10-bit scale of the video scopes with a scale based on nit values (or cd/m^2) instead.

The video scopes with HDR (ST.2084/HLG) on in the Waveform Scale Style settings in the Scopes option menu

IMPORTANT: If you are working in a non Davinci Resolve Color Managed workflow and activate the HDR (ST.2084/HLG) scopes, the waveform will always reflect HDR levels, even if you've manually selected the output color space as Rec.709, and thus not be 100% accurate.

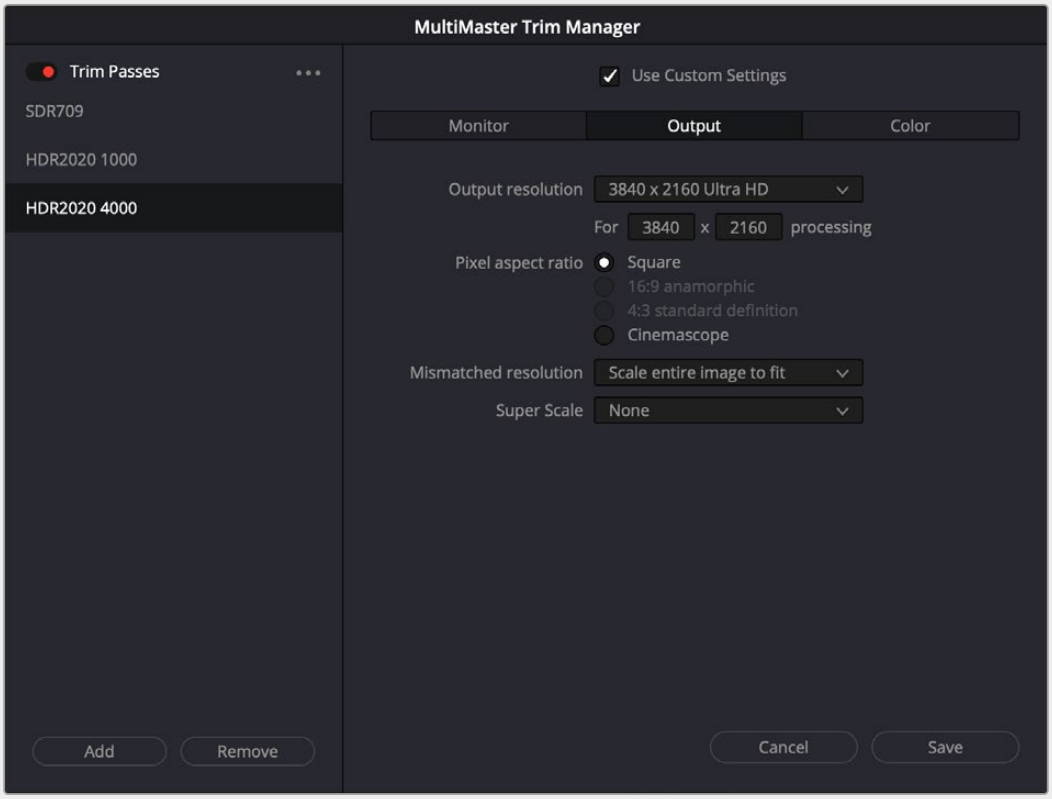
TIP: If you're unsatisfied with the amount of detail you're seeing in the 0–519 range (0–100 nits) of the video scope graphs, then you can use the 3D Scopes Lookup Table setting in the Color Management panel of the Project Settings to assign the appropriate "HDR X nits to Gamma 2.4 LUT," with X being the peak nit level of the HDR display you're using. This converts the way the scopes are drawn so that the 0–100 nit range of the signal takes up the entire range of the scopes, from 0 through 1023. This will push the HDR-strength highlights up past the top of the visible area of the scopes, making them invisible, but it will make it easier to see detail in the midtones of the image.

HDR Viewers

You can display the native viewers in DaVinci Resolve in HDR on Mac and Windows systems. The setting affects all DaVinci Resolve viewers, including the main page viewers, Cinema Mode, Fairlight Floating Viewer, Scene Cut Dialog, and the Video Clean Feed.

You will need an HDR-capable display and to turn on HDR in your OS:

- Activate the Windows HDR display settings (System > Display > HDR).
- Activate the Mac HDR display settings (System Settings > Displays > High Dynamic Range).
- In DaVinci Resolve Preferences > System > General, you will need to check the "Use 10-bit precision in viewers if available" box.

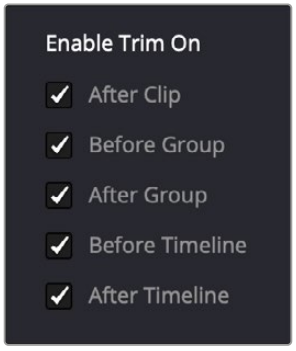


NOTE: The general controls/UI and non-viewer dialogs (e.g., secondary screen, project manager, floating Media Pool) are not affected.

MultiMaster Trim Manager (Studio Version Only)

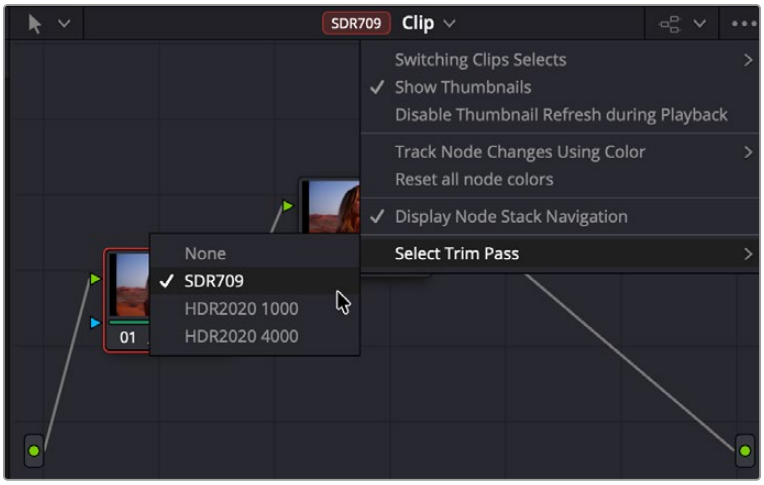
DaVinci Resolve has simplified the management of HDR grade trims with the new MultiMaster Trim Manager, which lets you manage multiple grade trims from a single timeline. The main node graph (including Pre- and Post-Group and node stack layers) serves as the hero grade for your timeline, while additional trim layers are grades that you can apply on top of the hero grade per deliverable.

For example, you can color grade your master 4000 nit HDR timeline, and simultaneously set up and manage trims for HDR 1000 and SDR Rec.709 output.



To enable the MultiMaster Trim Manager, go to Color > MultiMaster Trim Manager. Then toggle the Trim Passes switch located on the top left of the window.

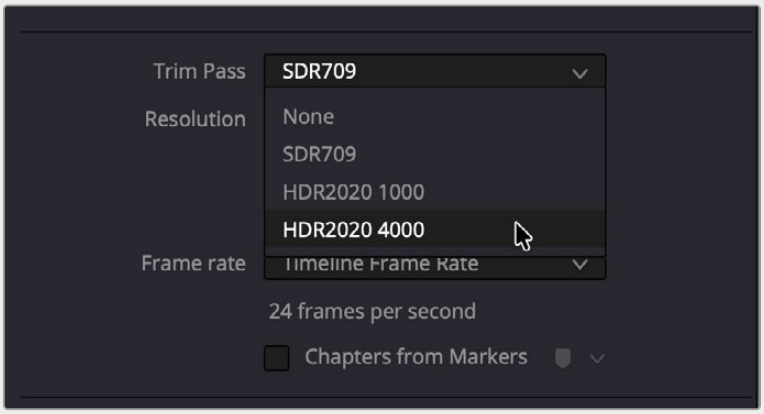
The MultiMaster Trim Manager.



This window lets you create and manage unlimited trims for your timeline. Add or remove trims by pressing the appropriate button. To rename a trim, click on its name in the list and start typing. Each trim can also be configured with custom monitoring, output, and color management output settings.

By default, each trim enables five types of node graphs: After Clip, Before Group, After Group, Before Timeline, and After Timeline. To enable/disable a specific node graph element, go to the 3-dot option menu > Trim Manager.

The Enable Trim On Selector.



To toggle your active trim, use the 3-dot option menu in the Color page node graph. The selected trim's name will be displayed at the top of the node graph, so you can easily identify which trim is active.

Selecting Trim Pass from the Node Graph option menu.

You can also set your blanking (at the clip level or timeline level) per trim in the Output Sizing palette. To do this, enable the Use Trim blanking checkbox, which will set the blanking at a trim level. Note that this feature is independent of the node stack layers that you enable for the main clip grade.

When it's time to output in the Deliver page, go to Video Settings and select the specific Trim Pass grade that you want to render for each output.

Go to the Video Render settings to select the Trim Pass you wish to output in the Deliver page.

Dolby Vision®

Long a pioneer and champion of HDR for enhancing the consumer video experience, Dolby Laboratories has developed a method for mastering and delivering HDR called Dolby Vision. As with most HDR standards discussed in this chapter, Dolby Vision uses the PQ (perceptual quantizer) electrical-optical transfer function (EOTF, which defines how an electronic video signal is presented on a display), which is defined by SMPTE ST.2084, along with a hierarchy of metadata that's embedded alongside the video stream. All metadata used by Dolby Vision is organized into levels, of which the following are important to the colorist:

- Level 0 metadata, which is global metadata that defines the Mastering Display (what the colorist is using), including aspect ratio, frame rate, color encoding and information on all the target displays that are used for the Level 2 and Level 8 trim metadata below.
- Level 1 metadata, which is the Dolby Vision v2.9 analysis metadata that's generated automatically when you use the Dolby Vision controls to analyze the clips in the timeline. The controls for automatically generating Level 1 metadata are available to all DaVinci Resolve Studio users.
- Level 2 metadata, which is the Dolby Vision v2.9 trimming metadata that's set by the colorist via the version 2.9 trim controls available in the Dolby Vision palette of the Color page. This trimming allows adjustment of how the Dolby Vision image is to be mapped to a target display (such as a 100 nit BT.709 display) that's different from the mastering display (such as a 1000 nit BT.2020 display). The purpose of this metadata is to maintain a program's artistic intent by providing guidance from the colorist over how the program's signal should be fit into the differing luminance ranges of a variety of displays with different peak luminance capabilities. Manually adjustable Level 2 metadata is only available to DaVinci Resolve Studio users via a license obtained from Dolby.
- Level 3 metadata, which is the offset for Dolby Vision v4.0 added to Level 1 metadata generated by the analyze buttons in the Dolby Vision controls. It also stores the mid tone offset data.
- Level 5 metadata, which provides information about the aspect ratio of the deliverable format, and the aspect ratio of the actual image within that format. This metadata is also applicable at the per clip level.
- Level 6 metadata, which stores the MaxCLL and MaxFALL levels required by the HDR10 mastering standard of HDR.
- Level 8 metadata, which is the updated Dolby Vision v4.0 trimming metadata that's set by the colorist via the v4.0 trim controls available in the Dolby Vision palette of the Color page. This evolved set of trimming commands allows more detailed adjustment of how the Dolby Vision image is to be mapped to a target display (such as a 100 nit BT.709 display) that's different from the mastering display (such as a 1000 nit BT.2020 display). Just like Level 2 metadata, the purpose of Level 8 metadata is to maintain a program's artistic intent by providing guidance from the colorist over how the program's signal should be fit into the differing luminance ranges of a variety of displays with different peak luminance capabilities. Manually adjustable Level 8 metadata is only available to DaVinci Resolve Studio users via a license obtained from Dolby. Whether you use Level 2 trim controls or Level 8 trim controls depends on the Dolby Vision version setting you choose in the Color Management panel of the Project Settings.

NOTE: It's currently recommended for all users to choose Dolby Vision v4.0 for analysis and trimming, as it provides superior results. If you're required to deliver Dolby Vision v2.9 metadata when mastering for backwards compatibility, DaVinci Resolve can now export v2.9 metadata from projects using v4.0 workflows.

The metadata levels described above are current of this writing. However Dolby Vision is a rapidly evolving technology, and as Dolby adds new features and metadata levels you should reference Dolby's website to keep track of the latest developments: https://professionalsupport.dolby.com/s/article/Dolby-Vision-Metadata-Levels?language=en_US

For the foreseeable future, the current consumer display landscape encompasses a wide variety of differently performing televisions and projectors that are guaranteed to improve year over year. This means that mastering for today's displays may render content less vibrant than content that emerges five years from now. This can be especially vexing for narrative content that will have a long lifespan on streaming services as new generations of viewers discover them. While one way of solving this would be to re-grade your program many times at a variety of nit levels to create deliverables suitable to a range of display capabilities, that's an enormous amount of work.

Dolby Vision offers a shortcut by using sophisticated algorithms to derive automatically analyzed metadata that intelligently guides how an image graded at one nit level (say 4000 nits) can be adjusted to be perceptually similar to viewers watching a 1000 nit display. Highlights and saturation that are too bright for a particular display will be adjusted to provide as close to the same experience without clipping or flattening image detail.

Furthermore, this automatic analysis can be manually trimmed by a colorist to account for the artistic intentions of the authors of a program, in cases where the automatic analysis doesn't do exactly what's wanted. This combination of auto-analysis and manual trimming is key to how Dolby Vision streamlines the process of mastering programs to accommodate backward compatibility with SDR displays, as well as the varying peak luminance capabilities of different makes and models of HDR consumer displays, both now and in the future. You're only required to make a 100 nit trim pass to guide the HDR program's conversion all the way down to SDR, and the Dolby Vision system can use that information to guide how intermediate presentations (such as at 700 or 1200 nits) should be adjusted. You can even do multiple trim passes at specific nit levels, such as a 100 nit pass and a 1000 nit pass, to give the Dolby Vision system more information to accurately guide intermediate presentations on different displays. Additionally, you don't have to trim every clip. If the analysis is good, you can skip those clips and only trim clips that need it. The overall system has been created to make it as efficient as possible for colorists to ensure that the widest variety of viewers see the image as it's meant to be seen.

This, in a nutshell, is the advantage of the Dolby Vision system. You can grade a program on a more future-proofed 4000 nit display, and use auto-analysis plus one or two manual trim passes to make the program backward compatible with SDR televisions, and capable of intelligently scaling the HDR highlights to provide the best representation of the mastered image for whatever peak luminance and color volume a particular television is capable of. All of this is guided by decisions made by the colorist during the grade.

At the time of this writing, all seven major Hollywood studios are mastering in Dolby Vision for cinema. Studios that have pledged support to master content in Dolby Vision for home distribution include Universal, Warner Brothers, Sony Pictures, and MGM. Content providers that have agreed to distribute streaming Dolby Vision content include Netflix, Vudu, and Amazon. If you want to watch Dolby Vision content on television at home, consumer television manufacturers LG, TCL, Vizio, HiSense, Sony, Toshiba, and Bang & Olfusen have all shipped models with Dolby Vision support.

Organizing Your Timeline for Dolby Vision Mastering

One of the first things you need to do before doing a Dolby Vision grade is to organize your timeline accordingly. Because each clip undergoes a visual analysis to facilitate the Dolby Vision workflow, there are specific limitations to how clips can appear in a timeline.

- All clips to be analyzed in a Dolby Vision workflow need to be on video track V1; clips on other tracks will be ignored.
- All clips that overlap one another as part of a composite must be turned into a single item in the timeline in order to be correctly analyzed. This means that each group of clips that create a composite in a timeline, be it multiple overlapping clips combined via keys or alpha channel transparency, multiple overlapping clips combined using composite or blend modes, or text generators appearing above one or more video clips, must be turned into a compound clip for Dolby Vision analysis to work correctly.

Letterboxing for Dolby Vision Mastering

The analysis of clips in a Dolby Vision workflow keeps track of the timeline aspect ratio, as well as the image aspect ratio of each clip in that timeline. Programs that mix different aspect ratios of letterboxing (or blanking) will be accommodated by the Dolby Vision analysis, however Dolby Vision does not support letterbox on two sides (both pillarbox and letterbox), only one at a time.

Setting Up Color Management for Dolby Vision Mastering

For an HDR signal to look correct, you need to output your graded program using the right EOTF for the HDR standard you're mastering. The EOTF maps the different levels DaVinci Resolve outputs to your HDR display using the SMPTE ST.2084 PQ setting required for outputting Dolby Vision.

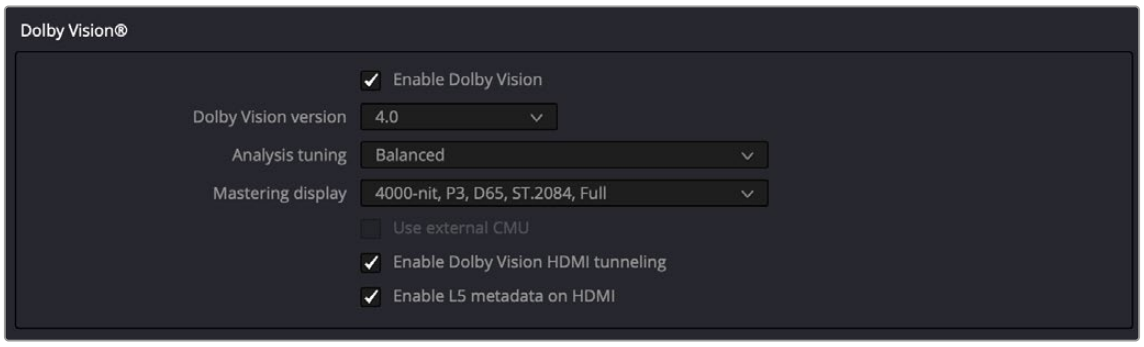
You can set this up in one of three different ways, as:

- Output Color Space and Gamma settings in RCM or ACES
- Color Space and Gamma settings within a series of Resolve FX Color Transform plugins that can be used at the end of each grade or at the end of a Timeline grade
- 3D LUTs used for converting signals from one standard to another that can be used at the end of each grade or at the end of a Timeline grade

While Dolby Vision content is not limited to a particular color space, Resolve Color Management provides a P3 D65 setting that matches the capabilities of most mastering displays in use at the time of this writing.

Choosing Mastering Displays for Dolby Vision

To do HDR grading, you need a suitable HDR display. Technically any monitor that supports SMPTE ST.2084 (aka PQ) will work. Happily, a growing number of professional displays from Sony, Flanders Scientific, TV-Logic, Canon, and Eizo are suitable for use in HDR grading suites. EBU Tech 3320 specifies the requirements for a Grade 1 HDR mastering monitor.



Dolby recommends the following minimum requirements for HDR monitors:

- A minimum Peak Luminance of 1000 nits
- A 200,000:1 contrast ratio
- Minimum black at 0.005 nits
- Capable of at least 99% of P3 gamut

For more information on Dolby best practices for color grading Dolby Vision, visit: https://www.dolby.com/us/en/technologies/dolby-vision/dolby-vision-for-creative-professionals.html.

Using the Dolby Vision Internal Content Mapping Unit (iCMU)

DaVinci Resolve has a GPU-accelerated “internal” software version of the Dolby Vision CMU (Content Mapping Unit) for previewing Dolby Vision mapping right in DaVinci Resolve. iCMU support can be enabled and set up in the Color Management panel of the Project Settings by turning on the Enable Dolby Vision checkbox. This is a DaVinci Resolve Studio-only feature.

Dolby Vision settings in the Color Management panel of the Project Settings

The Dolby Vision group of settings also exposes menus for choosing the version of Dolby Vision you want to use, the type of analysis and what kind of Master Display you’re using, and whether or not to use an eCMU (assuming you possess the option). In addition, there are options to enable HDMI tunneling (as described below). Finally, turning Dolby Vision on also enables the Dolby Vision palette and controls in the Color page, which are described in greater detail later in this chapter.

To master with Dolby Vision in DaVinci Resolve using the built-in iCMU, you still need a more specific hardware setup than the average grading and finishing workstation, consisting of the following equipment:

- Your DaVinci Resolve grading workstation using a DeckLink 8K Pro or DeckLink 4K Extreme 12G video interface.
- A mastering display capable of outputting HDR nit levels suitable for the deliverable you’re required to produce

Simultaneous Master and Target Display Output for Dolby Vision

When mastering HDR and trimming versions for more limited displays, it’s extremely useful to be able to evaluate your HDR grade and SDR trim pass side-by-side. It’s possible to output both the Master Display output and the Target Display output simultaneously when you’re grading with either Dolby Vision or HDR10+ enabled.

Necessary Hardware

To work in this manner, you must have the following equipment:

- Your DaVinci Resolve grading workstation must output via a DeckLink 8K Pro via the attached HDMI card. This will pass the Dolby Vision metadata through to the SDR display, so you will see the SDR out from the HDR grade.
- Your Mastering Display must be capable of HDR nit levels suitable for the deliverable you’re required to produce.
- A display that can be set to output calibrated SDR, probably using the BT.709 gamut

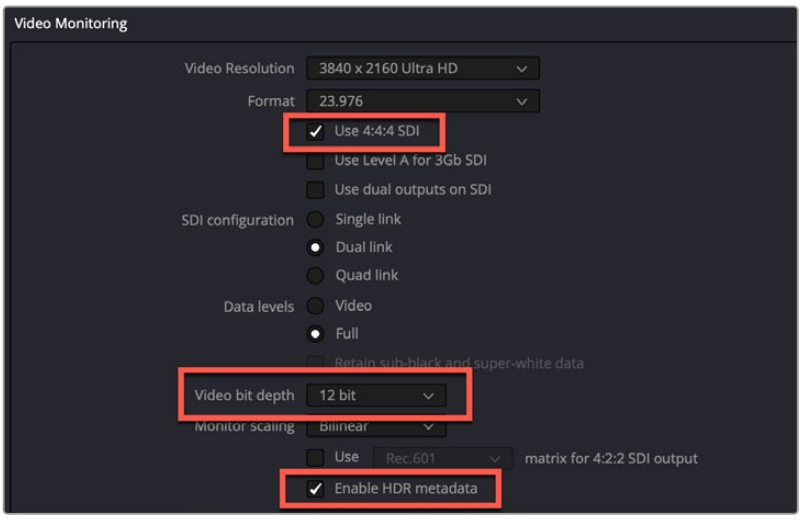
Enabling Simultaneous Monitoring

When you set up your display hardware, the HDR Master Display must be connected to output A, and the Target Display must be connected to output B of whichever BMD video output device you're using. Then, you need to turn on the "Use dual outputs on SDI" checkbox in the Master Settings of the Project Settings. At this point, assuming all of your connections are compatible with one another, you should see an HDR image output to your HDR display, and a trimmed image output to your SDR display.

HDMI Tunneling using DeckLink 8K Pro G2

HDMI Tunneling allows you to preview Dolby Vision content directly on a consumer display in real time. The variables involved in display type and manufacturer all have their own processing behaviors, so HDMI tunneling is not for reference grading but more of letting you get an idea of what the audience will be seeing at home for QC purposes.

Performing HDMI tunneling in DaVinci Resolve is possible using lower cost Blackmagic DeckLink cards instead of Dolby's dedicated eCMU hardware. Currently, the only DeckLink card that supports Dolby Vision HDMI tunneling is the DeckLink 8K Pro G2.



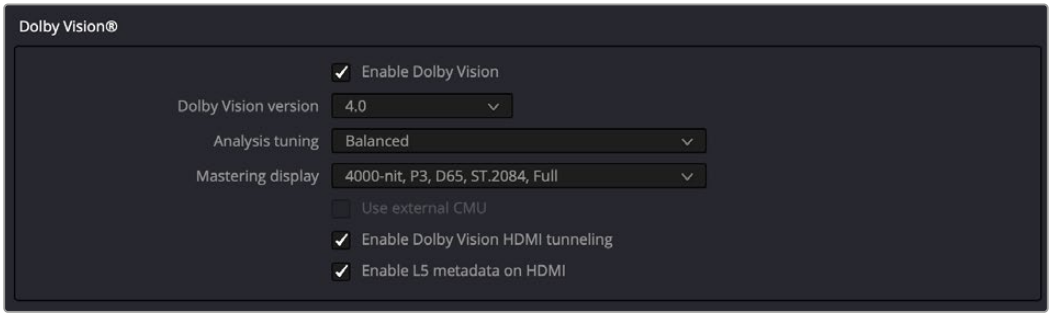
Setting up Dolby Vision HDMI Tunneling in DaVinci Resolve:

1. In Preferences > System > Video and Audio I/O, make sure that both the Capture Device and Monitor Device are set to the DeckLink 8K Pro.
2. In Project Settings > Master Settings > Video Monitoring, set the following parameters:

   Use 4:4:4 SDI: Check this box.

   Video bit depth: Set this value to 12 bit.

   Enable HDR metadata: Check this box.



The Project settings in Video Monitoring to enable Dolby Vision HDMI tunneling

3. In Project Settings > Color Management > Dolby Vision, set the following parameters:

   Enable Dolby Vision: Check this box.

   Enable Dolby Vision HDMI tunneling: Check this box.

   Enable L5 metadata on HDMI: Check this box.

The Project settings in Dolby Vision to enable HDMI tunneling

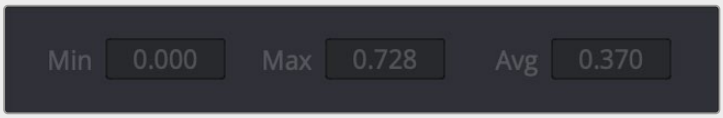
4 In the Color page, in the Dolby Vision palette, make sure that the Enable Tone Mapping Preview is disabled (the box is not checked). HDMI tunneling will not work if this box is checked.

Disable the Enable Tone Mapping Preview box in the Dolby Vision palette in the Color page

For more information on Dolby Vision HDMI tunneling refer to the Dolby's website: https://professionalsupport.dolby.com/s/article/HDMI-Tunneling?language=en_US

External Content Mapping Unit (eCMU) for Dolby Vision

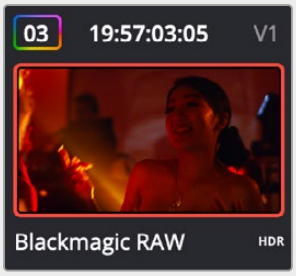
DaVinci Resolve supports the use of a Dolby External Content Mapping Unit (eCMU) for studios doing more intensive HDR mastering work, as it lets you monitor and adjust an HDR display simultaneously to an SDR display for side-by-side trimming at high resolutions via hardware. The eCMU also has the ability to preview Dolby Vision on a consumer display in real time via HDMI tunneling to view directly what the audience will see at home.



Auto Analysis is Available to All Studio Users

Resolve Studio enables either unlicensed or licensed users to automatically analyze the image and generate Dolby Vision analysis metadata. This metadata is used to deliver Dolby Vision content and to render other HDR and SDR deliverables from the HDR grade that you've made. This enables any DaVinci Resolve Studio user to create Dolby Vision deliverables with Level 1 metadata. However, manual trimming of the analysis metadata requires a license from Dolby.

The commands governing Dolby Vision auto-analysis, which are available to all Resolve Studio users, are available in the Color > Dolby Vision™ submenu, as well as the Dolby Vision palette, and consist of the following:



- **Analyze All Shots:** Automatically analyzes each clip in the Timeline and stores the results individually.
- **Analyze Selected Shot(s):** Only analyzes selected shots in the Timeline.
- **Analyze Selected And Blend:** Analyzes multiple selected shots as if they were a single sequence. The result is the same analysis being saved to each clip. Useful to save time when analyzing multiple clips that have identical content.
- **Analyze Current Frame:** A fast way to analyze clips where a single frame is representative of the entire shot.

Once you analyze a clip, the Min, Max, and Average fields automatically populate with the resulting L1 data; these fields are not editable.

The metadata fields for each clip

Additionally, clips that have been analyzed show an HDR badge in the Thumbnail timeline, to help you keep track of which clips have been analyzed and which have yet to be.

Analyzed clips have HDR badges to identify them

Licensing DaVinci Resolve to Expose Dolby Vision Trim Controls

To expose the Dolby Vision controls in DaVinci Resolve Studio that let you make manual trims on top of the automatic analysis that any copy of DaVinci Resolve Studio can do, you must email dolbyvisionmastering@dolby.com to receive more information about obtaining a license.

Once you've obtained a license file from Dolby, you can import it by choosing File > Dolby Vision > Load License, and its successful installation will enable the Dolby Vision controls to be enabled in the Color page. You should also receive a display configuration file, which can be loaded via the File > Dolby Vision > Load Configuration command and lets you populate the Dolby Vision dropdown menus with the most up to date options.

Dolby Vision® Trim Controls in DaVinci Resolve

Once you've analyzed a clip, you're in a position to trim the result. The latest version of the Dolby Vision palette exposes four sets of controls. The first are the main controls:

- **Target Display Output:** This dropdown specifies what Dolby refers to as the Target Display, used to display the tone mapped image. This menu lets you choose specific display properties to obtain a preview of what the trimmed image will look like on different displays with different gamuts and peak luminance capabilities. You can link the Target Display Output and the Trim Controls For fields by clicking on the little chain icon directly to the left of the options. This automatically changes the Trim Controls For field to the same value you set in the Target Display Output, ensuring your trim controls are always right for the selected display.
- **Trim Controls for:** Which Target Display you're currently trimming for. The default setting (100-nit, BT.709, BT.1886, Full) lets you monitor an SDR version of the HDR image, so you can see how the trim metadata tone maps the image on non-HDR televisions.
- **Analyze controls:** The commands governing Dolby Vision auto-analysis are available as buttons, which perform the same functions as their similarly named counterparts in the Color > Dolby Vision submenu. Please note that most trim controls are disabled until you perform an analysis, which is a necessary first step.

  All: Automatically analyzes each clip in the current Timeline and stores the results individually.

  Selected: Only analyzes selected shots in the Timeline.

  Blend: Analyzes multiple selected shots as if they were a single sequence. The result is the same analysis being saved to each clip. You need to use the blend option when analyzing two clips that meet at a through edit separating otherwise contiguous frames. It's also typical to use the Blend option when analyzing a scene of clips that take place at the same location at the same time, to ensure that natural variations in lighting don't add unwanted variations between the analyses of clips that are supposed to already be balanced with one another. Blend also saves time when analyzing multiple clips that have identical content.

  Frame: Useful in situations where part of a clip has an extreme level of color or lightness that's not typical of the rest of the clip, that incorrectly biases the analysis and produces a poor result. Placing the playhead on a frame that's representative of how the clip is supposed to look and using the Frame option bases the analysis on only that frame. This is also a fast way to analyze clips where a single frame is representative of the entire shot.
- **Enable Tone Mapping Preview:** Lets you see the target display output in the Color page Viewer and video output, so you can evaluate how the tone mapped version looks on your HDR display. This control is disabled when you enable "Use dual-outputs on SDI" in the Master Settings of the Project Settings, since the second output SDI now automatically displays the target display output.
- **Mid Tone Offset (CM v4.0 only):** This control is used to match the overall exposure between the tone mapped SDR signal to the HDR master. This offset is applied to the L1 Mid values, allowing the adjustment of mid tones without affecting the blacks and highlights. It can be used to shift overall L1 analysis to ensure the best preservation of artistic intent. This setting is shared among all trim passes you do at all nit levels, so if you've done two trim passes, one at 100 nits and another at 1000 nits, adjusting this setting always adjusts both trim passes at once. Changes made to this control are recorded to the L3 metadata for each clip.

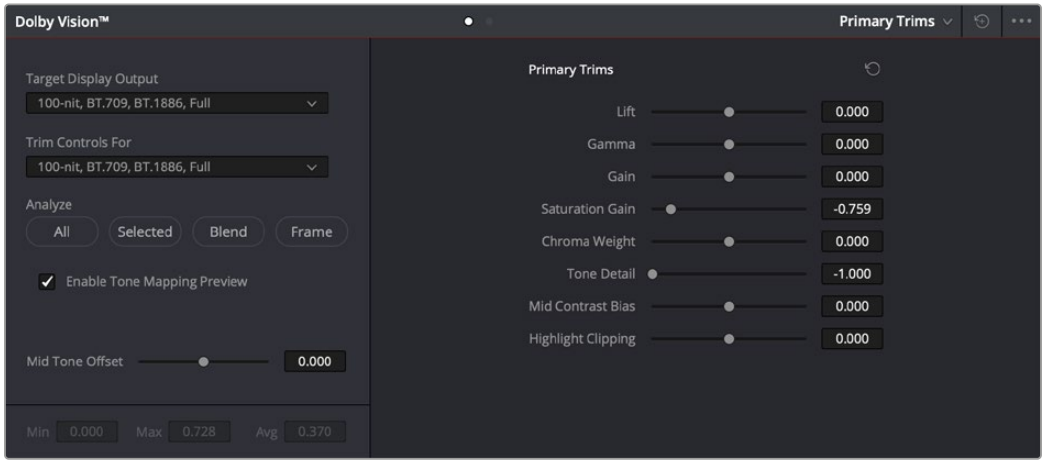
The second are the Min, Mid, and Max metadata fields that are populated by the analyzed values of the current clip. These fields cannot be edited, although analysis metadata can be copied and pasted among clips. These values represent the L1 analysis and are used to calculate how the HDR image should be trimmed to fit into the video standard specified by the Target Display.

The third are the Primary Trims, which are only editable if you've performed an analysis and if you have a license from Dolby. Which controls are exposed depends on the version of Dolby Vision you've selected in the Color Management panel of the Project Settings.

Reset Dolby Vision Analysis from the Option Menu

You can reset the Dolby Vision analysis from the three-dot option menu in the Dolby Vision pane of the Color page.

Dolby Vision CM v2.9 Controls

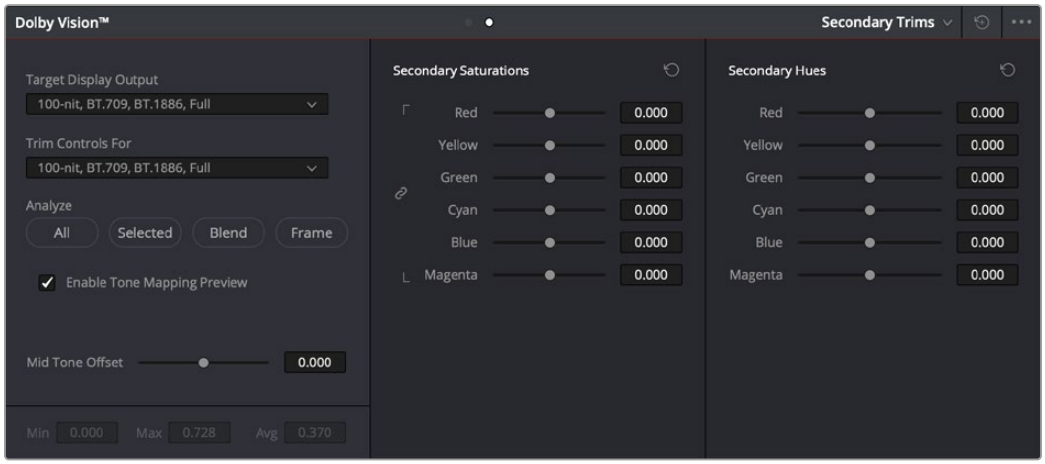


If you choose Dolby Vision 2.9 in the Color Management panel of the Project Settings, it activates the 2.9 version of Dolby's content mapping algorithm and exposes the original Dolby Vision trim controls. It is no longer suggested to use these, since you can do a Dolby Vision 4.0 analysis and trim, and still export converted 2.9 metadata for legacy workflows.

- **Lift/Gamma/Gain:** These controls function similarly to the Y-only Lift, Gamma, and Gain master wheels of the Color Wheels palette, to let you trim the overall contrast levels of the image. The Dolby Best Practices Guide recommends to limit positive Lift to no more than 0.025, and mostly restrict yourself to using Gamma and Gain if necessary to lighten the image.
- **Saturation Gain:** Lets you trim the saturation of the most highly saturated areas within a scene. Lesser saturated values will be less affected.
- **Chroma Weight:** Darkens saturated parts of the image to preserve colorfulness in areas of the image that are clipped by smaller gamuts that don't have enough headroom for saturation in the highlights.
- **Tone Detail:** Lets you preserve contrast detail in the highlights that might otherwise be lost when the highlights are mapped to lower dynamic ranges, usually due to clipping. Increasing Tone Detail Weight increases the amount of highlight detail that's preserved. When used, can have the effect of sharpening highlight detail.

Dolby Vision CM v4.0 Controls

If you choose Dolby Vision 4.0 in the Color Management panel of the Project Settings, it activates the 4.0 version of Dolby's content mapping algorithm, and exposes the following controls.



- **Lift/Gamma/Gain:** These controls function similarly to the Y-only Lift, Gamma, and Gain master wheels of the Color Wheels palette, to let you trim the overall contrast levels of the image. The Dolby Best Practices Guide recommends to limit positive Lift to no more than 0.025, and mostly restrict yourself to using Gamma and Gain if necessary to lighten the image.
- **Saturation Gain:** Lets you trim the saturation of the most highly saturated areas within a scene. Lesser saturated values will be less affected.
- **Chroma Weight:** Darkens saturated parts of the image to preserve colorfulness in areas of the image that are clipped by smaller gamuts that don't have enough headroom for saturation in the highlights.
- **Tone Detail:** Lets you preserve contrast detail in the highlights that might otherwise be lost when the highlights are mapped to lower dynamic ranges, usually due to clipping. Increasing Tone Detail Weight increases the amount of highlight detail that's preserved. When used, can have the effect of sharpening highlight detail.
- **Mid Contrast Bias:** Affects image contrast in the region around the computed average picture level. This lets you increase or decrease contrast in the midtones of the image.
- **Highlight Clipping:** Reduces details and affects the roll-off the brighter part of the image by clipping the highlights as required. This is useful when the tone mapped image is displaying unwanted details.

The Primary Trims controls that are found in the Dolby Vision palette are only enabled once you've authorized your system with a special license, available from Dolby.

The fourth set of controls is available via a second palette mode, the Secondary Trims. These are only editable if you've performed an analysis and if you have a license from Dolby.

- **Secondary Saturations:** A set of slider-based vector-style controls (similar to the Hue vs. Sat curve) lets you adjust the Saturation of Red, Yellow, Green, Cyan, Blue, and Magenta to help you selectively fine tune the results.
- **Secondary Hues:** Another set of slider-based vector-style controls (similar to the Hue vs. Hue≈controls) lets you adjust the Hue of Red, Yellow, Green, Cyan, Blue, and Magenta to help you fine tune the results.

The Secondary Trims controls, as seen on a licensed Dolby Vision system

Together, all of this trimming metadata lets the colorist guide how the iCMU or eCMU transforms the image from the Mastering Display specified in the Project Settings to the Target Display specified in the Dolby Vision palette. This metadata is carried throughout the ecosystem so that your artistic intent is preserved on a variety of platforms and displays.

Previewing and Trimming At Different Levels

Additionally, the iCMU or eCMU can be used to preview 100 nit, 600 nit, 1000 nit, and 2000 nit versions of your program, with different gamuts, if you want to see how your master will scale to those combinations of peak luminance levels and standards. This, of course, requires your DaVinci Resolve workstation or eCMU to be connected to a display that's capable of being set to those peak luminance output levels.

Though it's not at all typical, you also have the option to set the "Trim Controls For" dropdown menu to different combinations of peak luminance, gamut, and color temperature, in order to visually trim the grades of your program at up to four different peak luminance levels, including 100 nit, 600 nit, 1000 nit, and 2000 nit reference points. Choosing a setting from the "Trim Controls For" dropdown menu sets you up to adjust trim metadata for that setting.

Choosing different settings from the "Trim Controls For" dropdown menu lets you can optimize a program's visuals for the peak luminance and color volume performance of many different televisions with a much finer degree of control. If you take this extra step of doing a complete trim pass of your program at multiple nit levels (using the Dolby Vision controls), the Level 2, or Level 8 metadata you generate in each trim pass ensures that the artistic intent is preserved as closely as possible across a wide variety of displays, in an attempt to provide the viewer with the best possible representation of the director's intent, no matter where it appears.

> For example, if a program were graded relative to a 4000 nit display, along with a single 100 nit BT.709 trim pass, then a Dolby Vision-compatible television with 750 nit peak output will reference the 100 nit trim pass metadata in order to come up with the best way of "splitting the difference" to output the signal correctly. On the other hand, were the colorist to do three trim passes, the first at 100 nits, -cond at 600 nits, and a third at 1000 nits, then a 750 nit-capable Dolby Vision television would be able to use the 600 and 1000 nit trim metadata to output more accurately scaled color volume and HDR-strength highlights, relative to the colorist's adjustments, that take better advantage of the 750 nit output of that television.

Managing Dolby Vision™ Metadata

As you go through the process of analyzing and trimming the HDR grades displayed on your Master Display to look appropriate on your Target Display, you'll sometimes find it useful to copy and paste metadata from one clip to another. You can copy and paste Analysis Metadata separately from Trim Metadata and Mid Tone Offset, and you can choose to copy and paste metadata for all Target Displays when you're trimming multiple passes, or you can copy and paste metadata for only the current Target Display if you're trimming multiple passes and you only want to overwrite metadata for a single pass.

Methods of Copying and Pasting Dolby Vision Metadata:

To copy and paste Analysis Metadata: Select a clip you want to copy from, choose Copy Analysis Metadata from the Dolby Vision palette option menu, then select a clip you want to paste to, and choose Paste Analysis Metadata from the Dolby Vision palette option menu.

To copy and paste Trim Metadata for all Target Displays: Do one of the following:

- Select a clip you want to copy from, choose Edit > Dolby Vision > Copy Trim Metadata, then select a clip you want to paste to, and choose Edit > Dolby Vision > Paste Trim Metadata.
- Select a clip you want to copy from, choose Copy Trim Metadata from the Dolby Vision palette option menu, then select a clip you want to paste to, and choose Paste Trim Metadata from the Dolby Vision palette option menu.
- Select a clip you want to paste to, then press and hold the Option-Shift keys, and middle-click the clip you want to copy from.

- **To copy and paste Trim Metadata for the current Target Display:** Do one of the following:
  - Select a clip you want to copy from, choose Copy Trim Metadata from the Dolby Vision palette option menu, then select a clip you want to paste to, and choose Paste Trim Metadata to Current from the Dolby Vision palette option menu.
  - Select a clip you want to paste to, then press and hold the Option key, and middle-click the clip you want to copy from.
- **To copy and paste Mid Tone Offset:** Select a clip you want to copy from, choose Copy Mid Tone Offset from the Dolby Vision palette option menu, then select a clip you want to paste to, and choose Paste Mid Tone Offset from the Dolby Vision palette option menu.

Setting Up Resolve Color Management for Grading HDR

Once the hardware is set up, setting up Resolve itself to output HDR for Dolby Vision mastering is easy using Resolve Color Management (RCM). This procedure is pretty much the same no matter which HDR mastering technology you're using; only specific Output Color Space settings will differ.

1. Set Color Science to DaVinci YRGB Color Managed in the Color Management panel of the Project Settings.
2. Then, open the Color Management panel, and set the Output Color Space dropdown to the ST.2084 setting that corresponds to the peak luminance, in nits, of the grading display you're using. For example, if you're grading with a Sony BVM X300, choose ST.2084 1000 nit, but if you're grading with a Flanders Scientific XM310K, choose ST.2084 3000 nit, in order to use the full capabilities of each display. Be aware that whichever HDR setting you choose will impose a hard clip at the maximum nit value supported by that setting. This is to prevent accidentally overdriving HDR displays for which there are negative consequences (not all HDR displays have this limitation).
   - ST.2084 300 nit
   - ST.2084 500 nit
   - ST.2084 800 nit
   - ST.2084 1000 nit
   - ST.2084 2000 nit
   - ST.2084 3000 nit
   - ST.2084 4000 nit

   This setting is only the output EOTF (a sort of gamma transform, if you will, using the terminology that DaVinci Resolve's UI has used up until now).
3. Next, choose a setting in the Timeline Color Space that corresponds to the gamut you want to use for grading, and that will be output. For example, if you want to grade the Timeline as a log-encoded signal and "normalize" it yourself, you can choose ARRI Log C or Cineon Film Log (this workflow is highly recommended for the best results). If you would rather save time by having DaVinci Resolve normalize the Timeline to P3-D65 and grade that way, you can choose that setting as well. In terms of defining the output gamut, the rule is that if "Use Separate Color Space and Gamma" is turned off, the Timeline Color Space setting will define your output gamut. If "Use Separate Color Space and Gamma" is turned on, then you can specify whatever gamut you want in the left Output Color Space dropdown menu, and choose the EOTF from the right dropdown menu (as described in step 2).

4 Be aware that, when it's being properly output, HDR ST.2084 signals appear very "log-like," in order to pack a wide dynamic range into the bandwidth of a standard video signal. It's the HDR display itself that "normalizes" this log-encoded image to look as it should. For this reason, the image you see in your Color page Viewer is going to appear flat and log-like, even though the image being displayed on your HDR reference display looks vivid and correct. If you're using a typical SDR computer display, and you want to make the image in the Color Page Viewer look "normalized" at the expense of clipping the HDR highlights (in the Viewer, not in the grade), you can use the 3D Color Viewer Lookup Table setting in the Color Management panel of the Project Settings to assign the appropriate ST.2084 setting with a peak nit level that corresponds to the HDR broadcast display you're outputting to.

5 Additionally, the "Timeline resolution" and "Pixel aspect ratio" (in the project settings) that your project is set to use is saved to the Dolby Vision metadata, so make sure your project is set to the final Timeline resolution and PAR before you begin grading.

DaVinci Resolve Grading Workflow For Dolby Vision

Once the hardware and software is all set up, you're ready to begin grading HDR. The workflow is fairly straightforward.

1 First, grade the HDR image on your HDR Monitor to look as you want it to. Dolby recommends starting by setting the look of the HDR image, to set the overall intention for the grade.

2 When using various grading controls in the Color page to grade HDR images, you may find it useful to enable the HDR Mode of the node you're working on by right-clicking that node in the Node Editor and choosing HDR Mode from the contextual menu. This setting adapts that node's controls to work within an expanded HDR range. Practically speaking, this makes controls that operate by letting you make adjustments at different tonal ranges, such as Custom Curves, Soft Clip, and so on, work more easily with wide-latitude signals.

3 When you're happy with the HDR grade, click the Analysis button in the Dolby Vision palette. This analyzes every pixel of every frame of the current shot, and performs and stores a statistical analysis that is sent to the iCMU or eCMU to guide its automatic conversion of the HDR signal to an SDR signal.

4 Choose "Target Display Output" and "Trim Controls For" settings that you want to trim to. By default, these are set to "100-nit, BT.709, BT.1886, Full," which is a typical SDR deliverable. However, other options are available if you want to do multiple trim passes to obtain a more accurate result. Whichever setting you choose from, "Trim Controls For" dictates which trim pass you're doing. You can do multiple trim passes by choosing another option from this menu.

5 If you're not happy with the automatic conversion, use the trim controls in the Dolby Vision palette to manually trim the result to the best possible BT.709 approximation of the HDR grade you created in step 1.

6 If you obtain a good result, then move on to the next shot and continue work. If you cannot obtain a good result, and worry that you may have gone too far with your HDR grade to derive an acceptable SDR tone mapping, you can always trim the HDR grade a bit, and then retrim the SDR grade to try and achieve a better tone mapping. Dolby recommends that if you make significant changes to the HDR master, particularly if you modify the blacks or the peak highlights, you should reanalyze the scene. However, if you only make small changes, then reanalyzing is not strictly required.

As you can see, the general idea promoted by Dolby is that a colorist will focus on grading the HDR picture relative to the 1000, 2000, 4000, or higher nit display that is being used, and will then rely on the colorist to use the Dolby Vision controls to "trim" this into a 100 nit SDR version. This metadata is saved as part of the mastered media, and it's used to more intelligently tone map the entire image to fit within any given display's parameters. The colorist's artistic intent is used to guide all dynamic adjustments to the content.

Delivering Dolby Vision

Once you're finished grading the HDR and trimming the SDR tone mapping, you need to output your program correctly in the Deliver page.

Rendering a Dolby Vision Master

To deliver a Dolby Vision master after you've finished grading, you want make sure that the Output Color Space of the Color Management panel of the Project Settings is set to the appropriate HDR ST.2084 setting based on the peak output you want to deliver (any values above will be clipped). Then, you want to set your render up to use one of the following Format/Codec combinations:

- TIFF, RGB 16-bit
- EXR, RBG-half (no compression)

  When you render for tapeless delivery, all Dolby Vision metadata is recorded into a Dolby Vision XML and delivered along side either the Tiffs or EXR renders. To export a Dolby Vision XML file, select your timeline in the media pool and choose File > Export >Timeline. Navigate to where you want to save the file and select Dolby Vision v2.9 (or v4.0) MXF files from the file type selector and click save. These two sets of files are then delivered to a facility that's capable of creating the Dolby Vision deliverable file.

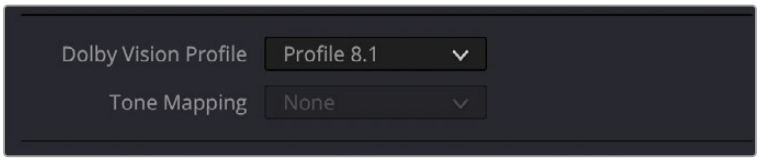
Rendering a Dolby Vision IMF

You can deliver directly to an IMF that includes an MXF with embedded Dolby Vision metadata in the package. To export a Dolby Vision IMF use the following Video settings in the Deliver page:

- **Format:** IMF
- **Codec:** Kakadu JPEG 2000
- **Type:** Dolby Vision (HD, 2K, UHD, or 4K) depending on your deliverable resolution.

  Configure the rest of the IMF settings as necessary for your project.

The Video settings to use for creating a Dolby Vision IMF in the Deliver page



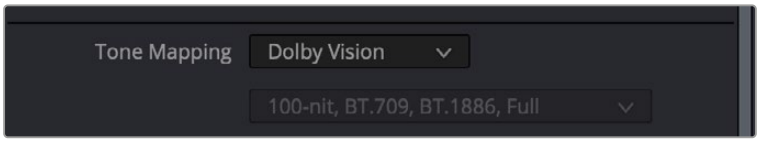
Rendering a Dolby Vision H.265 file

You can deliver directly to a Dolby Vision compatible H.265 file, which allows you to playback video that triggers playback in the Dolby Vision mode on your television or computer screen. To export a Dolby Vision H.265 file, use the following Video settings in the Deliver page:

- **Format:** MP4 or QuickTime
- **Codec:** H.265
- **Dolby Vision Profile:** Set the Dolby Vision profile you wish to use, or None to select the Tone Mapping manually.

- **Tone Mapping:** Choose None for no tone mapping, or Dolby Vision to expose a list of common deliverables to tone map to.

  Configure the rest of the H.265 settings as necessary for your project.



The Dolby Vision Profile and Tone Mapping settings in the H.265 Video section of the Deliver page

Rendering an Ordinary SDR Media File or Other Specific HDR Trim Pass

If you want to export the SDR trim pass, then you can choose Dolby Vision from the Tone Mapping dropdown menu in the Advanced Settings of the Render Settings list on the Deliver page, and choose the 100-nit, BT.709, BT.1886, Full setting below. With this enabled, you can output the SDR version of your program to any format you like.

You can also export the trims for other HDR nit levels for specific displays, at 600, 1000 or 2000 nits and in the either the BT.2020 or P3 gamuts.

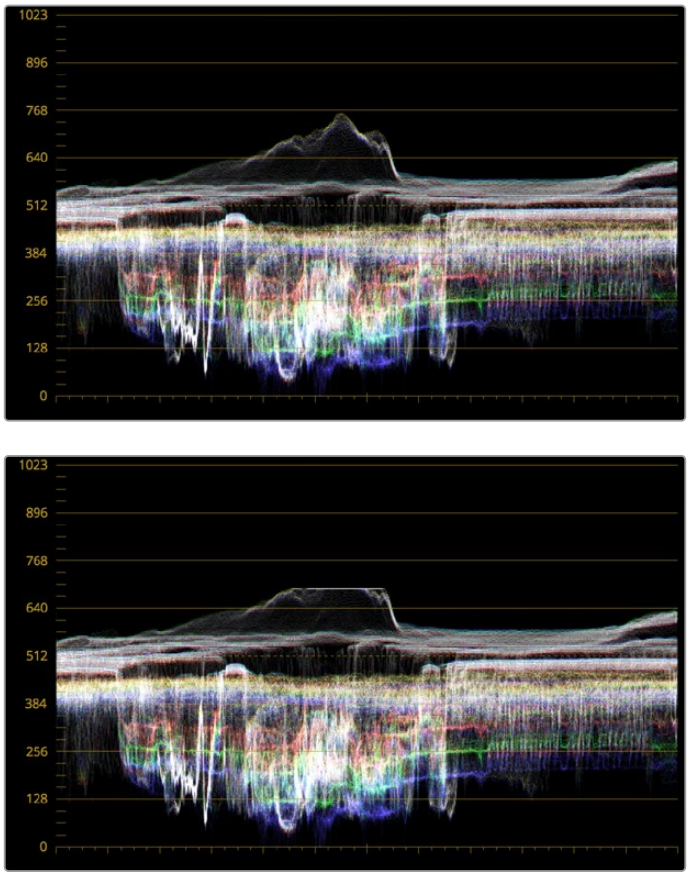
The Tone Mapping setting in the Advanced Settings of the Render Settings list

SMPTE ST.2084 and HDR10

Many display manufacturers who have no interest in licensing Dolby Vision for inclusion in their displays are instead going with the simpler method of engineering their displays to be compatible with SMPTE ST.2084. It requires only a single stream for distribution, there are no licensing fees, no special hardware is required to master for it (other than an HDR mastering display), and there's no special metadata to write or deal with.

Interestingly, SMPTE ST.2084 ratifies the "PQ" EOTF that was originally developed by Dolby, and which is used by Dolby Vision, into a general standard that accommodates encoding HDR at peak luminance values up to 10,000 cd/m^2. This standard requires at minimum a 10-bit signal for distribution, and the EOTF is mathematically described such that the video signal utilizes the available code values of a 10-bit signal as efficiently as possible, while allowing for such a wide range of luminance in the image.

SMPTE ST.2084 is also part of the "Ultra HD Premium" industry specification, which stipulates that televisions bearing the Ultra HD Premium logo have the following capabilities:



- A minimum UHD resolution of 3840 x 2160
- A minimum gamut of 90% of P3
- A minimum dynamic range of either 0.05 nits black to 1000 nits peak luminance (to accommodate LCD displays), or 0.0005 nits black to 540 nits peak luminance (to accommodate OLED displays)
- Compatibility with SMPTE ST.2084

Finally, ST.2084 has been included in the HDR 10 standard adopted by the Blu-ray Disc Association (BDA) that covers Ultra HD Blu-ray. HDR 10 stipulates that Ultra HD Blu-ray discs have the following characteristics:

- UHD resolution of 3840 x 2160
- Up to the Rec. 2020 gamut
- SMPTE ST.2084
- Mastered with a peak luminance of 1000 nits

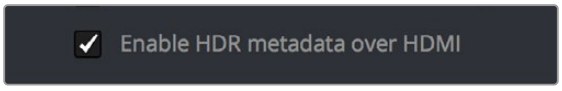
The downside is that, by itself, an HDR10 mastered program is not backward compatible with BT.709 displays using BT.1886 (although the emerging HDR10+ standard described later addresses this). Furthermore, no provision is made to scale the above-100 nit portion of the image to accommodate different displays with differing peak luminance levels. For example, if you grade and master an image to have peak luminance of 4000 nits, and you play that signal on an HDR10-compatible television (using ST.2084) that's only capable of 800 nits, then everything above 800 nits will be clipped, while everything below 800 nits will look exactly as it should relative to your grade.

This is because ST.2084 is referenced to absolute luminance. If you grade an HDR image referencing a 1000 nit peak luminance display, as is recommended by HDR10, then any display using ST.2084 will respect and reproduce all levels from the HDR signal that it's capable of reproducing as you graded them, up to the maximum peak luminance level it can reproduce. For example, on an HDR10-compatible television capable of outputting 500 nits, all mastered levels from 501–1000 will be clipped, as seen in the screenshot below.

Comparing the original 1000 nit waveform representing the grading monitor to a 500 nit clipped waveform representing the consumer television

How much of a problem this is really depends on how you choose to grade your HDR-strength highlights. If you're only raising the most extreme peak highlights to maximum HDR-strength levels, then it's entirely possible that the audience might not notice that the display is only outputting 800 nits worth of signal and clipping any image details from 801–1000 nits because there weren't that many details above 800 anyway. Or, if you're grading large explosive fireballs up above 800 nits in their entirety because it looks cool, then maybe the audience will notice. The bottom line is, when you're grading for displays that are only capable of ST.2084, you need to think about these sorts of things.

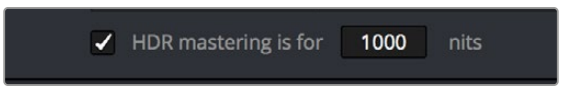
Monitoring and Grading to ST.2084 in DaVinci Resolve



Monitoring an ST.2084 image is as simple as obtaining a ST.2084-compatible HDR display and connecting it to the output of your DeckLink 8K, DeckLink 4K Extreme 12G, or UltraStudio 4K Extreme.

Setting up Resolve Color Management to grade for ST.2084 is identical to setting up to grade for Dolby Vision. You'll also monitor the video scopes identically, and output a master identically, given that both standards rely upon the same PQ curve.

TIP: If you're monitoring with the built-in video scopes in DaVInci Resolve, you can turn on "HDR (ST.2084/HLG)" in the Waveform Scale Style settings in the Scopes option menu, which will replace the 10-bit scale of the video scopes with a scale based on nit values (cd/m^2) instead.



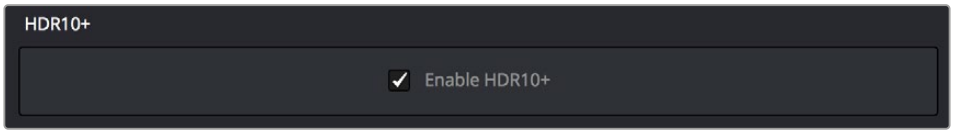
Connecting to HDR-Capable Displays using HDMI 2.0a

If you have a DeckLink 4K Extreme 12G or an UltraStudio 4K Extreme video interface, then DaVinci Resolve 12.5 and above can output the metadata necessary to correctly display HDR video signals to display devices using HDMI 2.0a when you turn on the "Enable HDR metadata over HDMI" checkbox in the Master Settings panel of the Project Settings.

The Enable HDR metadata over HDMI option in the Master Settings panel of the Project Settings lets you output HDR via HDMI 2.0a

When you do so, a setting in the Color Management panel of the Project Settings, "HDR mastering is for X" lets you specify the output, in nits, to be inserted as metadata into the HDMI stream being output, so that the display you're connecting to correctly interprets it. The output you specify should match what your display is expecting.

The "HDR mastering is for" setting lets you insert metadata for HDR output via HDMI 2.0a



HDR10+™

DaVinci Resolve supports the HDR10+ HDR format by Samsung. When enabled, an HDR10+ palette shows the results of the trimming analysis that make an automated downconversion of HDR to SDR, creating metadata to control how HDR-strength highlights look on a variety of supported televisions and displays.

Project Settings for HDR10+

An HDR10+ grade is set up in the Color Management panel of the Project Settings.

- **Color Science:** DaVinci YRGB Color Managed
- **Color Processing Mode:** HDR
- **Output Color Space:** HDR PQ
- **HDR mastering is for XXXX nits:** Type in the nit level of your mastering monitor.
- **Enable HDR10+ checkbox:** Check this box to enable HDR10+ and its palette in the Color page.

HDR 10+ settings in the Color Management panel of the Project Settings.

Monitoring and Grading to ST.2084 for HDR10+

When you're grading a program for HDR10+ output, you'll need to monitor an ST.2084 image, which is as simple as obtaining a ST.2084-compatible HDR display and connecting it to the output of your DeckLink 8K, DeckLink 4K Extreme 12G, or UltraStudio 4K Extreme.

Setting up Resolve Color Management to grade for ST.2084 is identical to setting up to grade for Dolby Vision or regular HDR10. You'll also monitor the video scopes identically, and output a master identically, given that each of these standards rely upon the same PQ curve.

TIP: If you're monitoring with the built-in video scopes in DaVinci Resolve, you can turn on "HDR (ST.2084/HLG)" in the Waveform Scale Style settings in the Scopes option menu, which will replace the 10-bit scale of the video scopes with a scale based on nit values (cd/m^2) instead.

Simultaneous Master and Target Display Output for HDR10+

When mastering HDR and trimming versions for more limited displays, you may want to evaluate your HDR grade and tone-mapped trim pass simultaneously. Starting in DaVinci Resolve 15, it's possible to output both the Master Display output and the Target Display output simultaneously when you're grading with either Dolby Vision or HDR10+ enabled.

Necessary Hardware

You must first have the following equipment:

- A DaVinci Resolve grading workstation, which must output via a DeckLink 8K, DeckLink 4K Extreme 12G, UltraStudio 4K Extreme video interface, or better.
- A Mastering Display, which must be capable of HDR nit levels suitable for the deliverable you're required to produce.
- An HDR target display that can be set to the appropriate tone-mapped output.

Enabling Simultaneous Monitoring

When you set up your display hardware, the HDR Master Display must be connected to output A, and the Target Display must be connected to output B of whichever Blackmagic Design video output device you're using.

Next, enable the "Use dual outputs on SDI" checkbox in Project Settings > Master Settings. If all your connections are compatible, you should see an HDR image output to your HDR display, and a trimmed image output to your SDR display.

HDR10+ Grading Workflow

The concept behind the HDR10+ workflow is that you'll grade the HDR version of each clip in your program first, and then use the automatic analysis to create a down-converted, tone-mapped version of each shot that's controlled by metadata. Once the HDR10+ trim pass is complete, you'll deliver the rendered HDR output along with a set of HDR10+ JSON metadata files to a facility for final mastering.

Exporting the HDR10+ .json sidecar file

You can export a separate .json file of your trim data that allows it to be reviewed, archived, and saved independently from the video file.

1. Right-click on your timeline in the media pool.
2. Select Timelines > Export > HDR10+ JSON from the context menu.
3. A file browser will appear for you to name and locate where you want to save the file.
4. Select HDR10+ Profile B Files (*.json) as the file type.
5. Click Save.

HDR10+ Auto Analysis Commands

After you've graded an HDR version of each clip in your program, a set of HDR10+ specific commands let you auto-analyze each clip to create custom HDR to SDR downconversion metadata that give you a starting point for the SDR trim pass you need to do. These commands are available in the Color > HDR10+ submenu:

- **Analyze All Shots:** Automatically analyzes each clip in the Timeline and stores the results individually.
- **Analyze Selected Shot(s):** Only analyzes selected shots in the Timeline.
- **Analyze Selected and Blend:** Analyzed multiple selected shots and averages the result, which is saved to each clip. Useful to save time when analyzing multiple clips that have identical content.
- **Analyze Current Frame:** A fast way to analyze clips where a single frame is representative of the entire shot.

Delivering HDR10+

Once you're finished grading the HDR and trimming the SDR downconversion, you need to output your program correctly in the Deliver page.

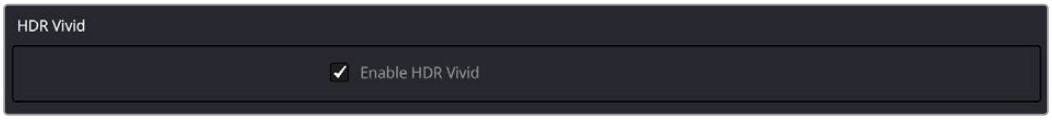
Rendering an HDR10+ Master

To deliver an HDR10+ master after you've finished grading, you want make sure that the Output Color Space of the Color Management panel of the Project Settings is set to the appropriate HDR ST.2084 setting based on the peak output you want to deliver (any values above will be clipped). Then, you want to set your render up to use the highest quality Format/Codec combination that can be delivered to whomever is doing the final mastering.

The HDR10+ analysis and manual trim metadata you generated while trimming is saved per clip, in a series of JSON sidecar files, which should then be exported by right-clicking that timeline in the Media Pool, and choosing Timelines > Export > HDR10+JSON.

These two sets of files are then delivered to a facility that's capable of creating an HDR10+ Mezzanine File (this cannot be done in DaVinci Resolve).

Rendering an HDR10+ HEVC File



To render an HDR10+ video file that's instantly viewable on an HDR10+ capable television without creating the Mezzanine File, simply encode it to an HEVC file using these video settings in the Deliver page:

- **Format:** MP4
- **Codec:** H.265
- **Embed HDR10+ Metadata:** Enable this box.
- **Encoding Profile:** Main10

When rendered with these settings, you can add the file on a USB drive and connect it to an HDR10+ television for playback on the television's menu system. To confirm the output works, press the center button on the TV remote to view the file information overlay with the HDR10+ logo. Alternatively, you can use third party video analysis software like MediaInfo. The correct parameter to look for in the video settings is: SMPTE ST 2094 App4, Version 1, HDR10+ Profile B.

HDR Vivid

HDR Vivid is the HDR video technology standard released by the UHD World Association (UWA). Mastering in this format assures wide compatibility with HDR televisions, phones, computers, and other devices adhering to this standard.

HDR Vivid settings in the Color Management panel of the Project Settings

Monitoring and Grading to ST.2084 for HDR Vivid

When you're grading a program for HD Vivid output, you'll need to monitor an ST.2084 image, which is as simple as obtaining a ST.2084-compatible HDR display and connecting it to the output of your DeckLink 8K, DeckLink 4K Extreme 12G, or UltraStudio 4K Extreme.

Setting up Resolve Color Management to grade for ST.2084 is identical to setting up to grade for Dolby Vision or regular HDR10. You'll also monitor the video scopes identically, and output a master identically, given that each of these standards rely upon the same PQ curve.

TIP: If you're monitoring with the built-in video scopes in DaVinci Resolve, you can turn on "HDR (ST.2084/HLG)" in the Waveform Scale Style settings in the Scopes option menu, which will replace the 10-bit scale of the video scopes with a scale based on nit values (cd/m^2) instead.

HDR Vivid Grading Workflow

The idea behind the HDR Vivid workflow is that you'll grade the HDR version of each clip in your program first, and then use the automatic analysis to create a downconverted tone mapped version of each shot that's controlled by metadata. Once the HDR Vivid trim pass is complete, you'll deliver the rendered HDR output with embedded HDR Vivid metadata.

Simultaneous Master and Target Display Output for HDR Vivid

When mastering HDR and trimming versions for more limited displays, it's extremely useful to be able to evaluate your HDR grade and tone mapped trim pass side by side. Starting in DaVinci Resolve 15, it's possible to output both the Master Display output and the Target Display output simultaneously when you're grading with HDR Vivid enabled.

Necessary Hardware

To work in this manner, you must have the following equipment:

- Your DaVinci Resolve grading workstation must output via a DeckLink 8K, DeckLink 4K Extreme 12G, UltraStudio 4K Extreme video interface, or better.
- Your Mastering Display must be capable of HDR nit levels suitable for the deliverable you're required to produce.
- An HDR target display that can be set to the appropriate tone mapped output.

Enabling Simultaneous Monitoring

When you set up your display hardware, the HDR Master Display must be connected to output A, and the Target Display must be connected to output B of whichever BMD video output device you're using. Then, you need to turn on the "Use dual outputs on SDI" checkbox in the Master Settings of the Project Settings. At this point, assuming all of your connections are compatible with one another, you should see an HDR image output to your HDR display and a trimmed image output to your SDR display.

HDR Vivid Trim Controls in DaVinci Resolve

The latest version of the HDR Vivid palette exposes three sets of controls. The first are the main controls:

- **Target Display Output:** This drop-down specifies what parameters are used to display the tone mapped image. This menu lets you choose specific display properties to obtain a preview of what the trimmed image will look like on different displays with different gamuts and peak luminance capabilities.
- **Trim Mode:** Determines the toolset used to create the trims, either Curve or Statistical modes.
- **Tone Mapping Mode:** Lets you choose between Low Light (for protecting shadow details in the trim) or Highlight (for ensuring the highlights don't blow out in the trim).
- **Analyze controls:** The commands governing HDR Vivid auto-analysis are available as buttons, which perform the same functions as their similarly named counterparts in the Color > HDR Vivid submenu. Please note that most trim controls are disabled until you perform an analysis, which is a necessary first step. An HDR indicator appears on the thumbnail of each analyzed clip. To filter timeline clips based on their status (Analyzed and/or Trimmed), click on the disclosure triangle in the Clips tab and select HDR Vivid.

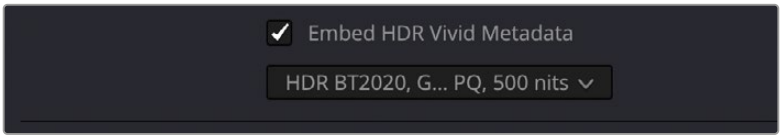
  All: Automatically analyzes each clip in the current Timeline and stores the results individually.

  Selected: Only analyzes selected shots in the Timeline.

  Frame: Useful when part of a clip has an extreme level of color or lightness that's inconsistent with the rest of the clip, resulting in a poor analysis result. Placing the playhead on a frame that's representative of how the clip is supposed to look, and using the Frame option, bases the analysis on only that frame. This is also a fast way to analyze clips where a single frame is representative of the entire shot.
- **Enable Tone Mapping Preview:** Lets you see the target display output in the Color page Viewer and video output, so you can evaluate how the tone mapped version looks on your HDR display.

The next set of controls activate based on which Trim Mode you have selected.

- **Curve:** The Curve trim mode exposes a variety of controls that lets the colorist adjust the trim metadata manually at the clip or frame level. Offset, Brightness, and Detail settings are available for the Dark and Bright parts of the curve. Midtones have a brightness control. Highlight Crop lets you bring any highlights back into range that may have exceeded the display's maximum brightness, thus blowing out. Separate Global and Highlight saturation settings are also possible.
- **Statistical:** The Statistical trim mode exposes controls that let you fine tune the automatic tone mapping algorithm used in the Analyze step.



HDR Vivid controls in the Color page.

Delivering HDR Vivid

Once you're finished grading the HDR and trimming the SDR downconversion, you need to output your program correctly in the Deliver page.

Rendering an HDR Vivid Master

To deliver an HDR Vivid master after you've finished grading, you want make sure that the Output Color Space of the Color Management panel of the Project Settings is set to the appropriate HDR ST.2084 setting based on the peak output you want to deliver (any values above will be clipped). Then, you want to set your render up to export an H.265, Quicktime, or MP4 codec in the Video Settings, check the Embed HDR Vivid Metadata box, and select the appropriate HDR mode that you used to grade the master in the dropdown box below.

HDR Vivid settings in the Video section of the Deliver page

Hybrid Log-Gamma (HLG)

The BBC and NHK jointly developed another method of encoding HDR video, referred to as Hybrid Log-Gamma (HLG). The goal of HLG was to develop a method of mastering HDR video that would support a range of displays of different peak luminance capabilities without additional metadata, that could be broadcast via a single stream of data, that would fit into a 10-bit signal, and that in the words of the ITU-R Draft Recommendation BT.HDR, "offers a degree of compatibility with legacy displays by more closely matching the previous established television transfer curves."

The basic idea is that the HLG EOTF functions very similarly to BT.1886 from 0 to 0.6 of the signal (with a typical 0–1 range), while 0.6 to 1.0 smoothly segues into logarithmic encoding for the highlights. This means that, if you just send an HDR Hybrid Log-Gamma signal to an SDR display, you'd be able to see much of the image identically to the way it would appear on an HDR display, and the highlights would be compressed to present an acceptable amount of detail for SDR broadcast.

On a Hybrid Log-Gamma compatible HDR display, however, the log-like highlights of the image (not the BT.1886-like bottom portion of the signal, just the highlights) would be stretched back out, relative to whatever peak luminance level a given HDR television is capable of outputting, to return the image to its true HDR glory. This is different from the HDR10 method of distribution described previously, in which the graded signal is referenced to absolute luminance levels dictated by ST.2084, and levels that cannot be represented by a given display will be clipped.

And while this facility to support multiple HDR displays with differing peak luminance levels is somewhat analogous to Dolby Vision's ability to tailor HDR output to the unique peak luminance levels of any given Dolby Vision-compatible television, HLG requires no additional metadata to guide how the highlights are scaled, which depending on your point of view is either a benefit (less work), or a deficiency (no artistic guidance to make sure the highlights are being scaled in the best possible way).

As is true for most things, you don't get something for nothing. The BBC White Paper WHP 309 states that, for a 2000 cd/m^2 HDR display with a black level of 0.01 cd/m^2, up to 17.6 stops of dynamic range without visible quantization artifacts ("banding") is possible. BBC White Paper WHP 286 states that the proposed HLG EOTF should support displays up to about 5000 nits. So, partially, the backward compatibility that HLG makes possible is due in part to discarding long-term support for 10,000 nit displays. However, it's an open question whether or not over 5000 nits is even necessary for consumer enjoyment.

Sony, LG, Panasonic, JVC, Phillips, Hisense, Hitachi, and Toshiba have all either announced or are shipping consumer HDR televisions capable of displaying HLG encoded video, and of course DaVinci Resolve supports this standard through Resolve Color Management.

Grading Hybrid Log-Gamma in DaVinci Resolve

Monitoring an ST.2084 image is as simple as getting a Hybrid Log-Gamma-compatible HDR display, and connecting the output of your video interface to the input of the display.

Setting up Resolve Color Management to grade for HLG is identical to setting up to grade for Dolby Vision, except that there are four HLG settings to choose from for the Output Color Space:

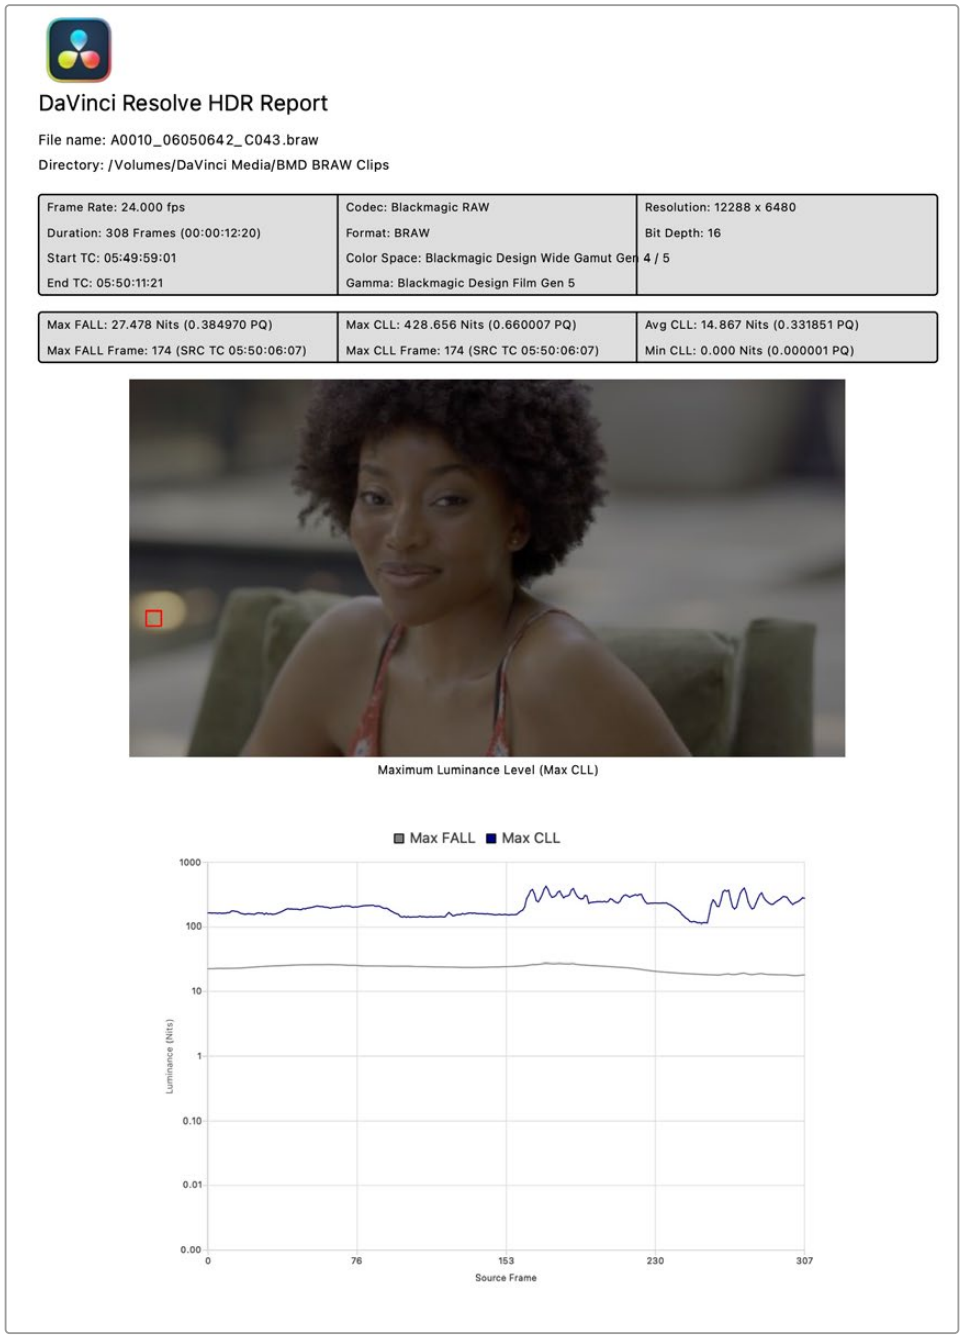
- Rec.709 HLG ARIB STD-B67
- Rec.2020 HLG ARIB STD-B67
- Rec.2100 HLG
- Rec.2100 HLG (Scene)

Optionally, if you choose to enable "Use Separate Color Space and Gamma," you can choose either Rec. 2020 or Rec. 709 as your gamut, and Rec. 2100 HLG as your EOTF.

The levels you'll be monitoring in your scopes will be different from the table of data to nit values listed previously for grading to the PQ EOTF.

Ouputting Hybrid Log-Gamma

Once you've created an HLG grade for your program, you can output it to any high-quality 10-bit capable media format.



Reset HDR Trim Analysis from the Option Menu

For any of the HDR standards, you can reset the HDR trim analysis from the three-dot option menu in their respective tabs from the Color page.

Generate HDR Light Level Report (Studio Version Only)

You can now generate HDR Light Level reports from the Media Pool. To do so, select a clip in the Media Pool, right-click it and choose Generate HDR Report from the context menu. The tool will prompt you to select a location to save the HDR Light Level report in .pdf format.

This tool analyzes all frames in rendered HDR clips and presents light level statistics, including MaxCLL and MaxFALL. It also includes a snapshot of the frame containing the maximum luminance level with a box highlighting the point where the maximum values were found.

An HDR Light Level report exported from DaVinci Resolve

Chapter 11

Image Sizing and Resolution Independence

DaVinci Resolve is a resolution-independent application. This means that, whatever the resolution of your source media, it can be output at whatever other resolution you like, and just about every size-dependent effect in your project, text, windows of grades, edit and input clip scaling, and other effects will scale appropriately to match the new output resolution.

This also means that you can freely mix clips of any resolution, fitting 4K, HD, and SD clips into the same timeline, with each scaling to fit the project resolution as necessary.

Your project's resolution can be changed at any time, allowing you to work at one resolution, and then output at another resolution. This also makes it easy to output multiple versions of a program at different resolutions, for example, outputting 4K, HD, and SD sized versions of the same timeline.

Additionally, most controls that let you transform clips, either to push into a clip for creative intent, or to pan and scan media of one format to fit better into a different output format, are smart enough to always refer back to the source resolution when combining resizing operations to shrink, then enlarge an image for various reasons as you work in the Cut, Edit, Fusion, and Color pages.

This chapter covers the relationship among the different sizing and transform controls found in DaVinci Resolve, showing how they work together to intelligently manage the sizing of clips and effects as you work.

About Resolution Independence

If you only read one paragraph of this chapter, read this: Resolution Independence in DaVinci Resolve means you can add clips to a timeline in any combination of resolutions to fit the project resolution you've chosen to work at, and you can later output that timeline to as many other resolutions as necessary in order to create multiple deliverables. When you do so, all effects and transforms will automatically readjust themselves to match the sizing of each new timeline resolution, and most transforms are calculated and processed using the full native resolution of the source media you've linked to that clip.

In short, what this means is that you can create multiple deliverables in multiple resolutions by simply changing the timeline resolution or by using a lower resolution setting in the Deliver page compared to the timeline resolution when you create a new job to render out, and every effect will be the right size automatically.

Timeline Resolution

The timeline resolution is one of the most fundamental settings of your project, defining its frame size. It's found in the Master Settings panel of the Project Settings, where you can choose a predefined resolution from the "Timeline resolution" dropdown menu, or you can type a custom resolution into the X and Y fields below.

The project-wide Timeline Resolution parameters found in the Master Settings panel of the Project Settings window

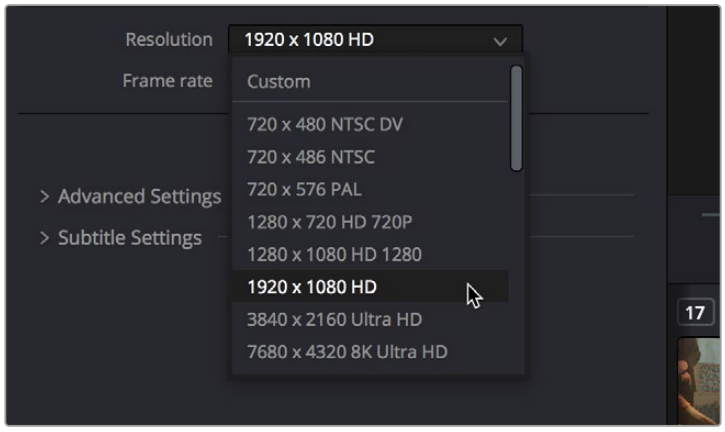
Mixing Clip Resolutions

Media used in a project does not have to match the timeline resolution. In fact, it's extremely common to mix multiple resolutions within the same timeline. Clips that don't match the current resolution will be automatically resized according to the currently selected Image Scaling setting (described below).

Changing the Timeline Resolution

As mentioned earlier, you can change the timeline resolution whenever you like. When you do so, each Edit page transform, Fusion clip effects output, Color page Power Window, Input and Output Sizing adjustment, tracking path, spatial keyframing value, as well as any other other resolution-dependent Resolve FX effect or transform operation in DaVinci Resolve is automatically and accurately scaled to fit the new resolution.

You Can Use Separate Timelines to Output Different Resolutions



Beginning in DaVinci Resolve 16, you have the option of creating separate timelines with individual Format (including Input Scaling), Monitoring, and Output Sizing settings for situations where you need to set up multiple timelines to create multiple deliverables with different resolutions, pixel aspect ratios, frame rates, monitoring options, or output scaling options than the overall project, including “Mismatched Resolution Files” settings.

For more information, jump to this chapter: Creating and Working with Timelines.

You Don’t Need Separate Timelines to Output Different Resolutions

Because of the way DaVinci Resolve works, it’s not necessary to create separate timelines when all you need is to output the same timeline at multiple resolutions. Instead, you can focus on mastering a single timeline, which you can output to as many other resolutions as you need.

For example, with only a single timeline in a project set to 4096x2160 (4K DCI) resolution, you can easily output UHD, HD, center-cut SD, and center-cut Instagram sized deliverables in any format you need by simply changing the Resolution dropdown setting in the Deliver page Render Settings before you create a job to render. DaVinci Resolve takes care of the rest.

The Deliver page dropdown menu in the Render Settings panel lets you choose what resolution you want to output the current timeline using

Using High Resolution Media in Lower Resolution Projects

Every set of transform and sizing parameters and settings that resize clips is combined intelligently, so that the full resolution of a clip’s source media is always used as the source for any transform. For example, if you’re using 8K media within a 1920x1080 project, and you need to enlarge a clip using the Input Sizing palette’s Zoom parameter to 200%, the image is scaled relative to the native 8K resolution of the source, and the result is fit into the current timeline resolution. This automatically guarantees the highest quality for any image transform you make so long as you don’t zoom in past the native resolution of any given clip.

This also applies to situations where, for example, you shrink a clip in the Edit page using the Edit Sizing controls, only to re-enlarge the same clip in the Color page, using the Input Sizing controls. In this situation, DaVinci Resolve is smart enough to do the math combining the project resolution, the Edit Sizing, and the Input Sizing controls so that a single transform is applied to the native source resolution of that clip, giving you the best quality result.

NOTE: This changes when you apply Fusion effects to any clip, as described later in this chapter.

Clip Source Resolution

Clip resolution in DaVinci Resolve is handled by the combination of Pixel Aspect Ratio and Resolution.

Pixel Aspect Ratio (PAR)

The Timeline Format settings, found in the Master Settings of the Project Settings, let you specify a Pixel Aspect Ratio for the project, in addition to the frame size. This setting defaults to Square Pixel, which is appropriate for high definition projects and most digital media. However, there are also options for 16:9 anamorphic, 4:3 standard definition, or Cinemascope. Which options are available depends on what timeline resolution you've selected.

In addition, each clip has individually adjustable PAR settings in the clip attributes, for situations where you're mixing multiple types of media within a single project. For example, if you're mixing SD clips with non-square pixels and HD clips with square pixels, you can sort out all of the SD clips in the Media Pool and assign them the appropriate NTSC or PAL non-square pixel ratio PAR setting.

For more information, jump to this chapter: Modifying Clips and Clip Attributes.

Clip Resolution

Ordinarily, the resolution of a clip is entirely dependent on the resolution that was selected when that media was shot, or rendered out of a compositing, VFX, or 3D application. Once a piece of media has been created, the native resolution of that media cannot be changed, and to maintain the ideal amount of sharpness for that clip, you need to make sure that whatever transforms you apply to resize a clip zoom into that clip no more than 10-20% over its native resolution (if even that), otherwise the image will visibly soften.

However, DaVinci Resolve provides advanced Super Scale image processing in the Clip Attributes of every video and image clip, that make it possible to resize clips beyond their native resolution while maintaining the perceptible sharpness of a clip that's still within it's native resolution. This is an illusion, but it's a convincing one.

The DaVinci Resolve Sizing Pipeline

This section discusses the various sizing controls that are available in DaVinci Resolve, and how they work together.

“Super Scale” High Quality Upscaling (Studio Version Only)

For instances when you need higher-quality upscaling than the standard Resize Filters allow, you can now enable one of the “Super Scale” options in the Inspector or in the Video panel of the Clip Attributes window for one or more selected clips. Unlike using one of the numerous scaling options in the Edit, Fusion, or Color pages, Super Scale actually increases the source resolution of the clip being processed, which means that clip will have more pixels than it did before and will be more processor-intensive to work with than before, unless you optimize the clip (which bakes in the Super Scale effect into the optimized media) or cache the clip in some way.

Super Scale options in the Video panel of the Clip Attributes

The Super Scale dropdown menu provides the options of 2-3-4x, and 2-3-4x Enhanced, as well as Sharpness and Noise Reduction options to tune the quality of the scaled result. Most of the Super Scale parameters are in fixed Low, Medium, or High increments, however the Enhanced modes let you apply them in variable amounts. Selecting one of these options enables DaVinci Resolve to use advanced algorithms to improve the appearance of image detail when enlarging clips by a significant amount, such as when editing SD archival media into a UHD timeline, or when you find it necessary to enlarge a clip past its native resolution in order to create a closeup.

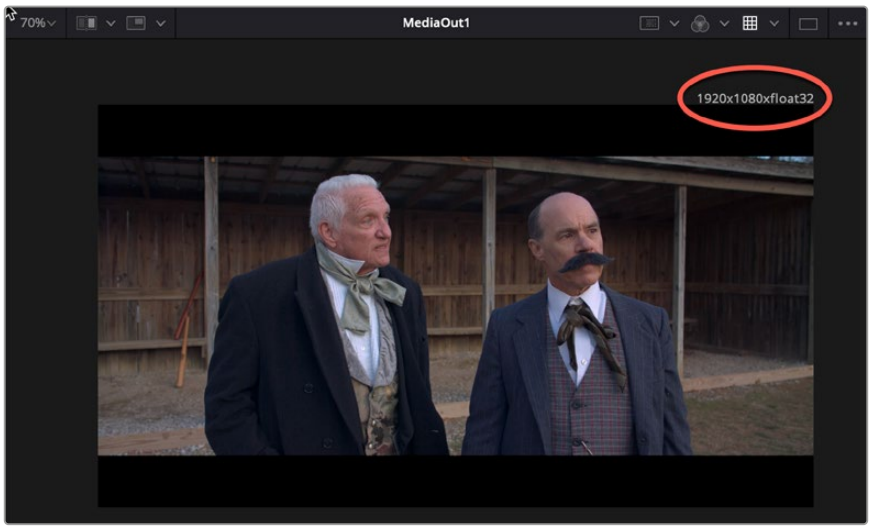
You may find that, depending on the source media you’re working with, setting Sharpness to Medium yields a relatively subtle result that can be hard to notice, but setting Sharpness to high should be immediately more preferable, while also sharpening grain and noise in the image to an undesirable extent at the default settings. However, while raising Noise Reduction will ameliorate this effect, it will also diminish the gains you obtained by raising Sharpness. In these cases, it’s worth experimenting with keeping Sharpness at Low or Medium so that Super Scale sharpens all aspects of a clip, but then using the Noise Reduction tools of the Color page (with their additional ability to be fine-tuned) to diminish the unwanted noise.

TIP: Super Scale, while incredibly useful, is a processor-intensive operation, so be aware that turning this on will likely prevent real-time playback. One way to get around this is to create Optimized Media for clips in which you’ve enabled Super Scale, since Optimized Media “bakes in” the Super Scale effect. Another way to work is to create a string-out of all of the source media you’ll need to enlarge at high-quality, turn on Super Scale for all of them, and then render that timeline as individual clips, while turning on the “Render at source resolution” and “Filename uses > Source Name” options.

Fusion Effects and Resolution

All image processing by the Fusion page takes place before effects that are applied by the Edit page, with the sole exception of the Lens Correction effect. When it comes to sizing and image resolution, whether or not the Fusion page affects resolution depends on how you use it.

Fusion Effects Inherit the Source Resolution of a Clip



When you open a clip on the Timeline in the Fusion page, the Fusion page is set to the full source resolution of that clip, regardless of the Timeline resolution. This can be seen if you look at the resolution that's listed above the upper right-hand corner of the Viewer. This means that if you don't apply any operations that reduces the image resolution (described later), subsequent sizing adjustments in other pages will refer to the same resolution as the source clip.

The available resolution and bit depth of the currently selected clip is visible above the upper right-hand corner of the Viewer, circled in red

Fusion Clips Inherit the Timeline Resolution

If you combine multiple clips on the Timeline into a Fusion clip, the Fusion page is set to the timeline resolution, regardless of the source resolution of the clip. The image is then output to the Edit page at this timeline resolution, and all subsequent sizing adjustments are performed relative to the timeline resolution, with no reference to the original resolution in the source clip.

The available resolution and bit depth of a clip that's been turned into a Fusion Clip, that's set to the timeline resolution of 1920x1080

Operations in the Fusion Page That Change Resolution

If you don't do anything to change the size of a clip in the Fusion page, then its resolution stays the same and you'll effectively output the source resolution of that clip to the Edit page.

However, if you Merge the image with a second clip attached to the background which has a different resolution, or if you use a Crop or Resize node to increase or decrease the resolution of the image, then the new resolution will be passed to the Cut and Edit pages as the effective source resolution of that clip.

In short, the Fusion page passes whatever resolution is output by the last node of your composition back to the Edit page as the effective resolution of that clip in the DaVinci Resolve image processing pipeline.

Fusion Page Transform Operations Are Resolution Independent

Within the Fusion page, multiple Transform nodes operate in a resolution independent manner relative to the resolution of the source clip. This means that if you shrink an image to 20% with one Transform node, and then enlarge it back up to 100% using a second Transform node, you end up with an image that has all the resolution and sharpness of the input image.

Fusion Page Resize Operations Are Not

Within Fusion there are two kinds of transform effects, the Transform node and the Resize node. Which of these nodes you use has a dramatic impact on resolution independence.

- The Transform node always refers back to the input resolution of the clip (as defined by the Clip Attributes) to enable resolution-independent sizing, such that multiple Transform nodes can scale the image down and up repeatedly within the Fusion page with no unnecessary loss of image resolution.
- The Resize node actually decreases image resolution when you shrink an image or increases image resolution (with filtering) when enlarging. This means that the Resize node will break resolution independence, and the resolution of the image will be fixed at whatever you specify from that point in your composite's node tree forward.

In most situations, you probably want to use the Transform node to maintain resolution independence relative to the source media, unless you specifically want to alter and perhaps reduce image resolution to create a specific special effect which purposefully degrades the image. For example, if you want a clip to be forced to a standard definition resolution in order to make it look like a low-resolution archival clip, the Resize node will accomplish this. Enlarging the result with a Transform node will then perform a filtered enlargement that will look like a real SD clip being enlarged.

Transforms from the Fusion Page to the Edit Page

All transform operations you apply on the Cut, Edit, and Color pages are resolution independent, referring to the original resolution of the source media, so long as you don't use the Fusion page. For example, if you shrink an image to 20% in the Edit page (using Edit sizing controls) and then enlarge it in the Color page back to 100% (using Input sizing controls), you end up with an image that has all the resolution and sharpness of the original media, because the final resolution is drawn from the original source media.

However, once you use the Fusion page to do anything to a clip, from adding a small effect to creating a complex composition, the resolution-independent relationship of the Edit and Color pages to the source media is broken, and whatever resolution is output from your Fusion composition is the new effective resolution of the clip that appears in the Timeline. This means if you shrink an image to 20% in the Fusion page (using a Transform node) and then enlarge it in the Color page by 150%, you end up with an image that isn't as sharp as the original because the downconverted image in the Fusion page is effectively the new source resolution of that clip.

Image Scaling

DaVinci Resolve has a dedicated mechanism for automatically managing the size of clips with resolutions that don't match the timeline resolution, and it's separate from the Zoom transform controls that are available for making creative adjustments to clips. This is called Image Scaling, and it's customizable in a few different areas.

Resize Filter Project Setting

The Resize Filter setting lets you choose the filter method that's used to interpolate image pixels when resizing clips:

- **Smoother:** May provide a more pleasing result for projects using clips that must be scaled down to standard definition as this filter exhibits fewer sharp edges at SD resolutions.
- **Bicubic:** While the sharper and smoother options are slightly higher quality, bicubic is still an exceptionally good resizing filter and is less processor-intensive than either of those options.
- **Blinear:** A lower quality setting that is less processor-intensive. Useful for previewing your work on a low-performance computer before rendering when you can switch to one of the higher quality options.
- **Sharper:** Usually provides the best quality for most projects, using an optical quality processing technique that's unique to DaVinci Resolve.
- **Custom:** This setting lets you take control of the exact algorithm used in all resizing operations. The custom Resize Filter options available are: Bessel, Box, Catmul-Rom, Cubic, Gaussian, Lanczos, Mitchell, Nearest Neighbor, Quadratic, and Sinc. In practice, the difference between these methods can be quite subjective. However, if you need to match a specific resizing method used from another application, you can do it here. For everyday use, the normal resizing filters in DaVinci Resolve should be sufficient.
- **Override Input scaling:** Checking this box lets you choose an Input Sizing preset to apply to the project.
- **Override Output scaling:** Checking this box lets you choose an Output Sizing preset to apply to the project.
- **Anti-alias edges:** A second group of settings lets you choose how to handle edge anti-aliasing for source blanking.

  Auto: Adds anti-aliasing when any of the Sizing controls are used to transform the image. Otherwise, anti-aliasing is disabled.

  On: Forces anti-aliasing on at all times.

  Off: Disables anti-aliasing. It might be necessary to turn anti-aliasing off if you notice black blurring at the edges of blanking being applied to an image.

- **Deinterlace quality:** (only available in Studio version) A fourth group of settings lets you choose the quality/processing time tradeoff when deinterlacing Media Pool clips using the Enable Deinterlacing checkbox in the Clip Attributes window. There are two settings:

  Normal: A high-quality deinterlacing method that is suitable for most clips. For many clips, Normal is indistinguishable from High. Normal is always used automatically during playback in DaVinci Resolve.

  High: A more processor-intensive method that can sometimes yield better results, depending on the footage, at the expense of slower rendering times.

  DaVinci Neural Engine: This option uses the advanced machine learning algorithms of the DaVinci Neural Engine to analyze motion between the fields of interlaced material and reconstructs them into a single frame. This option is very computationally intensive, but ideally will deliver an even more aesthetically pleasing result than the “high” setting.

Input Scaling Project Setting

If the native resolution of an imported clip doesn’t match the timeline resolution, then the currently selected Input Scaling Preset in the Image Scaling panel of the Project Settings dictates how mismatched clips will be handled project-wide. The default setting is “Scale entire image to fit,” which shrinks or enlarges the image to fit the current dimensions of the frame without cropping any part of the image, adding letterboxing or pillarboxing as necessary to fill the unused portion of the frame depending on whether the horizontal or vertical dimension of the image hits the edge of the frame first.

The Mismatched resolution files option let you choose how clips that don’t match the current project resolution are handled. The illustrated examples below show an SD clip being fit into an HD project using each of the different options.

Center crop with no resizing

Clips of differing resolution are not scaled at all. Clips that are smaller than the current frame size are surrounded by blanking, and clips that are larger than the current frame size are cropped. Keep in mind that this is a good setting to use if you’re importing a timeline from another NLE in which clip resolution adjustments are imported as scaling adjustments. Choosing “Center Crop with no resizing” prevents DaVinci Resolve from “double scaling” clips in imported timelines.

Center crop with no resizing

Scale full frame with crop

Clips of differing resolution are scaled so that the clip fills the frame with no blanking. Excess pixels are cropped. This is a good setting when you want clips that don't match the project resolution to automatically fill the frame, with no letterboxing or pillarboxing.

Scale full frame with crop

Stretch frame to all corners

Useful for projects using anamorphic media. Clips of differing resolutions are squished or stretched to match the frame size in all dimensions. This way, anamorphic media can be stretched to match full raster or full raster media can be squished to fit into an anamorphic frame. An added benefit of this setting is that it makes it easy to mix anamorphic and non-anamorphic clips in the same project.

Stretch frame to all corners

Scale entire image to fit

The default setting. Clips of differing resolution are scaled so that each clip fills the frame without cropping. The dimension that falls short has blanking inserted (letterboxing or pillarboxing). This is a good setting when you want clips that don't match the project resolution to automatically fit into the frame without being cropped in any way, and you're fine with letterboxing or pillarboxing as a result. However, if you've imported a timeline from another NLE and there are clips that are twice as big as they should be, it's because this setting is on by default, and your imported timeline has imported scaling settings used to resize clips that didn't match the timeline resolution. If this happens, switch to "Center crop with no resizing" instead, and that will fix the problem.

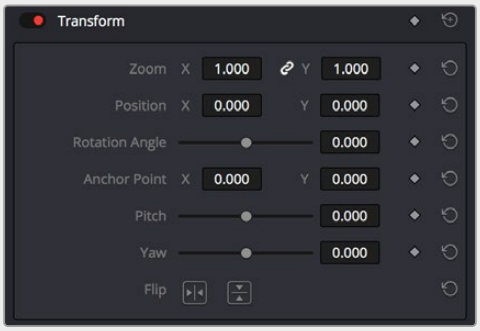
Scale entire image to fit

Output Image Scaling Project Settings

Another group of settings found in the Image Scaling panel of the Project Settings lets you optionally choose a different resolution to be output, either via the Deliver page, or via your video output interface for monitoring or outputting to tape.

In particular, if you set the “Resolution” in the Render Settings panel of the Deliver page to something other than the timeline resolution, these settings are used to make the change. This is useful in situations where you’re mastering a high resolution 4K project, but you want to monitor using an HD display, and you plan on eventually outputting HD resolution deliverables in addition to the 4K deliverables for which you want to use different Scaling and/or Resize Filter settings that work better at the lower resolution.

- **Match timeline settings:** This checkbox is turned on by default so that these settings mirror the Image Scaling and Input Scaling settings described above. Turning this checkbox off lets you choose different settings to be used when monitoring, outputting to tape, or rendering, using the other settings below.
- **Output resolution:** Lets you choose an alternate resolution for monitoring and delivery. You can also set this from the “Resolution” dropdown menu of the Video panel in the Render Settings of the Deliver page.
- **For “X x Y” processing:** Lets you specify a different custom alternate resolution.
- **Pixel aspect ratio:** Lets you specify an alternate pixel aspect ratio to match the alternate timeline format.
- **Mismatched resolution files:** Lets you choose an alternate way of handling mismatched resolution files that works better for the alternate resolution you’ve chosen. These options work similarly to those of the “Input Scaling” group. For example, for an HD or UHD resolution project you may have the Image Input Scaling set to “Scale Full Frame With Crop” so that all Standard Definition resolution files are center-cut to eliminate blanking. However, if you’re using Output Image Scaling to create a Standard Definition deliverable, you may want to set the Output Image Scaling > Mismatched resolution files setting to “Scale entire image to fit” in order to letterbox all HD or UHD resolution clips, while preserving the original aspect ratio of the SD clips.
- **Super Scale:** Sets a very processor-intensive and high quality upscaling algorithm that actually creates new pixels for the resized image. The possible values are None, 2-3-4x, 2-3-4x Enhanced, and Auto.

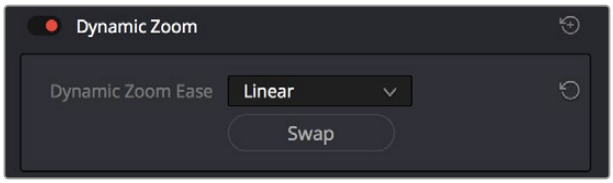


Clip-Specific Scaling Settings

There’s an additional set of Scaling and Resize Filter settings, available in the Video Inspector for selected clips, that provide the same options as those found in the Project Settings window, except that they let you choose settings that will be specific to a particular clip. These are valuable for situations where the project-wide scaling setting is working for most clips, but you have a handful of specific clips that would benefit from individual settings.

Edit Sizing in the Cut and Edit pages

The Video Inspector contains a set of Transform parameters with which you can alter clips in the Timeline. These parameters operate independently of the Input Sizing controls found in the Color page. Separate Edit sizing controls serve a number of different functions:



- They're convenient for editors and are easily animated for creating motion graphics effects right on the Cut and Edit page timelines. They also keep editor transform adjustments separate from colorist transform adjustments, for a clear division of labor and responsibility.
- Edit sizing parameters also store incoming transform data from imported AAF and XML projects that come from other applications, so that imported transforms are kept separate from adjustments made by colorists and finishing artists.

The Transform parameters in the Inspector of the Edit page

If, when importing an AAF or XML project file, you turned on the "Use sizing information" checkbox, then every clip that had position, scale, rotation, or crop settings applied in the originating NLE will have those adjustments applied to these transform parameters, which is convenient for keeping imported transform settings separate from other DaVinci Resolve-native transform settings.

Additionally, a set of Dynamic Zoom parameters also exists in the Video Inspector, which let you make quickly animated transforms using graphical controls that correspond to the start and end states of an animated transform. However, these transforms are lumped in with the other Edit page Transform parameters in terms of the order of sizing operations occurring throughout DaVinci Resolve.

The Dynamic Zoom settings in the Inspector of the Video Inspector

The transform that's made via the Edit Sizing controls refers back to either the source resolution of each clip, or the resolution output by the Fusion page if it's in use.

Image Stabilization

DaVinci Resolve provides Image Stabilization controls in the Cut, Edit, and Color pages that all control the same transform operation that happens between Edit sizing and Input Sizing in the image processing pipeline. The transform that's made via the Image Stabilization controls refers all the way back to either the source resolution of each clip, or the resolution output by the Fusion page if it's in use.

Input Sizing on the Color Page

The Sizing palette on the Color page has another dedicated set of keyframable transform parameters that work with the various DaVinci control panels to let the colorist apply pan and scan adjustments while working through a project. These parameters work independently of the Edit page Transform parameters, allowing you to keep imported transform settings separate from other transform settings that you apply. However, for convenience the Edit sizing controls are available in the Color page as well.

The transform that's made via the Input Sizing controls refers all the way back to either the source resolution of each clip, or the resolution output by the Fusion page if it's in use.

Node Sizing on the Color Page

Using Node Sizing, you can apply individual sizing adjustments to clips on a per-node basis within the Color page, which is similar in principal to using Transform nodes in the Fusion page. All Node Sizing adjustments within a grade are cumulative, and any keyframing done to Node Sizing parameters is stored in that node's Node Format keyframe track in the Keyframe Editor. Two good examples of Node Sizing include realigning color channels individually in conjunction with the Splitter/Combiner nodes or duplicating windowed regions of an image by moving them around the frame. Subsequent Node Sizing operations do not refer back to the source resolution of a clip, so using multiple Node Sizing operations to reduce and enlarge an image will reduce image resolution and sharpness.

Output Sizing on the Color Page

Output sizing is an additional transform that is applied after Edit sizing, Fusion sizing, Input sizing, and Node sizing. It's an overall adjustment that affects every clip at once, which is suitable for making last-minute format alterations that you want to affect the entire program. Technically, Output Sizing includes the Blanking controls, but those are important enough to discuss separately. Output Sizing also does not refer back to the source resolution of clips, so if you use Edit or Input Sizing to shrink a clip, and Output Sizing to enlarge it again, the final result will be somewhat softened as you're enlarging the lower resolution image output by Input Sizing.

Output Blanking

Output blanking is not a sizing operation, but it's often related and so worth mentioning here. Blanking is an adjustment you can use to add black areas to the top, bottom, left, or right of an image, in order to add "letterboxing" (black bars at the top and bottom of the image) or "pillarboxing" (black bars at the left and right of the image) that lets you fill in the unused parts of an image frame that's either shorter or thinner than the current output resolution.

Once all transforms, compositing operations, and color corrections have been applied by the DaVinci Resolve image processing pipeline, the very last operation to be performed is Output blanking, if it's enabled. This guarantees that overlapping images, grading, and other adjustments are properly "blacked out" no matter what you're doing to the program.

Output Blanking controls are found in the Timeline menu (as a series of aspect ratios) as well as in the Output Sizing parameters of the Color page Sizing palette (via Top, Right, Bottom, and Left controls).

TIP: Text and graphics superimposed via the Data Burn-In window, if enabled, are the only effects that will appear in front of picture areas affected by blanking. This lets you add timecode and other information over letterboxed areas that you don't want to obscure the picture.

Format Resolution on the Delivery Page

By default, the Format Resolution setting in the Render Settings of the Deliver page matches the timeline resolution when “Match timeline settings” is enabled in the Output Scaling Preset in the Image Scaling panel of the Project Settings.

Choosing a new resolution from the “Set Resolution to” dropdown menu lets you override the current Format Resolution setting before rendering. Using this control, you can queue up multiple jobs, each set to a different resolution, to output multiple formats during a single render session.

For more information on rendering and setting up jobs for the Render Queue, jump to this chapter: Using the Deliver Page.

Rendering Sizing Adjustments and Blanking

When rendering your final output, you have the option of choosing whether or not to “bake in” the sizing operations that have been performed. For example, you may have set up a whole set of specific sizing adjustments for the clips in a program, but then you’re requested to render the project and its media as individual clips for round trip re-delivery to the editor for further work. In this case, you can choose to either render the sizing into the final media, or not.

Whether or not sizing is rendered into your final media depends on the “Disable edit and input sizing” checkbox in the Advanced Settings options of the Render Settings panel. You can disable sizing and blanking either when rendering the current timeline as a single clip, or when rendering individual clips.

If “Disable sizing and blanking output” is turned off: Output Blanking, Cut and Edit page sizing adjustments, Color page Input and Output Sizing adjustments, and Image Stabilization are rendered into the final rendered media using the optical-quality sizing algorithms available to DaVinci Resolve. This is best if your sizing adjustments are approved and final, and you want to “bake” sizing adjustments into the final media you’re delivering.

If “Disable sizing and blanking output” is turned on: Output Blanking, Cut and Edit page sizing adjustments, Color page Input and Output Sizing adjustments, and Image Stabilization are not rendered, and each clip will be rendered either at the source resolution if “Render at source resolution” is enabled in individual clips mode, or to the currently specified resolution of the timeline or project. However, the sizing adjustments you’ve made will be exported as part of the XML or AAF file that you’re exporting. This is best for workflows where the editor wants to continue adjusting sizing after you’ve handed off the graded project relative to the original size of the clips.

Keep in mind that if you want to render Input Sizing adjustments into the media you’re outputting, the “Force sizing to highest quality” checkbox guarantees that DaVinci Resolve will use the highest-quality sizing setting, even if you’ve temporarily chosen a faster-processing option for a slower computer.

NOTE: “Disable sizing and blanking output” does not disable any transform operations that happen within the Fusion page. Those will continue to be applied to the final output.

Chapter 12

Data Burn-In

This chapter covers how to use the Data Burn-In window that's available to every page in DaVinci Resolve.

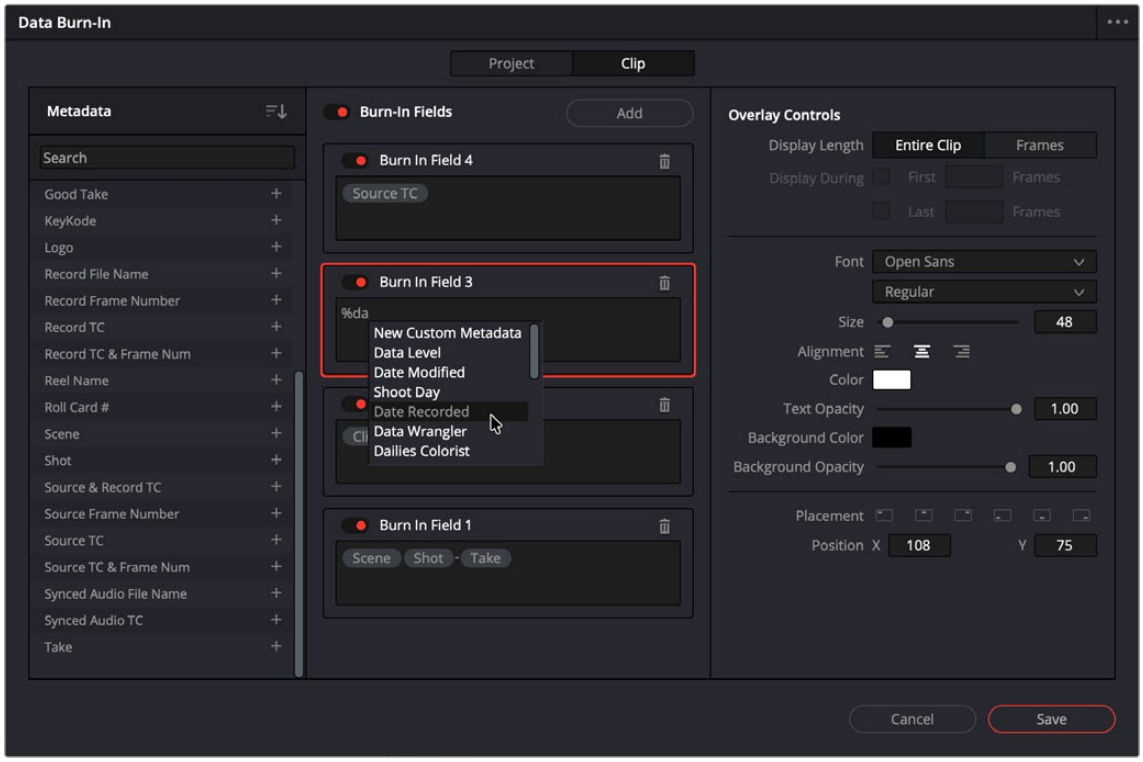
MEDIA

Contents

Data Burn-In 308
Using the Data Burn-in Window 309
Using a Logo Image as a Burn-in 310
Project vs. Clip Mode 311
Saving and Loading Burn-In Presets 311
Gang Rendered Text Styles 311

Data Burn-In

The Data Burn-In window lets you display select metadata as a timeline-wide “window burn” that’s superimposed over the image in the Viewer. This window burn is written into files that you render in the Deliver page, and it’s also output to video, for viewing on your external display, or for outputting to tape.



The Viewer displaying the record timecode, source timecode, and source clip name.

Traditionally, window burns are used to keep track of offline media. However, the Data Burn window has added flexibility. For example, you can watermark review files with custom text or graphics with alpha channels—or add graphical logos or “bugs” to programs in preparation for broadcast.

You could also superimpose custom reference guidelines over the images being monitored, or temporarily display timecode or clip names while editing, mixing, or reviewing graded dailies.

The Burn-In window is available by choosing Workspace > Data Burn-In.

Using the Data Burn-in Window

Data Burn-In window

The Data Burn-in Window has three columns:

1. The leftmost column lets you select the Metadata fields used in your burn-in. Type a term in the search box, or manually choose your metadata fields by clicking on the + icon. This adds them to the middle Burn-In Fields column.
2. The middle Burn-In Fields column lets you customize and format the exact data returned in the field. You can use any combination of text, metadata fields from the left column, and other custom metadata tags for any metadata field. To use custom metadata tags, first enter the % symbol, then type the name of the metadata field you wish to use, and select it from the dropdown. Each Field has its own on-off toggle, as well as a master on-off toggle at the top of the column. To add new blank fields, click on the Add button. Selecting a field lets you set its Overlay Controls in the rightmost column.
3. The rightmost Overlay Controls column lets you adjust the font format and positioning of the Burn-In Field in the frame.

   Display Length: Choose how long the field is displayed for. Your options are either the Entire Clip, or Frames (to set a custom length).

   Display During: When Frames is selected from the Display Length, these controls are activated. To determine when and for how long the field is displayed, check the First and / or Last boxes and enter a length in frames.

   Font: Choose the typeface of the field.

   Size: Lets you adjust the font size.

   Alignment: Choose either Left, Center, or Right text justification of the field.

   Color: Opens a color picker for your font color.

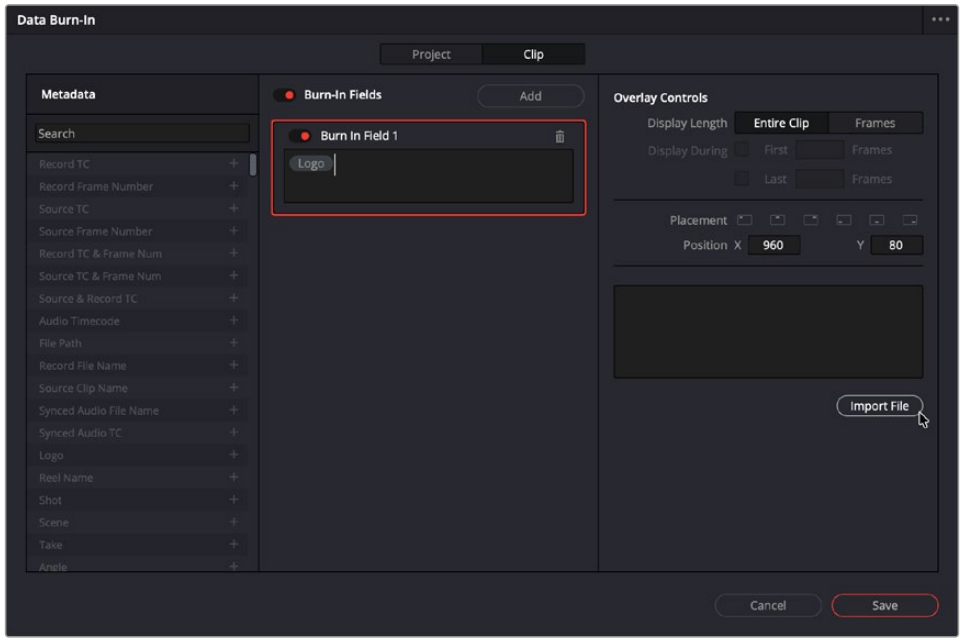
Text Opacity: Choose the level of font transparency.

Background Color: Opens a color picker to choose the background color of the field.

Background Opacity: Choose the level of background transparency.

Placement: Choose one of the icons to correspondingly position the field in the frame.

Position X/Y: Enter a value or drag inside the field to position the Burn-In within the frame.

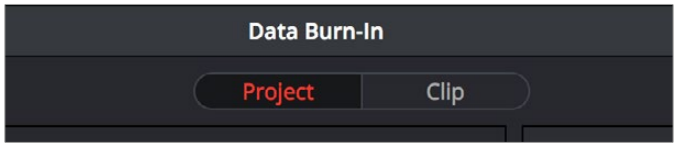


4 Press the Save button to activate the Burn-In.

The resulting Burn-In fields on the frame.

Using a Logo Image as a Burn-in

To use a logo image in the Burn-In Field, go to the leftmost Metadata column and select Logo by clicking the + icon. Then click the Import button in the Overlay Controls to select the image. You can reposition the image using the rest of the Overlay Controls.



Importing an image file to use as a burned-in logo.

Project vs. Clip Mode

Two buttons at the top of the Data Burn window let you choose whether you want to edit one set of burned-in metadata that will be displayed for the entire duration of the Timeline, or edit burned-in metadata on a clip-by-clip basis. You can combine the two, having timeline-wide window burn settings and separate clip-specific window burn settings for a handful of clips in that timeline at the same time.

When rendering in the Delivery page, window burns are applied both when rendering timelines as individual source clips and when rendering as one single clip.

Two separate panels let you adjust project-wide window burns vs. clip-specific window burns.

Saving and Loading Burn-In Presets

If there are common sets of metadata that you regularly use and switch among, you can save each set up as a preset for future use.

To save a burn-in preset:

1. Click the Option menu and choose Save As New Preset.
2. Type a name into the Burn In Preset dialog that appears, and click OK. That preset is added to the list of saved presets in the Option menu.

To delete a burn-in preset:

1. Choose a preset from the Option menu.
2. Click the Option menu, and choose Delete.
3. A dialogue box appears asking you to confirm the deletion.

To modify a burn-in preset:

1. Choose a preset from the Option menu.
2. Edit it however you like.
3. Click the Option menu, and choose Update.

Gang Rendered Text Styles

You have the option of independently styling each item of metadata, depending on whether the Gang Render Text Styles option is checked in the Data Burn-In window's Option menu. When turned on, all text metadata share the same font, size, color, background, justification, and opacity. When turned off, each item of metadata can have individual settings.

Chapter 13

Resolve Live

The Color page has another mode available to aid you in using DaVinci Resolve in on-set grading workflows. Turning the Resolve Live option on puts DaVinci Resolve into a live grading mode, in which an incoming video signal from a camera can be monitored and graded during a shoot.

More About Resolve Live

Resolve Live has been designed to let you use all of the features of DaVinci Resolve to grade these on-set video previews, in the process saving video snapshots that contain a captured image, your grade, and reference timecode from the camera. The idea is that, using Resolve Live, you can work with the cinematographer to develop looks and test lighting schemes on the footage being captured during the shoot, and then later you can use those looks to build dailies, and as a starting point for the final grade once the edit has been completed.

Additionally, you can use Resolve Live in conjunction with other Color page features such as the Alpha output to build test composites to check green screen shots, comparing them against imported background images in order to aid camera positioning and lighting adjustments. The built-in video scopes can also be used to monitor the signal levels of incoming video. Finally, you can use 1D and 3D LUTs to monitor and grade log-encoded media coming off the camera.

Configuring Your System for Resolve Live

Setting up your Camera and Hardware for Resolve Live

Setting up Resolve Live is straightforward. Whether you're using a tower workstation or a laptop, any of the Blackmagic Design DeckLink or UltraStudio video interfaces can be used to connect your DaVinci Resolve workstation to a camera and external video display. The important thing to keep in mind is that, if you want to connect to a live incoming signal and output that signal for monitoring at the same time, you need to either use two separate DeckLink PCIe cards or UltraStudio Thunderbolt interfaces, or a single DeckLink card/Ultrastudio with multiple separate inputs and outputs on a single PCIe card/device.

During the shoot, the digital cinema camera in use needs to be connected to your DaVinci Resolve workstation video input via HD-SDI or HDMI, which must be configured to carry both the video image and timecode that mirrors the timecode being written to each recorded clip. Most cameras allow timecode output over HD-SDI and HDMI, and both DeckLink and UltraStudio interfaces can pass this timecode to DaVinci Resolve. Without a proper timecode reference, you won't be able to take the shortcut of automatically syncing your saved Snapshots to recorded camera original media using ColorTrace, although you can always apply grades manually.

Resolve Live hardware checklist:

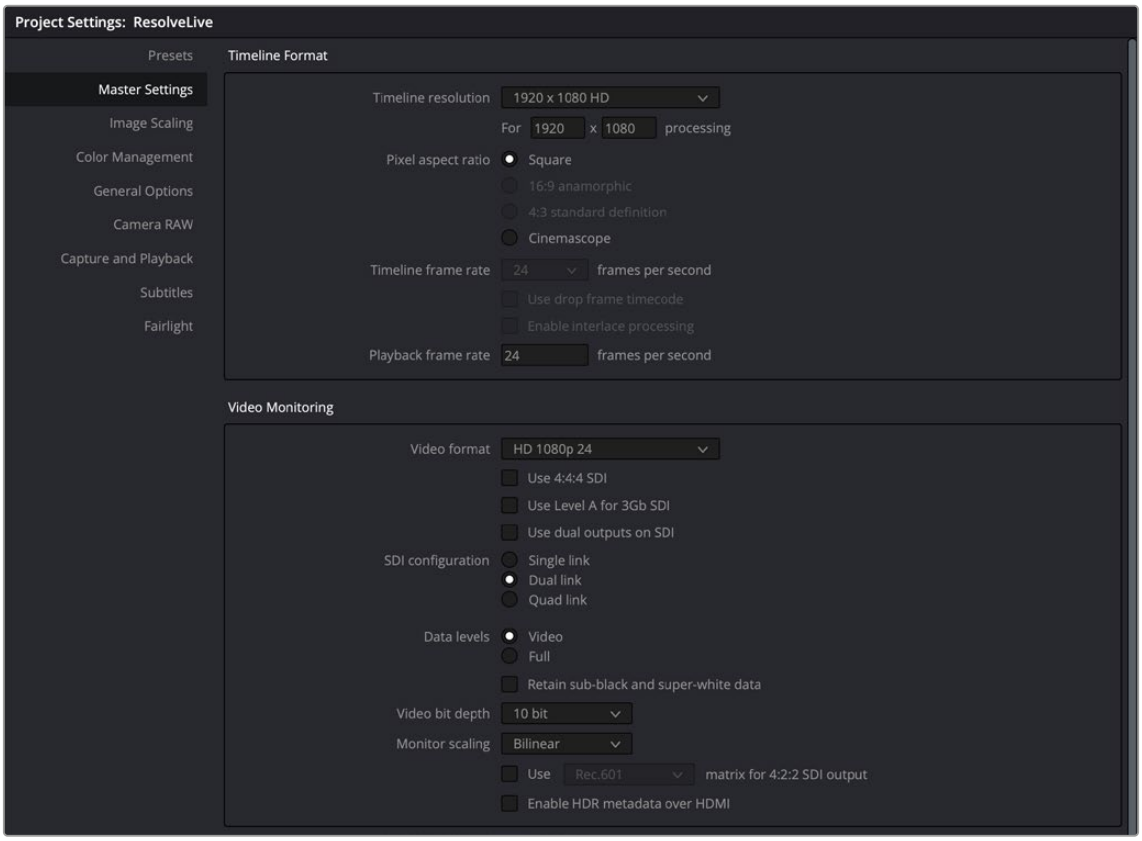
- Install and update the Blackmagic Design Decklink card or Ultrastudio device you will be using for live video input in your DaVinci Resolve workstation (see your Blackmagic Design hardware documentation for specific details).
- Connect the video camera's SDI or HDMI video output to the Blackmagic device's video input. Make sure that embedded timecode out of the camera is enabled as well.
- Select the appropriate video input for your device in the Blackmagic Desktop Video Setup application on your computer.

Video input options in the Blackmagic Desktop Video Setup

NOTE: The resolution and frame rate that your camera is outputting through the SDI/HDMI cable.

Setting up DaVinci Resolve for Resolve Live

Once the hardware is set up, you will need to check the configuration of DaVinci Resolve to be able to make use of the live grading features of Resolve Live.



The first setting is to select the appropriate video input hardware in the Video I/O settings. The Video I/O panel of the System Preferences provides two sets of options for configuring video interfaces connected to your computer, one for capture, and one for monitoring. Resolve Live uses the video hardware input selected in the capture device. You will need to restart DaVinci Resolve if you modify these settings.

Video input/output options in the System Preferences

Next, you should begin with a new empty project. You should set up the new project's Timeline and Video Monitoring settings to match the format and frame rate coming out of your camera.

IMPORTANT: You must set up the resolution and frame rate in your new project's Timeline format and Video Monitoring format in the project's Master Settings to match the resolution and frame rate of the video coming out of the camera.

Make sure your Timeline format and Video Monitoring size and frame rate match your camera's video output in the Master Settings

Then add a new empty timeline, since the live grading workflow involves capturing live graded snapshots to an otherwise unoccupied timeline. One recommended way of organizing the live grades of a shoot is to create one new project per day of shooting. This way, snapshots captured during shoots using all 24 hours of time-of-day timecode won't conflict with one another. Also, separate projects can make it easier to use ColorTrace to copy grades from your live grade snapshots to the camera original media you'll be creating dailies from, eventually.

TIP: Having an empty Media Pool and Timeline doesn't mean you can't install useful LUTs and pre-import reference stills and saved grades to the Gallery, as these can be valuable tools for expediting your on-set grading.

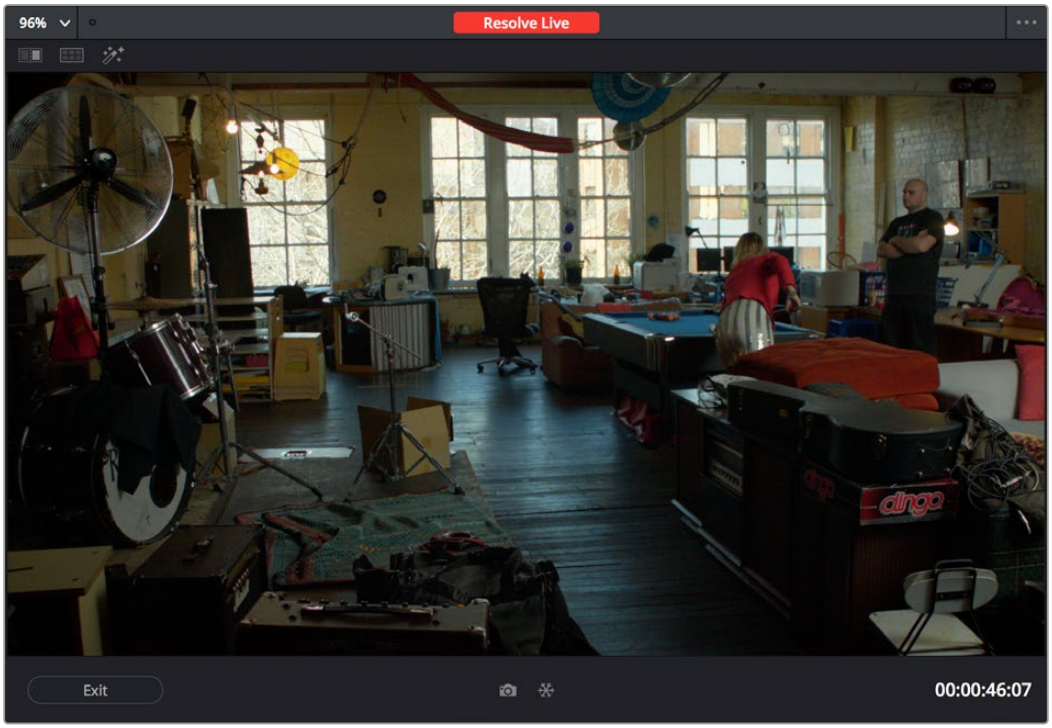
Once you've created your new project, you also need to choose the disk where all snapshots you take will be saved. By default, snapshots are saved on the scratch disk at the top of the Scratch Disks list in the Media Storage panel of the System Preferences. They're automatically saved in a folder named identically to the current project, inside a folder called Resolve Live.

Resolve Live software checklist:

- Choose the Capture Device for inputting the video signal from the Video Input/Output options in the System Preferences.
- Create a New Project.
- Make sure your Timeline format and Video Monitoring size and frame rate match your camera's video output in the project's Master Settings.
- Create a New Timeline.

Grading Live

Once your camera and computer are appropriately connected and configured, using Resolve Live is straightforward. This section describes the live grading workflow as it was designed to be used. Once you're familiar with the capabilities of Resolve Live, you may find your own ways of working that are more in tune to the needs of your particular project.



Going Live

Once you've created your day's project, you need to turn on Resolve Live to begin work.

To turn on Resolve Live:

1. Open the Color page.
2. Choose Color > Resolve Live (Command-R).

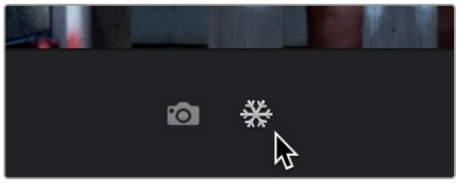
   A red Resolve Live badge at the top of the Viewer indicates that Resolve Live is turned on, and the transport controls are replaced by the Freeze and Snapshot buttons.

A red badge shows that Resolve Live is active and showing incoming video from the camera

At this point, the video from the connected camera should become visible within the Viewer, the camera timecode should be displayed in the Viewer's timecode window, and you can begin using all of the capabilities of the Color page to begin grading whatever is onscreen, including Gallery split-screens for matching and comparing. The current color adjustments in all palettes are automatically applied to both the image in the Viewer and the video output to an external display (if there is one).

While Resolve Live is on, much of DaVinci Resolve's non-grading functionality is disabled, so when you're finished, be sure to turn Resolve Live off.

To turn off Resolve Live, do one of the following:



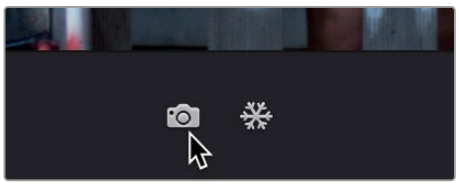
- Click the Exit button at the bottom left-hand corner of the Viewer.
- Choose Color > Resolve Live (Command-R).

Using Freeze

In Resolve Live mode, the Freeze button (it looks like a snowflake) freezes the current incoming video frame, so you can grade it without being distracted by motion occurring during the shoot. When you've made the adjustment you need, you can unfreeze playback in preparation for grabbing a snapshot.

To freeze incoming video:

- Click the Freeze button (that looks like a snowflake).
- Choose Color > Resolve Live Freeze (Shift-Command-R).



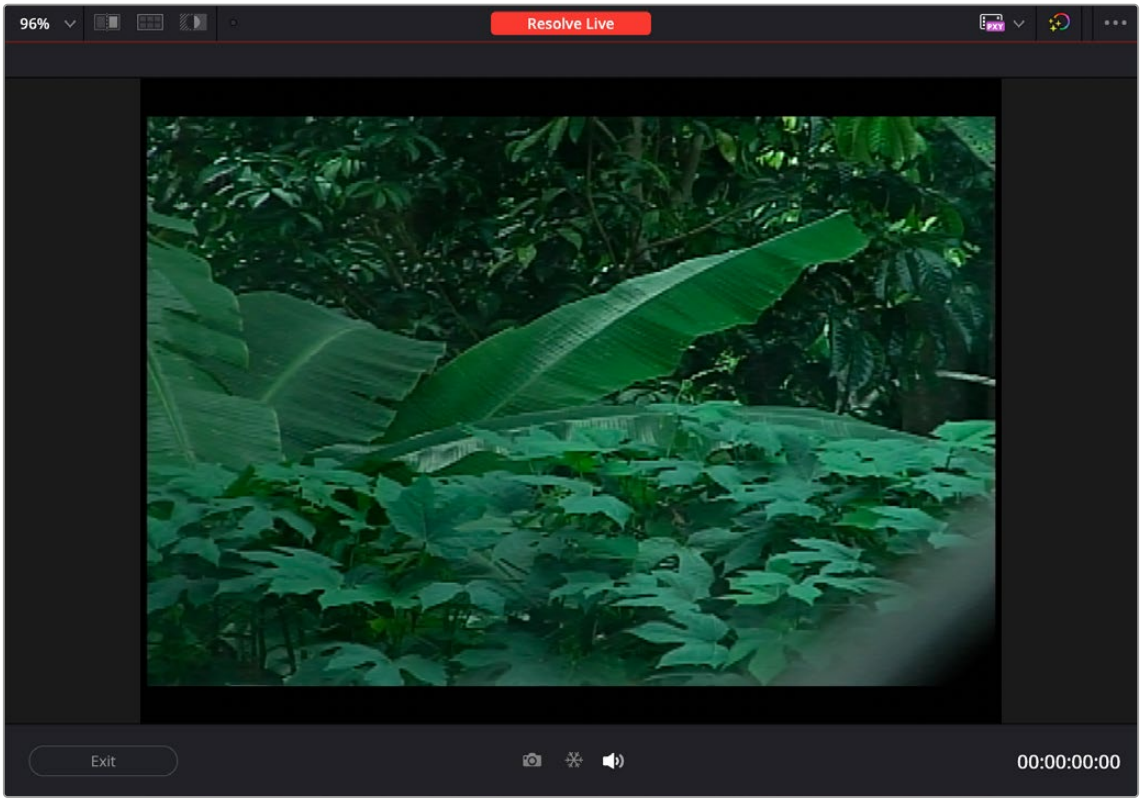
The snowflake button freezes the image so you can grade a particular frame

Using Snapshot

Once you're happy with a grade, clicking the Snapshot button saves a snapshot of the current still in the Viewer, the incoming timecode value, and your grade into the Timeline. Snapshots are simply one-frame clips. They use grades and versions just like any other clip. In fact, ultimately there's no difference between the timeline created by a Resolve Live session and any other timeline, other than that the Resolve Live timeline only has a series of one frame clips, which appear in the Timeline of the Edit page as a series of 1-frame stills.

To save a snapshot, do one of the following:

- Click the snapshot button (with a camera icon).
- Choose Color > Resolve Live Snapshot (Command-Option-R).



The snapshot button saves a frame and the grade for future use

For example, you may begin the process of building and refining a grade for a particular scene during an unrecorded run-through. Then, once shooting starts, you may take snapshots of each shot's slate, and then of significant takes that follow, tweaking where necessary and in conjunction with the DP's feedback once things get going. New camera setups may require further tweaks, which you'll save as snapshots for those shots, and as you work in this way you'll find yourself building up a timeline of snapshots that correspond to that day's shoot.

As you work, keep in mind that you must temporarily turn Resolve Live off in order to open a grade from a previous snapshot in the Timeline, in order to use it as a starting point for another shot. You can also save grades into the Gallery.

Resolve Live Audio Monitoring

When using Resolve Live, you can now hear the audio signal from the camera coming into the Decklink or Ultrastudio device as you grade. You can toggle this behavior on or off by clicking on the speaker icon underneath the Viewer.

Clicking on the speaker icon toggles the audio on and off during a Resolve Live session.

Using Resolve Live Grades Later

Since each Snapshot you capture during a Resolve Live session contains timecode that was captured from the camera, grades from snapshots with timecode that overlaps recorded camera original media can be synced using ColorTrace when the time comes to start making dailies.

Keep in mind that snapshot grades correspond to the monitored output of the camera during the shoot. If you shot using a raw format, you'll need to use whatever in-camera debayering settings were used for monitoring during the shoot if you want the grades from your snapshots to produce the same result.

For more information on using ColorTrace, jump to this chapter: Copying and Importing Grades Using ColorTrace.

Using LUTs in Resolve Live Workflows

Many on-set workflows use Lookup Tables (LUTs) to calibrate displays, normalize log-encoded media for monitoring, and preview looks in the video village to test how the current lighting scheme will work with the intended grade. You can apply LUTs using the Lookup Tables section of the Project Setting's Color Management panel, or within a grade as part of a node tree.

However, you can also export LUTs, if necessary for monitor previewing, that you can apply by loading them into a compatible LUT box of some kind, connected in-between the camera's video output and a display, or using a display capable of loading LUTs internally.

If you're exporting LUTs using the Generate 3D LUT command of the Thumbnail timeline's contextual menu, you should limit yourself to using only Primaries palette and Custom Curves palette controls within a single node. These are the only grading controls that can be mathematically converted into a LUT.

When exporting a LUT, any nodes that use Windows or OpenFX will be ignored along with all corrections made within these nodes. All other nodes with Primaries palette and Custom Curves palette adjustments that can be translated into a LUT will have their combined result translated into a LUT. For any nodes that mix supported and unsupported adjustments for LUT export (such as sharpening or blur filtering operations), the unsupported adjustments will simply be ignored.

For more information on exporting LUTs, jump to this chapter: Grade Management.

NOTE: DaVinci Resolve exports LUTs in the .cube format, which is a DaVinci-developed LUT format, with no relation to the Adobe SpeedGrade.cube format.

Chapter 14

Stereoscopic Workflows

DaVinci Resolve has robust support for a wide variety of stereoscopic workflows. Using the built-in tools of the Studio version of DaVinci Resolve, you can edit using stereoscopic clips, grade the resulting program, adjust each clip's stereo-specific properties such as convergence and floating windows, and master stereoscopic output, all within DaVinci Resolve.

Stereoscopic Workflows

Creating a stereo 3D project is a multi-step process that benefits from careful media organization. This chapter covers how to set up for working on stereoscopic projects, how to import stereoscopic projects, and how to export stereoscopic media.

First, stereoscopic pairs of clips, i.e., the individual left- and right-eye media files, are imported into the Media Pool, organized, and then linked together using the “Stereo 3D Sync” command to create a new set of linked stereo clips. Then, these clips stereo clips can be either edited or conformed to imported project data using a single Timeline. DaVinci Resolve lets you manage left- and right-eye grades and sizing in the Color page using the controls found in the shortcut menu of the Thumbnail timeline, and in the Stereo 3D palette.

If you’re using stereoscopic CineForm media, which contains muxed left-eye and right-eye image data that can be decoded by DaVinci Resolve, you still need to go through this process, although you’ll be using duplicate clips to populate Left and Right folders with matching sets of clips.

Hardware Requirements for Working in Stereo 3D

With DaVinci Resolve on Mac systems, dual 4:2:2 Y’CbCr stereoscopic video streams are output via SDI from a compatible Blackmagic Design video interface. You can select either Side-by-Side or Line Mesh output to be fed to your stereo 3D-capable display, depending on its compatibility. Alternately, if you turn on the “Enable Dual SDI 3D Monitoring” checkbox in the Video Monitoring group of the Master Settings panel of the Project Settings, your compatible Blackmagic Design video interface outputs full resolution 4:2:2 Y’CbCr for each eye to compatible displays.

When setting up a 3D-capable DaVinci Resolve workstation, keep in mind that the dual video streams of 3D projects make greater demands on disk bandwidth, media decoding via your workstation’s CPU, and effects processing via your workstation’s available GPU cards.

Setting Up to Display Stereo 3D via SDI

All DaVinci Resolve systems can output a side-by-side frame-compatible signal that can be viewed on a stereo 3D-capable display via a single SDI connection, output from a DeckLink HD Extreme card or better. For higher-quality monitoring, two SDI signals can be used to output the left-eye and right-eye images separately at full resolution using one of the following Blackmagic Design video interfaces:

- DeckLink HD Extreme 3D+
- DeckLink 4K Extreme
- DeckLink 4K Extreme 12G
- DeckLink 8K Pro
- UltraStudio 4K
- UltraStudio 4K Extreme
- UltraStudio 4K Extreme 3

Very old legacy systems accomplish this via NVIDIA dual SDI monitoring outputs.

NOTE: If your stereo display is not capable of multiplexing the two incoming SDI signals by itself, you can accomplish this using an external device to multiplex both SDI signals into a single stereo 3G signal that will be compatible. Check with your display manufacturer in advance to see if this is necessary.

The following procedures describe how to set up stereo 3D monitoring in two different ways.

Monitoring via dual SDI to dual SDI:

1 Open the Master Settings panel of the Project Settings, then do the following:
   — Make sure the Use 4:4:4 SDI checkbox is unchecked.
   — Turn on the "Use dual outputs on SDI" checkbox.

2 Open the Stereo 3D palette in the Color page, and do the following:
   — Set Vision to Stereo.
   — Set the Out pop-up menu to None.

NOTE: When "Enable dual SDI 3D monitoring" is turned on, split-screen wipes and cursors will not be visible on the grading monitor, nor will you be able to view image resizing.

Setting Up to Display Stereo 3D via HDMI

If your stereo-capable display only has HDMI input, you'll need to use the HDMI output of a compatible Blackmagic Design video interface that has HDMI 1.4 or better to output stereo 3D signals; see the documentation accompanying your video interface for more information.

Supported Stereo 3D Media

When importing stereo 3D media from other applications, there are two types of media that are compatible with DaVinci Resolve stereoscopic workflows.

Using Dual Sets of Media in Any Supported Format

When originally shot, the media corresponding to stereo 3D workflows consists of two directories, one for the left-eye media, and one for the right-eye media. For the most automated workflow possible, this media must be tightly organized. Each pair of left-eye and right-eye media files in both directories should have matching timecode, and reel numbers that clearly indicate which are the left-eye shots, and which are the right-eye shots. When organized in this way, it's relatively easy to use DaVinci Resolve to convert each matching pair of clips into the stereo 3D clips that you'll need to work in DaVinci Resolve. This process is covered in detail in a subsequent section.

Using Stereoscopic OpenEXR Media

DaVinci Resolve is compatible with stereo OpenEXR files to accommodate professional cinema and specialty workflows. Stereo OpenEXR clips include the media for both eyes stored as separate parts so that a single OpenEXR file may output either a single image or stereo 3D images when used with an application that supports it, such as DaVinci Resolve. This means you can edit stereo OpenEXR media, grade it, and make all of the stereoscopic adjustments that the Stereo palette of the Color page supports.

If you import stereo OpenEXR clips to the Media Pool, they will at first appear to be regular non-stereo clips that output a single image. However, these can easily be converted to stereo 3D clips using the following procedure.

To set stereo OpenEXR clips to be usable as stereo clips:

1. Import the OpenEXR media to the Media Pool as you would any other clips.
2. Select one or more OpenEXR clips, then right-click the selection and choose “Convert to Stereo” from the contextual menu. Those clips will now appear with a stereo 3D badge to indicate that they’re stereo.

Using Stereoscopic CineForm Media

DaVinci Resolve is also compatible with CineForm stereo QuickTime files. CineForm clips encode the media corresponding to both eyes and mux (multiplex) it together in such a way so that CineForm files may output either a single frame of image data, if used in an application that is not capable of stereoscopic processing, or stereo 3D media when used with an application that is, such as DaVinci Resolve. This means that you can edit CineForm media using nearly any NLE, export a project via whatever workflow is convenient, and end up with a stereoscopic project that can be graded in DaVinci Resolve.

There are two ways of creating CineForm files. One is by using a camera or recording system that processes dual synchronized video signals to create a single set of CineForm media. The other is to use the CineForm conversion tools that come with GoPro CineForm Studio to reprocess dual sets of stereo 3D assets into the CineForm format.

The CineForm codec itself encodes full-frame image data using wavelet compression, at any resolution, at up to 12-bits, in a choice of RGB, Y’CbCr, or RAW color spaces. DaVinci Resolve is compatible with CineForm in a QuickTime wrapper using any supported color space, allowing access to the dual streams of image data that are provided.

When the time comes to output your program, keep in mind that while DaVinci Resolve can read CineForm files, CineForm files cannot be rendered out of DaVinci Resolve unless you’ve purchased an encoding license for OS X or Windows from GoPro. Furthermore, DaVinci Resolve cannot render Stereoscopic CineForm files.

If you import stereo CineForm clips to the Media Pool, they will at first appear to be regular non-stereo clips that output a single image. However, these can easily be converted to stereo 3D clips using the following procedure.

To set stereo CineForm clips to be usable as stereo clips:

1. Import the CineForm media to the Media Pool as you would any other clips.
2. Select the CineForm media you need to convert, then right-click the selection and choose “Convert to Stereo” from the contextual menu. Those clips will now appear with a stereo 3D badge to indicate that they’re stereo.

Using Stereoscopic MXF Media

DaVinci Resolve is compatible with stereo MXF files to accommodate professional cinema and specialty workflows. stereoscopic MXF clips include the media for both eyes stored as separate parts so that a single MXF file may output either a single image or stereo 3D images when used with an application that supports it, such as DaVinci Resolve. This means you can edit stereo MXF media, grade it, and make all of the stereoscopic adjustments that the Stereo palette of the Color page supports.

If you import stereo MXF clips to the Media Pool, they will at first appear to be regular non-stereo clips that output a single image. However, these can easily be converted to stereo 3D clips using the following procedure:

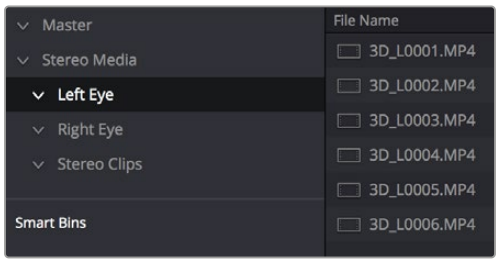
To set stereo MXF clips to be usable as stereo clips:

1. Import the MXF media to the Media Pool as you would any other clips.
2. Select one or more MXF clips, then right-click the selection and choose “Clip Attributes” from the contextual menu.
3. In Clip Attributes select the appropriate stereoscopic encoding mode (side by side or over/under), in the Stereoscopic Mode dropdown. If you have selected multiple clips, make sure you check the checkbox to the left of the Stereoscopic Mode dropdown to apply the mode to all clips.

Creating Stereo 3D Clips From Separate Files

If you’re working with stereo media that was either captured or created as individual left- and right-eye files, then you need to convert each matching pair of clips into the stereo 3D clips that you’ll need to work in DaVinci Resolve. This is a two-step procedure.

Step 1 – Import and Organize Your Media

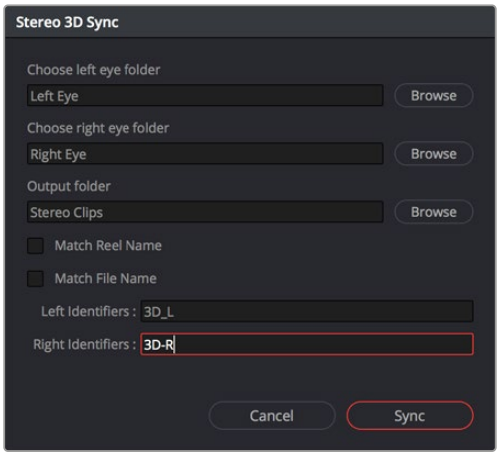


You need to import all of the left-eye and right-eye media into separate bins.

1. Open the Media page, and create three Media Pool bins named “Left,” “Right,” and “Stereo Clips.” The exact names are not important, but the way the media is organized is.
2. Import all left-eye media into the “Left” bin, and all right-eye media into the “Right” bin. If you’re importing stereoscopic Cineform media, you still need to create this kind of organization, which requires you to place duplicates of each clip into each of the “Left” and “Right” bins.

Step 2 – Generate 3D Stereo Clips

Once you've organized your media appropriately, you're set up to synchronize the left- and right-eye clips using timecode.



1 Create a new bin in the Media Pool, and name it "Stereo Clips." This is the bin that will eventually contain the linked stereo clips you're about to create.

How to organize media for working in stereo 3D

2 Right-click anywhere within the Media Pool and choose Stereo 3D Sync.

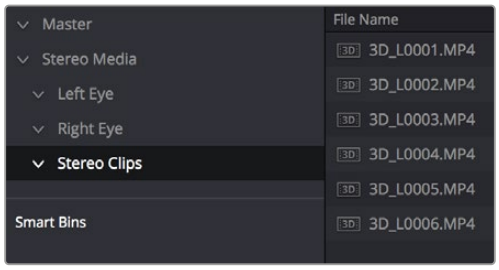
The Stereo 3D Sync dialog appears, with buttons for choosing the left-eye folder, choosing the right-eye folder, choosing the output folder, and checkboxes for specifying whether to match reel names and file names, and additional fields for entering characters that identify left- and right-eye clips.

The Stereo Media Sync window

3 Click the Browse button corresponding to "Choose left eye folder" and then use the hierarchical list of bins that appears to choose the bin you named "Left." Follow the same procedure to choose the right-eye media.

4 Click the Browse button corresponding to "Output folder" and then use the hierarchical list of bins that appears to choose the bin you named "Stereo Clips."

5 Choose which matching criteria to use. Ideally, you only need to use whichever one of the three criteria that apply. The three options are:



Match Reel Name: If the reel names of the left- and right-eye media match, turn this checkbox on.

Match File Name checkbox: If the file names of the left- and right-eye media match, turn this checkbox on.

Left Identifiers and Right Identifiers fields: If the left- and right-eye clips are identified by a special subset of characters within the file name (for example, "3D_R" and "3D_L"), then you can type each into the appropriate field, and these characters will be used to match the left and right eyes together.

6 Click Sync.

The original clips in the Left and Right bins disappear, and a full set of Stereo 3D clips appear in the output bin you selected in step four.

Final stereo clips, ready to be edited and graded

Step 3 – (Optional) Create Optimized Media

If your stereo media is excessively large, you can create optimized media.

1 Select the stereo clips you've created.

2 Right-click one of the selected clips, and choose Generate Optimized Media from the contextual menu. A window appears showing you ho.w long it will take to finish creating optimized media.

Monitoring Stereoscopic 3D in the Edit Page

You can now view a Stereoscopic 3D signal directly from the Edit page. Previously, the Edit page was restricted to left eye for video output monitoring. The Edit Page Viewer itself still shows only a single eye, but it now displays Stereoscopic 3D video from the Decklink or Ultrastudio video outputs. The 3D palette in the Color page has the stereoscopic controls to select the stereo viewing options (Side by Side, Anaglyph, Line by Line, etc.), as well as adjusting the convergence and other stereoscopic parameters.

Converting Clips Between Stereo and Mono

You also have the option of converting clips between mono and stereo 3D using a pair of commands in the Media Pool.

Converting Stereo Clips Back to Mono

If necessary, you can split one or more stereo clips into mono clips using a single command.

To convert stereo clips into mono clips:

1 Select one or more stereo clips in the Media Pool.

2 Right-click one of the selected clips and choose Split Stereo 3D Clips from the contextual menu.

Afterwards, two new bins are created named Left and Right, containing the individual left- and right-eye clips that you've split apart.

Converting Mono Clips or an Entire Timeline to Stereo

Non-stereo clips (for which there are not separate left- and right-eye media files) can be converted into stereo clips either individually or throughout an entire timeline for one of two different reasons:

- You can convert non-stereo clips into stereo for use in a stereo project, so they output properly along with the rest of a stereo timeline, albeit without adjustable convergence or depth effects.
- If you want to grade an HDR and non-HDR version of your program at the same time, converting non-stereo clips to stereo makes it possible for you to a) manage two separate SDR and HDR grades for each clip in a timeline using the left- and right-eye channels, and b) output the SDR and HDR signals separately via your compatible Blackmagic Design interface's left- and right-eye SDI outputs when you turn on the "Use dual outputs on SDI" checkbox in the Video Monitoring section of the Master Settings panel of the Project Settings.

To convert mono clips into stereo clips:

1. Select one or more non-stereo clips in the Media Pool.
2. Right-click one of the selected clips and choose Convert to Stereo from the contextual menu.

Afterwards, that clip appears in the Media Pool as a Stereo 3D clip, and when edited into a timeline, can expose its controls in the 3D Stereo palette in the Color page.

If you have a timeline full of clips that you've just converted into stereo using the above procedure, you need to take the additional step of setting the Timeline to stereo in order to create stereo grades for each clip.

To convert a timeline to have stereo grades for simultaneous HDR/SDR output while grading:

- Right-click a timeline in the Media Pool and choose Timelines > Set Timeline to Stereo.

For more information about using stereo timeline workflows for simultaneous HDR and SDR grading, jump to this chapter: Data Levels, Color Management, and ACES .

Attaching Mattes to Stereo 3D Clips

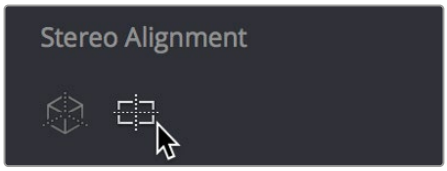
If you have left- and right-eye mattes that need to be attached to stereo clips, the process works identically to importing mattes for regular clips, except that when you've selected a stereo 3D clip in the Media Pool, you have two matte import commands, "Add As Left Eye Matte," and "Add As Right Eye Matte."

Organizing and Grading Stereo 3D Dailies

A common workflow is the creation of digital dailies within DaVinci Resolve before editing in an NLE. This provides the editors, director, and producers with the advantage of having more attractive media to work with, that's also more comfortable to view if handled with the automatic geometry and color-matching functions that match the media of each pair of shots together for a preliminary left- and right-eye balance. The resulting Timelines can then be output to whichever media format is most convenient to use.

Step 1 – Create 3D Stereo Clips

The very first step in the process of creating dailies is to import all of the left-eye and right-eye media into individually organized bins, and to then link them together to create stereo 3D clips, as described in the previous section.



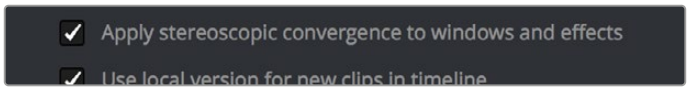
Step 2 – Edit the New Stereo Clips Into One or More Timelines for Grading

Now that you've created a set of Stereo 3D clips, you're ready to edit them into one or more Timelines for grading. You can do this by simply creating a new Timeline and deselect the Empty Timeline checkbox. A new Timeline will be created with the stereo 3D clips you created.

Step 3 – Align Your Media

For the stereoscopic effect to work without causing headaches, it's critical that both eyes are aligned. This can be tricky to adjust using manual controls, but is something that can be automatically analyzed. You can perform stereo 3D alignment to a single clip using the Stereo 3D Palette controls, or you can select a range of clips to align all of them automatically at once. There are two methods of alignment; which is more appropriate depends on the type of geometry issues you have to address.

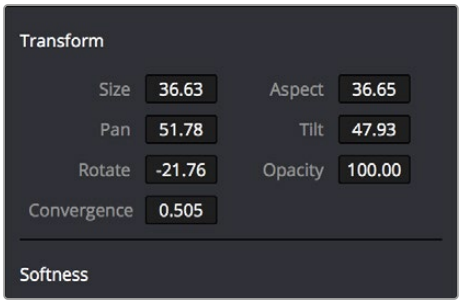
- **Transform Alignment:** Analyzes the image and makes vertical and rotational adjustments to line up the left- and right-eye images as closely as possible.
- **Vertical Skew:** Analyzes the images and makes a vertical-only adjustment to line up the left- and right-eye images.



Controls for aligning the left- and right-eye media

Step 4 – Grading Stereo Media

Grade the clips in the Timeline as you would any other digital dailies, with the sole addition of using the controls in the Stereo 3D palette to control monitoring and manage the adjustments made to each eye as necessary. The currently selected eye will be reflected in the video scopes. As when creating any other kind of dailies, you can use LUTs, the Timeline Grade, and individual clip grading to make whatever adjustments are necessary to create useful media for editing.



Grading Windows

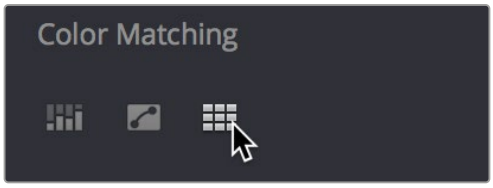
If you're using windows, The Color group of the General Options panel of the Project Settings has a checkbox called "Apply stereoscopic convergence to windows and effects" that correctly maintains the position of a window that's been properly placed over each eye when convergence is adjusted.

You must turn on a checkbox in the Project Settings to enable stereo convergence for windows

When this option is enabled, the Window palette displays an additional Transform parameter, "Convergence," that lets you create properly aligned convergence for a window placed onto a stereoscopic 3D clip.

The Convergence control in the Transform section of the Window palette

After placing a window over a feature within the image while monitoring one eye, you can enable Stereo output in the Stereo 3D palette and use the Pan and Convergence controls to make sure that window is properly stereo-aligned over the same feature in both eyes. At that point, adjusting the Convergence control in the Stereo 3D palette correctly maintains the position of the window within the grade of each eye.



A convergence-adjusted window in stereo

Matching Media From Left and Right Eyes

To help you manage the visual differences between left- and right-eye clips, there are also three automatic color matching commands that can be used to batch process as many clips as you need to adjust at once.

- **Stereo Color Match (Primary Controls):** Uses the Lift/Gamma/Gain controls to match one eye to the other. The result is a simple adjustment that's easy to customize, but may not work as well as Custom Curves in some instances.
- **Stereo Color Match (Custom Curves):** Uses the Custom Curves to create a multipoint adjustment to match one eye to the other. Can be more effective with challenging shots.
- **Stereo Color Match (Dense Color Match):** Performs a pixel by pixel, frame by frame color match that is incredibly accurate. This operation is processor intensive, so if you're going to batch process many clips, or if you're matching long clips, you'll want to make sure you have adequate time. Because this is such a precise match, it's recommended to use Dense Color Match after you've used one of the stereo alignment commands.

Controls for matching the grade of the left and right eye media

Step 5 – Output Offline or Online Media for Editing

When you're done applying whatever grading is necessary to make the media suitable for editing, you'll need to export each clip as separate left- and right-eye clips using the controls of the Deliver page.

1. Open the Deliver page, and set up your render to output the format of media you require. Be sure to do the following:
   - — Set Render Timeline As to Individual source clips.
   - — Turn on the "Filename uses Source Name" checkbox.
   - — To render both eyes' worth of media, choose "Both eyes as" from the Render Stereoscopic 3D option, and choose Separate Files from the accompanying pop-up menu. Optionally, you could also choose to render only the left-eye or right-eye media.
2. Choose how much of the Timeline to render from the Render pop-up menu in the Timeline toolbar; to render everything, choose Entire Timeline.
3. Click "Add Job to Render Queue."
4. Click Start Render.

DaVinci Resolve will now render either two sets of left- and right-eye clips, or one set of media corresponding to the eye you chose.

To make sure that the resulting edited project conforms easily to the originating DaVinci Resolve project, it's important to be sure that you render individual source clips, and that you turn on the "Filename user Source Name" checkbox, in order to clone the timecode, reel numbers, and file names of the source media.

Conforming Projects to Stereo 3D Media

Since DaVinci Resolve manages stereo via a single set of specially created stereo 3D clips, you can use the same project import methods to import stereo 3D projects as you would for any other project. Only a single imported timeline is necessary.

This also means that you can edit stereo projects in NLEs that aren't otherwise stereo-aware, and finish them in full stereo 3D in DaVinci Resolve. To do this, you need to make sure that you edit the left-eye media in your NLE, and then export either an EDL or XML file to conform in DaVinci Resolve.

To conform an EDL to stereo 3D media:

1. Open the Media page, and create the necessary set of stereo 3D clips that will correspond to the project you're going to import, as described previously.

   Open the Edit page, and then use the Import AAF/EDL/XML command to import your edit.

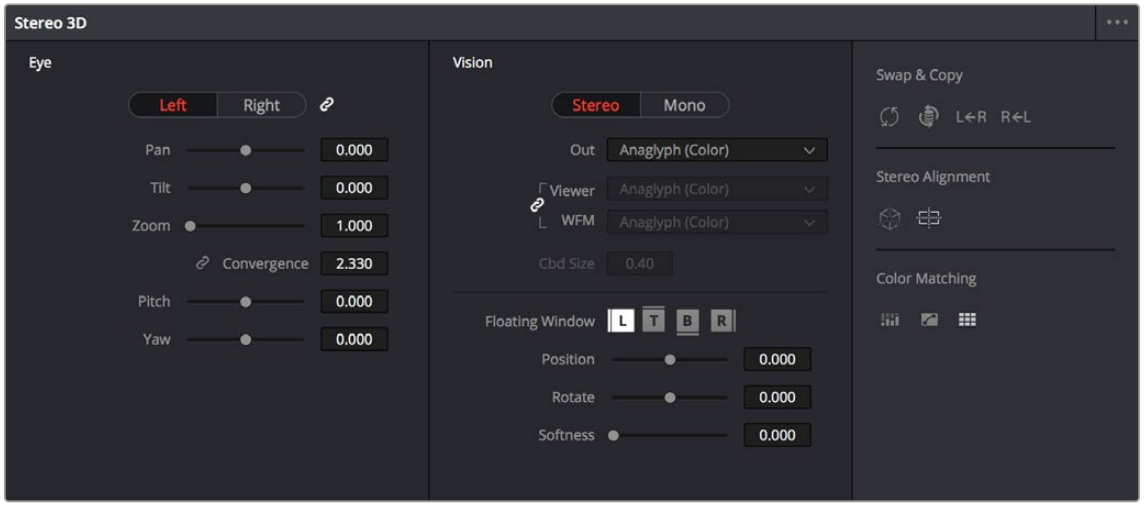
2. When the Load EDL/XML dialog appears, do the following:

   — If importing an EDL, verify that the frame rate is correct, and click OK.

   — If importing XML, make sure you turn off the "Automatically import source clips into Media Pool" checkbox, since you want to relink the imported project to the stereo 3D clips you created in step one.

   The left-eye media timecode and reel information that's embedded within each stereo 3D clip will be used to conform the stereo 3D clips with the imported EDL, and you should be ready to work.

Grading Mastered Stereoscopic Media From Tape



If you've been handed a stereo 3D muxed tape with a mastered program that needs to be graded, but you haven't been given a project file or EDL, you can ingest it as individual left- and right-eye media files with a supported VTR, such as HDCAM SR with 4:2:2 x 2 mode, by turning on the "Use left and right eye SDI" checkbox in the Capture and Playback panel of the Project Settings. When muxed stereoscopic signals are ingested, each eye is separated into individual left-eye and right-eye image files

Once ingested, you can use Scene Detection to split the left-eye media in one bin, and to create an EDL, you can use to split the right-eye media in the same way in another bin, so that you can create a sequential set of stereo clips for grading.

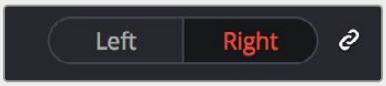
Adjusting Clips Using the Stereo 3D Palette

Once you've either created or imported a stereoscopic 3D-identified timeline, you're ready to begin grading. The left eye will be displayed in the Edit and Color pages by default; however, you can right-click on the Timeline and select Stereo 3D Mode to view the other eye. Most colorists work by grading one eye first (typically the left), and rippling their grades to the other eye, making separate adjustments to each eye's clips when necessary to match undesirable variation between cameras. DaVinci Resolve lets you do this automatically.

Setting up stereo 3D media enables the Stereo 3D palette on the Color page. This palette contains all the controls necessary for working on stereoscopic projects. It provides controls for choosing which eye to grade, adjusting convergence, swapping and copying grades and media between matching left- and right-eye clips, auto-processing the color and geometry of left- and right-eye clips to match, stereo 3D monitoring setup, and controls for floating windows.

Stereoscopic 3D palette

Your project must contain stereo 3D clips in order to open this palette.



For more information on setting up a stereo 3D project, jump to this chapter: Creating Stereo 3D Clips From Separate Files.

Stereo Eye Selection

Most colorists work by grading one eye first (typically the left), and rippling their grades to the other eye, making separate adjustments to each eye's clips when necessary to match undesirable variation between cameras.

The first three buttons in the Stereo 3D palette let you choose which eye to grade while you're working, as well as whether or not to ripple each clip's grade to the matching opposite-eye clip. Whenever you switch eyes, the 3D badge above each clip's thumbnail changes color (blue for right, red for left) and the thumbnails themselves update to show that eye's media.

- **Left button:** Displays the left-eye image and grade.
- **Ripple Link button:** When enabled (orange), all changes you make to the grade of the currently selected eye are automatically copied to the correspondingly opposite eye. When disabled (gray), grades made to the currently selected eye are made independently.
- **Right button:** Displays the right-eye image and grade.

The Left eye is master and ganged with the Right

You can also choose which eye you're viewing and grading by right-clicking a clip's thumbnail and choosing Stereo 3D > Switch Eye or by choosing View > Switch Eye To > Left Eye or Right Eye.

Using Ripple Link When Grading Stereo 3D Clips

You would turn Ripple Link off to suspend rippling when you want to make an individual adjustment to the grade of one eye to obtain a better match between the two. When you're finished matching the two clips, you can turn it back on to resume automatic grade rippling.

Stereo 3D grade rippling is always relative, so differences between the grades that are applied to the left- and right-eye clips are preserved. In fact, when you add or remove nodes to or from one eye, the same nodes are automatically added to or removed from the corresponding clip it's paired with, regardless of whether or not Ripple Linked is enabled.

IMPORTANT: Regardless of whether or not Ripple Link is enabled, local versions created for one stereo 3D-identified clip are automatically available to the paired timeline.

Stereo 3D Geometry Controls

The next group of parameters lets you adjust the geometry of stereo 3D clips. The Pan, Tilt, and Zoom controls are provided as a convenience, and simply mirror the same parameters found in the Transform palette's Input mode, but made specific to the geometry of the left- and right-eye media. Convergence, Pitch, and Yaw are the three parameters that are unique to the Stereo 3D palette.

Stereoscopic 3D Geometry controls

- **Convergence:** Adjusts the disparity between the left and right eyes, to define the point of convergence (POC), or the region within the image where the left- and right-eye features are in perfect alignment. If necessary, Convergence can be animated using the Stereo Format parameter group in the Sizing track of the Keyframe Editor. If you want to adjust convergence in pixels, open the Stereo 3D palette option menu, and turn on "Show convergence in pixels."

  Features that overlap perfectly in both right- and left-eye clips are at zero parallax, putting that feature's depth at the screen plane. Matching features that are divergent in the left- and right-eye clips have increasingly positive parallax, and appear to be farther away from the audience. Matching features that are divergent and reversed in the left- and right-eye clips have increasingly negative parallax, and appear to be closer to the audience than the screen plane.
- **Linked Zoom button:** When enabled (white), both the left- and right-eye clips are automatically zoomed whenever Convergence is adjusted so that both eyes always fill the screen. When disabled (gray), changes to Convergence will cause the opposing left and right edges of each eye's clip to have blanking intrude.
- **Pitch:** Pivots the image around the horizontal center plane of the frame.
- **Yaw:** Pivots the image around the vertical center plane of the frame.

Sizing Repositioning in Stereo 3D

Generally, you'll want to reposition stereo 3D clips with Ripple Link turned on, but you may occasionally find yourself needing to make a manual adjustment to one eye in particular with Ripple Link disabled. As with color adjustments, Sizing adjustments made with Ripple Link disabled are only applied to the clip in the current Timeline. When Ripple Link is turned on, all Sizing adjustments are automatically copied to the correspondingly numbered shot of the other stereo 3D timeline.

WARNING: It is not advisable to use the Rotate parameter when transforming stereo 3D clips. Geometrically, rotation tilts a stereo pair of clips inappropriately, and ruins the "side by side" convergence that's necessary to create the stereoscopic illusion.

Protecting Stereo Adjustments When Copying Grades

Each version of a grade has independent stereo adjustments stored along with the Sizing settings. To prevent accidental overwrite of convergence and alignment data when copying grades from one clip to another, you can right-click within the Gallery and choose one of the following options to turn them on:

- **Copy Grade:** Preserve Convergence
- **Copy Grade:** Preserve Floating Windows
- **Copy Grade:** Preserve Auto Align

When enabled, these options let you overwrite a clip's grade without overwriting specific Stereo 3D parameters.

TIP: Stereo 3D and Sizing settings are processed before node-based corrections in the DaVinci Resolve image processing pipeline.

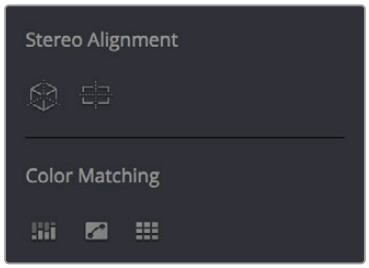
Swap and Copy Controls

Another set of controls at the right of the Stereo 3D palette lets you swap and copy grades, and swap clips, in situations where you need to reverse what's applied to a pair of left- and right-eye clips.

Swap and Copy grades between eyes

- **Swap Grade:** Exchanges the grades that are applied to the left- and right-eye clips.
- **Swap Shot:** A checkbox that, when enabled, switches the actual media used by two corresponding left- and right-eye clips. Useful in situations where the eyes of a stereo 3D clip were mislabeled, and you want to switch the clips without rebuilding both EDLs.
- **Copy Right to Left:** Copies the right-clip grade to the corresponding left-eye clip.
- **Copy Left to Right:** Copies the left-clip grade to the corresponding right-eye clip.

Batch Grade Management for Stereo 3D Projects



There are also a series of batch-processing commands that are useful for stereoscopic grading that are available when you right-click one or more selected clips in the Thumbnail timeline:

- **Stereo 3D Batch Copy:** Copies every grade from the left-eye clips to the right-eye clips.
- **Stereo 3D Batch Sync:** Copies grades from one eye to the other only when their node graphs have the same number of nodes. This prevents you from accidentally overwriting a custom grade with a different node structure that was necessary to match two eyes for a problem shot.

The Copy Grade, Swap Grade, Swap Shots, Ripple Link, and Switch Eye commands are also available from the Stereo submenu of the Timeline contextual menu.

Automatic Image Processing for Stereo 3D

It's common during stereoscopic shoots for minor divergences in geometry and color to appear in the source footage. To make the process of grading stereo 3D media less onerous, DaVinci Resolve provides a set of auto-adjustment controls at the right of the Stereo 3D palette that gives you a starting point for matching left- and right-eye clips together.

Auto align and color match buttons

Options for Auto Processing

You can choose which frame should be used to automatically analyze and process stereo clips using the Alignment and Matching controls from the Stereo 3D palette option menu. You can choose Auto Process > First or Middle, depending on what works best for your media.

Auto Process—Stereo Alignment

For the stereoscopic effect to work without causing headaches, it's critical that both eyes are aligned. This can be tricky to adjust using manual controls, but is something that can be automatically analyzed. You can perform stereo 3D alignment to a single clip, or you can select a range of clips to align all of them automatically at once. There are two options. Which is more appropriate depends on the type of geometry issues you're needing to address.

- **Transform Alignment:** Analyzes the image and makes vertical and rotational adjustments to line up the left- and right-eye images as closely as possible.
- **Vertical Skew:** Analyzes the images and makes a vertical-only adjustment to line up the left- and right-eye images.

To align one or more clips automatically:

1. Select one or more stereo clips in the Thumbnail timeline of the Color page.
2. Choose which frame of each clip you want to use for the analysis by opening the Stereo 3D palette, clicking the Option menu, and choosing Auto Process > First or Auto Process > Middle.
3. Click either of the Stereo Alignment buttons. The button to the left is for Automatic Transform, while the button to the right is for Automatic Vertical Skew.

   If you selected multiple clips, then the Stereo Alignment window appears, and a progress bar shows the remaining time this operation will take.

Auto Process—Color Matching

Due to the design of different stereo 3D rigs, sometimes the color and contrast of one eye's media doesn't precisely match that of the corresponding eye. DaVinci Resolve provides two commands for quickly and automatically matching two eyes together.

- **Stereo Color Match (Primary Controls):** Uses the Lift/Gamma/Gain controls to match one eye to the other. The result is a simple adjustment that's easy to customize, but may not work as well as Custom Curves in some instances.
- **Stereo Color Match (Custom Curves):** Uses the Custom Curves to create a multipoint adjustment to match one eye to the other. The result can be more effective with challenging shots.
- **Stereo Color Match (Dense Color Match):** Performs a pixel by pixel, frame by frame color match that is incredibly accurate. This operation is processor intensive, so if you're going to batch process many clips, or if you're matching long clips, you'll want to make sure you have adequate time. Because this is so precise match, it's recommended to use Dense Color Match after you've used one of the stereo alignment commands.

TIP: For the best results, it's recommended to use automatic color matching in a separate node, independent of other corrections.

Stereo 3D color match works differently depending on whether or not one of the stereo 3D-paired clips has already been graded. The following procedure shows how to match a pair of left- and right-eye clips before you make any manual adjustments of any kind.

To match a pair of left- and right-eye clips automatically:

1. Select one or more clips in the Thumbnail timeline of the Color page.
2. Open the Stereo 3D palette, and click one of the three Color Match controls.

The Color Matching window appears, and a progress bar shows the remaining time this operation will take. You can also use automatic color matching to match an ungraded clip to a paired clip that's already been graded. This only works for grades consisting of one or more primary corrections; secondary corrections cannot be auto-matched.

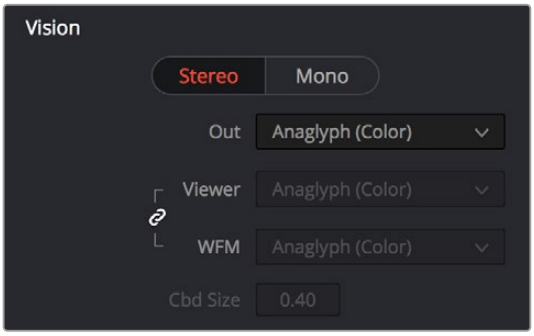
To match an ungraded clip automatically to a paired stereo clip that's graded:

1. To suspend stereo grade linking temporarily:
   - — Open the Stereo 3D palette, and turn off the Ripple Link button.
   - — Right-click the Thumbnail timeline, and choose Stereo 3D > Ripple Link > Solo.
2. Make a primary adjustment to a clip in the left-eye timeline to create a simple base grade. The left-eye clip now has a grade, and the right-eye clip does not.

3 Do one of the following to switch eyes:

— In the Stereo 3D palette, click Right.

— Right-click the Thumbnail timeline again, and choose Stereo 3D > Switch Eye.



This procedure only works when you use the Stereo Color Match commands on the ungraded clip of a left- and right-eye stereo pair, to match it to the graded clip.

4 To make the match, do the following:

In the Stereo 3D palette, click one of the three color match controls. Both clips should match one another very closely.

Stereo 3D Monitoring Controls

To output both eyes to a stereo 3D display, you need to click the Vision: Mono or Stereo button, and then choose a display mode from the Out pop-up menu.

Monitoring controls for Stereo 3D

- **Vision:** Click a button to choose between Stereo, where both eyes can be displayed in the Viewer and output to video in a variety of different formats, and Mono, where only one eye is monitored in the Viewer and your video output interface.
- **Out:** A pop-up menu that provides different stereo viewing options for previewing stereo 3D signals in different ways. By default, this option is also linked to the Viewer display Internal Video Scope options. For detailed descriptions of each stereo 3D viewing mode, see the following section, “Stereo 3D Output Options.”
- **Link button:** When enabled, the Viewer and internal video scopes both use the Out pop-up menu’s option for stereo 3D viewing. When disabled, you can choose different stereo 3D viewing options for the Viewer and internal video scopes.
- **Viewer:** Lets you choose a stereo 3D viewing option for the Viewer.
- **WFM:** Lets you choose a stereo 3D viewing option for the internal video scopes.
- **Cbd Size:** If any stereo 3D viewing options are set to Checkerboard, this parameter becomes enabled, and lets you define the size of the checkerboard boxes, in pixels.

  Dual 4:2:2 Y’CbCr stereoscopic video streams are output via HD-SDI on selected Blackmagic I/O devices when you turn on the ”Use left and right eye SDI output” checkbox on the Master Settings panel of the Project Settings. You can select either Side-by-Side or Line-by-Line output to be fed to your stereo-capable display, depending on your display’s compatibility.

Stereo 3D Output Options

Additionally, the Viewer and video scopes can be set to display both “eyes” in one of a variety of different modes.

- **Side by Side:** Displays both images side by side. Each eye is squeezed anamorphically to fit both eyes into the same resolution as the GUI viewer.
- **Top and Bottom:** Displays both images one over the other. Each eye is squeezed vertically to fit both eyes into the same resolution as the GUI viewer.
- **Line by Line (Even/Odd):** An interlaced mode where each eye is displayed on alternating lines. The thickness of the lines as seen in the Viewer depends on how zoomed in you are.
- **Checkerboard:** Displays both eyes via an alternating checkerboard pattern. This is an excellent mode for identifying regions of the image where there’s variation in color or geometry between the two eyes.
- **Anaglyph (B/W):** Each eye is desaturated and superimposed via Red/Cyan anaglyph to show the disparity between both eyes in different regions of the image. Left-eye divergence is red, and right-eye divergence is cyan. Regions of alignment between both eyes appear grayscale.

  Anaglyph modes are useful for evaluating the geometric differences between both eyes, as well as for identifying the point of convergence (where both eyes align most perfectly) that places a region of the image at the screen plane.

  Red/cyan color coding also identifies the direction of parallax. For any given feature, disparity such that red is to the right and cyan is to the left indicates positive parallax (backward projection away from the audience). Red to the left and cyan to the right indicates negative parallax (forward projection towards the audience).
- **Anaglyph (Color):** Similar to Anaglyph (B/W), except that regions of close alignment are shown in full color. Incidentally, both anaglyph modes can be previewed on ordinary displays using old-fashioned red/cyan anaglyph glasses, enabling stereo 3D monitoring on non-stereo 3D-capable displays.
- **Difference:** Superimposes grayscale versions of both eyes using the difference composite mode. Corresponding left/right-eye pixels that are perfectly aligned appear black, while pixels with disparity appear white. This mode is extremely useful for evaluating geometric differences between both eyes, as well as for identifying the point of convergence, without the distraction of color that the anaglyph modes present.

NOTE: Only displays the eye corresponding to the currently selected timeline in the Viewer. However, this option also works in conjunction with the “Use Dual Outputs on SDI” checkbox in the Master Settings of the Project Settings which, when turned on, outputs each eye to an individual HD-SDI output of your Blackmagic I/O card.

The Viewer set to display an anaglyph stereo image in color

Floating Windows

Floating Windows are meant to correct for “Window violations,” where elements of the image with negative parallax, that project forward from the screen plane towards the audience, are cut off by the edge of the frame. In these instances, differences between the images being shown to the left and right eyes can result in a visual paradox that’s difficult for viewers to reconcile. Specifically, when a forward-projecting element is cut off by the left or right edge of the frame, one eye sees things that the other eye does not.

If the subject is moving quickly, this may not be an issue, but if the cut off (or occluded) element lingers onscreen, it causes problems for viewers that defeat the stereo 3D illusion. The viewer’s binocular vision (or stereopsis) is providing one depth cue, while occlusion is providing a completely different depth cue.

To fix this, you can use Floating Windows to crop the cut off object from the eye on the side of the object that’s cut off, thus eliminating the portion of the stereo image that is unseen to the other eye that causes the problem.

Floating Window controls

The objective of using Floating Windows is to manipulate the illusion of the viewer’s “window into the scene.” In addition to fixing Window violations, it has been proposed that Floating Windows can be used as a creative tool by manipulating the geometry of this Window to alter subtly the viewer’s perception of the screen orientation.

- By cropping the right-hand side of the right-eye frame, you also create the illusion that the right edge of the “window into the image” is tilted farther forward toward the viewer.
- By cropping the left-hand side of the left-eye frame, you create the illusion that the left edge of the Window is tilted toward the viewer.
- If you crop both the left-hand side of the left-eye frame and the right-hand side of the right-eye frame, you create the illusion that the entire plane of the “virtual screen” is coming toward you.
- If you apply opposite-angled Windows to the left- and right-eye clips at one or both of the edges of the frame, it appears to “tilt” the screen toward or away from the viewer.

Animating Floating Windows

Floating Windows can be animated using the Float Window keyframing track, found within the Sizing track of the Keyframe Editor, to push the edge of the frame in as needed, and then pull it back out when the partially occluded subject has moved fully into the frame.

For more information about animating keyframing tracks, jump to this chapter: Keyframing in the Color Page.

Floating Windows have the following controls and parameters.

- **L/R/T/B buttons:** Lets you choose an edge to which to apply a Floating Window. Click the button corresponding to the edge you want to adjust. Each edge has its own position, rotate, and softness settings.
- **Position:** Adds masking to the currently selected edge.
- **Rotate:** Rotates the currently selected edge, letting you create an angled Window.
- **Softness:** Feathers the edge of the currently selected edge, letting you create a soft Window that can be less noticeable to viewers.

To add a Floating Window to fix a Window violation:

1. Choose to which eye you want to add the Floating Window.
   - To apply a Floating Window to eliminate a Window violation on the right-hand side of the screen, click the right eye view.
   - To apply a Floating Window to eliminate a Window violation on the left-hand side of the screen, click the left eye view.
2. Choose which edge you want to adjust by clicking the L or R buttons.
   - To eliminate a Window violation on the right-hand side, click R.
   - To eliminate a Window violation on the left-hand side, click L.
3. Adjust the Position parameter as necessary to crop the portion along the edge of the selected eye that's not visible in the other.
4. Optionally, if you feel that the Window adjustment you've just made is too obvious, increase the Softness parameter to make that edge less noticeable.

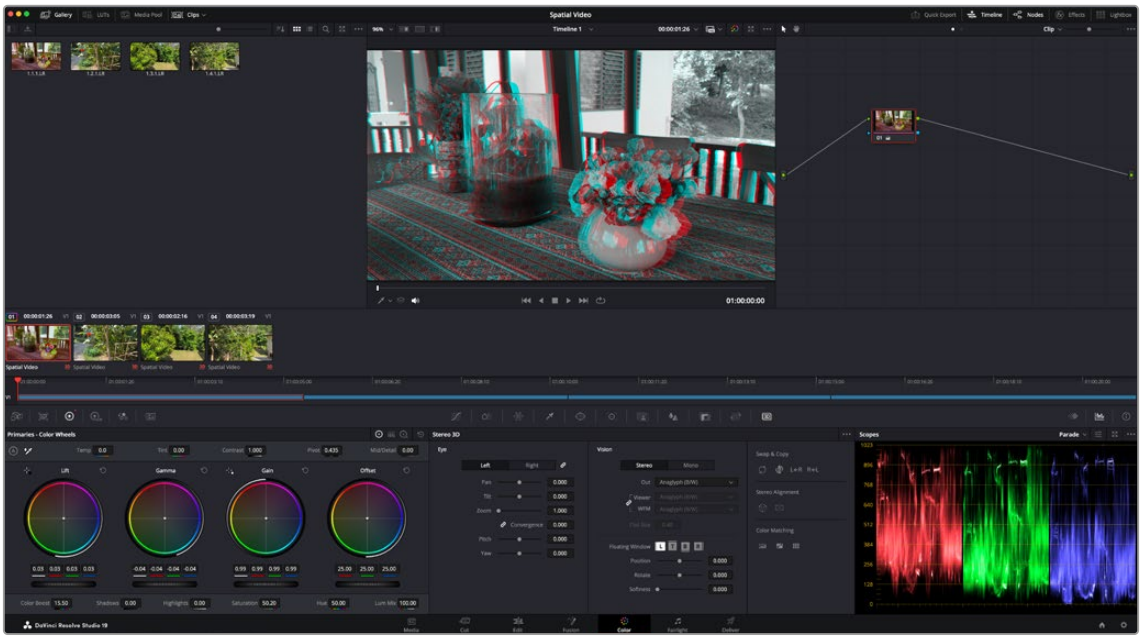
Outputting Stereo 3D Media in the Deliver Page

To render full frame media, you'll need to render each stereo 3D eye separately using the controls of the Deliver page, outputting whatever media format is required by the client.

Rendering Frame-Compatible Media

Frame-compatible media has both the left- and right-eye images squeezed anamorphically into a single media file. To create frame-compatible media, choose the "Both eyes as" option from the Render Stereoscopic 3D controls at the bottom of the File output options of the Deliver page, and then choose a method of output from the Mesh Options pop-up menu.

Stereoscopic 3D mesh render options on the Deliver page



You can choose Side-by-Side, Line-by-Line, or Top-Bottom. You can also choose Anaglyph if you want to output a traditional anaglyph red/cyan stereo 3D image for viewing on any display.

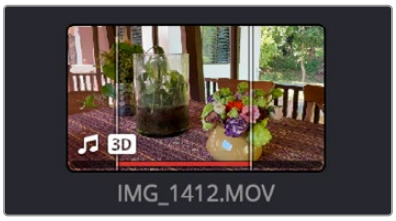
Rendering Individual Left- and Right-Eye Clips

If your workflow requires you to deliver separate sets of left- and right-eye media, this is easily accomplished by either setting up a render job with “Render Stereoscopic 3D” set to either “Right eye” or “Left eye,” or selecting “Both eyes as” and choosing the “Separate files” option.

Apple Spatial Video (MacOS Only)

Recent models of Apple iPhone have a Spatial Video mode that creates 3D videos designed to be viewed in a VR headset. These spatial videos are automatically recognized by DaVinci Resolve and allow you to use all of DaVinci Resolve’s features, including the full 3D toolset described above.

Grading an Apple Spatial Video in the Color page using Anaglyph (B/W) mode (not pictured: goofy 3D glasses on the colorist)



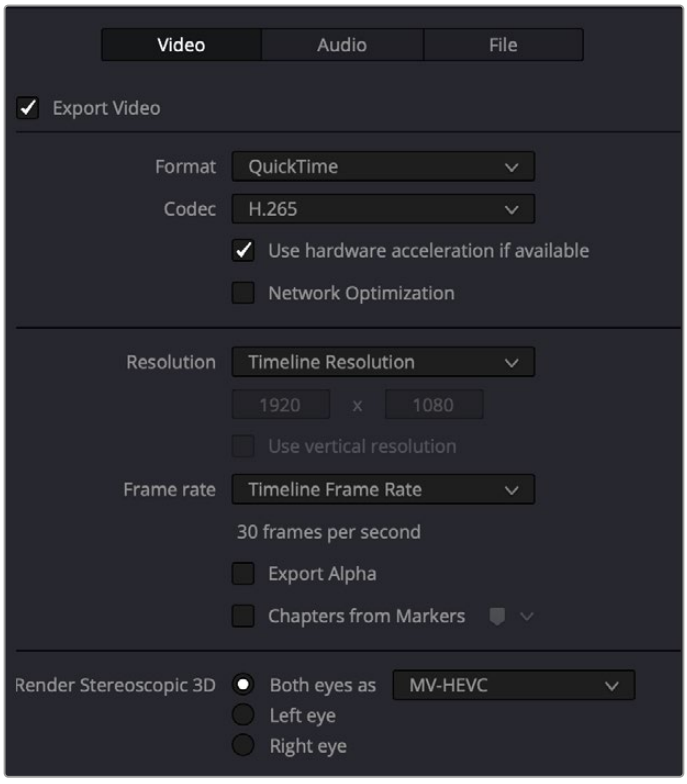
Using Apple Spatial Video in DaVinci Resolve

Spatial Video footage recorded on an iPhone is easily transferred into DaVinci Resolve but is only available on the MacOS version.

To import iPhone Spatial Video footage into DaVinci Resolve:

1. On your iPhone, the camera mode must be turned to Spatial Video (not photo) before you record the video.
2. Once the video is finished, find the video in the Photos app and press the Share icon.
3. Now export the spatial video via AirDrop or other method to your computer.
4. Open DaVinci Resolve and import the spatial video clips into the Media Pool as normal.
5. Properly imported spatial video clips will have a 3D icon automatically applied to their thumbnails.

Once imported, you can edit, color, audio mix, and create visual effects using all of DaVinci Resolve's toolset, just as if it were normal 3D footage.



Spatial Video clips imported correctly should have a 3D icon applied on their thumbnails.

Tips for using Apple Spatial Video in DaVinci Resolve:

- Currently Apple Spatial Video is required to be 1080p at 30fps. Ensure your project settings match this.
- In the 3D tools in the Color page, make sure that the Left/Right eyes and Convergence are linked.

When exporting a Spatial Video for playback in various VR headsets, the Deliver page Video Settings should be:

- **Format:** QuickTime
- **Codec:** H.265
- **Render Stereoscopic 3D:** Both eyes as: MV-HEVC

Spatial Video export settings

Chapter 15

Using Variables and Keywords

This chapter describes how to use metadata variables and keywords to help you manage your clips.

Using Metadata Variables 345
Where Variables Can Be Used 345
How to Edit Metadata Variables 345
Current Date and Time Metadata Variables 346
Using Keywords 347
Keyword Dictionary 348
Assign and Apply Favorite Keywords to Clips and Markers 350

Using Metadata Variables

If you're an enthusiastic user of clip metadata (and you should be), you can use "metadata variables" that you can add into supported text fields that let you reference other metadata for that clip. For example, you could add the combination of variables and text seen in the following screenshot. Variables, once they've been entered, are represented as graphical tags shown with a background, while regular text characters that you enter appear before and after these tags.

Variables and text characters entered to create a display name based on a clip's metadata

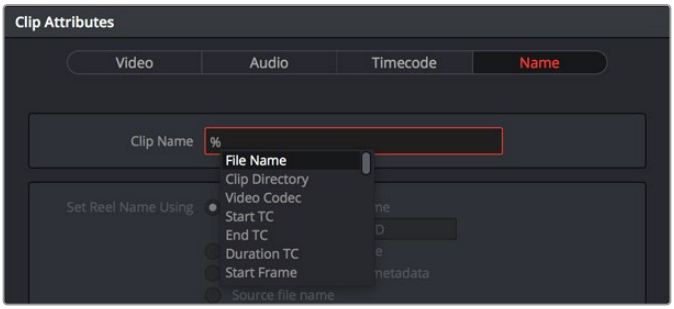
As a result, that clip would display "12_A_3" as its name if scene "12," shot "A," and take "3" were its metadata. When you do this, you can freely mix metadata variables with other characters (the underscore, as in the example above) to help format the metadata to make it even more readable.

Be aware that, for clips where a referenced metadata field is empty, no characters appear for that corresponding metadata variable's tag wherever it happens to be used.

Where Variables Can Be Used

Metadata variables are extremely flexible, and can be used to procedurally add metadata to several functions in DaVinci Resolve. Here's a partial list of where you can use variables.

- **Clip names:** You can use variables in the Clip Name column of the Media Pool in List view, or in the Clip Name field of the Clip Attributes window's Name panel, to use each clip's metadata to generate a more readable and useful display name.
- **Other metadata fields in the Metadata Editor:** You can use variables to reference metadata in other fields.
- **Automatic labeling of stills in the Gallery:** You can choose an option from the Color group in the General Options panel of the Project Settings to "Automatically label Gallery stills" in the Gallery, and you can use variables to do so.
- **Custom text in the Data Burn palette:** You can use variables to automatically populate metadata in different combinations as a window burn.
- **The Filename field of the Render Settings in the Deliver page:** Using variables, you can automatically set the name of rendered clips to follow any metadata that's associated with a timeline or individual clip. This is especially useful when you want to generate specific file names when rendering individual source clips.



How to Edit Metadata Variables

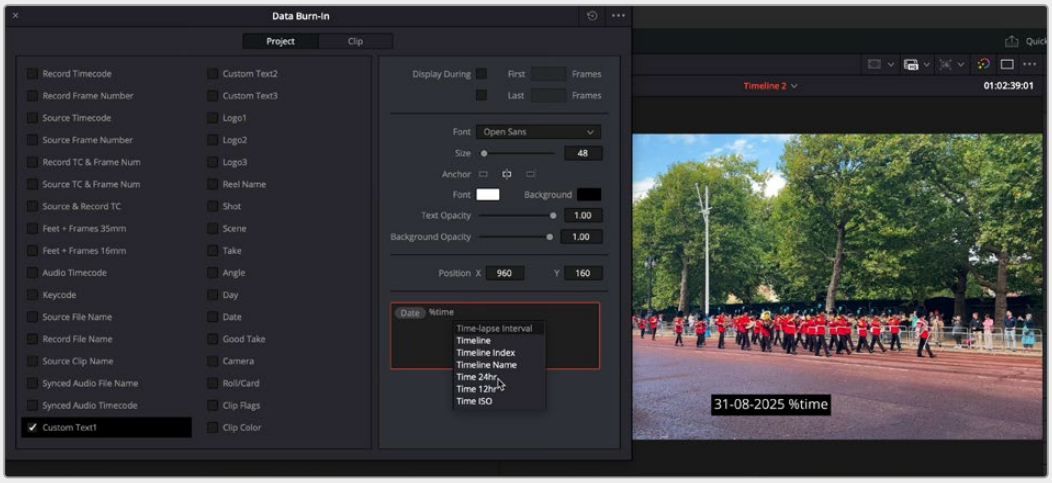
Every single item of metadata that's available in the Metadata Editor can be used as a variable, and several other clip and timeline properties such as the version name of a clip's grade, a clip's EDL event number, and that clip's timeline index number can be also referenced via variables.

To add a variable to a text field that supports the use of variables:

1. Type the percentage sign (%) and a scrolling list appears showing all variables that are available.
2. To find a specific variable quickly, start typing that variable's name and this list automatically filters itself to show only variables that contain the characters you've just typed.
3. Choose which variable you want to use using the Up and Down Arrow keys, and press Return to choose that variable to add.

As soon as you add one or more metadata variables to a field and press Return, the string is replaced by its corresponding text. To re-edit the metadata string, simply click within that field to edit it, and the metadata variables will reappear as the graphical tags that they are.

The variable list that appears when you type the % character



To remove a metadata variable:

- Click within a field using variables to begin editing it, click a variable to select it, and press Delete.

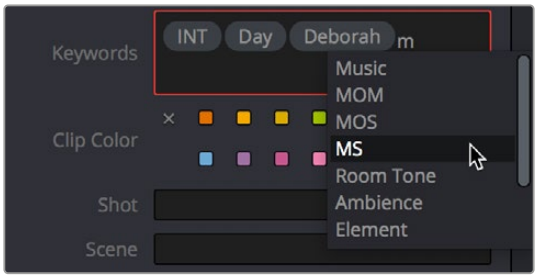
Current Date and Time Metadata Variables

You can use the current Date and Time as metadata variables in the Data-Burn-In window, and render paths for delivery. These variables represent the actual date and time as of the output, rather than the date and time a clip was shot.

- **Date Variable:** Enter %date in the appropriate field, and select either Date, Date ISO, or Date US formats.
- **Time Variable:** Enter %time in the appropriate field, and select either Time, Time 24, or Time ISO formats.

Using the Date and Time variables in the Data Burn-in Custom Text1 field

Using Keywords



While most metadata in the Metadata Editor is edited via text fields, checkboxes, or multiple button selections (such as Flags and Clip Color), the Keyword field is unique in that it uses a graphical “tag” based method of data entry. The purpose of this is to facilitate consistency with keyword spelling by making it easy to reference both a built-in list of standardized keywords, as well as other keywords that you’ve already entered to other clips.

Once added, keywords are incredibly useful for facilitating searching and sorting in the Media Pool, for creating Smart Bins in the Media and Edit pages, and for use in Smart Filters on the Color page. Reaping these benefits by adding and editing keywords is simple and works similarly to the method of entering metadata variables that’s described above.

To add a keyword:

1. Select one or more clips, then click in the Keyword field of the Metadata Editor, and begin typing the keyword you want to use. As you begin typing, a scrolling list appears showing all keywords that are available using the string of characters you’ve just typed.
2. To find a specific keyword in the list, start typing that keyword’s name and this list automatically filters itself to show only keywords that contain the characters you’ve just typed. Choose which keyword you want to use in the list using the Up and Down Arrow keys, and press Return to choose that keyword to add.
3. If you selected multiple clips, don’t forget to click Save or you’ll lose your changes. If you only selected a single clip, your changes will be saved automatically.

   As soon as you add one or more keywords, they appear as a graphical tag. To re-edit any keyword, simply click anywhere within the Keyword field to edit it.

The keyword list that appears when you type within the Keyword field

To edit a keyword:

- Double-click any keyword to make it editable, then edit it as you would any other piece of text, and press Return to make it a graphical keyword tag again.

To remove a keyword:

- Click any keyword to select it, and press Delete.

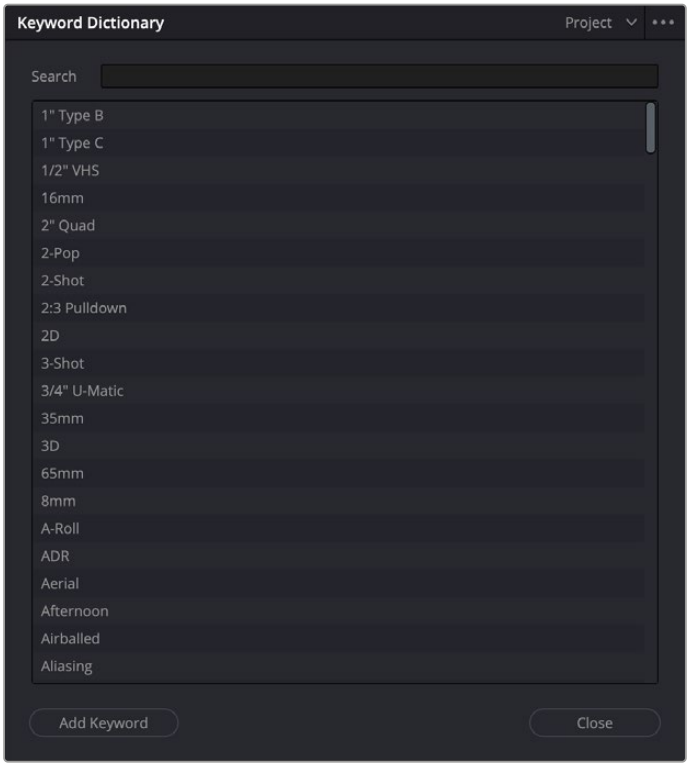
Keyword Dictionary

DaVinci Resolve comes with a suggested set of built in keywords, but by using the Keyword Dictionary, you can add a new set of keywords or delete previously entered keywords that no longer are applicable to your project.

- To access the Keyword Dictionary go to Workspace > Keyword Manager.

  The Keyword Dictionary presents a list of all currently suggested and assigned keywords, a search field, and the ability to add your own keywords to the list.

  Any keyword that you add will be added to both the Project and User keyword dictionaries.
- To switch between Keyword Dictionaries, select Project or User from the menu on the toolbar.



The User Dictionary

The User Dictionary shows keywords that will be remembered and suggested for autocomplete across all projects in this library. The User Dictionary is always based on the last inputs entered.

The Project Dictionary

The Project Dictionary shows keywords that will be remembered and suggested for autocomplete for only this project.

You can also Import and Export keywords in .txt format into and out of the Project Dictionary. This lets you prepare a list of custom keywords in any text editor and import them all at once into the Keyword Dictionary.

The Keyword Dictionary

To Import a .txt File into the Keyword Dictionary:

1. Create a plain text file (.txt) of your keywords, either one word per line or as comma-separated values.
2. In the Keyword Dictionary Option Menu (three dots), select Import Project Dictionary.
3. Navigate to your .txt file in the file browser and press Open.

You can also export any custom keywords in the Keyword Dictionary to a plain text file (.txt) of your keywords, one word per line.

To Export a .txt File from the Keyword Dictionary:

1. In the Keyword Dictionary Option Menu (three dots), select Export Project Dictionary.
2. Navigate to where to want your .txt file to be saved in the file browser and press Save.

You can add your own keywords, one at a time as needed, to the Keyword Dictionary.

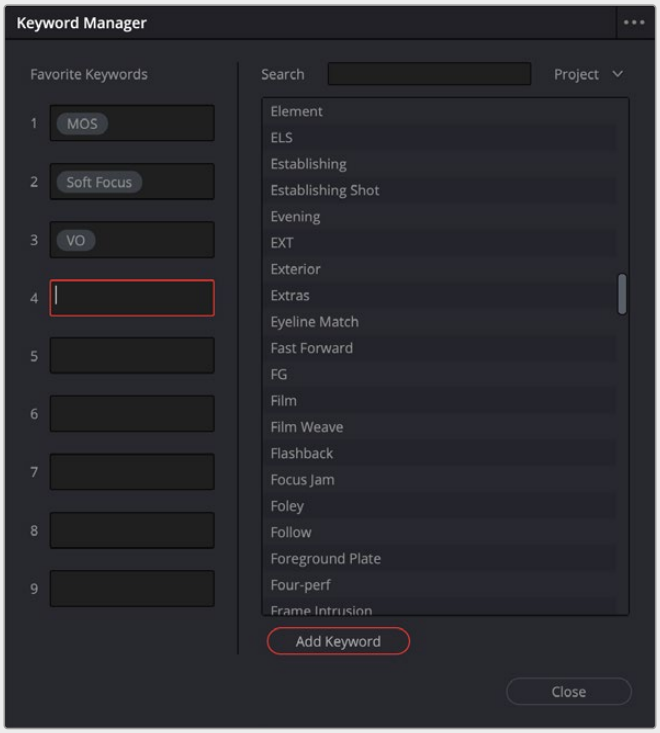
To Add a Keyword to the Keyword Dictionary:

1. Press the Add Keyword button.
2. Type in the new keyword into the text field and hit return.

The new keyword is initially added to the bottom of the Keyword list for easy access, but once the Keyword Dictionary has been closed and reopened, the new keyword will appear in alphabetical order.

You can also remove a keyword from the Keyword list if it is no longer applicable, or misspelled.

To Delete a Keyword from the Keyword Dictionary:



1. Hover the pointer over the keyword that you want to delete.
2. Press the trashcan icon to the right of the keyword.

The keyword will instantly be removed from the list, and this action is not undoable. Please note that the default keyword set that comes with DaVinci Resolve cannot be deleted.

Assign and Apply Favorite Keywords to Clips and Markers

You can now set up to nine keywords as favorites in the Keyword Manager in the Workspace menu. Simply type your new keyword in the slots on the left of the Keyword Manager to set them.

You can quickly assign these keywords to selected clips or in a marker window from the Mark > Favorite Keywords menu. Or even faster, use the default keyboard shortcuts Option-Shift 0 through 9. The same menu also has an action to clear all keywords from a clip or marker.

The nine Favorite Keywords slots in the Keyword Manager

Chapter 16

Using the Media Page

The Media page is the primary interface for media import and clip organization in DaVinci Resolve. It's also where all timelines that you edit in DaVinci Resolve or import from other applications are organized.

While timelines and clips are both saved in the Media Pool, it's central to the way DaVinci Resolve works that the source media used by a project is managed separately from your timelines. In this way, you can manage and update the clips used by timelines with ease, importing and reorganizing clips, switching between offline and online media, and troubleshooting any problems that occur.

The Media page also contains much of the core functionality used for on-set workflows, as well as most of the functions that are used in the ingest, organization, and sound-syncing procedures corresponding to digital dailies workflows.

Understanding the Media Page User Interface

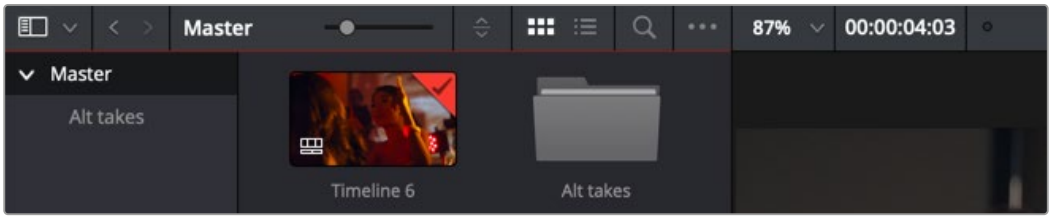
By default, the Media page is divided into five different areas, designed to make it easy to find, select, and work with media in your project.

The Media page.

Much of the functionality and most of the commands are found within the contextual menus that appear when you right-click clips in the Media Storage browser or Media Pool.

The Interface Toolbar

At the very top of the Media page is a toolbar with buttons that let you show and hide different parts of the user interface. These buttons are as follows, from left to right:

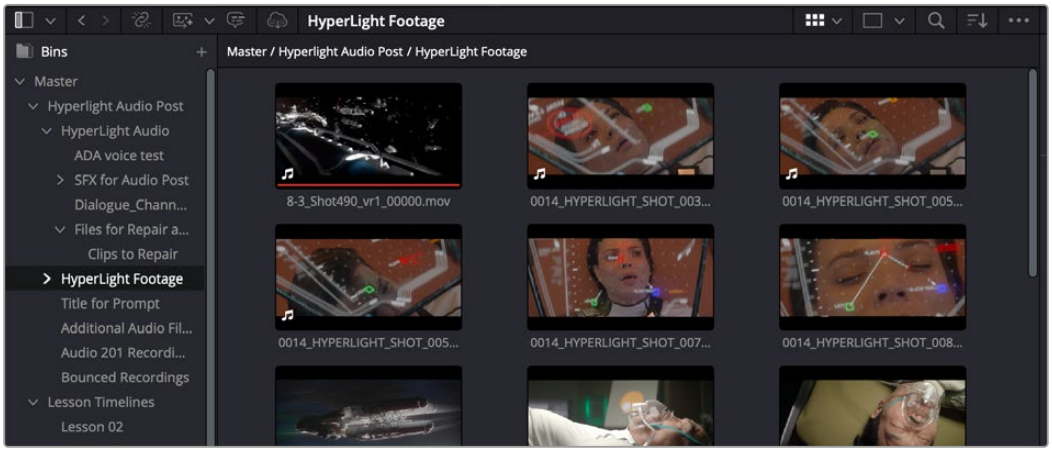


The Interface toolbar

- **Media Storage full/half height button:** Lets you set the Media Storage browser to take up the full height of your display, if you need more area for browsing at the expense of a smaller Media Pool.
- **Media Storage:** Lets you hide or show the Media Storage browser. Hiding the Media Storage browser creates more room for the Viewer.
- **Clone Tool:** Shows or hides the Clone tool, used for cloning media from camera cards or hard drives.
- **Audio Panel:** Hides or shows the Audio Panel.
- **Metadata:** Hides or shows the Metadata Editor.
- **Inspector:** Hides or shows the Inspector Panels.
- **Capture:** Switches the Viewer and Audio Panel to Capture Mode, exposing the controls necessary for cuing up a device-controllable deck, and batch recording from tape.
- **Audio Panel/Metadata Editor full/half height button:** Lets you set the Audio Panel or Metadata Editor to take up the full height of your display, if you need more area for either of those functions.

Showing Which Panel Has Focus

Whenever you click somewhere on the DaVinci Resolve interface using the pointer, or use a keyboard shortcut to “select” a particular panel (such as in the Edit page), you give that panel of the user interface “focus.” A panel with focus will capture specific keyboard shortcuts to do something within that panel, as opposed to doing something elsewhere in the interface.



Disabled by default, checking the “Show focus indicators in the user interface” box in the UI Settings section of the User Preferences causes an orange highlight to appear at the top edge of the focused panel, allowing you to keep track of which part of the current page is taking precedence. You can switch focus as necessary to do what you need to do.

The Focus indicator shown at the top edge of the Media Pool, s
hown next to a Viewer that doesn’t have focus

The Media Storage Browser

The Media Storage browser lets you see all of the volumes connected to your workstation, browsing them for media that you want to preview and eventually import into your DaVinci Resolve project in one way or another. Whereas other applications rely on some sort of import dialog, DaVinci Resolve provides the Media page for doing complex media import tasks. To facilitate media import, the Media Storage browser is divided into two areas, the Volume List, and the Media Browser.

The Media Storage browser.

Playing Media in the Media Storage Browser

You can select media in the Media Storage Browser to play directly in the Media page Viewer, without importing it, so long as it’s in a format that DaVinci Resolve supports. This is useful for previewing clips that you’re considering using in a project, but it’s also useful for quality control review sessions of media that you’ve exported from DaVinci Resolve. All clips that are played in the Media page Viewer are also output to video, if you have a supported Blackmagic output interface. You can also

output the video to a second monitor by choosing Workspace > Video Clean Feed, and selecting your monitor. Additionally, if you choose Workspace > Dual Screen > On, the second computer display is capable of displaying a set of video scopes on the Media page, which can help you QC a program you're delivering.

Playing DCP and IMF Packages

It's also possible to use the Media Storage Browser to select and play DCP and IMF packages that have been exported either using EasyDCP or using the native DCP/IMF export capabilities of DaVinci Resolve. Simply locate the package, select it, and play it in the Viewer like any other clip. It will be output to video and analyzed by the video scopes.

DCP and IMF packages can also be imported from Media Storage to the Media Pool for various workflows. For more information, jump to this chapter: Delivering DCP and IMF.

The Media Storage Browser's Volume List

At the left of the Media Storage browser is a list of all volumes that are currently available to your DaVinci Resolve workstation. It's used to locate media that you want to import manually into your project.

- **Scratch volumes:** Indicated by a usage statistic to the right of the volume name that lists how full that volume is, these are disks that you've added to the Media Storage panel of the System Preferences window. The topmost of these scratch disks is used to store Gallery stills and cache files.
- **Available volumes:** Indicated by disk icons, this is a list of all fixed, removable, and network volumes that are currently available to your workstation. When the "Automatically display attached local and network storage locations" checkbox is turned on in the Media Storage panel of the DaVinci Resolve Preferences, new volumes that are attached to your workstation should automatically appear in this list.

This is a hierarchical list; clicking the disclosure triangle to the left of any volume opens up an additional list of that volume's subdirectories, with additional disclosure triangles next to each subdirectory. Using the Media Storage browser, you can drill down into as many subdirectories as you need to.

Adding Volumes That Don't Appear in This List

If you need to access a storage volume that doesn't appear on this list, for example if you're using the version of DaVinci Resolve that is available in the Apple App Store, then you can right-click anywhere in the background of the Volume list and choose "Add New Location" to open a dialog you can use to choose a volume you want to add.

If you're using the Apple App Store version of DaVinci Resolve, auto-mounting of attached storage volumes is not enabled automatically. However, you can enable this in the Media Storage panel of the DaVinci Resolve Preferences.

For more information, refer to the DaVinci Resolve Preferences section, jump to this chapter: System and User Preferences.

Media Storage Browser Favorites

Underneath this is the Favorites area. If there are special directories that you find yourself frequently accessing, you can add them to the Favorites in order to avoid having to traverse complex hierarchies in order to access the media you need. The Favorites can be easily customized and used.

Methods of organizing favorite file system locations in the Media Storage Browser:

- **To add a favorite:** Right-click any folder in the Media Storage browser folder list, and choose "Add folder to favorites" from the contextual menu. The new favorite appears at the bottom of the Favorites area.
- **To open a favorite:** Click any favorite to expose the contents of the corresponding directory in the Media Storage browser.
- **To remove a favorite:** Right-click the favorite you want to remove, and choose "Remove folder from favorites" from the contextual menu.

The Media Storage Browser Area

Once you've selected a volume or subdirectory in the Media Storage browser, you can view its contents in List view, Thumbnail view, or Metadata view to search through the media that's available to you as you try to find what you need.

List View

In List view, the following columns are available for sorting media prior to importing it into the Media Pool:

- **File name:** The name of a file.
- **Reel name:** The reel name as it's currently derived according to the Conform Options that are currently chosen in the General Options panel of the Project Settings.
- **Start TC:** The first timecode value in the source media.
- **Start:** The first frame number in the source media.
- **End:** The last frame number in the source media.
- **Frames:** The duration of each clip in frames.
- **Resolution:** The frame size of the source media.
- **Bit Depth:** The bit depth of the source media.
- **Video Codec:** The codec used for the video track of supported media.
- **Audio Codec:** The codec used for the audio tracks of supported media.
- **FPS:** The frame rate of the source media.
- **Audio Ch:** The number of audio channels within the source media.
- **Date Created:** The date a media file has been created.
- **Date Modified:** The date a media file has been changed in some way and saved.
- **Shot:** Additional metadata from media formats that support it.
- **Scene:** Additional metadata from media formats that support it.
- **Take:** Additional metadata from media formats that support it.
- **Angle:** Additional metadata from media formats that support it.
- **Good Take:** Additional metadata from media formats that support it.

If you work in List view, you gain additional organizational control by exposing columns that show the metadata that each clip contains, prior to media being added to your timeline. You can use these columns to help organize your media.

Methods of customizing metadata columns in List view:

- **To show or hide columns:** Right-click at the top of any column in the Media Storage browser and select an item in the contextual menu list to check or uncheck a particular column. Unchecked columns cannot be seen.
- **To rearrange column order:** Drag any column header to the left or right to rearrange the column order.
- **To resize any column:** Drag the border between any two columns to the right or left to narrow or widen that column.
- **To sort by any column:** Click the column header you want to sort with. Each additional time you click, the same header toggles that column between ascending and descending sort order.

You can also customize column layouts in the Media Storage area. Once you've customized a column layout that works for your particular purpose, you can save it for future recall.

Methods of saving and using custom column layout:

- **To create a column layout:** Show, hide, resize, and rearrange the columns you need for a particular task, then right-click any column header in the Media Pool and choose Create Column Layout. Enter a name in the Create Column Layout dialog, and click OK.
- **To recall a column layout:** Right-click any column header in the Media Pool and choose the name of the column layout you want to use. All custom column layouts are at the top of the list.
- **To delete a column layout:** Right-click any column header in the Media Pool and choose the name of the column layout you want to delete from the Delete Column Layout submenu.

Thumbnail View

While in Thumbnail view, you can scrub through a clip's icon to see its contents, and you can also click the Clip Info drop-down menu at the bottom right corner of any clip's thumbnail to see an instant summary of that clip's vital information, including:

- **File name:** The name of that file.
- **In timecode:** The first frame in the source media.
- **Out timecode:** The last frame in the source media.
- **Duration:** The total duration of the source media.
- **Resolution:** The frame size of the source media.
- **Frame Rate:** The frame rate, in fps, of the source media.
- **Pixel Aspect Ratio:** The aspect ratio of the source media.
- **Codec:** Which codec is used by the source media.
- **Date Created:** The date created metadata from the source media file.
- **Flags:** Flag metadata applied either by the camera that shot the media, in the Metadata Editor, or in the Color page Timeline.

Also while in Thumbnail view, you can use the Thumbnail Sort drop-down menu (between the Search and Option menu) to choose a criteria by which to organize the thumbnails. A wide variety of metadata options appear, including: File Name, Reel Name, Start TC, FPS, Audio Ch, etc. You can also sort in ascending or descending order.

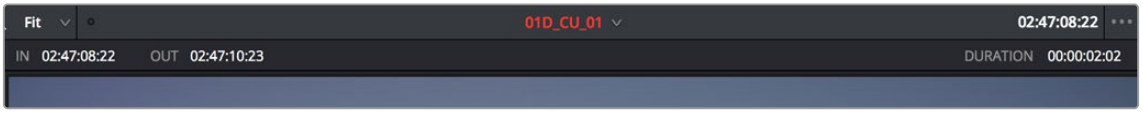
Revealing a Finder Location in the Media Browser

If you drag a folder from the macOS Finder into the Media Storage browser, the Media Storage browser will immediately update to show the location of that folder.

Viewer

Clips that you select in any area of the Media page show their contents in the Viewer. The current position of the playhead is shown in the timecode field at the upper right-hand corner of the Viewer.

The Media page Viewer



Simple transport controls appear underneath the jog bar, letting you Jump to First Frame, Play Backward, Stop, Play Forward, and Jump to Last Frame. A jog control to the left of these buttons lets you move through a long clip more slowly; click it and drag to the left or right to move through a clip a frame at a time.

Audio playback can be turned on or off by clicking on the speaker icon, or adjust the level by right-clicking on the speaker icon and dragging the slider.

To the right of the transport controls, In and Out buttons let you set In and Out points for the current clip. The clip's timecode is also displayed at the top right.

A jog or scrubber bar appears directly underneath the image, letting you drag the playhead directly with the pointer. The full width of the jog bar represents the full duration of the clip in the Viewer. You can skim footage in any viewer in the Media, Cut, Edit, Color, and Deliver pages by holding down the C key, and scrubbing the pointer back and forth in the viewer.

The Media Viewer has an option menu that looks like three dots in the upper right corner. Clicking on this menu reveals the options below.

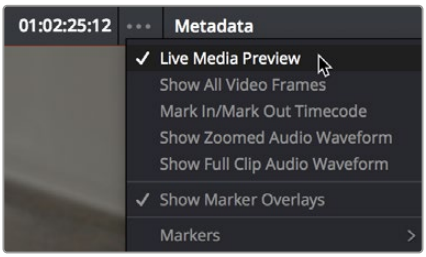
An optional info bar for showing the timecode and duration of a marked section of media

Media Viewer Option menu: Contains the following commands:

- **Live Media Preview:** Enabled by default, makes it possible for thumbnails that you're skimming in the Media Pool to show the skimmed frame in the Viewer. When skimming with Live Media Preview enabled, the playhead that appears in the thumbnail is locked to the playhead displayed in the Viewer's jog bar.
- **Show All Video Frames:** When available processing power is insufficient to play the clip or clips at the position of the playhead due to the grade, transforms, or effects that are applied at that moment in the Timeline, you have the ability to choose exactly how performance in DaVinci Resolve degrades. When off, DaVinci Resolve prioritizes audio playback at the expense of dropping video frames when processing power is tight, resulting in a more conventional playback experience. When on, audio quality is compromised while every frame of video plays in slower-than-real time to maintain playback.
- **Show Timecode Toolbar:** The Timecode Toolbar shows the In/Out point timecodes as well as the total duration set.
- **Show Audio Waveforms in Source Clip:** When enabled, shows an audio waveform overlay at the bottom of the Source Viewer that displays the audio over the entire duration of the clip.
- **Show Audio Waveforms Zoomed In:** When enabled, shows an audio waveform overlay at the bottom of the Source Viewer with a zoomed in section of the audio surrounding the current position of the playhead.
- **Previous Clip:** Goes to the previous clip in the Media Pool.
- **Next Clip:** Goes to the next clip in the Media Pool.
- **Clear Recently Viewed Clips:** Clears the memory of the recent clips in the Source Viewer.
- **Show Marker Overlays:** Enabled by default, markers that intercept the playhead when playback is paused appear superimposed in the Viewer.
- **Markers submenu:** When one or more markers are applied to the clip in the Source Viewer, they appear in this list in chronological order, listed by Name and Note. Choosing a marker from this menu jumps the playhead to that marker in the Source Viewer.

You can also put the Viewer into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (Command-F), so that it fills the entire screen. This command toggles Cinema Viewer mode on and off.

Export The Current Frame from The Viewer

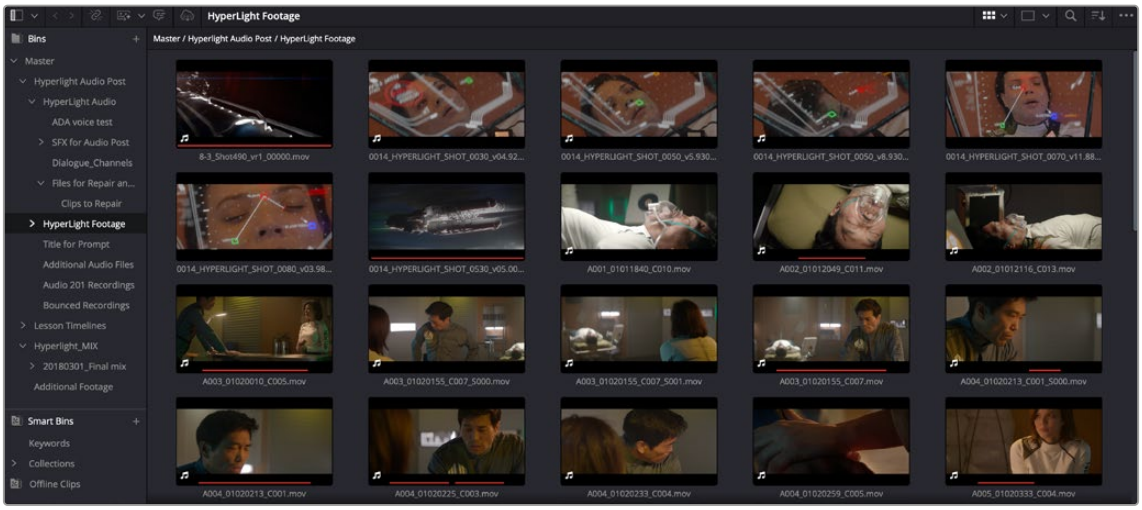


You can now export a still frame from the Viewer in the Media, Cut, and Edit pages.

To Export a Still Frame from the Viewer:

1. Use the Viewer's playback controls to navigate to the frame you want to export.
2. Select File > Export > Current Frame as Still.
3. Enter the name of the still frame in the File System viewer.
4. Enter the desired format of the still frame in the File System viewer.
5. Click on the Export button.

Live Media Preview



Enabled by default, the Live Media Preview setting found in the Viewer options menu (the three-dots menu found at the upper right-hand corner of the Viewer) makes it possible for thumbnails that you're skimming in either the Media Storage browser or Media Pool to show the skimmed frame in the Viewer. When skimming with Live Media Preview enabled, the playhead that appears in the thumbnail is locked to the playhead displayed in the Viewer's jog bar. You can turn Live Media Preview on or off.

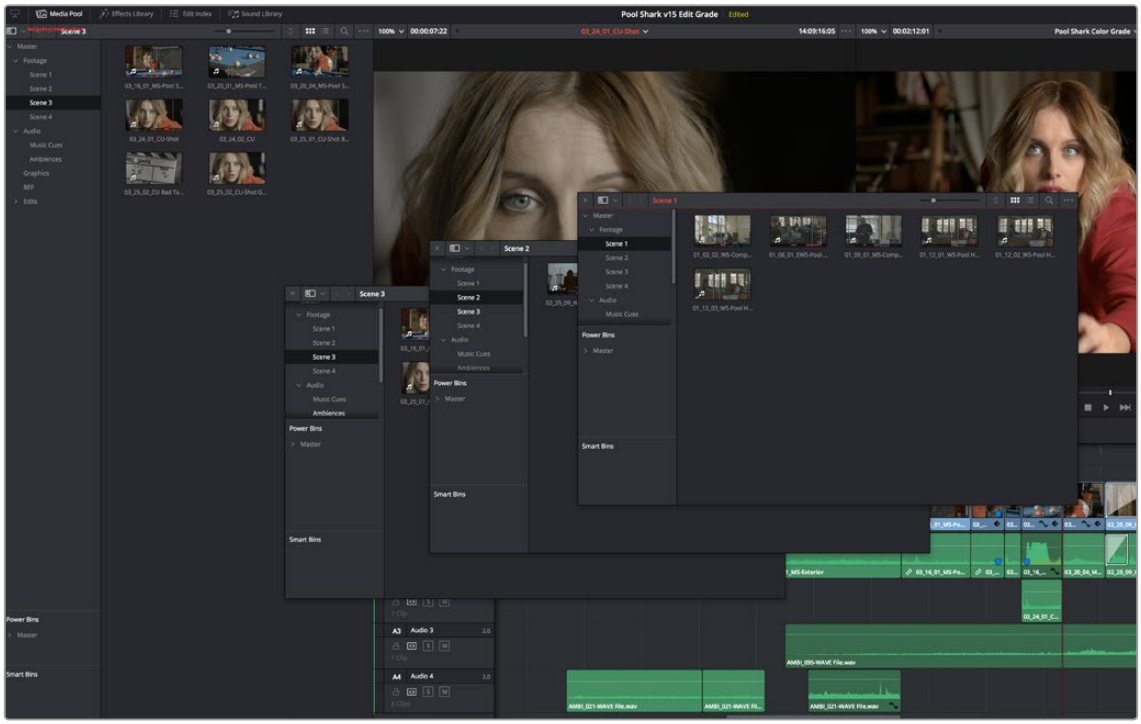
When Live Media Preview is on in the Viewer options menu, skimming thumbnails mirrors to the Viewer

Media Pool

The Media Pool is central to the DaVinci Resolve experience. It contains all of the media that you import into the current project, as well as all of the timelines you create. It also contains all media that's automatically imported along with Projects, Timelines, or Compositions that have themselves been imported into DaVinci Resolve. In the Media page, enough room is given to the Media Pool to make it an ideal place to sort, sift through, and organize the clips in your project. However, the Media Pool is also mirrored in the Cut, Edit, Fusion, Color, and Fairlight pages, so you can access clips as you build timelines, composites, grades, and sound design.

The Media Pool with the Bin list open.

The Bin List



Ordinarily, all media imported into a project goes into the Master bin, which is always at the top of the Bin list and encompasses everything in a given project. However, you can add bins of your own, and the Media Pool can be organized into as many user-definable bins as you like, depending on your needs. Media can be freely moved from one bin to another from within the Media Pool. When working in projects with multiple bins, you can choose to expose the bin structure in one of two ways:

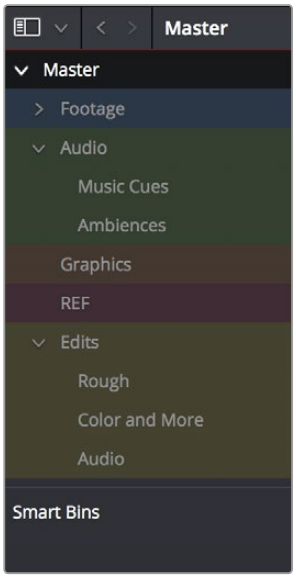
- **Bin list open:** The Bin List button at the upper left-hand corner of the Media Pool lets you open a separate List view showing all bins in your project, hierarchically. Bins that contain other bins appear with a disclosure button to their left, that you can use to show or hide the contents. With the Bin list exposed, it's easy to organize clips among a large collection of bins.
- **Bin list closed:** When the Bin list is closed, all bins are hidden, and contents of whichever bin is currently selected populate the Media Pool browser.

Showing Bins in Separate Windows

If you right-click a bin in the Bin list, you can choose "Open As New Window" to open that bin into its own window. Each window is its own Media Pool, complete with its own Bin, Power Bins and Smart Bins lists, and display controls.

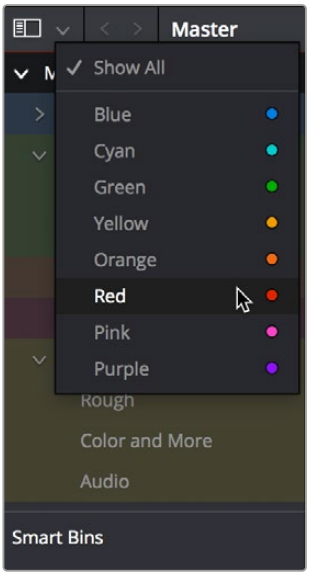
This is most useful when you have two displays connected to your workstation, as you can drag these separate bins to the second display while DaVinci Resolve is in single screen mode. If you hide the Bin list, not only do you get more room for clips, but you also prevent accidentally switching bins if you really want to only view a particular bin's contents in that window. You can have as many additional Bin windows open as you care to, in addition to the main Media Pool that's docked in the primary window interface.

Media Pool bins opened as new windows



Bins, Power Bins, and Smart Bins

There are actually three kinds of bins in the Media Pool, and each appears in its own section of the Bin list. The Power Bin and Smart Bin areas of the Bin list can be shown or hidden by using the Media Pool option menu and selecting/deselecting Show Smart Bins and Show Power Bins. Here are the differences between the different kinds of bins:



- **Bins:** Simple, manually populated bins. Drag and drop anything you like into a bin, and that's where it lives, until you decide to move it to another bin. Bins may be hierarchically organized, so you can create a Russian dolls nest of bins if you like. Creating new bins is as easy as right-clicking within the Bin list and choosing Add Bin from the contextual menu.
- **Power Bins:** Hidden by default. These are also manually populated bins, but these bins are shared among all of the projects in your current project library, making them ideal for shared title generators, graphics movies and stills, sound effects library files, music files, and other media that you want to be able to quickly and easily access from any project. To create a new Power Bin, show the Power Bins area of the Bin list, then right-click within it and choose Add Bin.
- **Smart Bins:** These are procedurally populated bins, meaning that custom rules employing metadata are used to dynamically filter the contents of the Media Pool whenever you select a Smart Bin. This makes Smart Bins fast ways of organizing the contents of projects for which you (or an assistant) has taken the time to add metadata to your clips using the Metadata Editor, adding Scene, Shot, and Take information, keywords, comments and description text, and myriad other pieces of information to make it faster to find what you're looking for when you need it. To create a new Smart Bin, show the Smart Bin area of the Bin list (if necessary), then right-click within it and choose Add Smart Bin. A dialog appears in which you can edit the name of that bin and the rules it uses to filter clips, and click Create Smart Bin.

Filtering Bins Using Color Tags

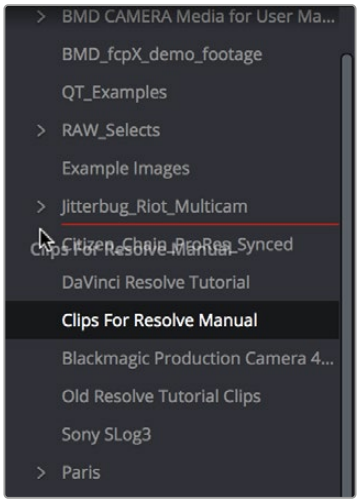
If you're working on a project that has a lot of bins, you can apply color tags to identify particular bins with one of eight colors. Tagging bins is as easy as right-clicking any bin and choosing the color you want from the Color Tag submenu.

Using Color Tags to identify bins

Using Color Tag filtering to isolate the blue bins

For example, you can identify the bins that have clips you're using most frequently with a red tag. A bin's color tag then appears as a colored background behind that bin's name.

Once you've tagged one or more Media Pool bins, you can use the Color Tag Filter drop-down menu (the drop-down control to the right of the Bin List button) to filter out all but a single color of bin.



To go back to seeing all available bins, choose Show All from the Color Tag Filter drop-down.

Sorting the Bin List

The Bin list (and Smart Bin list) of the Media Pool can be sorted by bin Name, Date Created, or Date Modified, in either ascending or descending order. Simply right-click anywhere within the Bin list and choose the options you want from the Sort by submenu of the contextual menu.

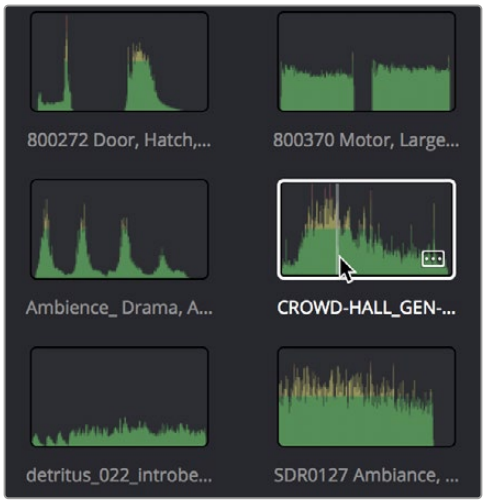
You can also choose User Sort from the same contextual menu, which lets you manually drag all bins in the Bin list to be in whatever order you like. As you drag bins in this mode, an orange line indicates the new position that bin will occupy when dropped.

If you use User Sort in the Bin list to rearrange your bins manually, you can switch back and forth between any of the other sorting methods (Name, Date Created, Date Modified) and User Sort and your manual User Sort order will be remembered, making it easy to use whatever method of bin sorting is most useful at the time, without losing your customized bin organization.

Dragging a bin to a new position in the Bin list in User Sort mode

Thumbnail, List, and Metadata Views in the Media Pool

The contents of the Media Pool can be browsed in the following traditional ways:



- **Thumbnail view:** Each clip is represented by an icon, with its file name appearing underneath. When you move the pointer over a clip's icon, DaVinci Resolve automatically scrubs through that clip, showing you its contents. Also, a Clip Info drop-down menu appears in the lower right-hand corner. Click the Clip Info drop-down to see an overlay appear showing essential information about that clip. In Thumbnail view, you can use the Sort Order drop-down to choose how clips are sorted.

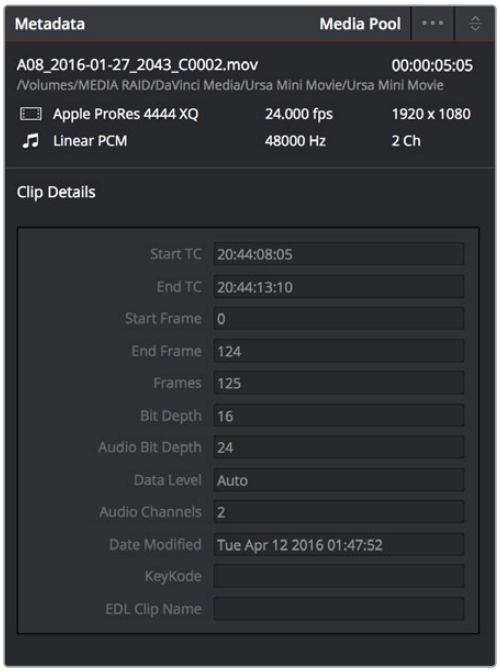
- **List view:** Each clip is represented by an item on a text list. Additionally, multiple columns of information appear, organized by headers. Clicking any header lets you sort the list by that column, in either ascending or descending order.
- **Metadata view:** Each clip is represented by its own card with a thumbnail and basic clip metadata information visible. This view is designed to have more metadata information than a thumbnail but more targeted information than the List view.

For more information on browsing the contents of the Media Pool, jump to this chapter: Adding and Organizing Media with the Media Pool.

Display Audio Clip Waveforms in Media Pool and Media Storage

The Media Pool option-menu presents an option to Show Audio Waveforms. When you do so, every audio clip in the Media Pool appears with an audio waveform within its thumbnail area. If Live Media Preview is on in the Source Viewer, you can then scrub through each clip and hear its contents. If you don't want to see audio waveforms, you can turn this option off.

You can now enable waveform thumbnails in the Media Pool that you can scrub with Live Media Preview.



Deleted Timeline Backups

From the Media Pool Options menu, you can select Deleted Timeline Backups and examine deleted timelines and available backup files for each timeline. You can select backups to be restored or choose to permanently delete selected backups.

Metadata Editor

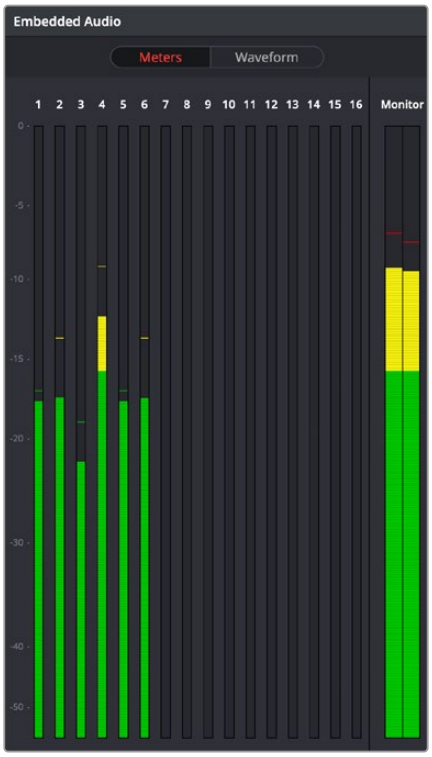
Both the Media and Edit pages have a Metadata Editor. When you select a clip in any area of the Media page, its metadata is displayed within the Metadata Editor. If you select multiple clips, only the last clip's information appears. The Metadata Editor's header contains uneditable information about the selected clip, including the file name, directory, duration, video codec, frame rate, resolution, audio codec, sample rate, and number of channels.

Because there are so very many metadata fields available, two drop-down menus at the top let you change which set of metadata is displayed in the Metadata Editor.

Clip Metadata Editor showing the Clip Details panel

- **Metadata Presets (to the left):** If you've used the Metadata panel of the User Preferences to create your own custom sets of metadata, you can use this drop-down to choose which one to expose. Surprisingly enough, this is set to "Default" by default.
- **Metadata Groups (to the right):** This drop-down menu lets you switch among the various groups of metadata that are available, grouped for specific tasks or workflows.

TIP: The heart of the Metadata Editor is a series of editable fields underneath the header that let you review and edit the different metadata criteria that are available.



For more information on editing clip metadata and creating custom metadata presets, jump to this chapter: Using Clip Metadata.

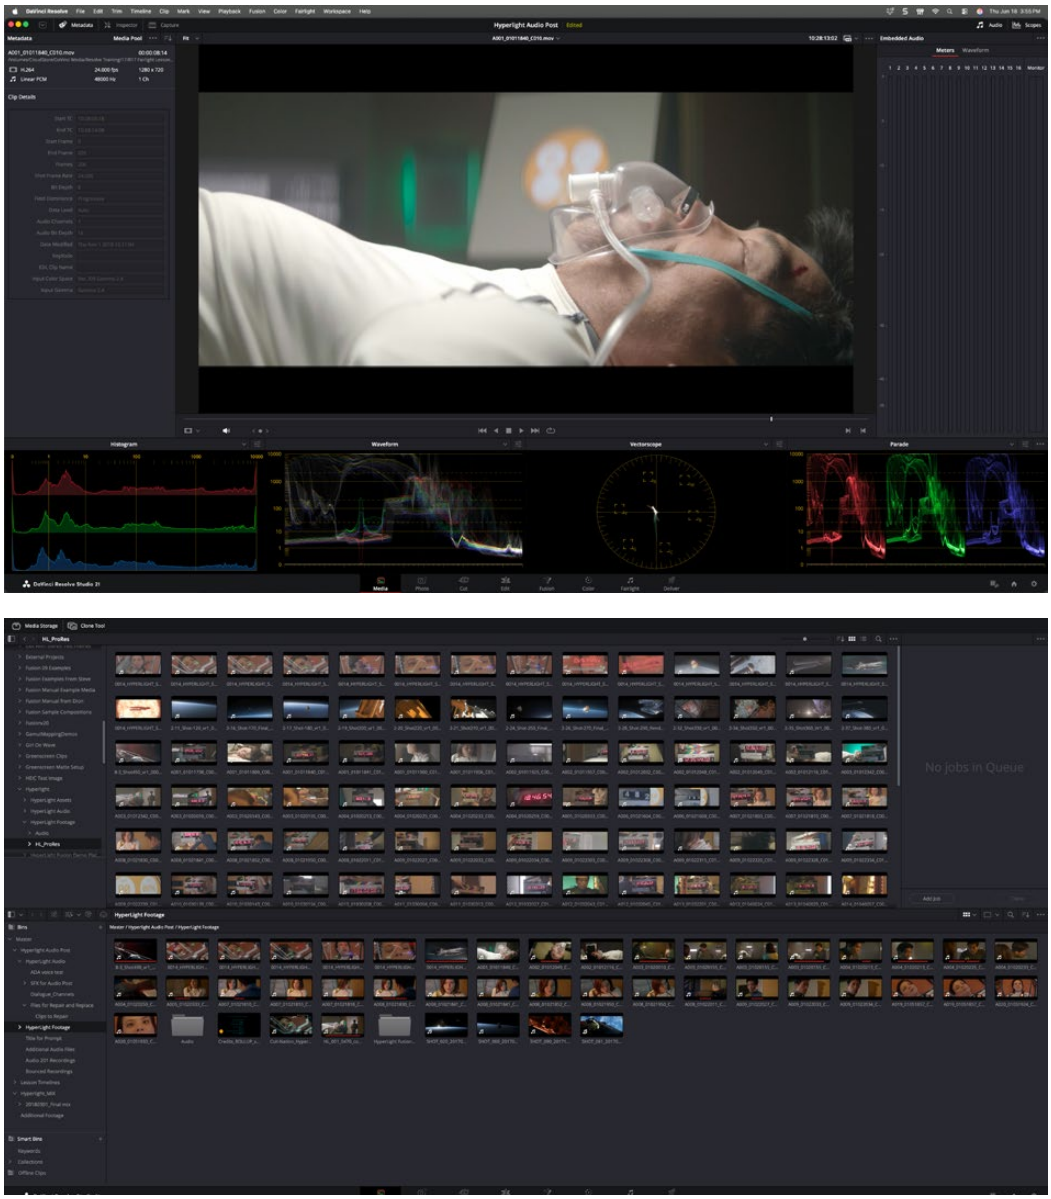
Audio Panel

The Audio Panel can be put into one of two modes via an option menu. In the default Meters mode, audio meters are displayed that show the levels of audio in clips you're playing. In Waveform mode, you can open audio clips side by side with video clips in the Viewer in order to sync them together manually.

For more information on manually syncing audio to video, jump to this chapter: Syncing Audio and Video.

When set to Levels mode, you can check audio embedded within clips you've imported into the Media Pool. As you play a clip, each audio meter shows the levels for whichever of these tracks contain audio. A Mute button in the Viewer lets you disable and enable audio playback.

Audio Meters Exposed



Dual-Monitor Layout

The Media page has a dual-monitor layout that provides maximum space for the Media Storage browser and Media Pool on the primary monitor, and an enlarged Viewer, Audio Panel, and Metadata Editor on the secondary monitor, along with a complete set of video scopes for helping you to evaluate media as you organize it. The second screen of a dual-screen layout can be resized but not reorganized.

If you have an single ultra-wide monitor, you can also use the Dual-Monitor Layout, and DaVinci Resolve will scale the interface as if you had two normal monitors side by side.

To enter dual screen mode:

- Choose Workspace > Dual Screen > On.

The Media page in dual-screen mode.

To switch which UI elements appear on which monitors:

Choose Workspace > Primary Display > Display 1 or Display 2, which reverses the contents of both monitors in dual screen mode.

Customizing the Media Page

The Media Page can be customized to create more room in different areas to accommodate specific tasks.

To resize any area of the Media page:
Drag the vertical or horizontal border between any two panels to enlarge one and shrink the other.

Methods of hiding different parts of the Media page:
To toggle the Clone Tool on and off: Click the Clone Tool button in the UI toolbar at the top.
To toggle the Audio Panel on and off: Click the Audio button in the UI toolbar at the top.
To toggle the Metadata Editor on and off: Click the Metadata button in the UI toolbar at the top.
To toggle the Media Storage browser folder list on and off: Click the button at the top-left corner of the Media Browser.
To toggle the Media Pool Bin list on and off: Click the button at the top-left corner of the Media Pool.

Methods of organizing favorite file system locations in the Media Storage browser:
To add a favorite: Right-click any folder in the Media Storage browser folder list, and choose "Add folder to favorites" from the contextual menu.
To remove a favorite: Right-click the favorite you want to remove, and choose "Remove folder from favorites" from the contextual menu.

To return all pages to their default layout:
Choose Workspace > Reset UI Layout.

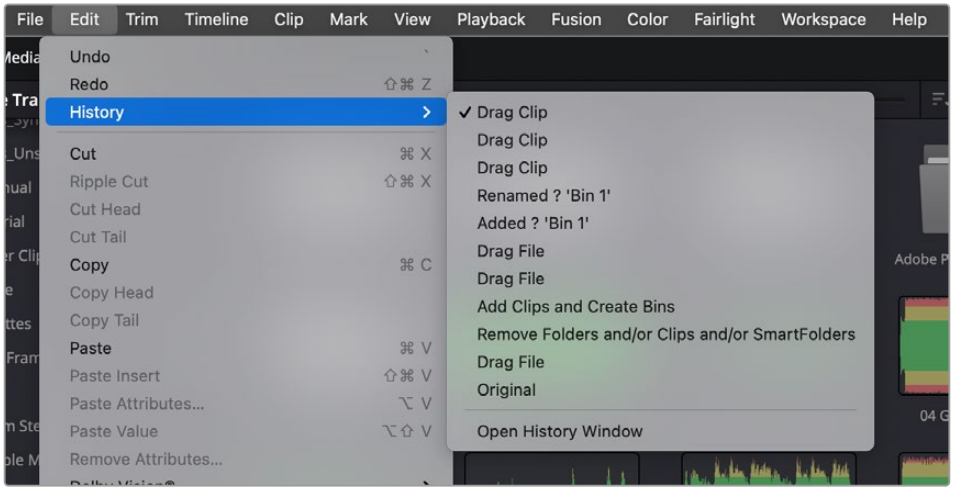
Undo and Redo in DaVinci Resolve

No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you've taken or commands you've executed and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you've done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo "stacks" to help you manage your work.

- The Media, Cut, Edit, and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
- Each clip in the Fusion page has its own undo stack so that you can undo changes you make to the composition of each clip, independently.
- Each clip in the Color page has its own undo stack so that you can undo changes you make to grades in each clip, independently.

In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you're in.



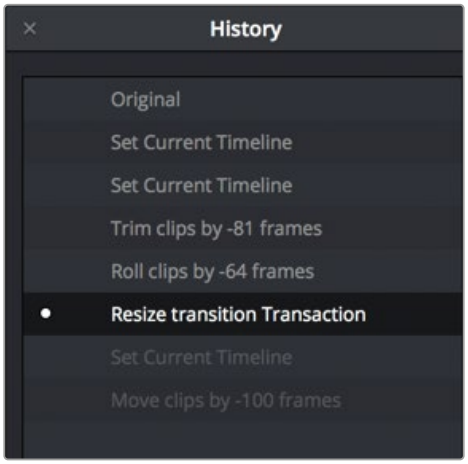
To simply undo or redo changes you've made one at a time:

- Choose Edit > Undo (Command-Z) to undo the previous change.
- Choose Edit > Redo (Shift-Command-Z) to redo to the next change.

You can also undo several steps at a time using the History submenu and window. At the time of this writing, this only works for multiple undo steps in the Media, Cut, Edit, and Fairlight pages.

To undo and redo using the History submenu:

1. Open the Edit > History submenu, which shows (up to) the last twenty things you've done.
2. Choose an item on the list to undo back to that point. The most recent thing you've done appears at the top of this list, and the change you've just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what's possible. However, if you've undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.



The History submenu, which lets you undo several steps at once

Once you've selected a step to undo to, the menu closes and the project updates to show you its current state.

To undo and redo using the Undo window:

1. Choose Edit > History > Open History Window.
2. When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you've done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.
3. When you're done, close the History window.

The Undo history window that lets you browse the entire available undo stack of the current page

Chapter 17

Adding and Organizing Media with the Media Pool

Before you can edit or grade media, you need to add it to the Media Pool, which is the central repository of clips in DaVinci Resolve. The Media Pool is a feature-rich environment, giving you many different methods of importing clips into your project and organizing them.

Copying Media Using the Clone Tool

One of the few things you may want to do before you add media to your project is to clone all camera original media onto a safe set of backup volumes, for redundancy in case any one volume fails. Additionally, you should consider cloning all media to an off-site backup as well.

Whether you're on-set working as a DIT, or doing data ingest at a post facility, the Clone Tool in the Media page lets you safely and accurately copy media from SD cards, SSDs, or disk drives, to multiple destinations, with a checksum report (based on a choice of six checksum options) written to the root of each destination volume that verifies the absolute accuracy of the duplicate media saved to each destination.

To duplicate media using the Clone Tool:

1. Open the Clone Tool by clicking the Clone button at the far left of the Media Pool toolbar, which reveals the Clone Tool palette.
2. Click the Add Job button at the bottom left to create a new job. A job item appears within the Clone Tool palette, with overlays to guide you through its use.
3. Drag a volume or folder from the Media Storage panel to the "Drop source here" drop zone. Alternately, you can right-click any volume or folder in the Media Storage panel and choose Set As Clone Source.
4. Next, drag one or more volumes or folders from the Media Storage panel to the "Drop destination here" drop zone. Alternately, you can right-click any volume or folder in the Media Storage panel and choose Set As Clone Destination. You can have more than one destination.
5. If you want to preserve the top level folder name from the source volume or folder, click the Clone Tool panel's option menu, and choose "Preserve Folder Name." The overall folder structure of the cloned media is always preserved.
6. If you want to change the checksum method used by DaVinci Resolve to verify that each clip has copied properly, you can choose an option from the Checksum submenu of the Clone Tool's option menu. Each option is a tradeoff between the speed of your file copy operation and the security of the verification process. Greater security generally means a slower copy operation. The options are:

   None: Disables data verification, sacrificing safety for speed.

   File Size: Fast, but minimal data verification. Data verification is done simply by comparing the file size of a duplicate file with that of the original. "Collision resistance" refers to whether two files (or a file and an incorrectly duplicated file) may coincidentally have the same comparison value (be it file size, an error-detecting code, or a hash). File Size is very fast, but it's minimally collision resistant.

   CRC 32: Faster than MD5, but less secure. An error-detecting code rather than the hash used by the next three options. A "check value" is generated based on the remainder of a polynomial division of the file's contents. By comparing the check value derived from an original file with that derived from a copy, data integrity can be verified. This is a much faster data verification scheme than MD5 (the default), but it is significantly less collision resistant.

   MD5: This is the default setting. A reasonable tradeoff between speed and security. A hash function generates a 128-bit value that's unique to a particular file; Data integrity is checked by comparing the hash value generated by the original file to that generated by the copied file. MD5 is not as collision resistant as the SHA options, but it's a faster operation, and the probability of such collisions in conventional film and video workflows is probably small.

SHA 256, SHA 512: Slower, but more secure. SHA is a more collision resistant hash function than MD5; options are provided for 256- and 512-bit value generation, with 512 being even more collision resistant than 256. However, these options are progressively slower than MD5, and will result in significantly slower copy times. Similarly to MD5, data integrity is checked by comparing the hash value generated by the original file to that generated by the copied file.

XXHASH64: This is by far the fastest checksum method and also provides good collision protection. This speed is very welcome when verifying terabytes of data.

7 When you're ready, click the Clone button to initiate the cloning process.

The Clone tool with a job set up

To duplicate media quickly using the Clone Tool:

1 Right-click any volume or folder in the Media Storage panel, and choose Set as Clone Source. A job item appears within the Clone Tool palette, populated by the volume or folder you selected.

2 Next, right-click any volume or folder in the Media Storage panel, and choose Set As Clone Destination. You can do this more than once because you can have more than one destination.

3 If you want to preserve the top level folder name from the source volume or folder, click the Clone Tool panel's option menu, and choose "Preserve Folder Name." The overall folder structure of the cloned media is always preserved.

4 When you're ready, click the Clone button to initiate the cloning process.

Adding Media to the Media Pool

At minimum, you'll be using the Media page to add clips to a project to begin editing, in preparation to create dailies, or as a prelude to conforming a project using an EDL. All clips you want to work with must first be added to the Media Pool to be available for grading and processing in DaVinci Resolve, regardless of whether or not there's edited project data to go along with it.

If you import XML or AAF projects, you can choose to automatically import all accompanying media as part of the import process you initiate in the Edit page. However, if you find yourself needing to replace updated effects or stock footage in the Timeline, or you're called upon to add additional media such as animated titles or superimposed clips for compositing, then you'll still need to use the Media page to do so.

Whatever kind of project you're working on, you can add clips to the Media Pool from as many different volumes as you need. All imported clips are linked to the original media on whichever disks you found them; files are not moved, copied, or otherwise transcoded when you add them to the Media Pool. Consequently, it's a good idea to make sure that all media you want to import into your project has already been copied to a suitably fast volume before importing it.

Basic Methods for Adding Media in the Media Page

There are several ways of adding clips to the Media Pool.

To add individual clips from the Media Storage panel to the Media Pool:

1. Use the Media Storage panel to find a media file to import.
2. If you have multiple bins available in the Bin list, choose the bin you want to add the incoming media to.
3. Do one of the following:

   Shift-click or Command-click multiple files, then right-click one of the selected files and choose "Add into Media Pool."

   Drag a clip from the Media Storage panel browser to the Media Pool or to a specific bin in the Bin list.
4. If a dialog appears asking if you want to change your project to match the criteria, click "Change" to alter the project's settings, or click "Don't Change" to continue importing the media while leaving the project at its previous frame rate. Once clips have been imported into the Media Pool, the frame rate cannot be changed again, so choose carefully.

   You also have the option of dragging media directly from the file system of supported platforms into the Media Pool.

To drag one or more clips from the File System to the Media Pool (supported platforms only):

1. Select one or more clips in your File System.
2. Drag those clips into the Media Pool of DaVinci Resolve or to a specific bin in the Bin list.

   Those clips are added to the Media Pool of your project.

   If you need to add the contents of all directories and subdirectories to the Media Pool as a flat group of media, that's easily accomplished. A good example of this is when you're importing camera original media from a cloned file structure, in which clips are organized into subdirectories that are many levels deep. DaVinci Resolve can easily import all of these clips and put them all into the same bin.

To add the entire contents of one or more directories of clips to the Media Pool:

1. Use the Media Storage panel to find and select one or more directories containing media files you need to import.
2. If you have multiple bins available in the Bin list, select the specific bin you want to add the incoming media to.
3. Do one of the following:
   - Right-click the selected directory or directories in the Media Storage panel, and choose “Add Folder into Media Pool” to add only clips from the selected directory. Subdirectories are ignored.
   - Right-click the directory in the Media Storage panel, and choose “Add Folder and SubFolders into Media Pool” to add clips from the selected directory and those from all subdirectories within.
   - Drag one or more selected directories you want from the Media Storage panel’s browser area to the browser area of the Media Pool to add its contents, and the contents of all subdirectories within, to the currently selected bin in the Bin list.

You also have the option of using the directories and subdirectories that organize media in your file system as bins in the Media Pool, so that you can preserve the original organization of your media.

To add all clips and folders in a directory organized into matching folders in the Media Pool:

1. Use the Media Storage panel to find the directory containing the files you need to import.
2. Do one of the following:
   - Right-click the directory and choose “Add Folder and SubFolders into Media Pool (Create Bins)”
   - Drag the folder you want to import from the Media Storage panel to the Bin list of the Media Pool to add that folder, and all subfolders within, as a new bin in the Bin list.

   A folder appears in the Media Pool with the same name as the folder you dragged in. All clips and all subdirectories appear within, nested hierarchically in the Media Pool as they were in the file system.

Import Hierarchically Organized Nests of Empty Directories

You can also import a nested series of directories and subdirectories that constitutes a default bin structure you’d like to bring into projects, even if those directories are empty, by dragging them from your file system into the Media Pool Bin list of a project. The result is a hierarchically nested series of bins that mimics the structure of the directories you imported. This is useful if you want to use such a series of directories as a preset bin structure for new projects.

Adding Subclips From the Media Storage Panel

If you're browsing long source clips in the Media Storage panel, but you only want to import a small segment of a much longer clip into the Media Pool, you can create subclips directly from the Media Storage panel.

To add a subclip from a clip in the Media Storage panel to the Media Pool:

1. Single-click any clip in the Media Storage panel to open it into the Viewer in order to create a subclip without needing to first import that clip into the Media Pool.
2. Set In and Out points in the Source Viewer to define the section you want to turn into a subclip.
3. Do one of the following:
   - Right-click the jog bar and choose Make Subclip from the contextual menu
   - Drag the clip from the Viewer to the Media Pool to add it as a subclip

Adding Individual Frames From Image Sequences

If you're working with image sequences, or with sequentially numbered image files from any source, DaVinci Resolve automatically presents them as clips in the Media Storage panel. This is good if that's what they are, but there are instances where sets of photos, of which each frame is in actuality a separate media file, are also sequentially numbered. For this reason, you can import individual frames, rather than entire image sequences.

To choose between adding individual frames from a number sequence of images, or adding them as image sequence clips in the Media Storage panel:

1. Click the Media Storage panel option menu, and choose Frame Display Mode.
2. Close one of the drop-down options:

   Auto: DaVinci Resolve will automatically select Individual Frames or Image Sequence based on file type. For example, DPX and EXR files will be imported as image sequence clips, while JPG files will be imported as individual frames.

   Individual: Each image sequence is now separated into its individual frames, allowing you to select only the frames you need.

   Sequence: Will group sequentially numbered files together as an image sequence clip, regardless of file type.

3. Use any of the previous described methods to add the frames you want to the Media Pool as individual clips or image sequences.

Adding OGraf HTML Graphics and Lottie Animations

DaVinci Resolve supports OGraf (.json) and Lottie (.lottie) HTML-based animation on macOS and Windows. Whether it's something you found online or created from scratch, animations can now be added directly to your timeline. Simply export your .json or .lottie file, then drag and drop it into your Media Pool just like any other media.

You can also drop it straight into the timeline, where it will be recognized as a fully rendered animation clip. The alpha background is recognized too, so transparency is maintained. You can add the clip over another layer and it will composite correctly, which makes it perfect for use as a stinger or transition.

Adding Media Based on EDLs

Another strategy for adding media to the Media Pool is to use an EDL to add only the clips it refers to from a directory. This lets you add only the clips that are necessary for conforming a particular imported project before conforming an EDL, and eliminates the need to add too much media to the Media Pool, which might slow you down in the case of projects referencing terabytes of media. Furthermore, you can choose multiple EDLs to base the import on, and many directories to examine.

The EDLs will reference clips via their timecode and sometimes reel name and path. It is these settings and the conform frame rate that you made previously in the Configuration screen that are now used to place images correctly into the Media Pool.

To add only media used in an EDL to the Media Pool:

1. If necessary, open the General Options panel of the Project Settings, turn on the "Assist using reel names from the" checkbox, and choose a method with which to extract reel name information from the media files you're about to import.

   For more information, jump to this chapter: Using Clip Metadata.

2. Right-click a directory in the Media Storage panel, and choose one of the following commands:
   - Add Folder Based on EDLs into Media Pool
   - Add Folder and SubFolders Based on EDLs into Media Pool
3. Using the file dialog that appears, select one or more EDLs to use.

TIP: DaVinci Resolve searches the directory hierarchy, either one level deep or all levels deep, for every media file matching the source timecode and the reel ID of an event in one of the selected EDLs.

Splitting Clips Based on EDLs

You can also use EDLs to split a media file into multiple clips in the Media Pool, either as an alternate means of "preconforming" a flattened master media file, or to import multiple sections of a longer media file that happen to be referenced by an EDL.

To split and add clips based on an EDL:

1. Right-click a directory in the Media Storage panel, and choose "Split and add into Media Pool."
2. Using the file dialog that appears, select an EDL to use, and click Open.
3. Choose a frame rate to use to conform the clips to in the "File Conform Frame Rate" dialog, and click OK.
4. Choose a handle size, in frames, and whether or not you want to split unreferred clips from the "Enter handle size for splitting" dialog, and click Split & Add. The media file is split into the component clips specified in the EDL, and added to the Media Pool.

TIP: Turning on the Split Unreferred Clips checkbox automatically splits out sections of the file that were not referred to by the EDL you selected, and adds them to the Media Pool separately, giving you access to every piece of media that's available.

Import Clips With Metadata Via Final Cut Pro 7 XML

In order to support workflows with media asset management (MAM) systems, DaVinci Resolve supports two additional Media Pool import workflows that use Final Cut Pro 7 XML to import clips with metadata.

To import clips with metadata using Final Cut Pro 7 XML files, do one of the following:

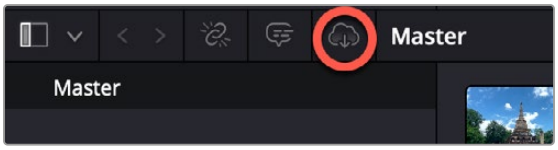
- Right-click anywhere in the background of the Media Pool, choose Import > Media from File, and then choose the XML file you want to use to guide import from the import dialog.
- Drag and drop any Final Cut Pro 7 XML file into the Media Pool from the macOS Finder.

Every single clip referenced by that XML file that can be found via its file path will be imported into the Media Pool, along with any metadata entered for those clips. If the file path is invalid, you'll be asked to navigate to the directory with the corresponding media. Additionally, the following metadata is imported:

- Clips
- Browser metadata
- Subclips
- Clip Markers, with colors and duration
- Bin Hierarchy
- Comments

Adding Media With Offset Timecode

Sometimes source media was created with incorrectly offset timecode, due to mistakes made earlier in the postproduction process. If this offset is consistent, you can use the "Add Folder with Source Offset" command to add media to the Media Pool as clips with a timecode offset.



To add a folder of clips to the Media Pool with offset timecode:

1. Right-click a directory in the Media Storage panel, and choose one of the following commands:
   - Add Folder with Source Offset
   - Add Folder and SubFolders with Source Offset
2. Choose a number of frames with which to offset the timecode from the "Change Frame Offset" dialog, and click Apply.

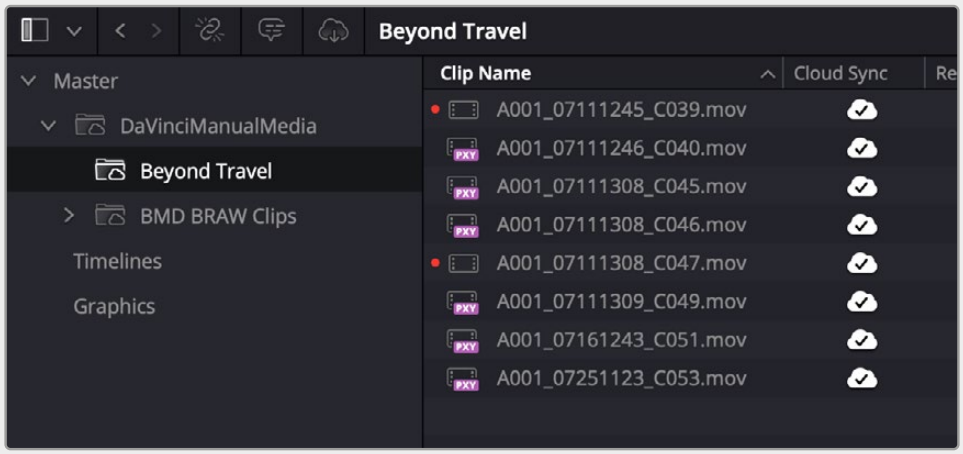
The media is imported as clips with offset timecode in the Media Pool. However, the original source timecode of the clips on disk has not been altered. All media rendered out of the Deliver page will reflect the offset timecode.

Import Blackmagic Cloud Shared Folders to Media Pool

You can now import and sync Blackmagic Cloud Folders into the Media Pool. This allows you to connect to one or more cloud media folders and selectively download media from them to your local machine. Blackmagic Cloud Folders are online common storage folders that are not tied to a specific project. This lets you create a pool of commonly used media assets, such as title sequences, credits, bumpers, etc., and share them online without having to import them separately into each individual project.

The Import Cloud Folder icon at the top of the Media Pool

To link a Blackmagic Cloud Folder to your project:

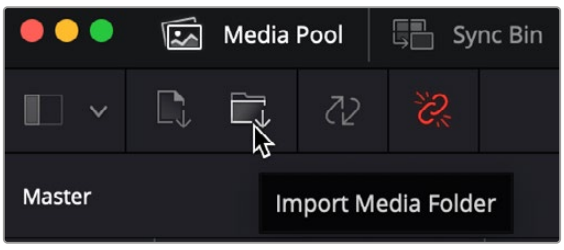


1. Sign into your Blackmagic Cloud account in DaVinci Resolve.
2. Click on the Import Blackmagic Cloud Folder icon at the top of the Media Pool in any page.
3. In the Blackmagic Cloud Folder dialog, click select to choose a Blackmagic Cloud Folder. The choices here will show any Blackmagic Cloud Folder that you have created or someone else has shared with you. Click the Add button.
4. In the Download Folder Location, select a file location on your local system that you want the media from the Blackmagic Cloud Folder to be stored in.
5. Choose whether you want to sync proxies only, or proxies and used originals.
6. Press Download to add the Cloud Folder to your Media Pool.

The Blackmagic Cloud Folder link dialog

When you open the Blackmagic Cloud Folder in the Media Pool, it will be empty and populate one clip at a time as their clip names (not their media) are downloaded from the cloud. Also, the Blackmagic Cloud Folder is not actually linked to your project yet; it is only linked when the first media clip is “used.”

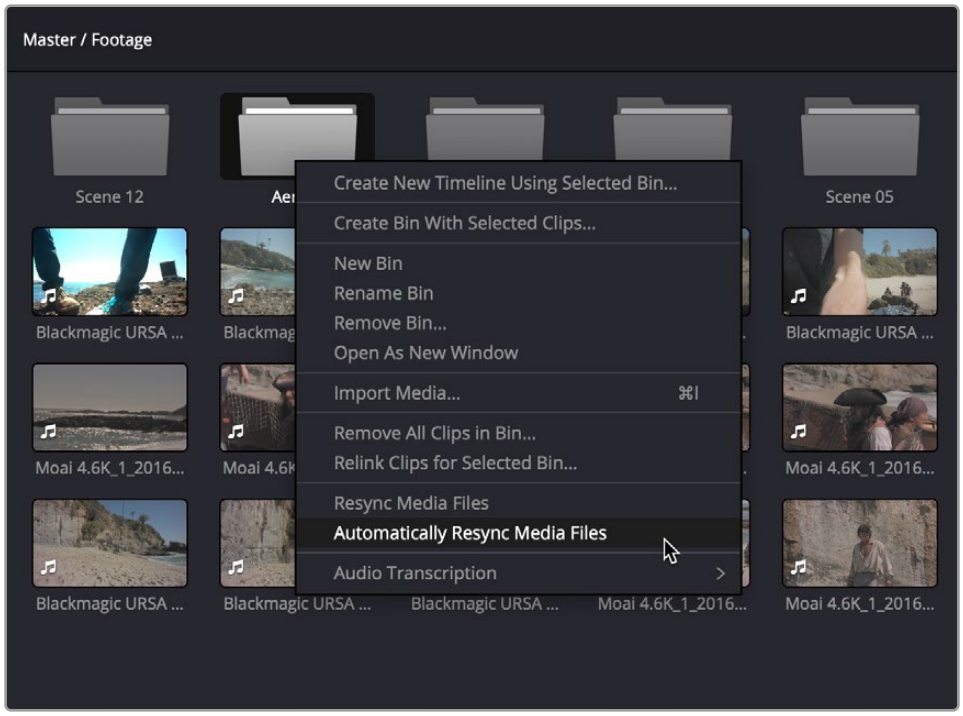
A “used” clip is new terminology in DaVinci Resolve and simply means a clip that has been altered in any way inside the project. A clip can be used be by putting it on a timeline, certainly, but also includes other actions like applying a flag, altering its metadata, transcribing it, etc. Once a clip is used, its media will start to download to your local machine. Clips that are used are denoted by a red dot next to them in the Media Pool. Any unused clips will remain as virtual clips in the Cloud Folder until used. Once downloaded, clips in Cloud Folders can be used just like any other clip in the Media Pool.



The Cloud Folder linked in List view. Clips with red dots are “used,” and the original media has been downloaded. Unused clips have just their proxies available to view. The Cloud Sync column shows that the media is registered and synced with the Blackmagic Cloud.

Sync Media Pool Bins with File System Folders

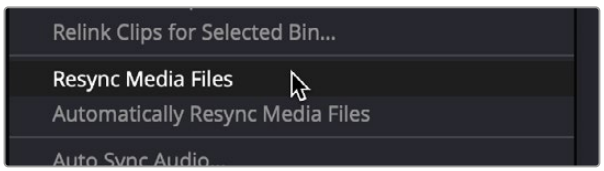
You can sync a Media Pool bin with a folder on your computer’s file system (MacOS, Windows, Linux, etc.). This allows you to add additional media into a folder on your computer and have it automatically import to its respective bin in DaVinci Resolve.



To set up a folder with Automatic Syncing:

1 On the Cut page, use the Import Folder icon on the top menu bar to set up matching folder and sub folder names.

Use the Import Media Folder icon in the Cut page



2 Right-click on the imported folder and choose ”Automatically Resync Media Files.“

Right-click on the bin and select Automatically Resync Media Files

Newly added clips in this folder will be added automatically to the media bin. This can be useful when working with cloud-synced media files (as when using DaVinci Resolve’s Replay capabilities), or any files that may be added to the folder later.

To manually resync the contents of a Media Pool bin once, right-click a bin and choose ”Resync Media Files.”

Right-click on the bin and select Resync Media Files to perform the sync operation manually.

For both Resync actions, ensure that:

- At least one clip is present in the media bin.
- All existing clips in the media bin share the same file path.

The media bin name matches the parent folder of the clip paths. You can ensure this is set up correctly by using “Import Media Folder” in the Cut page, or “Add Folder and SubFolders into Media Pool (Create Bins)” in the Media page.

Sync actions will add new clips from sub-folders if the corresponding sub-bins exist. However, newly created sub-folders without corresponding media bins are not tracked, and new media bins without the corresponding sub-folders are skipped.

For example, say you were editing a sporting event, and you had a graphics operator creating animated lower-thirds for each of the players. By creating a common network folder called "CG" and automatically syncing it in DaVinci Resolve, each time a new lower-third was finished and saved, it would automatically appear in your bin in the Media Pool ready for use.

Here's how you would set this up:

- Create a folder on your network storage called "CG." Both the editor and the graphics operator need to have access to this folder.
- Note that because this folder is currently empty, it can not be used in a Resync action yet. Only after there is at least one media file in the folder can you perform a Resync.
- The graphics operator finishes his first animated lower third and saves it to the "CG" folder as a .mov file (though any DaVinci Resolve readable media format would work).
- The editor then imports the "CG" folder into the Media Pool in DaVinci Resolve and selects Automatically Resync Media Files from the context menu.
- As the graphics operator finishes and saves additional lower thirds into that folder, they automatically appear in the Editor's "CG" bin in the Media Pool, without having to specifically import them.
- For organizational purposes, the graphics operator then creates a new folder in "CG" for the other team, called "Team B." Unfortunately, because this folder structure was not in the original imported bin, it does not show up in the editor's media pool. However, if they had created this Team B folder before the editor imported it, and it had media in it, it would been there.
- Now in this case, the editor simply imports the same bin again, selects Automatically Resync Media Files, and the new folder and all its media appear as expected. Any further files in dropped in "Team B" will show up in the editor's media pool.

IMPORTANT: Media entries for clips that are removed or not found on the file system are set as offline media. This allows for retention of metadata and is useful when the clip path is temporarily offline, on cloud storage where file status may be in flux, or moved away by apps or workflows seeking to write a new version in its place.

Adding Media to the Cut, Edit, Fusion, and Fairlight Pages

While adding clips to the Media Pool in the Media page provides the most organizational flexibility and features, if you find yourself in the Cut, Edit, Fusion, or Fairlight page and you need to quickly import a few clips for immediate use, you can do so in a couple of different ways.

To add media by dragging one or more clips from the Finder to the Media Pool (macOS only):

1. Select one or more clips in the Finder.
2. Drag those clips into the Media Pool of DaVinci Resolve, or to a bin in the Bin list.

   Those clips are added to the Media Pool of your project.

To use the Import Media command in the Media Pool:

1. Right-click anywhere in the Media Pool, and choose Import Media.
2. Use the Import dialog to select one or more clips to import, and click Open.

   Those clips are added to the Media Pool of your project.

Removing Media From the Media Pool

If you've added clips to the Media Pool that you need to eliminate, this is easy to do, either singly, or in the aggregate.

To remove clips from the Media Pool, do one of the following:

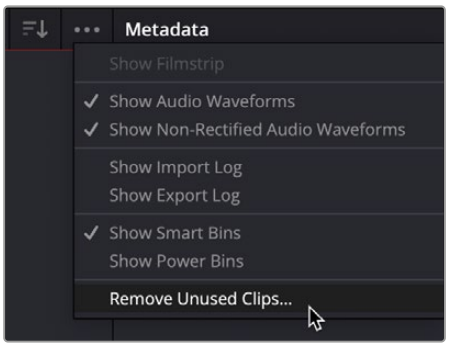
- Select one or more clips in the Media Pool, then press the Delete or Backspace key.
- Select one or more clips in the Media Pool, right-click one of the selected clips, and then choose Remove Selected Clips.
- Right-click anywhere in the Media Pool, and choose Remove All Clips in Bin.

NOTE: If you've turned on "Automatically match master timeline with media pool" in the General Options panel of the Project Settings, you cannot remove all clips from the Media Pool if there are other timelines using that media.

To remove clips from the Master Timeline (if it's exposed):

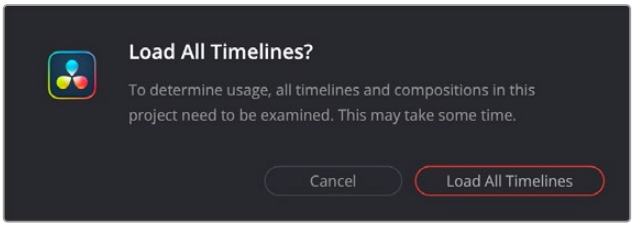
- Open the Edit page, then select one or more clips in the Media Pool, right-click one of the selected clips, and choose "Remove Selected Clips from Master Timeline."

For more information on using the Master Timeline, jump to this chapter: Using the Edit Page.



Removing Unused Media from a Project

You can have DaVinci Resolve automatically remove any unused media clips from the Media Pool in preparation for archiving or handing off a clean project to another workstation. This action loads all timelines, compound clips, and Fusion compositions then analyzes them for media usage. Any clips not found during this analysis are removed from the Media Pool. This option does not delete any clips from your disk, it only removes them from the Media Pool and the Project. This operation is un-doable.



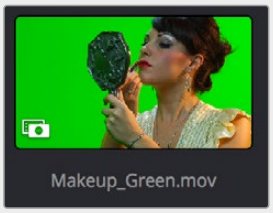
NOTE: Depending on the size of the Project, this operation can take several minutes.

To remove unused media from a Project:

1. Click on the Media Pool Option (3-dot) menu.
2. Select Remove Unused Clips from the drop-down menu.
3. Click on the Load All Timelines button to start the operation, or Cancel to abort it.

Select Remove Unused Clips from the Media Pool Option menu

Click the Load All Timelines button to start the analysis



Adding and Removing External Mattes

If you've been provided with matte files to accompany one or more media files used by a program you're grading, you can attach them directly to specific clips in the Media Pool, in order to use them as key sources for a Clip Grade in the Node Editor of the Color page. You can even use matte files that pack multiple mattes within a single piece of media. This can be done by either writing different mattes to each of the red, green, and blue channels of a clip, or by embedding multiple matte passes within a single OpenEXR file.

Matching RGB and Matte images

When the Media Pool is in Icon view, clips with clip mattes appear with a badge.

A clip matte, seen in Icon view

Clip mattes appear listed underneath a clip in the Media Pool when it's in List view.

Clip Name	Start TC	End TC
Makeup_BG.mov	07:10:54:04	07:11:10:10
Makeup_Green.mov	07:10:54:04	07:11:10:10
Makeup_Matte.mov	07:10:54:04	07:11:10:10

A clip matte, seen in List view

Alternately, you can add a timeline matte to the Media Pool, which isn't attached to any clip, that can be used as a key source in the Color page within any clip's Clip grade, or within a Timeline Grade. Timeline mattes appear as stand-alone clips in the Media Pool.

A timeline matte,
seen in Thumbnail view

What Are Mattes For?

Matte files are useful for two things. Traditionally, mattes are grayscale media files that identify regions of varying opacity, with white representing solid areas, and black representing transparency. For example, exported clips from a compositing application sometimes are accompanied by one or more matte files that correspond to keys or rotoscoped mattes from the composite. By importing these matte files using the "Add as Matte" command, you can attach them to the clips they belong to in the Media Pool, so that they're only available to the clips they're synced to.

However, mattes can also be used as creative tools to apply grain and texture for effect. What a matte does depends on how you connect it in the Node Editor of the Color page. These are media files that you may want to use as mattes for potentially any clip, so they can also be added to the Media Pool as a so-called timeline matte, that can be applied to any clip you want.

TIP: If necessary, you can also apply LUTs to both clip mattes and timeline mattes in the Media Pool, simply by right-clicking a matte, and choosing a LUT from the 1D LUT or 3D LUT submenus. This can be helpful for adjusting incorrectly formatted mattes.

Adding Mattes

To use mattes, you need to add them in very specific ways.

To assign a matte to a clip in the Media Pool:

1. Select a clip in the Media Pool to which you want to attach an external matte.
2. Select the matching external matte file in the Media Storage panel, right-click it, and choose Add to Media Pool as a Matte.

   The matte is attached to the clip as a clip matte. A badge indicates that clip has a matte when the Media Pool is in Icon view, and the matte itself can be seen, if you put the Media Pool into List view, appearing as a nested item underneath the clip it's attached to.

Removing mattes from clips in the Media Pool:

1. Put the Media Pool into List view.
2. Right-click the external matte file you need to remove, and choose Remove Selected Clips.

   Removing an external matte clip also removes that matte's key from any clip grades that use it, such that any clips using it as a key input change from a secondary operation to a primary operation, where the color adjustment affects the entire image.

To add a timeline matte to the Media Pool:

1. Make sure no clip is selected in the Media Pool.
2. Select an external matte file in the Media Storage panel, right-click it, and choose Add to Media Pool as a Matte.

   The external matte appears in the Media Pool as a timeline matte.

   You can also assign mattes to clips directly in the Color page, which can sometimes be faster.

To assign a matte to a clip in the Color page:

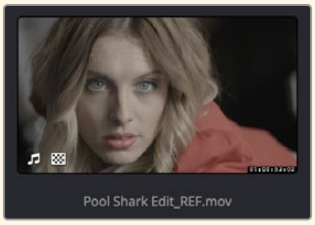
- Drag any clip from the Media Pool to the Node Editor.

  That clip appears an an External matte for the current clip's grade in the Node Editor, and it's also automatically assigned to the current clip in the Media Pool.

For more information on using external matte clips as keys when grading, Combining Keys and Using Mattes.

Using Embedded Mattes in OpenEXR Files

If you're importing OpenEXR files with embedded matte passes, there's nothing special you need to do, as the mattes are within the clip you've just imported into the Media Pool.



For more information on how to use mattes within OpenEXR files, jump to this chapter: Combining Keys and Using Mattes.

Adding Offline Reference Movies

When moving a project from another application to DaVinci Resolve, it's useful to export the entire program as a single media file for use as an Offline Reference Movie. Then, you can import this file in a special way to use for dual Viewer comparison in the Edit page, or as a split-screen comparison for fade wipe in the Color page. As of DaVinci Resolve 16 it's no longer necessary to import reference movies in this way to make an offline comparison, but it can still be convenient when managing multiple timelines and versions that require great specificity.

To add a clip as an offline reference clip:

- Right-click it in the Media Storage panel, and choose "Add As Offline Clip."
- That clip appears with a small checkerboard badge in its icon in the Media Pool, or as the icon to the left of the Media Pool.

Checkerboard icon indicating an Offline comparison video

For more information on using an offline video to compare with an imported Timeline in the Edit page, jump to this chapter: Importing and Conforming Timelines.

For more information on split-screen reference of Offline video in the Color page, jump to this chapter: Using the Color Page.

Extracting Audio in Media Storage

If there's a video clip in the Media Storage panel that has audio you need, but you don't want the video component, you can use the Extract Audio command to create a self-contained audio clip that you can then import into the Media Pool by itself.

To extract the audio from a media file:

1. Right-click a clip in the Media Storage panel, and choose Extract Audio.
2. Click the Browse button in the Extract Audio dialog to find another disk location for the extracted clip.
3. Click Extract. The audio channels are extracted and written as a .WAV file to the selected destination.
4. After you've extracted the stand-alone .WAV file, you'll need to import it into the Media Pool if you want to use it in your project.

Manually Organizing the Media Pool

Whether you're doing onset work, creating digital dailies, organizing media to edit, or ingesting media to conform to an imported project, it's vitally important to stay organized. The Media Pool provides many different tools for doing so. This section examines how you can create bins to manually organize collections of clips.

To Select Clips in the Media Pool

There are a variety of ways you can make clip selections in the Media Pool in preparation for relinking, unlinking, moving, duplicating, deleting, or doing any other operation to them.

- Click any clip to select it.
- Drag a bounding box around several clips to select them all.
- Hold the Command or Shift keys down and drag a bounding box around another discontiguous group of clips to either add them to the current selection or remove them from the current selection.
- Click one clip, then Shift-click another to select both clips and make a continuous selection of all clips in-between. Shift-clicking another clip can expand or contract the selection.
- Command-click individual clips to select a discontiguous number of clips. Command-click a clip that's already selected to individually de-select it, while leaving the rest of the selection alone.
- With one clip selected, hold the Shift or Command keys down and use the Arrow keys to expand the selection to other clips.

Organizing Media into Bins

You can easily organize clips into different bins in the Media Pool. For some workflows, this is required, while with other workflows it's purely optional.

Methods of working with bins in the Media Pool:

- **To add a bin to the Media Pool:** Right-click in the Bin list and choose Add Bin. To add a bin inside another bin, right-click any bin and choose Add Bin.
- **To move selected clips into a new bin:** Select all the clips you want to put into a new bin, then right-click one of the selected clips, and choose Create Bin With Selected Clips.
- **To rename a bin:** Select the bin you want to rename, and then click its name a second time to make it editable. With the bin name highlighted, type a new name and press Return. Alternately, you can right-click a bin, choose Rename Bin, and then type a new name and press Return.
- **To add incoming clips to a specific bin in the Media Pool:** Click a bin to select it, then use any of the previously described methods to add media from the Media Storage panel directly to that bin.
- **To move media from one bin to another:** Drag one or more selected clips from their current location in the Media Pool into that bin. Multiple clips in the Media Pool can be selected by Shift-clicking or Command-clicking them, or by dragging a bounding box over a group of clips. You can also drag one bin into another one.
- **To delete a bin:** Select the bin you want to delete, and press the Backspace or Delete key. Or, right-click a bin and choose Delete Bin. Deleting a bin with nested bins inside of it results in that entire set of bins being deleted.

- **To sort bins:** Right-click on any bin, and choose an option from the Sort By submenu. You can choose from Name, Date Created, Date Modified, and User Sort.
- **To reorganize bins manually:** Right-click anywhere within the Bin list, and choose Sort By > User Sort. Then, drag bins up or down in the Bin list to put them into the order you want. An orange dividing line shows where dragged bins will be placed when you drop them and helps you see when a bin you're dragging will become nested within another bin or not. The User Sort order is saved even when you change to another sort order, and selecting User Sort again results in your custom sort order being recalled.

Import and Export DaVinci Resolve Project Bins (.drb)

You can import/export specific bins from one DaVinci Resolve project to another, allowing you to pass bins quickly between projects and workstations that have access to the same media. All Metadata, In/Out points, Timelines, etc. are transferred along with the clips in the bin, but none of the actual media files are included.

To export bins from the Media Pool:

1. Select one or more bins in the Media Pool.
2. Right-click the selection and choose "Export Bin," or choose File > Export > Export Bin.
3. Choose where to save the DaVinci Resolve Bin file (.drb) in the file system dialog, and click Save.

To import bins into the Media Pool:

1. Right-click in the Media Pool and choose "Import Bin," or choose File > Import > Import Bin.
2. Do one of the following:
   - Choose a DaVinci Resolve Bin file (.drb) from the file system dialog.
   - Double click the .drb file in your file system.

   The bin or bins will appear in the Media Pool. Any bins imported this way will have the word "import" appended to their name, to avoid duplicate names. If you import a bin that contains clips that were already in the Media Pool, the potentially duplicate clips are excluded from the import and instead relinked to the media referenced by your project. This keeps your Media Pool tidy. However, if the bin or bins have been moved to another computer, you may have to relink offline media.

Import and Export Power Bins

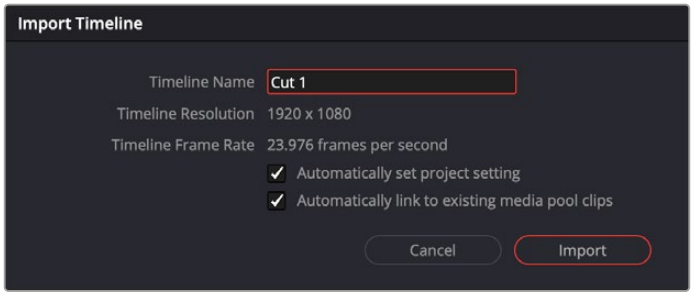
You can import and export Power Bins (bins that persist from project to project) as .drb files, just like normal bins. Power Bins are hidden by default and can be turned on by clicking on the Media Pool Option (3-dot) menu and selecting Show Power Bins.

Import and Export DaVinci Resolve Timelines (.drt)

You can export and import individual timelines from one DaVinci Resolve project into another previously existing DaVinci Resolve project, allowing you to pass timelines quickly between projects and workstations, without creating additional imported project files. Just the timeline and its associated clip information is exported, none of the actual media files are included.

To export a timeline from the Media Pool:

1. Select a timeline from the Media Pool.
2. Choose File > Export > Export AAF, XML, DRT (Shift-Command-O).
3. Choose “DaVinci Resolve Timeline Files (*.drt)” from the format options popup in the file system dialog.
4. Choose where to save the DaVinci Resolve Timeline file (.drt) in the file system dialog, and click Save.



To export multiple timelines from the Media Pool:

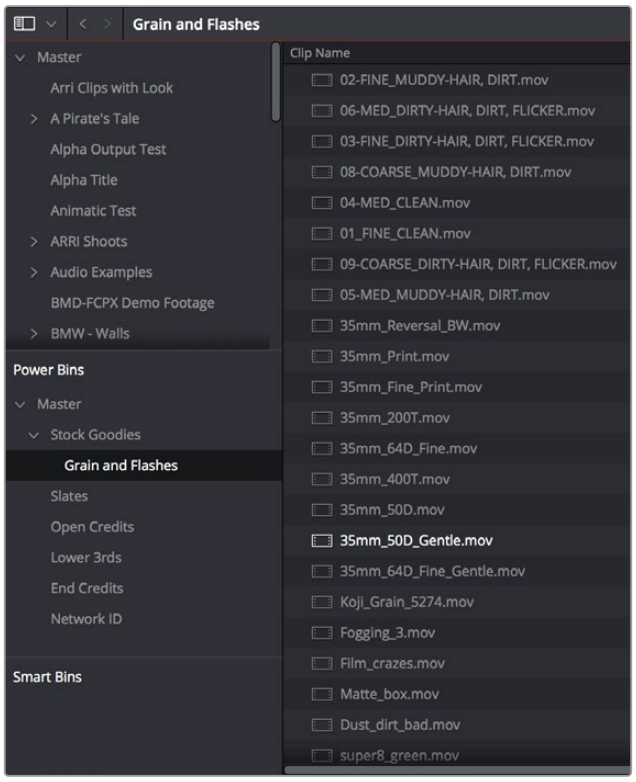
1. Select multiple timelines from the Media Pool.
2. Right-click on a timeline and choose Timelines > Export > DaVinci Resolve Timeline Files.
3. Select the folder where you wish to save them from your file browser.

> Unlike exporting individual timelines, when exporting multiple timelines you will not be able to rename the .drt files on export. They will retain the timeline name they have in the Media Pool.

To import a timeline into the Media Pool:

1. Choose a bin in the Media Pool in which you want the imported timeline to be saved.
2. Do one of the following:
   - Choose File > Import Timeline > Import AAF, XML, DRT (Shift-Command-I), then select a DaVinci Resolve Timeline file (.drt) from the file system dialog, and click Open.
   - Double click the .drt file in your file system..
3. An Import Timeline dialog opens, showing you the timeline settings, along with a checkbox option to set project settings based on the imported timeline. You can also enable the Automatically link to existing media pool clips box, which saves you the step of manually relinking the files in the Media Pool.
4. Click Import.

The Import Timeline dialog box.



The timeline will appear in the Media Pool, along with all of the clips associated with it, including any media sync information. Any timelines imported this way will have the word “import” appended to their name, to avoid duplicate names. The imported timeline will be automatically conformed to corresponding media that’s already in the Media Pool. However, if the timeline has been moved to another computer, you may have to reimport or relink missing or offline media in to bring the imported timeline fully online.

NOTE: Only a single timeline can be imported and exported at a time using this method. To import or export multiple timelines, use the Import/Export Bin function described above.

Sharing Media Among Projects Using Power Bins

Power Bins provide a way of importing and organizing media that you want to be available to all projects in DaVinci Resolve. Power Bins reside in a separate area of the Media Pool, with resizable dividers separating them from both the ordinary bins and Smart Bins areas. Power Bins are hierarchical, just like regular bins, and you can nest as many as you like, one inside another.

Like regular bins, Power Bins must be manually created by right-clicking within the Power Bins area and choosing Add Bin. The difference is that whatever clips you import into Power Bins are shared among all projects in a single-user installation, or all projects belonging to a particular user in a multi-user installation. In this way, they’re similar to Power Grades in the gallery of the Color page. This makes Power Bins ideal for storing shared media that’s re-used often, such as stock video, sound effects, stills, and things like company slates and network graphics and animations that go into every show of a series.

The Power Bins area of the Bin list

Power Bins are created and used like any other bin, using the procedures described previously.

To show or hide the Power Bin area of the Bin list:

Choose Show Power Bins from the Media Pool option menu to toggle the visibility of all power bins on and off.

Automated Organization Using Smart Bins

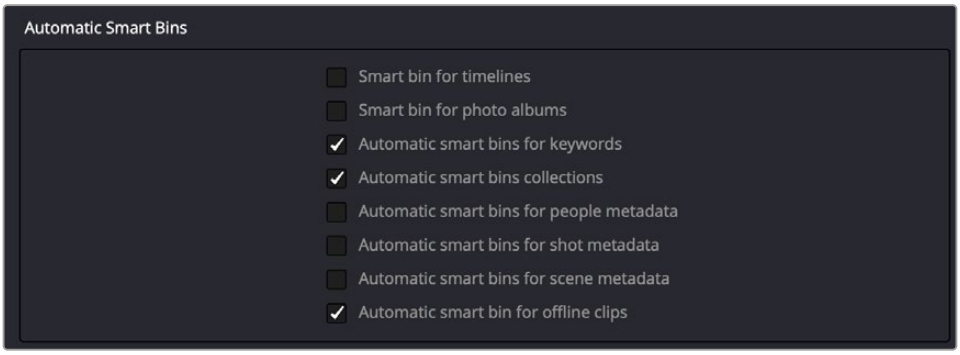
A completely automated way of organizing media in the Media Pool is to use Smart Bins that are either automatically or manually created, in order to collect all clips and timelines in the Media Pool that have commonalities based on any of the intrinsic or user-editable metadata that's available in the Metadata Editor and Media Pool. If you're familiar with the Color page, Smart Bins work much the same way as Smart Filters, and they're created and edited using much the same procedures.

For more information about Smart Filters, jump to this chapter: Using the Color Page.

Smart Bins are incredibly flexible. Using one or more metadata-based rules, they can be as simple or sophisticated as you require. They're even capable of using multiple groups of multiple rules for situations where you need to gather clips that match all of one set of criteria, but only one of a second set of criteria. In this way, you can use Smart Bins to solve a wide variety of organizational needs as you edit your program.

Smart Bins Are Only As Good As Your Metadata

It's important to point out, however, that as much intrinsic metadata is available to every clip in DaVinci Resolve automatically (clip properties such as frame rate, frame size, codec, file name, and so on), the more time you take entering extra metadata in the Metadata Editor to prepare your project for editing and grading, the more powerful Smart Bins can be in helping you to sift and sort through the contents of a program you're grading. Examples of metadata entry that will guarantee immediate benefits from Smart Bins include the entry of scene, shot, and take information, keywords identifying key descriptors (day and night, interior and exterior, framing, and so on), and using Face Detection to assign character names. These categories of metadata can be used for the automatic creation of Smart Bins, but they can also be used in combination when manually creating Smart Bins that are even more specific.



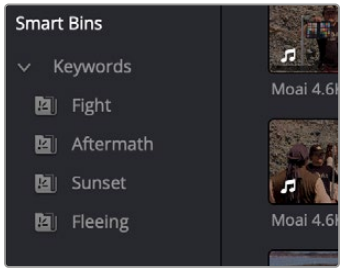
Imagine being able to gather all the clips in a particular scene, find all the interview clips for a particular subject, or find all the edited timelines corresponding to a particular name, all by simply selecting a Smart Bin that automatically examines the current contents of the Media Pool. If you or an assistant can take the time to enter metadata for the source material in a project that identifies these characteristics, you'll be able to work even more quickly to find the clips you need for any given situation.

Smart Bins Update Their Contents Dynamically

Smart Bins are always dynamically up to date and include whatever new media is added to the Media Pool. This makes it easy to stay organized, even when working on projects where new media is being added to the Media Pool every day, such as when editing during a shoot. By using metadata entered either in-camera, by the DIT or media wrangler managing ingest, or by an Assistant Editor who's working with you, Smart Bins will automatically include all clips in the Media Pool that have matching criteria, whether they were added a month ago or a minute ago.

Automatic Smart Bin Creation

The process of adding metadata to your clips can be used for the automatic creation of sets of "Smart Categories," which are Smart Bins that are generated and organized by the presence of specific categories of metadata and appear in the Smart Bins section of the Media Pool sidebar. To enable or disable this behavior, open the Editing panel of the User Preferences, and click on your preferred checkboxes in the Automatic Smart Bins group to define which metadata can automatically create Smart Bins.



Preferences governing which metadata can automatically create Smart Bins.

Metadata capable of creating Automatic Smart Bins include:

- Timelines
- Photo Albums
- Keywords
- Collections
- People (added via People Detection)
- Shot metadata
- Scene metadata
- Offline Clips

These categories are hierarchically organized, with each category closed by default to save space. Click the disclosure triangle of any category to reveal all Keyword, People, Scene, or Shot Smart Bins that are available in the current project. Selecting the Smart Category's top bin lets you see every clip referenced by every Smart Bin inside of it, whereas selecting individual Smart Bins shows you only the clips referenced by that Smart Bin.

A Smart Category seen in the Smart Bins area of the Media Pool sidebar

Drag and Drop Clips to Assign Automatic Smart Bin Properties

Metadata entry does not need to be a one way process, starting with typing in the metadata editor. For certain Automatic Smart Bin categories (keywords, shot, and scene), you can drag multiple clips from the Media Pool on top of an existing smart bin to assign the properties of that bin to all the clips at once.

To automatically assign Smart Bin Properties to a range of clips:

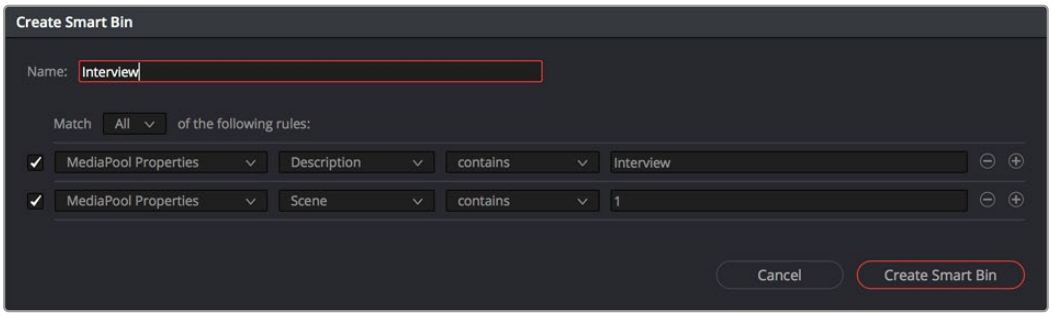
1. Create a Smart Bin in one of the following categories: Keywords, Shot, or Scene.
2. Select all of the clips that you want to apply the Smart Bin property to.
3. Drag those clips from the Media Pool and drop them on top of the Smart Bin.

For example, you could make a smart bin with the Keyword: “Sunset.” That bin would automatically show up under the Keywords category in the Smart Bins. Then you could select all the sunset shots in your Media Pool, and drag them on top of that bin to apply the “sunset” keyword to all the clips at the same time.

NOTE: Dragging and dropping clips to assign Smart Bin properties only works with the Automatic Smart Bin Keywords, Shot, or Scene categories. Dragging clips to any other Smart Bin will have no effect.

Manual Smart Bin Creation

It’s easy to manually create Smart Bins with customized rules to filter very specific collections of media and timelines that you want to use.



To show or hide the Smart Bin area of the Bin list:

- Choose Show Smart Bins from the Media Pool option menu to toggle the visibility of all Smart Bins on and off.

To create a Smart Bin:

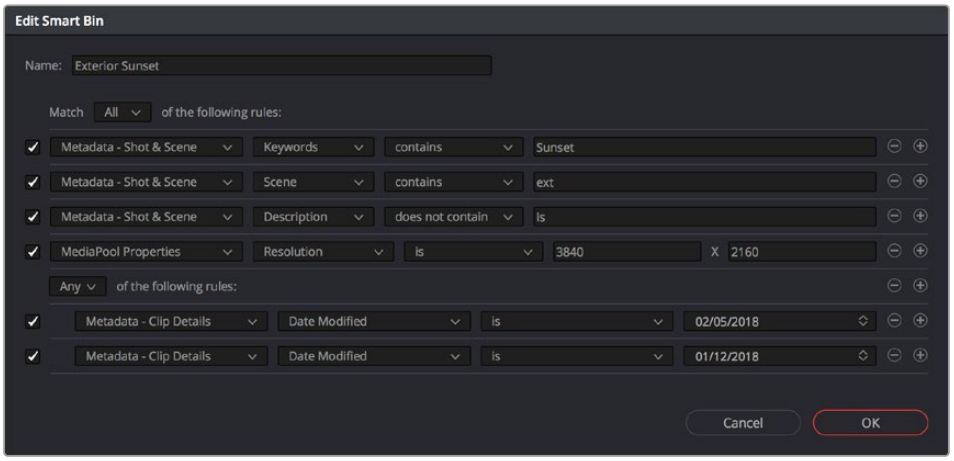
1. If necessary, open the Bin list, choose Show Smart Bins from the Media Pool option menu, then right-click anywhere in the background of the Smart Bin area of the Bin list, and choose Create Smart Bin.

2 In the Create Smart Bin dialog, enter a name for the filter, and use the following controls to create one or more filter criteria (you can have as many filter criteria as you like):

The Create Smart Bin dialog

Show in all projects checkbox: Lets you create a persistent Smart Bin that appears in all projects in your project library. Smart Bins created this way will be found in the User Smart Bins folder inside every project's Smart Bin area in the Media Pool.

Match options: For multi-criteria filtering, choosing All ensures that every single criteria you specify is met for a clip to be filtered. Choosing Any means that if only one out of several criteria is met, that clip will be filtered.



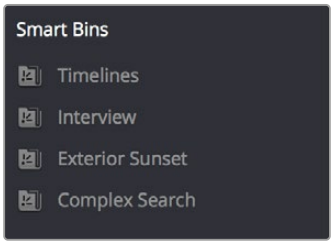
Filter criteria enable checkbox: Lets you enable or disable any criteria without having to delete it.

Metadata category drop-down: Lets you choose which category of metadata you want to select a criteria from. Each category of metadata that's available in the Metadata Editor is available from this drop-down menu. Additionally, Color Timeline Properties (containing many properties unique to the Color page timeline) and Media Pool Properties (containing every column in the Media Pool) provide access to additional metadata you can use for filtering.

Metadata type drop-down: For choosing which exact type of metadata to use, of the options available in the selected metadata category.

Metadata criteria drop-down: Lets you choose the criteria by which to filter, depending on the metadata you've selected. Options include "true/false," integer ranges, date ranges, string searches, flag and marker colors, et cetera.

Add filter criteria button: Lets you add additional criteria to create multi-criteria filters. You could use multiple criteria to, for example, find all exterior clips, that also contain the keyword "Sunset," that aren't closeups, in order to find all the exterior long and medium shots in sunset lighting. Additionally, if you Option-click this button, you can add a nested match option in order to create even more sophisticated filters, such as when the filter must match all of one set of criteria, and any of another set of criteria.



A complicated Smart Bin with multiple criteria and a second match option setting

As you're editing the filter criteria, the thumbnail timeline automatically updates to show you how the Smart Bin you're creating is working.

3 When you're done editing the filter criteria, click Create Smart Bin. The resulting Smart Bin appears in the Smart Bin area of the Bin list, at the left of the Media Pool's browser area.

Once you've created a Smart Bin, it appears in the lower half of the Media Pool's Bin list, alongside every other Smart Bin in that project. This keeps them organized, separate from the manually created bin shown above.

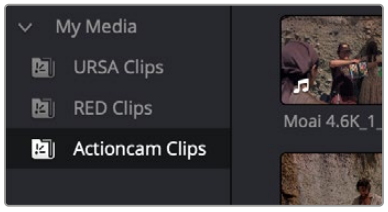
All Smart Bins appear together at the bottom of the Media Pool's Bin list

Once you've created a Smart Bin, you can re-edit it whenever the situation requires.

Methods of modifying existing Smart Bins:

- **To rename a Smart Bin:** Right-click the Smart Bin you want to rename, choose Rename from the contextual menu, enter a new name, and press Return.
- **To edit a Smart Bin:** Double-click the Smart Bin, then edit the filter criteria, and click OK.
- **To duplicate a Smart Bin:** Right-click any Smart Bin and choose Duplicate from the contextual menu. This is a good way to create multiple variations of a Smart Bin that you created with complex rules, where you need to create variations by modifying those rules without needing to reinvent the wheel each time.
- **To delete a Smart Bin:** Right-click the Smart Bin you want to delete, choose Delete Smart Bin from the contextual menu, and click Delete in the warning dialog. Deleting a Smart Bin does not delete any gathered media associated with that bin.

Smart Bins Work Better With Metadata



Keep in mind that the more metadata you associate with each clip, the more methods you have at your disposal for creating custom Smart Bins (for editing) and Smart Filters (for grading) with which to zero in on the clips you need for any given situation. This will not only make it easier to find what you need, but it'll help you to work faster. At the very least, it would be valuable for you to use the Metadata Editor to add information to each clip such as a Description, Shot and Scene designations, take information, and possibly some useful keywords such as character names, shot framing, interior or exterior keywords, and so on.

For example, if you've entered enough metadata, then you can create multi-criteria Smart Bins or Smart Filters that let you find the equivalent of "every close-up of Sally inside the diner," or "every long shot of Antonio outside in the parking lot." In a documentary, you could easily isolate "every interview shot of Louis from camera 1," or "every B-roll clip with Robyn." All of this will help you find media faster for editing, or quickly isolate similar clips that you need to match together for grading.

For more information about using the Metadata Editor, jump to this chapter: Using Clip Metadata.

Organizing Smart Bins

Manually created Smart Bins can be organized into Folders and Sub-Folders for better sidebar management, just like regular bins.

Smart Bins organized into folders

To add a Smart Bin folder:

- Right-click in the Smart Bins area and choose Add Folder from the contextual menu to create folders that you can drag Smart Bins into. Each folder has a disclosure triangle, so you can show or hide its contents.

> **NOTE:** Another benefit of Folders is that when you select a Folder, you can see the full contents of all Smart Bins inside of it in the Media Pool browsing area. Selecting any one Smart Bin then restricts the Media Pool to showing only the media reference by that Smart Bin.
>
> Folders can be renamed, removed, opened as a new window, or sorted along with all other Smart Bins by right-clicking them and using commands in the contextual menu.

Duplicating Clips in the Media Pool

You can duplicate clips in order to create an instance of that media that's treated as a completely new source clip, entirely separate from the original instance of that clip that was imported into DaVinci Resolve. The duplicate is capable of storing individualized metadata and markers that are completely distinct from the original clip that was imported into your project.

To duplicate one or more clips:

1. Select one or more clips to duplicate.
2. Do one of the following:
   - Choose Edit > Duplicate Clip
   - Hold the Option key down while dragging one or more selected clips to another bin
   - Right-click a clip in the Media Pool, and choose Duplicate Clip from the Contextual Menu

Adding Clips From the Timeline to the Media Pool

You can also drag one or more clips from the Timeline back into the Media Pool to create a duplicate.

As with duplicating clips in the Media Pool, each duplicate is created as a new source clip that's entirely separate from the original instance of that clip that was imported into DaVinci Resolve and is capable of storing individualized metadata and markers that are completely distinct from the original clip that was imported into your project.

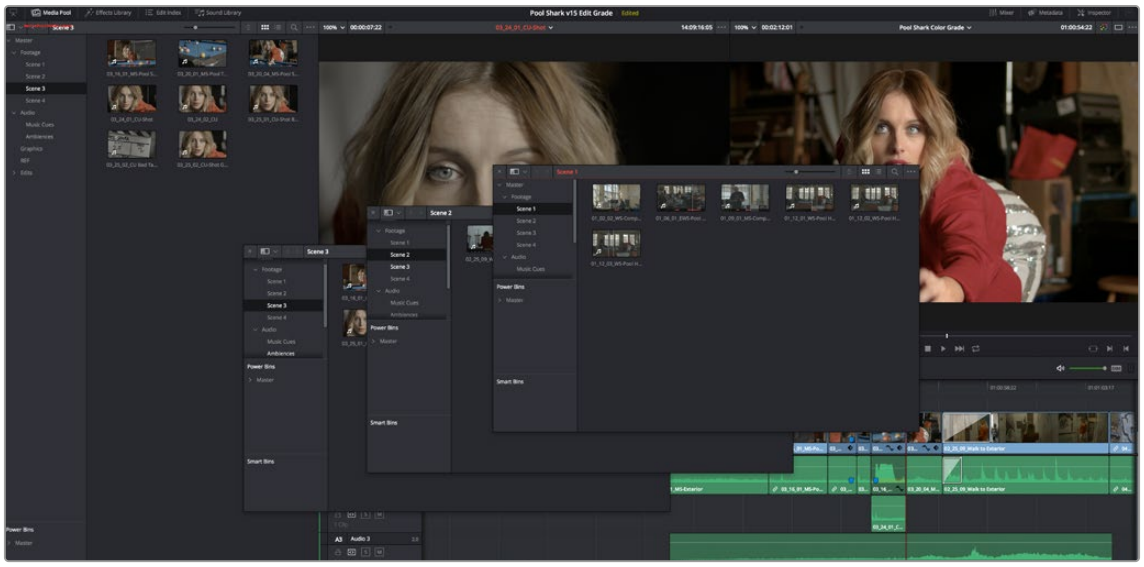
For example, the original clip in the Timeline remains conformed to the original clip that was first imported into the Media Pool; deleting the original clip from the Media Pool will make that clip “non-conformed” in the Timeline, while the duplicate you just created remains linked and available. If you’re in this situation, you can always turn Conform Lock Enabled off for that clip in the Timeline and reconform the Timeline Clip to the duplicate you just created, but that’s an extra step because the duplicate clip is considered by DaVinci Resolve to be a whole new piece of media that just happens to share the same clip details.

This may seem strange, but there are a variety of finishing workflows that use this capability, so it’s good to know about.

Duplicating Timelines

Timelines can be duplicated for a variety of reasons: to create a backup of a timeline at a specific date, to create a variation of an edit, or to create separately graded versions.

To duplicate a Timeline:



- Select a Timeline in the Media Pool, and choose Edit > Duplicate Timeline.
- Press Command-4 to give focus to the Timeline, and choose Edit > Duplicate Timeline.

Choosing How to Display Bins

Once you’ve created a bin structure for your project, you can customize how your bins are displayed, depending on how you like to work.

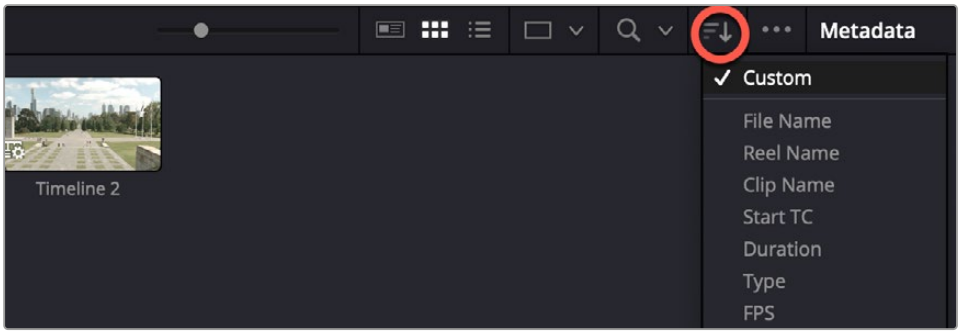
Showing Bins in Separate Windows

If you right-click a bin in the Bin list, you can choose “Open As New Window” to open that bin into its own window. That window is basically its own Media Pool, complete with its own Bin list, Power Bins and Smart Bins lists, and display controls.

Multiple Media Pool bins opened as new windows

When multiple Media Pool windows are open, the Workspace > Media Pool Windows submenu lets you bring a floating Media Pool window into focus when you have one or more open and hidden.

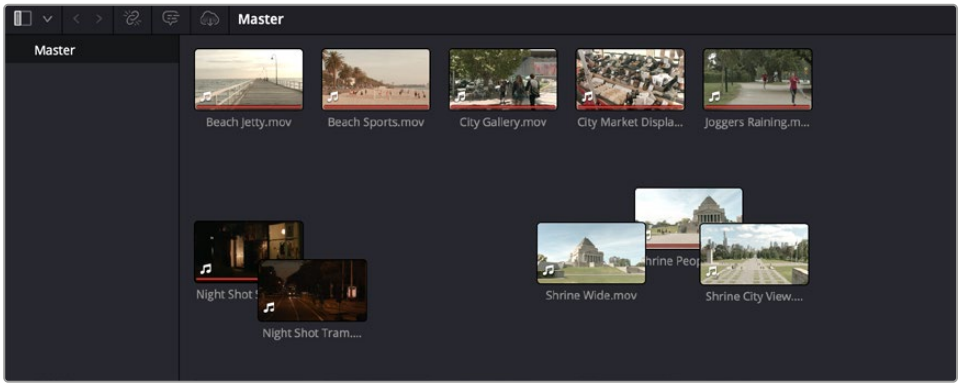
This is most useful when you have two displays connected to your workstation, as you can drag these separate bins to the second display while DaVinci Resolve is in single screen mode. If you hide the Bin list, not only do you get more room for clips, but you also prevent accidentally switching bins if you really want to only view a particular bin's contents in that window.



Using the Media Pool in Thumbnail View

If you work in Thumbnail view using the controls at the top right of the Media Pool, you have the option to resize the thumbnails to make them easier to see, and you can move the mouse pointer over each clip to hover scrub through its contents. Clicking any clip to select it displays it in the Media page Viewer. Whichever clip is currently selected is also output to video for monitoring.

In Thumbnail view, you can use the Sort Order drop-down, at the top right of the Media Pool, between the Icon Size slider and the Icon/List view buttons, to choose how clips are sorted. There are fourteen options: File Name, Reel Name, Clip Name, Start TC, Duration, Type, FPS, Audio Ch, Flags, Date Modified, Date Created, Shot, Scene, and Take.

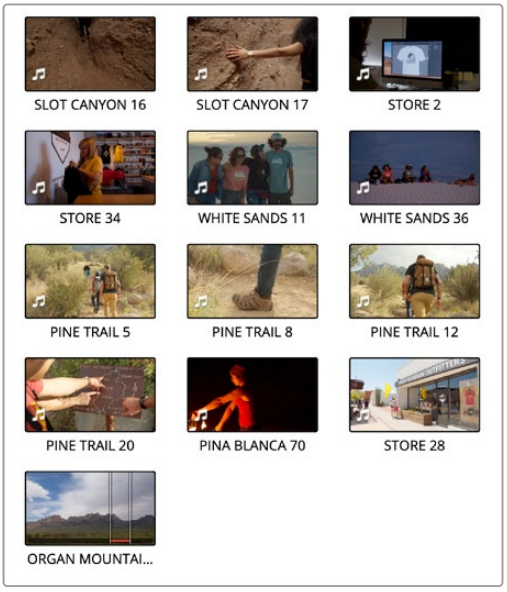


Custom Sort of Clip Thumbnails in the Media Pool

You can now manually reposition Media Pool clips in Thumbnail view, allowing you to group clips together in any way that visually makes sense to you.

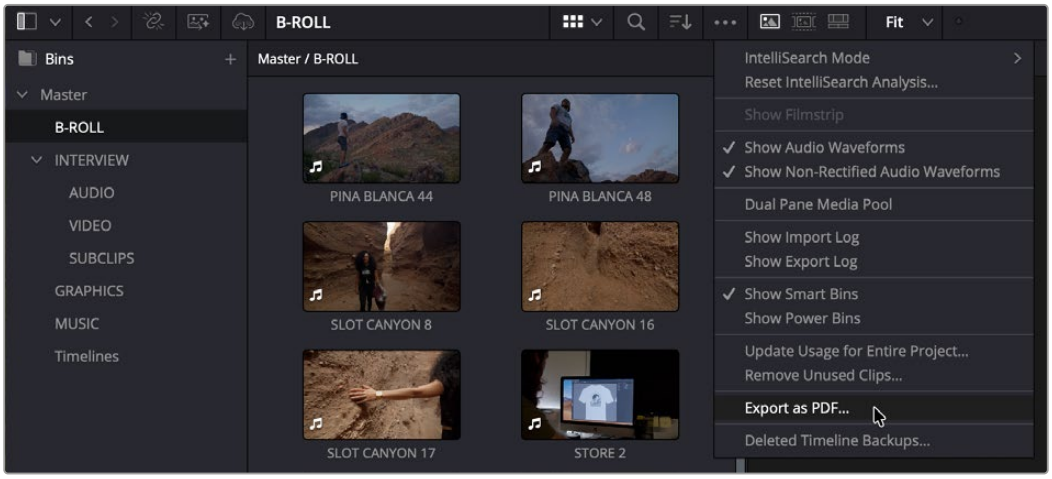
You can turn on Custom Sort by selecting Custom in the Sort menu in the Media Pool.

Select Thumbnail View in the Media Pool, and from the sort menu select Custom. Then you can drag your thumbnails around in any order or grouping that you wish. If Snap to Grid is selected in the Sort menu, the icons will line up in neat rows and columns. Turn off Snap To Grid to enable freeform positioning. If two thumbnails are overlapping, the last one moved will show on top.



With Snap to Grid deselected you can rearrange thumbnails in any way (even overlapping), and it is retained throughout the Medial Pool on all pages.

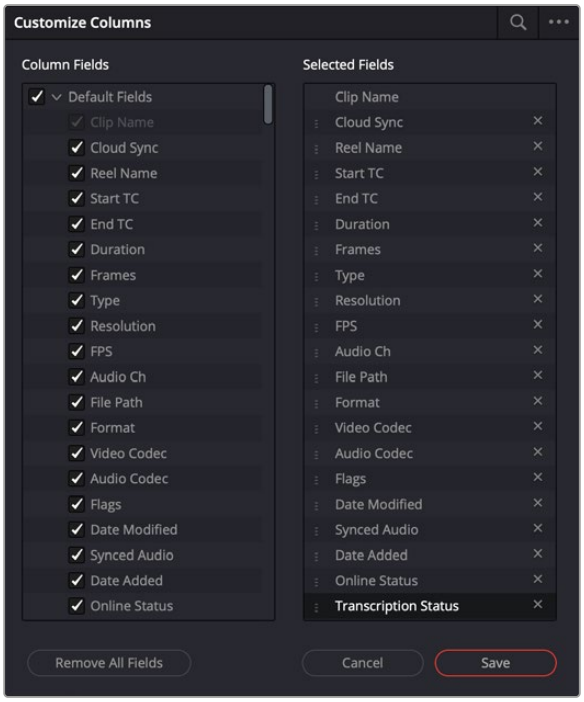
The position of your icon thumbnails is consistent in the Media Pools across all pages within DaVinci Resolve. Your positioning also remains unchanged even if you choose another Sort order, then return to the Custom sort.



Export Media Bin Thumbnails as a PDF

You can export the thumbnails in a Media Pool bin as a PDF file, which gives you a digital “contact sheet” of sorts. This helps you easily see which clips are inside a particular bin. The PDF also respects the thumbnail image size set in the Media Pool. By default, the view will attempt to fit the thumbnails on a single page PDF file—but if you have large or multiple custom-sorted bins, the PDF will be exported as a single expanded document, rather than broken into pages.

A PDF export of a Media Pool bin.



To export a PDF of Media Pool bin thumbnails: Open the bin you want to export, click on the Media Pool 3-dot option menu, and select Export as PDF from the context menu. Then choose where to save it.

Choosing Export as PDF from the Media Pool option menu.

Working With Columns in List View

If you work in List view using the controls at the top right of the Media Pool, you gain additional organizational control by exposing columns that show the metadata that each clip contains, prior to media being added to your timeline. You can use these columns to help organize your media.

The Customize Columns window, accessed by right-clicking on a column header in List View

Methods of customizing metadata columns in List view:

- **To show or hide columns:** Right-click at the top of any column in the Media Pool to reveal the Customize Columns window. In the Column Fields, click the checkboxes of any columns you want to show or hide. Unchecked columns cannot be seen. When you're finished, click save.
- **To rearrange column order:** Drag any column header to the left or right to rearrange the column order, or drag the column names to your preferred order in the Selected Fields section of the Customize Columns window.
- **To resize any column:** Drag the border between any two columns to the right or left to narrow or widen that column.
- **To sort by any column:** Click the column header you want to sort with. Each additional time you click, the same header toggles that column between ascending and descending sort order.

  Once you've customized a column layout that works for your particular purpose, you can save it for future recall.

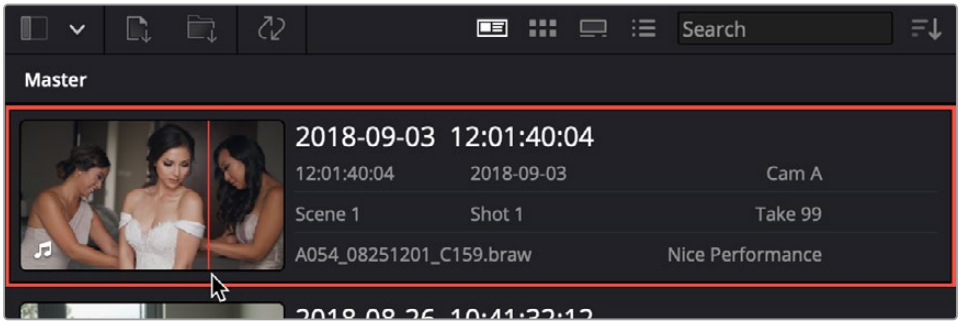
Methods of saving and using custom column layouts:

- **To create a column layout:** Show, hide, resize, and rearrange the columns you need for a particular task, then right-click any column header in the Media Pool, and:
  - Choose Customize Columns.
  - Click on the option menu, and select Save as New Preset.
  - Enter a new name for your column layout and press OK.

- **To recall a column layout:** Right-click any column header in the Media Pool, and choose Load Custom Layout and choose the name of the column layout you want to use from the contextual menu. Or select Load Preset from the preset name in the Customize Columns option menu.
- **To edit a column layout:** Load the column layout you want to edit, make whatever changes you need to, then right-click any column header in the Media Pool, and choose Customize Columns. In the Customize Columns window click on the Save button. You can also select Update from the preset name in the Customize Columns option menu.
- **To delete a column layout:** Right-click any column header in the Media Pool, and select Customize Columns . Then select Delete Preset from the preset name in the Customize Columns option menu. Click delete again to confirm.

  While the available columns of metadata correspond to those fields shown in the Metadata Editor, the available columns in the Media Pool of the Media and Edit pages are a subset of the total amount of metadata that's available. You can use any metadata field, including custom metadata fields, in your Column layouts.

Editable Name, Description, Keyword, and Comments Columns

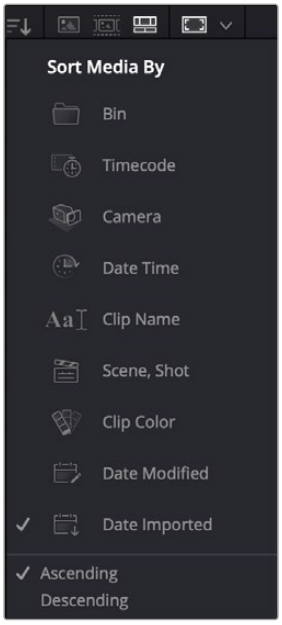


In addition to the Clip Name, when the Keyword, Description and Comments columns are displayed by the Media Pool in List view, you can edit their contents by clicking once within a clip's Description or Comments field, waiting a moment, and then clicking a second time to select that field.

Using Metadata View in the Media Pool

In the Metadata View mode, each clip is represented by its own card with a thumbnail and basic clip metadata information visible. This view is designed to have more metadata information than a thumbnail but more targeted information than the List view. This feature, combined with its sort modes, is a powerful way to organize and reorganize your clips in the Media Pool.

The metadata fields of the Metadata view (from the top down):

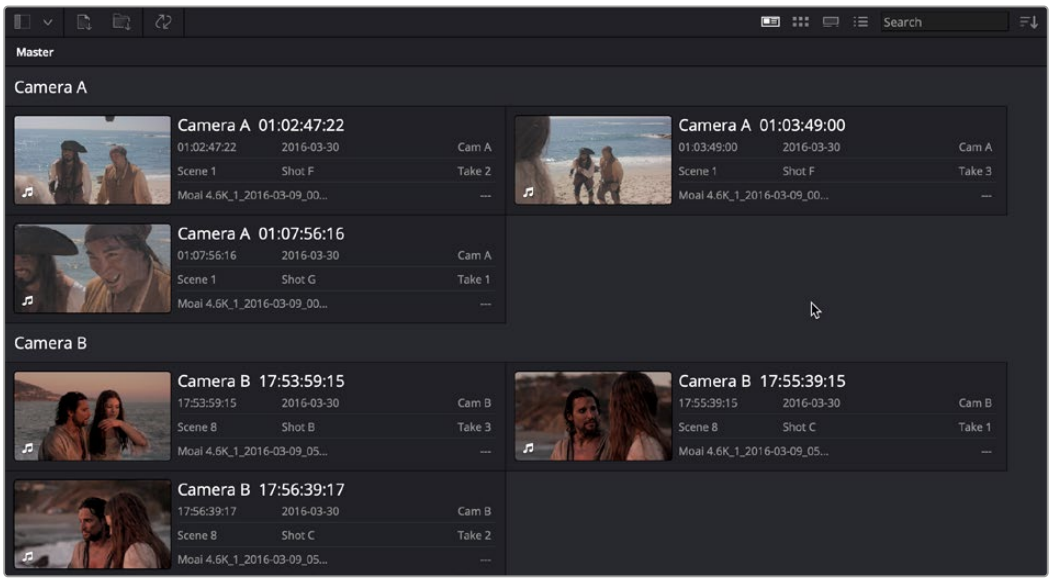


- **Thumbnail:** A scrubbable thumbnail image of your clip.
- **Row 1:** A main description field that is variable and determined by the sort order selection.
- **Row 2:** Start Timecode, Date Created, Camera #.
- **Row 3:** Scene, Shot, Take.
- **Row 4:** Clip Name, Comment.

The Metadata View icon view (highlighted icon in the top bar), showing the thumbnail being scrubbed next to the clip's metadata

The strength of the Metadata view is the automatic clustering of your clips based on the sort order you choose in the Media Pool Sort By menu, at the very upper-right corner of the Media Pool.

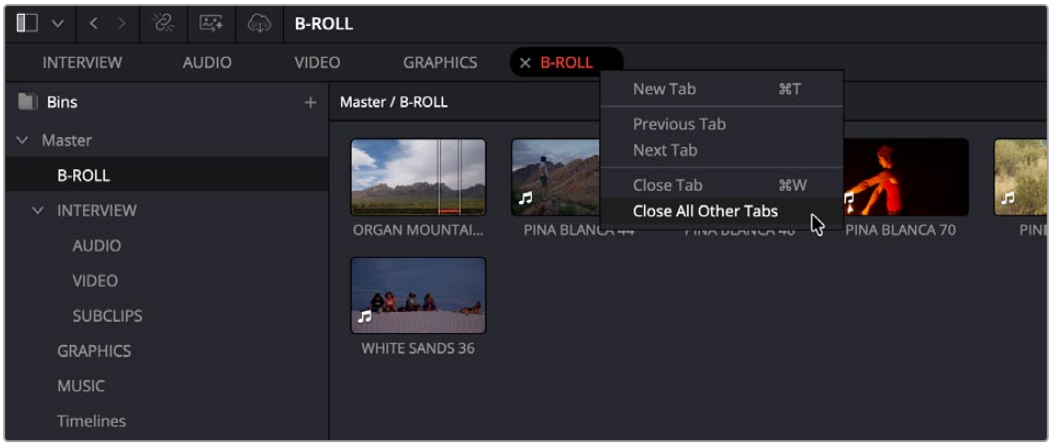
Each different sort mode changes the main description field on the card, as well as re-arranging the Media Pool to reflect the selected organization method.



The Media Sort options

The sort modes available in the Metadata view are:

- **Bin:** This mode clusters the clips by bin, changes the main description field to clip name, and orders the list by timecode.
- **TImecode:** This mode clusters the clips by creation date, changes the main description field to creation date and start timecode, and orders the list by timecode.
- **Camera:** This mode clusters the clips by camera #, changes the main description field to camera # and start timecode, and orders the list by timecode.
- **Date Time:** This mode clusters the clips by day, changes the main description field to creation date and file name, and orders the list by timecode.
- **Clip Name:** This mode clusters the clips by the first letter of the clip name in alphabetical order, changes the main description field to clip name, and orders the list by timecode.
- **Scene, Shot:** This mode clusters the clips by scene, changes the main description field to scene-shot-take, and orders the list by scene-shot-take.
- **Clip Color:** This mode clusters the clips by clip color name, changes the main description field to creation date and start timecode, and orders the list by timecode.
- **Date Modified:** This mode clusters the clips by day, changes the main description field to creation date and file name, and orders the list by the last time the clip was modified by the OS filesystem.
- **Date Imported:** This mode clusters the clips by day, changes the main description field to creation date and file name, and orders the list by the date the clip was added to the Media Pool.

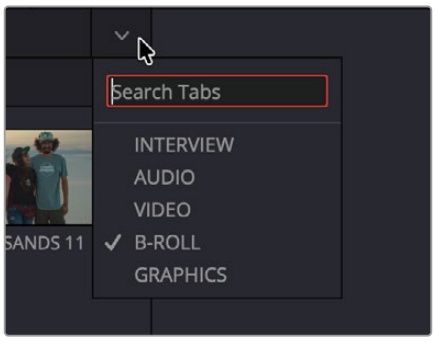


- **Ascending:** Orders the Media Pool from lowest numerical value to highest, and alphabetically from A to Z.
- **Descending:** Orders the Media Pool from highest numerical value to lowest, and alphabetically from Z to A.

The Metadata view with the same clips sorted by Camera

Media Pool Tabs

The Media Pool lets you create tabs as shortcuts to specific bins. Each tab is displayed at the top of the Media Pool, as well as Media Pool windows in other pages. Tabs can be set for conventional bins, smart bins, and power bins.



The Media Pool tabs, and the right-click context menu.

To create a new bin tab, right-click on a bin and select Open as New Tab from the context menu. When you click on a tab name, it opens that bin in the Media Pool. Further bin navigation in an open tab will replace the active bin with the newest and most current bin selection.

You can also right-click on a tab to do the following:

- **New Tab:** Create a new tab (Command T).
- **Previous / Next Tab:** Navigate to the previous or next tab in the tab bar.
- **Close Tab:** Close the current tab (Command-W) (CTL-W on Windows and Linux).
- **Close All Other Tabs:** Close all other tabs except the current one.

To search for tabs, click on the dropdown icon on the right side of the tab bar.

You can also search for specific tabs by using the dropdown to the right of the tab bar. Clicking this icon will give you a list of current tabs, and a search box. Note that this search box is for tab names only, and will not return results for Media Pool clips.

Thumbnail, List and Metadata Views Can Be Set Per Bin

Bins can be set to always open in a specific layout view (Thumbnail, Metadata, and List), regardless of the current bin view settings. For example, you might choose to always open a bin containing audio clips in List view, since thumbnails are often unnecessary for audio-only media.

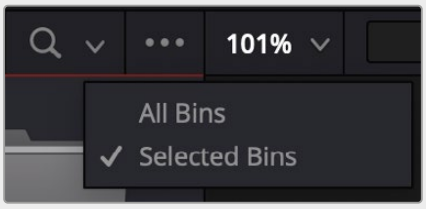
To set a layout view for a bin:

1. Select the view you want the bin to Always open as.
2. Right-click on the bin you want to apply this view to.
3. Select Always Open in XXX View, where XXX will be the name of the view that you've chosen.

   DaVinci Resolve will remember this bin view across sessions, but it will not affect other users and machines working on the same project.

Finding Clips, Timelines, and Media

There are several ways to locate different items in the Media Pool and Media Storage, be they clips, timelines, or media on disk.



Finding Clips and/or Timelines Within the Media Pool

Clicking the magnifying glass button at the upper right-hand corner of the Media Pool exposes the Search Options, which by default can be used to locate one or more clips in the currently selected bin or bins, based on the metadata that's selected in the Filter By drop-down menu to the left of it.

The Search Options drop-down menu (as seen in the Edit page Media Pool) lets you choose what metadata you're searching

A drop-down menu right next to the magnifying glass icon lets you choose the scope of your search. This lets you choose whether a search looks through all bins in the current project for the specified criteria, or just looks at the currently open bin, or currently selected bins in the Bin list, in cases where you're looking for an instance of media in a specific hierarchical location of the Media Pool.

The drop-down menu next to the magnifying glass icon lets you set the bin search parameters

To find a clip in the Media Pool:

1. (Optional) Use the drop-down menu next to the Search button that exposes the Search and Filter by controls in the Media Pool to choose whether you select All Bins or Selected Bins.
2. (Optional) If you're searching Selected Bins, then open the Bin list and select one or more bins in which to search.

3 (Optional) Choose a criteria from the Search Options drop-down menu at the top right of the Media Pool; you can choose All Fields to do a simultaneous search of every metadata column in the Media Pool at once, or you can choose a specific criteria to restrict your search.

4 Type a search term in the Search field. As soon as you start typing, all clips that don't match the search criteria are temporarily hidden. To show all clips in the Media Pool again, click the cancel button at the right of the search field.

Finding Synced Audio

If you've synced dual-system audio and video clips together in DaVinci Resolve, you can find the audio clip that a video clip has been synced to using the following procedure.

To find the audio clip that a video clip has been synced to:

- Show the Media Pool in List view, and reference file name in the Synced Audio column.
- Right-click a video clip that's been synced to audio, and choose "Reveal synced audio in Media Pool" from the contextual menu. The bin holding the synced audio clip is opened and that clip is selected.

Finding Timeline Clips in the Media Pool

If you have a clip in a timeline and you want to find the corresponding clip that it's conformed to in the Media Pool, you can right-click that clip, and choose Find in Media Pool from the contextual menu.

Finding Timelines in the Media Pool

If you'd like to find the currently open timeline's location in the Media Pool, you can choose Timeline > Find Current Timeline in Media Pool.

Finding Media in the Media Storage Panel and Finder

If you find yourself needing to determine the location of a clip's source media file on disk, you can right-click an item in the Media Pool and choose Reveal in Media Storage panel. The Library automatically opens to the folder containing the media file you've selected, with that media file selected in the Library browser to the right.

Another feature that's only available for macOS systems is the ability to right-click an item in the Media Pool and choose Reveal In Finder. A file system window opens up, revealing the media file that clip is linked to.

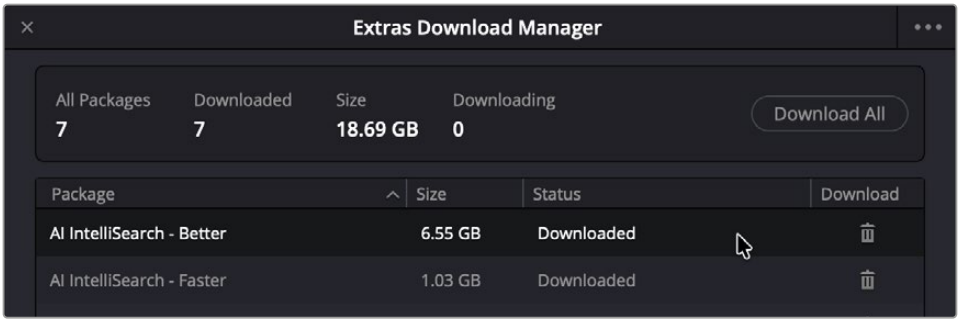
Reveal Media Pool Bin from Multi-Bin or Search Displays

If you've searched for a clip and have results across multiple bins, you can now reveal where that clip is in the Media Pool by right-clicking on the clip and selecting Reveal Media Pool Bin from the contextual menu.

Going Immediately to a File System Location in the Media Browser

Conversely, if you drag a folder from the macOS Finder into the Media Storage panel, the Media Storage panel will immediately update to show the location of that folder.

IntelliSearch (Studio Version Only)



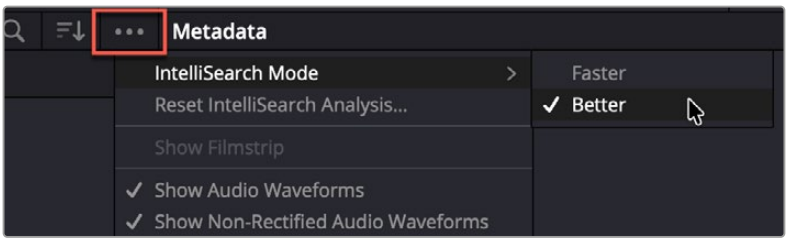
IntelliSearch is an AI-powered tool that provides a fast, comprehensive search of your media pool for people and objects. This means you'll no longer have to manually sift through your media pool in search of a specific clip.

Setting up IntelliSearch

To start, download the corresponding AI model package from the Extras Download Manager. Once installed, you can then analyze the media in your media pool before using IntelliSearch from the search bar.

Downloading the IntelliSearch Models

Download the IntelliSearch models from DaVinci Resolve > Extras Download Manager. There are two model packages: Faster mode, and Better mode. Your modes will be limited to the packages you have installed.

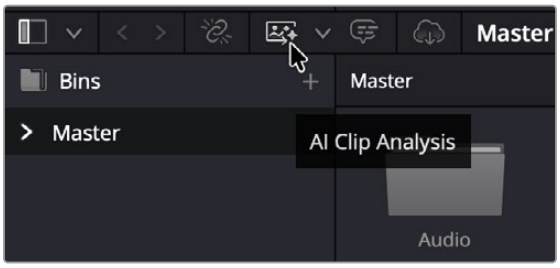


There are two IntelliSearch AI model packages available or download: Better mode, and Faster mode.

Selecting the IntelliSearch Mode

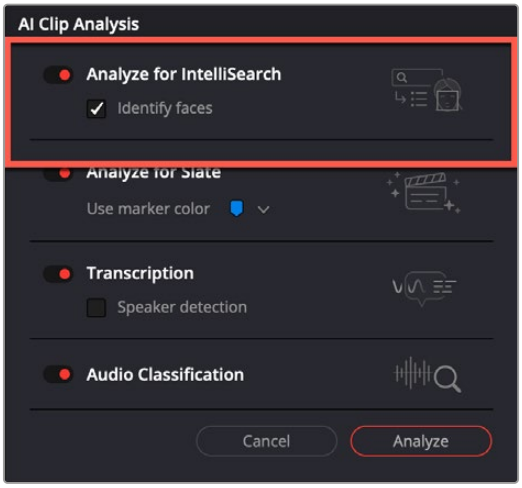
You should first decide whether to run IntelliSearch in Faster or Better mode. The tradeoff is analysis time and the size of the model download. Both modes are equally quick once analysis is complete, but Better mode uses a larger model and can take significantly longer to analyze your clips in exchange for more accurate results.

A suggested workflow is to start in Faster mode, then run the analysis in Better mode when your workstation has more downtime.



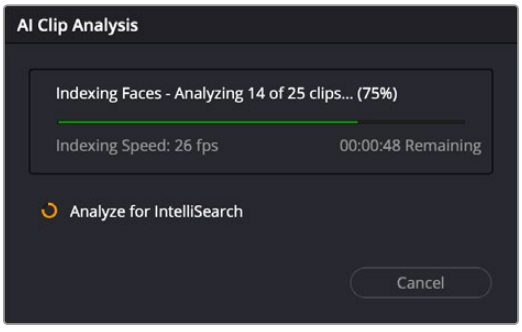
You can choose your preferred mode via the Media Pool three-dot option menu, under IntelliSearch Mode.

Choose between Faster or Better mode for IntelliSearch.



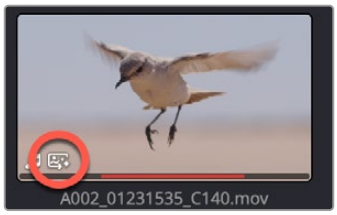
Analyzing Media in IntelliSearch

Once you've chosen a model, you can run the IntelliSearch analysis on your Media Pool clips with the AI Clip Analysis tool. This tool provides a single location to selectively apply different AI analysis models on the clips in your Media Pool for a variety of AI-driven features in DaVinci Resolve. By default, it analyzes all the clips in your media pool. To analyze only selected clips, use the dropdown menu to the right.



The AI Clip Analysis icon in the Media Pool.

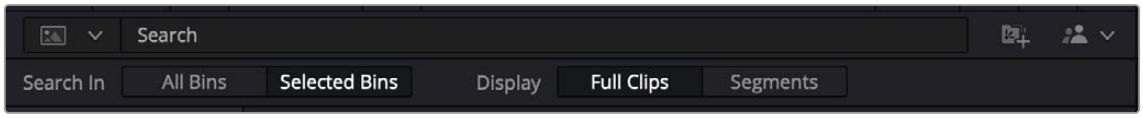
To start your IntelliSearch analysis, ensure the toggle located beside Analyze for IntelliSearch is switched on. You can optionally enable the "Identify faces" checkbox beneath it—this lets IntelliSearch recognize individual humans. You can then add these individuals' names as search criteria in the Manage Faces window of the IntelliSearch interface.



Make sure the toggle beside Analyze for IntelliSearch is switched on.

Next, click the Analyze button. A progress window will appear, letting you know the approximate analysis time remaining.

The AI Clip Analysis progress bar.



Once complete, your analyzed clip will have the AI Analysis icon on its thumbnail, so you'll know at a glance which clips have been processed.

This icon appears after a clip has been analyzed for IntelliSearch.

Using IntelliSearch

To access IntelliSearch, simply click on the magnifying glass search icon in the Media Pool. This exposes a search bar and its surrounding toolset.

The IntelliSearch toolbar.

- **Search Parameters:** Choose what kind of search analysis to apply to your search terms.

  Search All: Returns results from all types of AI analysis and entered metadata.

  Search Visual Only: Returns results from the image analysis only. The Visual search allows you to search for objects and other contents in the scene.

  Search Transcript Only: Returns results from the audio transcript only. The Transcription search limits your search to transcribed audio, which is useful if you're looking for exact phrases.

  Metadata Search: Returns results from any or all of the metadata fields. The Metadata search can be used to filter by keywords and other metadata (including custom metadata) and clip properties. This mode also gives you a dropdown menu to search all fields, or filter by file name, timecode and other metadata fields.

- **Search Field:** You can search for virtually anything here: an object, a person, a color, a camera number, or even a line of dialog.
- **Add as SmartBin:** Pressing this icon will open the Create Smart Bin tool, with the parameters you've chosen already added to the Smart Bin criteria. This helps you to create a consistent Smart Bin of your search results.
- **Show Face Gallery:** Displays a thumbnail view of every detected human face. Click on a thumbnail to view all shots that feature that human. You can also limit a search result to that human.

  Manage Faces: Opens the Manage Faces tool, which lets you name and curate the various faces detected.

- **Search In:** Lets you choose where to search.

  All Bins: Searches all bins in the project.

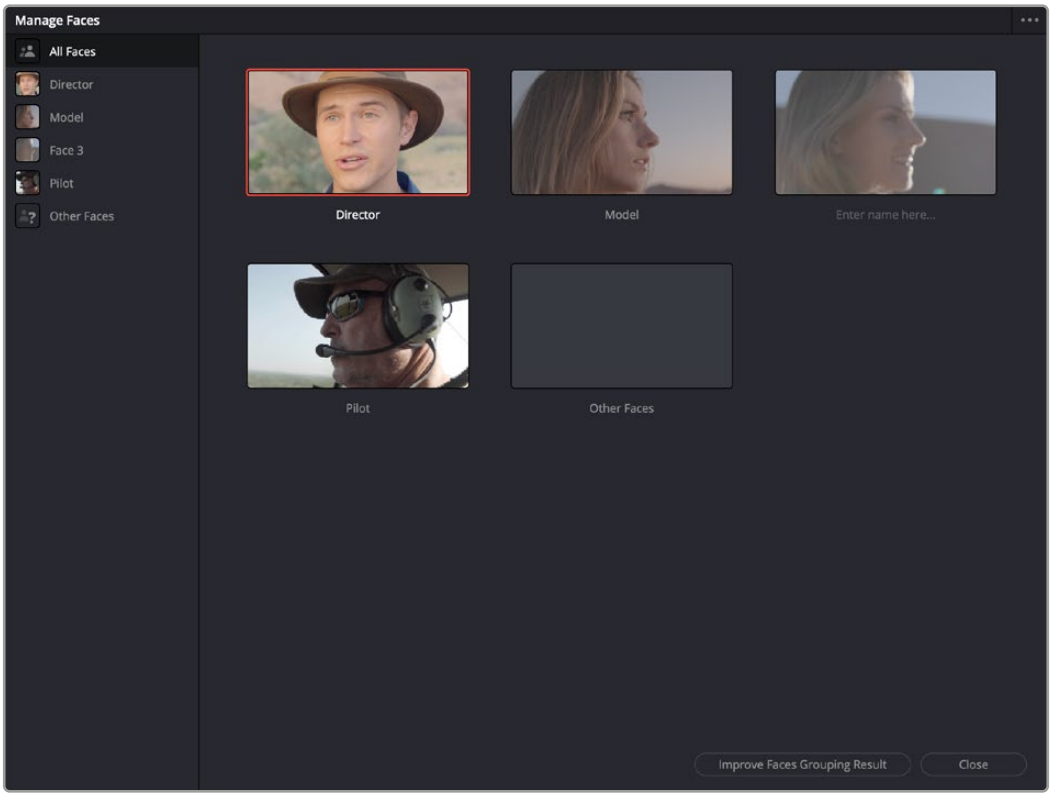
  Selected Bins: Searches only bins that have been selected.

- **Display:** Choose how the results are displayed (Search All, Visual only, and Transcript only).

  Full Clips: Returns the entire clip as a match.

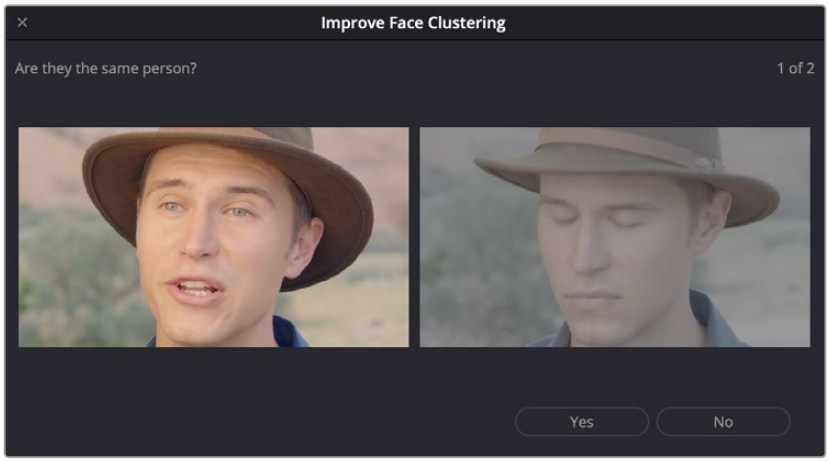
  Segments: Returns just the matching segments of each clip, effectively making it a subclip.

Face Gallery



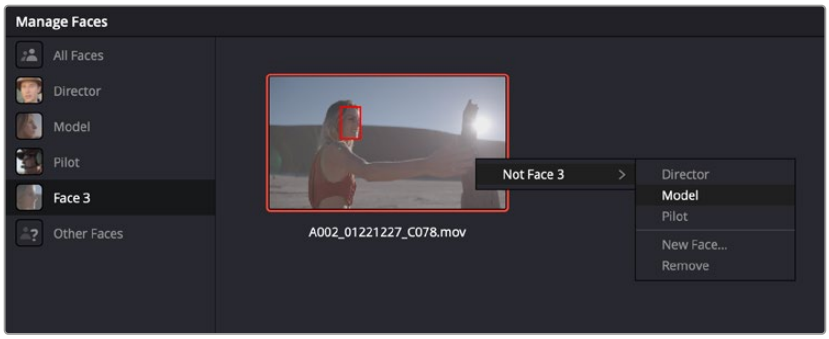
Clicking on the Show Face Gallery icon in the IntelliSearch bar opens a thumbnail view of each human face detected in your clips. Clicking on a face will limit the search results to just that human.

For example, you can click on a face thumbnail named “Chloe”, then type “red dress” in the search bar. The search results will return only images of Chloe wearing a red dress, and not the other actors.



The Face Gallery. When the woman’s face is selected in the small thumbnail, you’ll only see the clips she is in.

To attach a name to a face, go to the Manage Faces tool. Then click underneath the face thumbnail, and type the name into the field. This name is now metadata that’s attached to the face under the People field.



The Manage Faces tool, where you can type a name under the thumbnail to assign it to a face.

If Face Detection made an error, you can also fix that in the Manage Faces tool. When you click on the Improve Faces Grouping Result button, you'll be asked to confirm if two different shots are indeed of the same person. You can also manually assign a name to a face by right clicking on the thumbnail and selecting "Not XXX", then reassigning it to another face in the dropdown menu.

The Improve Faces Grouping Result tool has an automated yes / no interface to confirm if the face matches the assigned name.

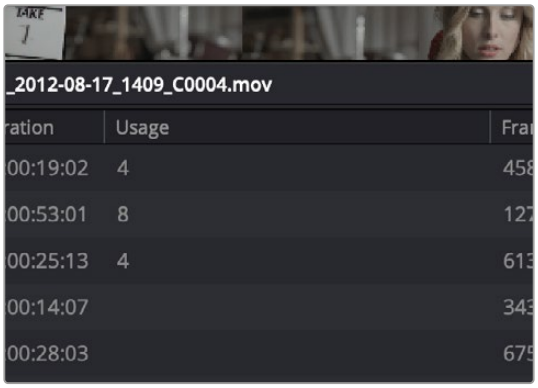
You can reassign a face manually by right-clicking on a thumbnail.

Tracking Media Usage

As clips are added to timelines, two mechanisms come into play for keeping track of which clips are used in which timelines.

Thumbnail Clip Usage Indicators

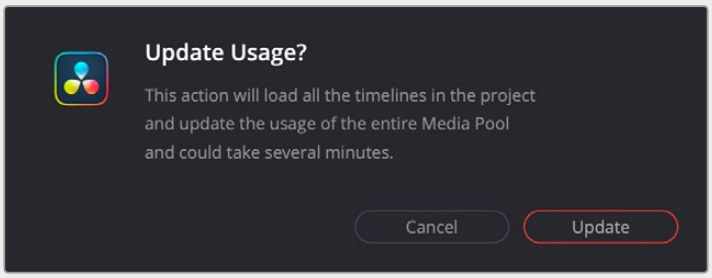
Whenever you open a timeline, all thumbnails in the Media Pool automatically update to show highlighted usage bars to let you know which parts of that clip are used in that timeline.



Two colored highlights at the bottom of the thumbnail indicate which parts of a clip are used by the currently open timeline

If you right-click on a thumbnail that shows usage, a Usage submenu shows you a list of each instance of that clip in the currently open timeline. Choosing an instance from this list jumps the playhead to that clip in the Timeline.

List View Clip Usage Column



Exposing the Usage column when the Media Pool is in List view lets you see a value for the number of times a clip appears in the current timeline. This usage column is now automatically updated; no user intervention is required.

A Usage column shows how many times a clip is used in a timeline, after analysis.

Updating Clip Usage for all Timelines

You can also see which clips have been used across all the timelines in your project. From the Media Pool Options menu, select the “Update Usage for Entire Project” option.

The Update Usage dialog

DaVinci Resolve may prompt the user to load all timelines, if necessary, and update usage counts for Media Pool clips. This can take some time, depending on the complexity and number of timelines you have in your project.

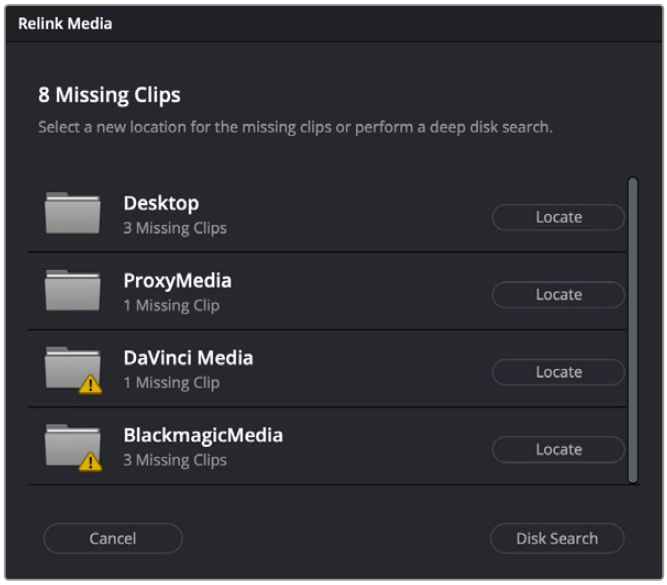
Once completed, the usage count across all timelines will appear in the Usage column in the List view of the Media Pool.

NOTE: The Usage column increments for each clip item that appears in the Timeline. This means that if a clip consists of one video item and one video item linked together, the Usage column will show the number 2.

Relinking Media Simply

DaVinci Resolve keeps track of the relationship between clips in your project and their corresponding source media on disk. If, for whatever reason, source media that links to clips in your project becomes unavailable, DaVinci Resolve has several different methods of relinking those clips in the Media Pool.

This section summarizes the methods of relinking. For more comprehensive information on conforming projects and relinking media, jump to this section: Conforming and Relinking Media.



Relink Media

If DaVinci Resolve fails to find your media, a Relink Media icon in the Cut and Edit page's Media Pool will highlight orange.

The Relink Media icon that appears for unlinked media

Clicking this icon opens a dialog box showing the volumes that the missing files initially belonged to. You can then use this information to track down the media on your file system, find that specific hard drive, or ask a client if they provided you the media from this volume. Clicking the Locate button lets you re-connect the missing clips to a new file location of your choosing. If the quick search initiated by the Locate buttons doesn't find media that you know is there, you can initialize an exhaustive deep disk search for the media by clicking on the Disk Search button.

The Relink Media dialog showing the volume names where the missing clips originated

Relink Selected Clips

The easiest method of relinking clips in your project that have gone offline is to use the appropriately named “Relink selected clips” command. This is the most flexible method of relinking clips in your project with clips in a file system directory of your choice, using file name and timecode as the primary criteria for drawing a correspondence between each clip and the corresponding media file on disk. When you relink clips this way, the original file path in DaVinci Resolve is ignored, so this is a good command to use to relink to media that’s been reorganized on disk.

To relink selected clips:

1. Do one of the following:
   - Select one or more clips in the Media Pool browser that you want to relink, then right-click one of the selected clips or the selected bin, and choose “Relink Selected Clips” from the contextual menu.
   - Select a bin in the Media Pool Bin list that contains clips you want to relink, then right-click one of the selected clips or the selected bin, and choose “Relink Clips for Selected Bin” from the contextual menu.
2. When the Relink File dialog opens, choose a directory in which to look for the files you want to relink to, and click OK. DaVinci Resolve attempts to find every clip with a matching file name in the subdirectories of the directory you chose, using the original file paths of the clips being relinked to do this as quickly as possible. By first looking for the clips in the directories they were originally in, relinking can be quite fast.
3. If there are any clips that couldn’t be found using the method in step 2, you’re prompted with the option to do a “deep search” by a second dialog. If you click Yes, then DaVinci Resolve will look for each clip inside every subdirectory of the directory you selected in step 2. This may take significantly longer, but it should be completely successful so long as the media that’s required is within the selected directory structure.
4. If there are still other clips that couldn’t be found, you’re prompted to either choose another directory altogether to continue searching, or quit.

Change Source Folder

If you’ve used your file system to move media that’s associated with a DaVinci Resolve project, but you haven’t changed the directory structure with which it’s organized, you can use the Change Source Folder command to quickly relink selected clips in the Media Pool to the new file path of the media on disk, using the original file paths as a guide. This is a good relinking method to use, if possible, for projects on a SAN where you don’t want to risk the excessively long search times that could result from using the Relink command to examine a nested hierarchy of folders in a more flexible way.

To relink your Media Pool clips to a new location:

1. Select one or more clips in the Media Pool, then right-click one of the selected clips, and choose Change Source Folder from the contextual menu. The Relink Media window appears displaying the original path for the material, with controls for choosing a new directory.
2. Click the “Browse” button to the right of the Change To field, and then use the file navigation dialog to find the new location of the media file, select it, and click Open.
3. If you succeeded in finding the appropriate media file, click Change. Otherwise, click Cancel.

Chapter 18

Using Clip Metadata

DaVinci Resolve has powerful tools for viewing, editing, exporting, and importing metadata associated with each clip in the Media Pool.

Once your metadata house is in order, you can use this metadata in the Cut, Edit, Color, and Fairlight pages to find, sort, and organize the clips in your project, so you can work faster.

Editing Clip Metadata

Whether you've imported media in preparation for editing, or you've imported a project for grading that resulted in media being imported automatically, once you've added clips to the Media Pool, it would behoove you to consider taking the time to review and add metadata to your clips.

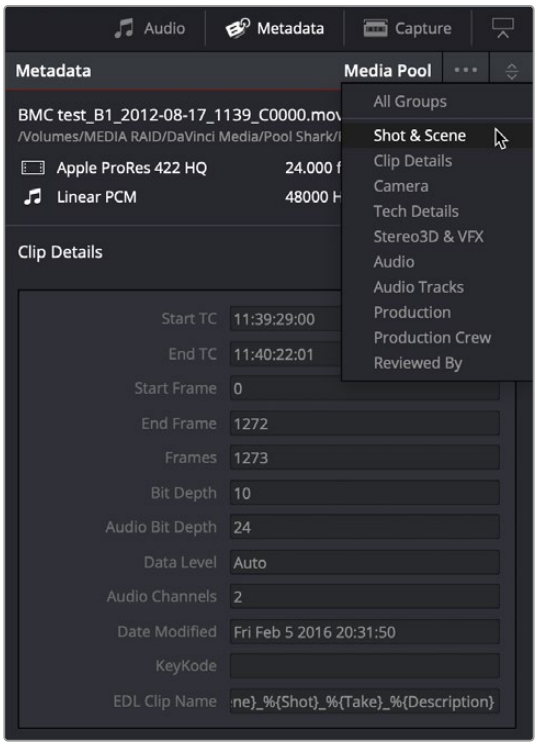
At the very least, it would be valuable for you to use the Metadata Editor that's available in either the Media page or the Edit page to add information to each clip such as a Description, Shot and Scene designations, Take information, and possibly some useful keywords such as Character Names, Shot Framing, Interior or Exterior keywords, and so on. If you're especially ambitious (or you have a very responsible assistant), you could go further and add Shoot Day, Camera Type, Audio Notes, and other valuable information. Much of the metadata that is useful in the day to day work of editing and grading can be found in the Shot & Scene group, but there are many other potentially useful groups as well that you should explore.

Keep in mind that the more metadata you associate with each clip, the more methods you have at your disposal for creating custom Smart Bins (for editing) and Smart Filters (for grading) with which to zero in on the clips you need for any given situation. This will not only make it easier to find what you need, but it'll help you to work faster.

> For example, if you've entered enough metadata, then you can create multi-criteria Smart Bins or Smart Filters that let you find the equivalent of "every close-up of Sally inside the diner," or "every long shot of Antonio outside in the parking lot." In a documentary, you could easily isolate "every interview shot of Louis from camera 1," or "every B-roll clip with Robyn." All of this will help you to find media faster for editing, or to quickly isolate similar clips that you need to match together for grading.

Automatically Imported Metadata

In many instances, metadata is also imported along with the media you've added to the Media Pool. For example, media recorded on BMD cameras may have had a variety of metadata entered into the camera or automatically generated by the camera, and this metadata is automatically available in the Metadata Editor. Similarly, Broadcast WAVE files can have quite a bit of metadata entered at the time of recording, such as scene and take numbers and channel names describing each microphone. Still images are imported with EXIF metadata. In all cases, available metadata is imported along with the media and exposed in the Metadata Editor to facilitate workflows where valuable organizational metadata is being entered on set during the shoot or immediately after ingest.



Using the Metadata Editor

Whenever you select a clip in the Media Pool, its editable metadata appears in the appropriately named Metadata Editor (so long as it's displayed). You can use this editor to further massage the metadata of the clips in a project, adding information on set that will be of help later during editing and finishing.

By default, clips initially appear with a set of clip metadata called "Clip Details," that shows some of the most fundamental details of the clip such as start and end timecode, duration, bit depth, and so on.

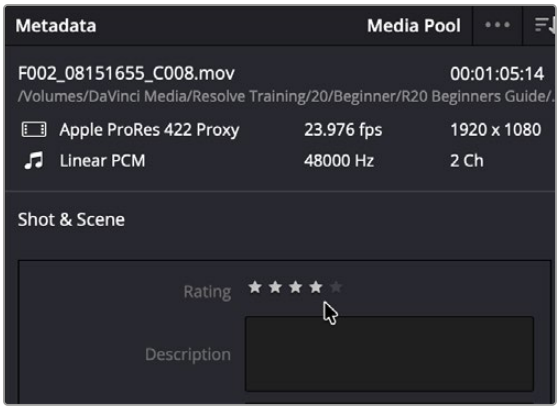
Because there are so very many metadata fields that are available, two drop-down menus at the top right of the Metadata Editor let you change which set of metadata is displayed.

- **Metadata Presets (to the left):** If you've used the Metadata panel of the User Preferences to create your own custom sets of metadata, you can use this drop-down to choose which one to expose. Surprisingly enough, this is set to "Default" by default.
- **Metadata Groups (to the right):** This drop-down menu lets you switch among the various groups of metadata that are available, grouped for specific tasks or workflows.

Metadata categories drop-down menu

If you want to see a list of every piece of metadata in a clip, you can choose All Groups. Otherwise, you can choose any set of metadata to narrow your focus to just those items of information.

To edit metadata for a single clip:



Select any clip in the Media Pool, and edit whatever metadata fields you require. The edited metadata is immediately saved.

To edit metadata for multiple clips:

1. Choose a metadata set using the drop-down menu in the Metadata Editor.
2. Select multiple clips in the Media Pool by Shift-clicking, Command-clicking, or dragging a bounding box around them.
3. Edit whichever metadata fields you want to. Checkboxes are automatically turned on for any metadata fields you edit.
4. When you're done, click the Save button at the bottom of the Metadata Editor. When you've edited metadata for multiple clips at once, you'll be prompted to save your changes if you create a new selection in the Media Pool without clicking the Save button first.

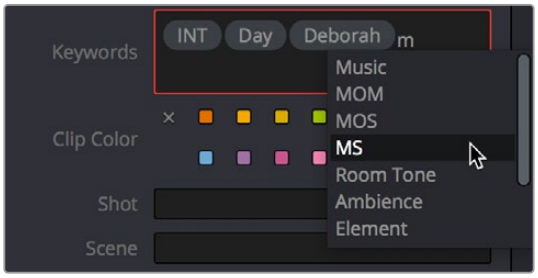
Editing Star Ratings For Clips

You can rate media pool clips from one to five stars in the Shot & Scene Metadata Panel, as well as still photos from multiple Photo Page controls.

Giving a clip a four star rating in the Shot & Scene metadata.

Click on the star rating to rate that shot and scene—you can also change your rating at any time by clicking on it again. To sort by Rating in the list view of the media pool, use Rating as a Smart Bin criteria and sort an album by rating in the Photo page.

Editing Keywords



While most metadata in the Metadata Editor is edited via text fields, checkboxes, or multiple button selections (such as Flags and Clip Color), the Keyword field is unique in that it uses a graphical "tag" based method of data entry. The purpose of this is to facilitate consistency with keyword spelling by making it easy to reference both a built-in list of standardized keywords, as well as other keywords that you've already entered to other clips.

Once added, keywords are incredibly useful for facilitating searching and sorting in the Media Pool, for creating Smart Bins in the Media and Edit pages, and for use in Smart Filters on the Color page. Reaping these benefits by adding and editing keywords is simple, and works similarly to the method of entering metadata variables.

For more information on metadata variables, jump to this chapter:
Using Variables and Keywords.

To add a keyword:

1. Select the Keyword field of the Metadata Editor, and begin typing the keyword you want to use. As you begin typing, a scrolling list appears showing all keywords that are available using the string of characters you've just typed.
2. To find a specific keyword in the list, start typing that keyword's name and this list automatically filters itself to show only keywords that contain the characters you've just typed. Choose which keyword you want to use in the list using the Up and Down Arrow keys, and press Return to choose that keyword to add.

The keyword list that appears when you type within the Keyword field

As soon as you add one or more keywords, they appear as a graphical tag. To re-edit any keyword, simply click anywhere within the Keyword field to edit it.

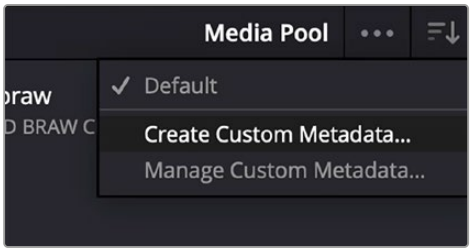
To edit a keyword:

- Double-click any keyword to make it editable, then edit it as you would any other piece of text, and press Return to make it a graphical keyword tag again.

To remove a keyword:

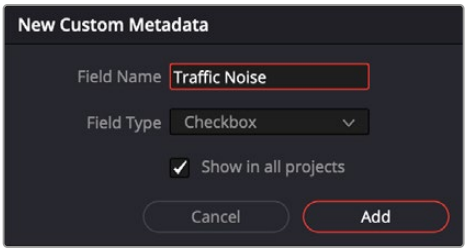
- Click any keyword to select it, and press Delete.

TIP: In macOS, any color tags that are set and defined in the Finder can automatically be imported as keywords alongside their media clips. To do so check the "Import Finder tags as Keywords" box in the General Settings panel of the Editing section in the User Preferences.



Adding and Populating Custom Metadata Fields

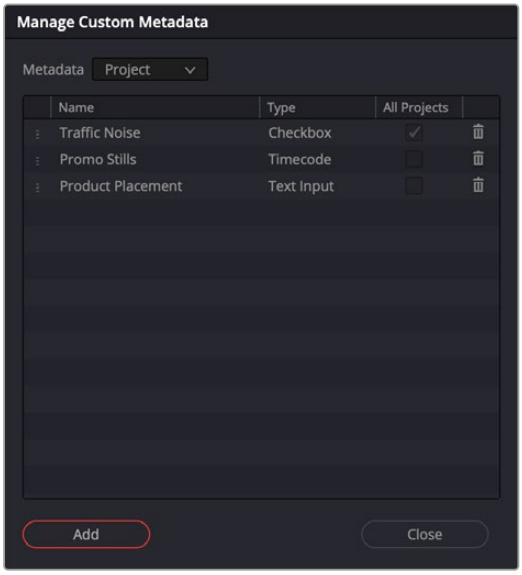
You can add your own custom Metadata fields to clips in the Media and Edit pages. These fields can be defined for the current project only, or across all your projects. Metadata fields can be of the following types:



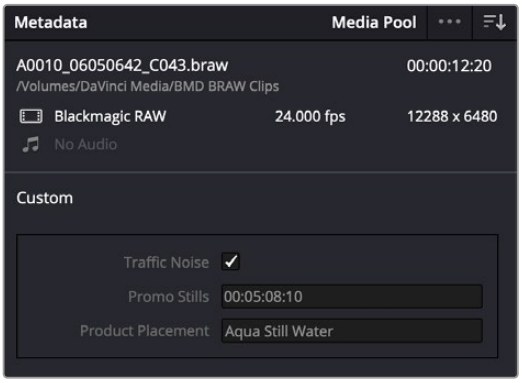
- **Text Input:** A field consisting of one line to enter text into.
- **Text Area:** A field of multiple lines to enter text into, for more detailed metadata.
- **Numeric:** A field that accepts a numeric value.
- **Timecode:** A field that accepts a single timecode entry.
- **Checkbox:** A simple on/off checkbox.

To add or edit custom metadata, select Create Custom Metadata from the three dot options menu in the Metadata tab.

Next, define the field name and field type and whether you want to see the fields across all projects. Then repeat as needed to add all your custom metadata fields.



The Create Custom Metadata option in the Metadata tab's three dot option menu



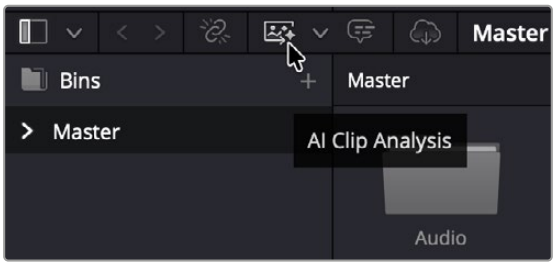
The new custom metadata dialog

To Manage Custom Metadata to re-order, edit, and delete custom metadata types, select Manage Custom Metadata from the Metadata three-dot option menu, then make any adjustments in the Manage Custom Metadata interface.

The Manage Custom Metadata interface

The populated Custom Metadata fields

Once the fields are determined you can populate them just like any other metadata field in the Metadata Tab. To view just the custom metadata fields, select the group filter dropdown menu in the top-right of the Metadata tab, and select Custom.



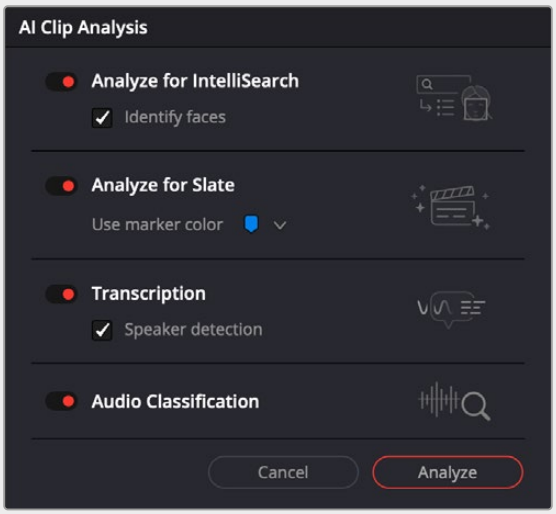
You can define metadata fields for the current project, or select "show in all projects" to see that field across all of your projects. Project metadata is saved alongside the project and is available to all users of that project. Cross-project metadata definitions are remembered and displayed across projects and project libraries for you. When you add a value to a cross-project metadata field, it is saved to the project and becomes available to other users of the project. The custom metadata panel displays a superset of project persisted custom metadata and cross-project metadata fields.

Use Custom Metadata in Smart Bins, Clip Filters, Data Burn-in and Naming Tags

You can use any Custom Metadata fields that were previously created in the Metadata Editor as criteria for Smart Bins, Clip Filters, Data Burn-ins, and Tags.

AI Clip Analysis

The AI Clip Analysis window lets you perform several AI-assisted metadata functions from its interface. To access it, clicking on its corresponding icon, located at the top toolbar of the Media Pool.



The AI Clip Analysis icon. To open the clip selection range dropdown menu, click on the caret (the dropdown arrow) beside it.

Next to the AI Clip Analysis icon is a caret (the small dropdown indicator). Clicking on this lets you choose the clip selection range for the AI analysis.

- **Perform AI Analysis in all Clips:** Runs all selected AI Analysis tools on all clips in the bin.
- **Perform AI Analysis in Selected Clips:** Runs all selected AI Analysis tools on only the selected clips in the bin.

When you expand the dropdown, you are presented with a set of AI-based functions and a toggle switch for each. To run an AI analysis on the selected clip(s), choose your preferred function(s) by toggling their corresponding switches, then click Analyze.

To exclude a particular AI analysis function, slide the toggle off. In this way, you can queue several AI analysis jobs at once, and have them run sequentially without any further user input needed.

The AI Clip Analysis window with all functions toggled on.

The current AI Clip Analysis Tools are:

- **Analyze for Intellisearch:** Runs the Intellisearch Analysis, with a checkbox option to find faces in the search.

  For more information on Intellisearch, jump to this chapter: Adding and Organizing Media with the Media Pool.

- **Analyze for Slate:** Runs the Slate Finder Analysis, with a dropdown option to choose the marker color. For more information on Slate Finder, see the Slate Finder and Slate ID section below.
- **Transcription:** Runs the Audio Transcription Analysis. For more information on Audio Transcription, jump to this chapter: Text Based Editing.
- **Audio Classification:** Runs the Audio Classification Analysis, with a dropdown option to choose the marker color.

  For more information on Audio Classification, jump to this chapter: Audio Classification for Clips below.

Editing Metadata Using the File Inspector

The File tab of the Inspector provides a consolidated way to view and edit a subsection of a clip's most commonly used media file metadata. It's easily accessible in the Inspector across the Media, Cut, Edit, and Fairlight pages. The tab is composed of the following parts:

- **Clip Details:** Presents data about the clip's data format (codec, resolution, frame rate, etc.).
- **Metadata:** Presents a reduced set of common metadata fields for quick user entry.

  Timecode: The start timecode of the clip. This field is editable if you want to manually change the clip's starting timecode.

  Date Created: The date that the clip was created. This field is editable if you want to manually change the clip's creation date.

  Camera: Sets the Camera # metadata.

  Reel: Sets the Reel/Card ID.

  Scene: The Scene number of the clip.

  Shot: The Shot letter/number of the clip.

  Take: The Take number of the clip.

  Good Take: This checkbox indicates if the clip is a good or circled take.

  Clip Color: Assign a specific color to a clip that is reflected in the Timeline.

  Name: The clip name field; this can be entered manually.

  Comments: Add a text description to the clip.

- **Auto Select Next Unsorted Clip:** When this box is checked, the next clip in the Media Pool is selected when you hit the return button after entering a metadata field, and the cursor is automatically placed in the same field. This allows rapid sequential metadata entry without having to manually click to load each individual clip in the Media Pool. The Next Clip button will select the next clip in the Media Pool, regardless of the checkbox status.

The File Inspector parameters

Tips for Editing Metadata

Editing metadata is like taking vitamins. Nobody wants to, but you know you probably should. To encourage you to undertake this task so you can reap the benefits, here are a few pointers.

- Don't start editing until you review your footage and add metadata. If you get into the habit of entering your clip metadata before you get preoccupied with your edit, you'll be in a much better position to edit faster using organizational tools that leverage the metadata you've entered.
- Enter metadata starting with groups of clips and then moving to individual clips. Since the Metadata Editor lets you add metadata for multiple selected clips at once, it becomes easy to select groups of clips based on their thumbnails for entering information such as Scene designations, Interior or Exterior keywords, Character keywords, and Framing keywords. You'll be surprised how fast this goes, and how useful this information is later on, for both editing and grading.
- After you've entered all the metadata you can in groups of clips, then switch to entering clip-specific metadata such as Shot designations, Take numbers, descriptions of action, and other clip-specific keywords.
- There's no right or wrong way to edit or use metadata, but a lack of consistency will make it less useful. For example, if you're identifying each clip that takes place at the same diner, try to use the same keyword or descriptive text. If you call half the shots "diner" and the other half "restaurant," your ability to easily search for all the diner shots will be compromised.

Slate Finder and Slate ID (Studio Version Only)

Slate Finder uses AI to automatically detect slates (clapper boards) and mark their positions using a duration marker on your clips. This lets you quickly jump to the slate for information about the scene.

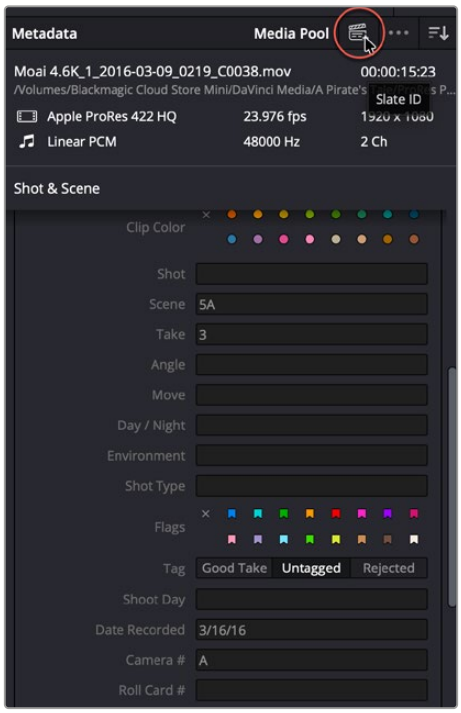
To use Slate Finder and Slate ID, download its corresponding AI model from DaVinci Resolve > Extras Download Manager.

To analyze slates:

1. Select the clip or clips with slates you want to analyze in the Media Page.
2. Right-click on one of them and select AI Tools > Analyze for Slate. Or toggle on Analyze for Slate in the AI Clip Analysis tool whose icon is at the top of the bin column.
3. A progress box will appear showing you the status of the Slate Finder operation.
4. Once completed, a duration marker will be added the the clip(s) analyzed for the time that the slate is in the frame and readable.

The Slate Finder has identified the frames in which the slate appears, a nd marked them as a blue duration marker.

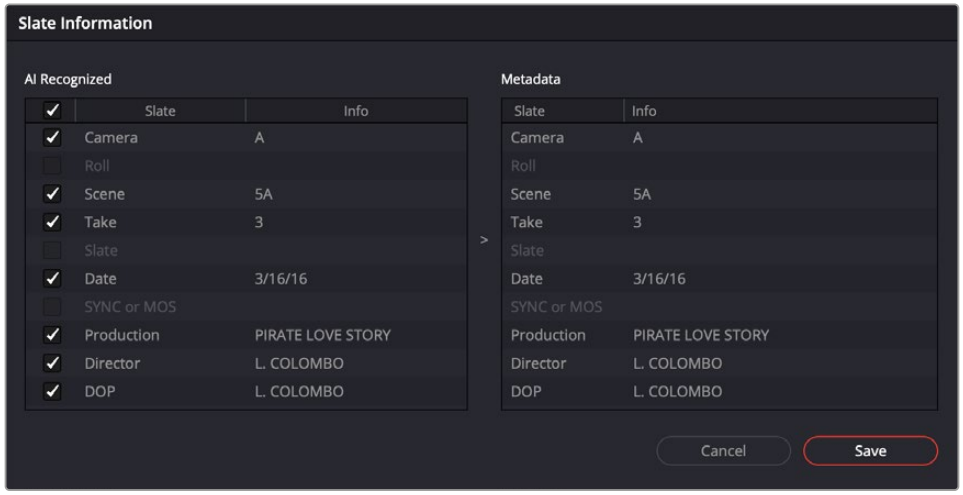
Slate ID



When a slate is found using Slate Finder, you can click on the Slate ID icon in the Metadata pane to view Scene, Take, Shoot Day, and other information written on the slate. You'll also have options to populate a clip's metadata based on these values automatically.

The Scene, Take, and other information handwritten on this slate can be extracted using Slate ID.

To automatically populate clip metadata based on Slate ID:

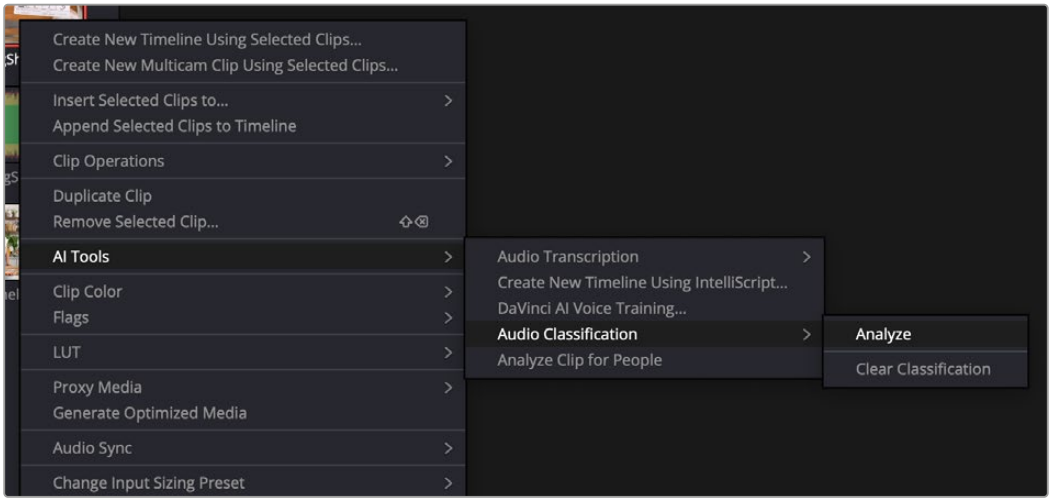


1 Select the clip you want to extract the slate metadata from. This clip must have been previously analyzed with Slate Finder.

The Slate ID icon (circled red), with the metadata from the slate populating the Scene, Take, Date, and Camera # fields.

2 Click on the Slate ID icon at the top of the Metadata bar.

3 A progress box will appear, indicating the status of the Slate ID operation.



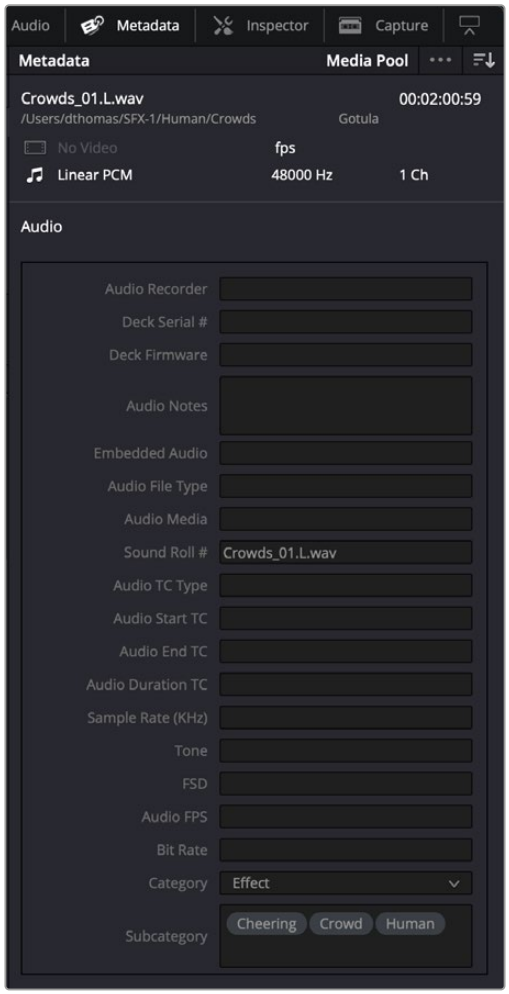
The Slate Information window.

4 Once finished, a Slate Information window will appear with metadata details pulled from your Slate ID operation. The right side of the window (marked Metadata) indicates the metadata fields and information that will be populated. To select the metadata you want to save, locate the checkboxes on the far-left of the window and enable or disable them accordingly. While none of this data is editable, you can change individual fields by going to the Metadata Editor field and manually entering the amended metadata values.

5 Click the Save button to add the information in the selected fields to the clip's metadata.

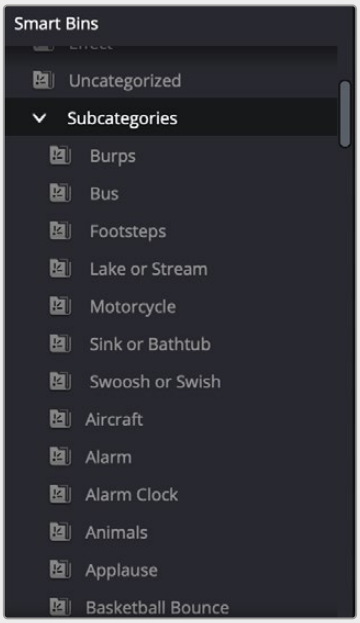
Audio Classification for Clips (Studio Version Only)

You can have DaVinci Resolve's Neural Engine analyze the audio for any clip in the Media Pool, and then automatically assign it a Category and add keywords about its contents in the clip's Subcategory audio metadata. This lets you categorize and organize large amounts of audio clips extremely efficiently by letting the computer do the tedious work of listening to all the media and assigning it metadata for you. Of course, you can then modify or change any metadata necessary in the Metadata Editor in case the computer had miscategorized it.



Analyzing an audio clip

Each clip analyzed gets Audio Category and Subcategory metadata applied to it. Audio Categories are types of audio commonly used in post-production; as of this writing the available choices are: Dialogue, Effect, Music, Silence, and Uncategorized. Subcategories are more detailed keywords that are assigned based on what sounds the Neural Engine can recognize in the clip. Subcategories can be anything like sirens, water, dog, etc. Audio Category and Subcategory are available as Smart Bin filters that let you quickly organize persistent folders for whatever combination of Categories and Subcategories you desire. For example, you could create a Smart Bin that contains all clips that have both Dialogue (category) and sirens and dogs (subcategories) in them.



To Automatically Classify an Audio Clip:

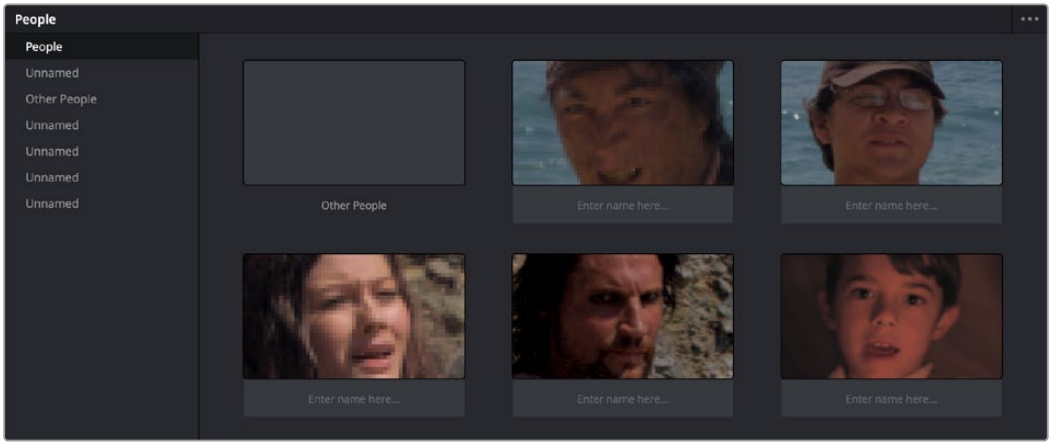
1. Select the clip or clips in the Media Pool you want to classify the audio for.
2. Right-click on any of the selected clips and select AI Tools > Audio Classification > Analyze from the contextual menu. DaVinci Resolve will work its way through analyzing all the selected clips and will automatically add the metadata to the Audio Metadata for each clip.
3. Optionally, you can then review the Audio Metadata for each clip and correct, delete, or add additional metadata manually.

The results of the analysis in Category and Subcategory

Each Category and Subcategory found by this process automatically creates Smart Bins in the Collections folder, based on that metadata. You can also define your own Smart Bins based on combinations of these keywords.

Subcategories folder list showing folders created from analysis

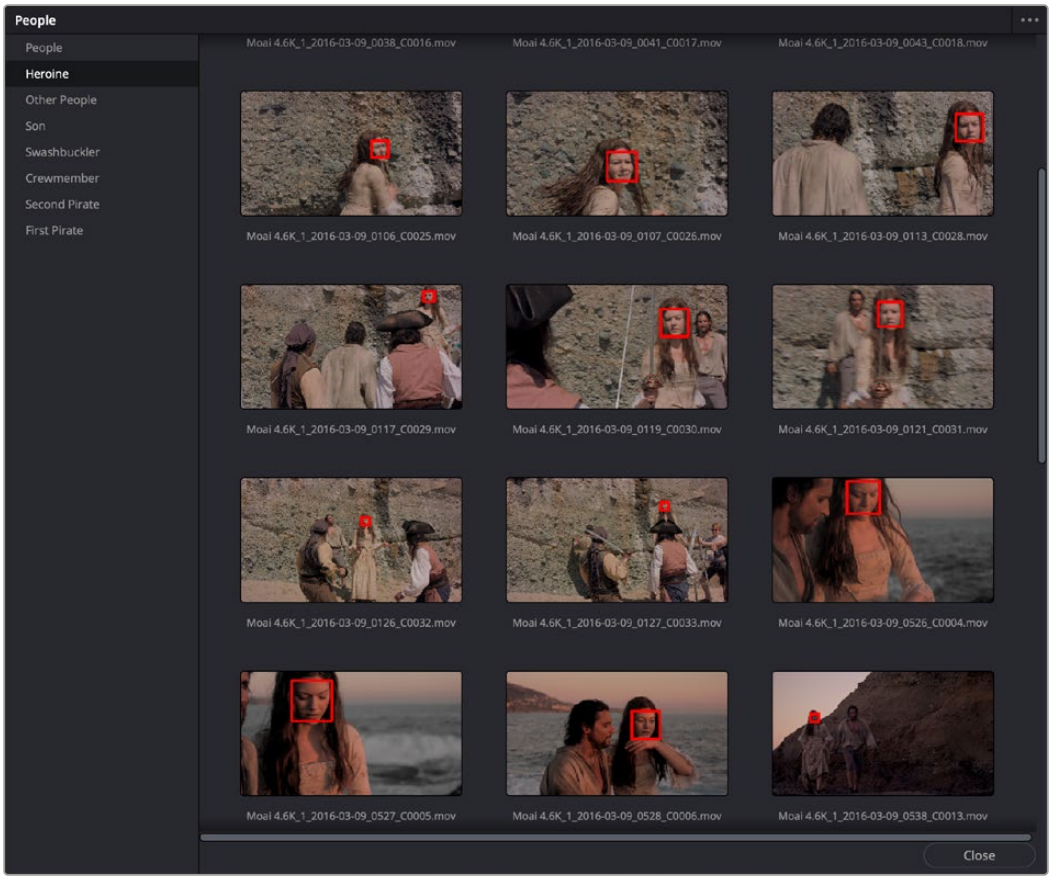
To Remove Classification Metadata from an Audio Clip:



1. Select the clip or clips that have Category and Subcategory metadata that you want to remove.
2. Right-click on any of the selected clips and select Audio Classification > Clear Classification from the contextual menu, then click on Remove in the warning dialog box that appears. There is no undo for this feature.

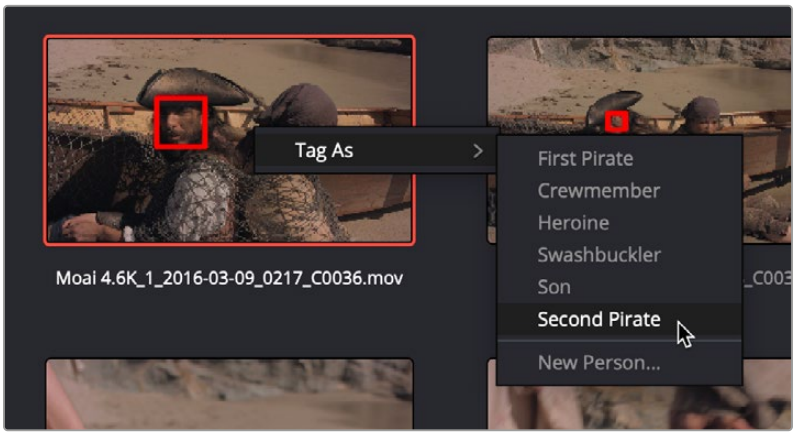
Face Detection to Generate People Keywords

You can select multiple clips in the Media Pool, then right-click the selection and choose AI Tools > Analyze clips for people from the context menu to automatically analyze all selected clips using the DaVinci Neural Engine, identifying faces that can be used to help organize the media. A progress dialog shows you how long until the analysis is finished (you can cancel the operation if necessary).



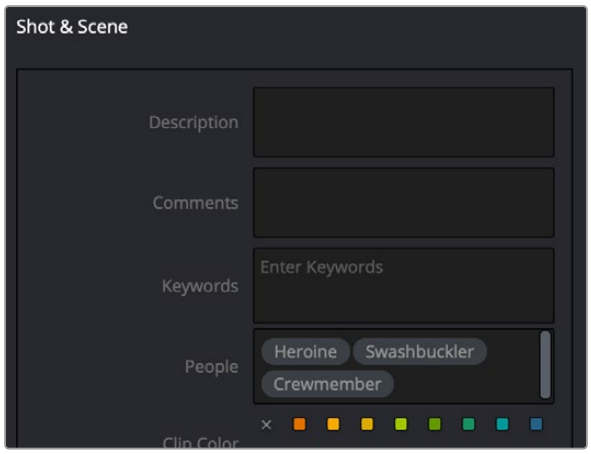
Afterwards, the People Management window appears that shows you the results, automatically organized into a number of bins in a sidebar.

- A “People” bin shows each face that has been recognized as an individual person. Click, pause, then click again underneath any thumbnail to edit the name or role of that person. You must assign a name if you want a keyword to appear for that individual in the People field of the Metadata Editor. Assigning names renames the bins corresponding to each found person and enables retagging to fix mistaken identification.



The Face Recognition window seen immediately after a Face Recognition operation

- Individual bins collect all clips with a particular person, allowing you to evaluate whether or not the contents have been identified correctly. If you see an incorrectly identified clip, you can right-click it and re-tag it from the contextual menu, or choose “Untag” if it’s a new person that has not been identified at all.



A bin for a particular person lets you evaluate the contents

- An “Other People” bin shows all faces that could not be identified. You can right-click any of these to re-tag it as one of the people that have been already identified, or you can choose New Person if it’s someone who wasn’t initially identified (this sometimes happens when multiple people have very similar features).

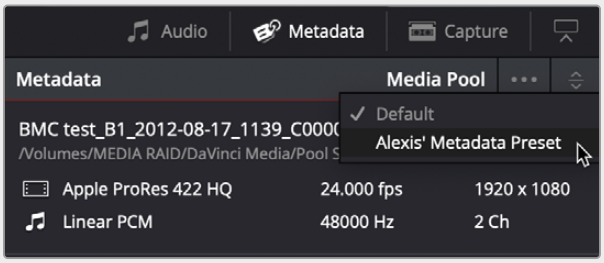
The Face Recognition window seen immediately after a Face Recognition operation

Clicking the Close button closes this window and assigns the names you edited as keywords to the People field of the “Shot & Scene” group in the Metadata Editor. Clips with multiple people who have been identified have multiple keywords assigned.

The People keywords field of the Shot & Scene group in the Metadata Editor, populated with who is in that shot

Once People keywords are assigned to one or more clips, a People smart category of smart bins can automatically be created in the Smart Bins sidebar of the Media Pool, making it easy to immediately begin finding clips that have specific people in them. To create this People Smart Bin, select “Automatic Smart Bins for People Metadata” box in the Preferences > User > Editing window.

You can reopen the Face Recognition window at any time to make modifications by choosing Workspace > People. You can reset all faces by clicking the People Management Option menu and choosing “Reset Face Database.”



NOTE: A command in the Option menu of the Face Recognition window, Reset Face Database, lets you reset all analyzed results if the results are not acceptable and you don’t want to save the resulting metadata.

Creating Custom Metadata Groups

The Metadata panel in the User Preferences lets you create custom sets of metadata parameters that will be exposed in the Metadata Editor. Using this panel, you can create customized subsets of metadata that are focused on your particular needs.

Presets that you create are available from the Option menu that's just to the left of the Metadata categories drop-down menu.

Choose any custom preset to restrict the Metadata Editor to only showing the metadata fields in that preset. To see the full set of custom metadata fields you've saved to a particular preset, you should set the Metadata Categories drop-down menu to All Groups. To make the full set of metadata fields reappear, just choose default presets in the same drop-down.

Custom Metadata Categories drop-down menu

Making and managing metadata presets is simple.

To create a new metadata preset:

1. Open the Metadata panel of the User pane of the Preferences window, and click New.
2. Click the checkboxes of every metadata tag you want to include in this preset, or click the checkbox of a group name on the list to include all metadata tags within it.

   Every single metadata tag available in DaVinci Resolve appears within one of several groups that appear as a list. To open any group to see its contents, move the pointer over that group's entry on the list, and click the Open button when it appears.
3. When you're finished, click the Save button under Metadata Options.
4. Click the Save Button for the User Preferences.

To edit an existing metadata preset:

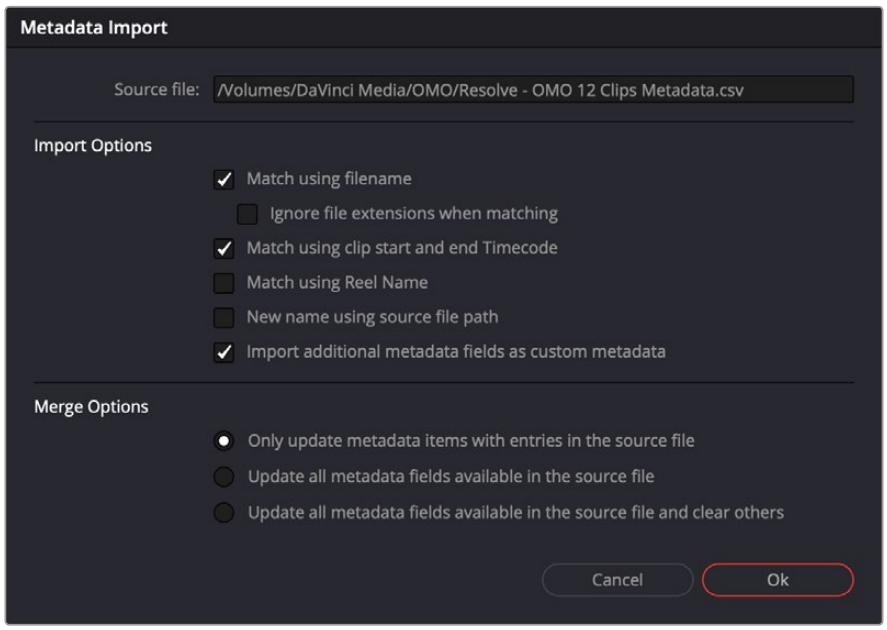
1. Select a preset from the list, and click Edit.
2. Turn checkboxes on and off to include or exclude whatever tags you need.
3. Click the Save button under Metadata Options.
4. Click the Save Button for the User Preferences.

To delete a metadata preset:

Select a preset from the list and click Delete.

Importing and Exporting Media Pool Metadata

Once you've taken the trouble to add metadata to the clips in your project, DaVinci Resolve makes it possible to export metadata from the Media Pool of one project for import into the clips of another project, for instances where you need to move metadata around.



For example, a DIT might have entered a lot of metadata to the DaVinci Resolve project used for generating dailies, but then an impatient editor might have created a separate project to begin editing those dailies. Instead of requiring the editor to enter each clip's metadata all over again, you can export the metadata from the DIT's project and import it into the editor's new project, automatically matching the relevant metadata to each corresponding clip.

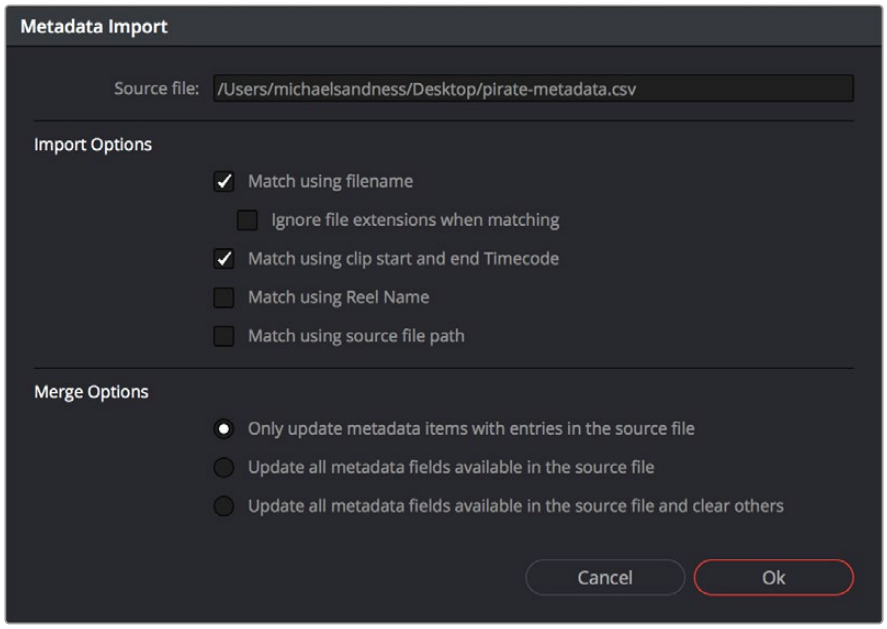
To export Media Pool metadata:

1. Open a project containing Media Pool metadata you want to export.
2. Optionally, select which clips in the Media Pool you want to export metadata for.
3. Choose File > Export Metadata From > Media Pool to export metadata from every clip in the Media Pool, or choose File > Export Metadata From > Selected Clips to only export metadata from clips you selected in step 2.
4. When the Export Metadata dialog appears, enter a name and choose a location for the file to be written, then click Save. All metadata is exported into a .csv file that can be viewed and/or edited in any spreadsheet application, or an Avid Log Exchange (.ale) file if you need compatibility with Avid Media Composer.

   If you open the resulting metadata .csv file, the first line is a header that lists what metadata is to be found for each item listed in this document, and in what order. Only metadata fields that have been populated for at least one clip are exported and listed in this header; unused metadata fields in the Metadata Editor or Media Pool are ignored.

   This file can now be imported into another project file to reattach the metadata to the same clips.

The Metadata Import Dialog



To import Media Pool metadata:

1. Open a project containing clips you want to populate with imported metadata.
2. Optionally, select which clips in the Media Pool you want to import metadata to.
3. Choose File > Import Metadata To > Media Pool to import metadata to potentially every clip in the Media Pool, or choose File > Import Metadata To > Selected Clips to only import metadata to clips you selected in step 2.
4. When the Import Metadata dialog appears, choose a metadata .csv or .ale file to import, and click Open.
5. When the Metadata Import dialog appears, choose the Import Options you want to use to match the .csv file's metadata to the correct clips in the currently open project. By default, DaVinci Resolve tries to use "Match using filename" and "Match using clip start and end Timecode" to match each line of metadata in the .csv file with a clip in the Media Pool, but there are other options you can use such as ignoring file extensions, using Reel Name, and using source file paths. You can also decide whether to import any additional metadata fields as custom metadata.
6. Next, choose which Merge Option you want to use in the Metadata Import dialog. There are three options:

   Only update metadata items with entries in the source file: The default setting. Only updates a clip's metadata if there's a valid entry in the imported .csv file. Other clip metadata fields are left as they were before the import.

   Update all metadata fields available in the source file: For each clip that corresponds to a line of metadata in the imported .csv file, every single metadata field referenced by the .csv file is overwritten, regardless of whether or not there's a valid entry for that field.

   Update all metadata fields available in the source file and clear others: For each clip that corresponds to a line of metadata in the imported .csv file, every single metadata field referenced by the .csv file is overwritten, regardless of whether or not there's a valid entry for that field. Furthermore, metadata fields that aren't referenced by the imported .csv file are cleared of whatever metadata was there before.
7. When you're finished choosing options, click Ok and all available metadata from the source .csv file will be imported.

The Metadata Import dialog that lets you choose options for how to match and merge imported metadata

Different Ways of Using Clip Metadata

To encourage you to take advantage of the clip metadata tools that exist in DaVinci Resolve, here's a short list of the many different ways you can use clip metadata to help you work faster.

- Searching for clips in the Media Pool
- Searching for clips in the Timeline
- Sorting the Media Pool by metadata columns in list view
- Creating Smart Bins in the Edit page
- Creating Timeline Filters in the Color page
- Using Metadata to create clip Clip Names
- Displaying Metadata in frame using the Color page Burn In palette

Renaming Clips Using Clip Names

The most fundamental piece of clip metadata is each clip's name, which is used to identify clips nearly everywhere they appear inside DaVinci Resolve. By default, clips show the file name of the corresponding media file on disk. Since the dawn of tapeless recording, however, editors have been stuck with camera original media having names that are not exactly "human readable."

Fortunately, you have the option of entering a more user-friendly clip name to use instead, while preserving the original file name that's critical for maintaining the link between a clip and its media, as well as for tracking an offline clip's corresponding link to the online media from which it originated. There are a few ways you can edit the clip name of a clip.

> **NOTE:** You can also edit the clip names of timelines, compound clips, and multicam clips, so that you can have two sets of naming conventions for these items, one for when you're doing creative editing, and one for when you're doing finishing tasks.

To edit a clip's clip name, do one of the following:

- In the Media Pool's Icon view, click a clip's name once, pause a moment, then click a second time to select the name, type a new name, then press return to accept the name.
- In the Media Pool's List view, the Clip Name mirrors the source clip's file name (hidden by default), but you can click the Clip Name column for any clip to add a new name from scratch.
- With the Clip Name column exposed in the Media Pool's List view, Option-click the Clip Name column for any clip to edit the file name, rather than entering a brand new name.
- To edit the clip name of multiple clips, select all of the clips for which you want to change the clip name, then right-click one of the selected clips and choose Clip Attributes. Open the Name panel of the Clip Attributes window, edit the Clip Name field, and click OK.

After you've changed a clip's clip name, that clip appears in the following places using the clip name instead of the original file name:

- The Media Pool's Thumbnail view
- The name bar of each clip in the Timeline
- The Source Viewer title bar
- The Clip Name field of the Clip Attributes dialog's Name panel

Switching Between File Names and Clip Names

Since different tasks require different information, you have the ability to switch between using clip file names and clip names. For example, finishing editors will probably have more reason to refer to the file name of each clip, making it easier to troubleshoot problems with reconforming and relinking. Creative editors, on the other hand, will want to use easier-to-read clip names to make it easier to find what they need.

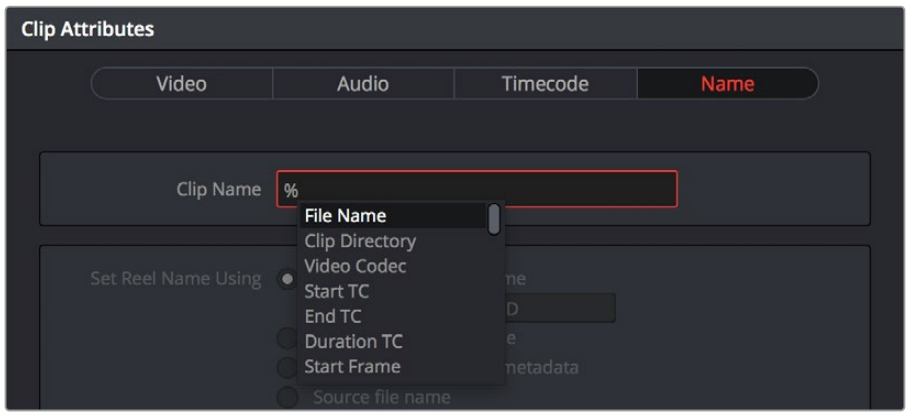
To switch between file names and clip names:

- Choose View > Show File Names to toggle between both naming conventions.

Using Metadata to Define Clip Names

If you're an enthusiastic user of clip metadata (and you should be), you can use "metadata variables" that you can add into a field that let you reference other metadata for that clip. For example, you could add the combination of variables and text seen in the following screenshot to define a clip name automatically. Variables, once they've been entered, are represented as graphical tags shown with a background, while regular text characters that you enter appear before and after these tags.

Variables and text characters entered to create a clip name based on a clip's metadata



As a result, that clip would display "12_A_3" as its name if scene "12," shot "A," and take "3" were its metadata. When you do this, you can freely mix metadata variables with other characters (the underscore, as in the example above) to help format the metadata to make it even more readable.

Every single item of metadata that's available in the Metadata Editor can be used as a variable, and several other clip and timeline properties such as the version name of a clip's grade, a clip's EDL event number, and that clip's timeline index number can be also referenced via variables.

Since the use of metadata variables is a great way to automatically generate names for multiple clips, you may find it more useful to add metadata variable-driven clip names by selecting all of the clips you want to edit, and opening the Clip Attributes window. By editing the Clip Name field found in the Name panel, you can add a single clip name to all selected clips at once.

To add a variable to a text field that supports the use of variables:

1. Type the percentage sign (%) and a scrolling list appears showing all variables that are available.
2. To find a specific variable quickly, start typing the characters of that variable's name and this list automatically filters itself to show only variables that contain the characters you've just typed.
3. Choose which variable you want to use using the Up and Down Arrow keys, and press Return to choose that variable to add.

The variable list that appears when you type the % character

As soon as you add one or more metadata variables to a clip's Clip Name column and press Return, the string is replaced by its corresponding text. To re-edit the metadata string, simply click within that column, and the metadata variables will reappear. Be aware that, for clips where a referenced metadata field is blank, no characters appear for that corresponding metadata variable in the Clip Name column.

To remove a metadata variable:

- Click within a field using variables to begin editing it, click a variable to select it, and press Delete.

For more information on the use of variables, as well as a list of all variables that are available in DaVinci Resolve, jump to this chapter: Using Variables and Keywords.

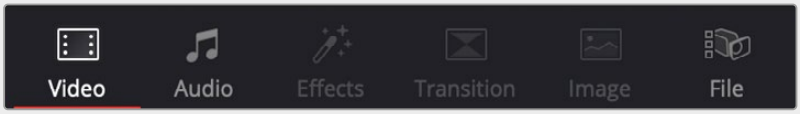
Chapter 19

Using the Inspector in the Media Page

The Inspector holds all the controls to modify, resize, retime, and generally adjust anything related to a clip, transition, or effect on the Media page Timeline.

Contents

Using the Inspector 440
Adjusting Media Pool Clips in the Inspector 440
Video 441
Audio 445
Image 447
File 448



Using the Inspector

The Inspector has been redesigned to make it easier to find specific controls and to adjust common settings for your clips. Instead of a long vertical list, different aspects of the Inspector have now been organized into panels, with each controlling specific grouped sets of parameters for your clip.

The Inspector is activated by clicking on the Inspector Panel in the upper-right section of the User Interface toolbar. The Inspector is broken up into individual Video, Audio, Effects, Transition, Image, and File panels. Inspector panels that are not applicable to your clip or selection are grayed out.

The Inspector Panel icon in
the upper right of the UI toolbar

The Inspector panels showing Video, Audio, and
File parameters available for adjustment; others are grayed out.

Methods of using controls in the Inspector:

- **To activate or deactivate a control:** Click the toggle to the left of the control's name. The orange dot on the right means the control is activated. A gray dot on the left means the control is deactivated.
- **To reveal a control's parameters:** Double-click the control's name.
- **To reset controls to their defaults:** Click the reset button to the right of the control's name.

Adjusting Media Pool Clips in the Inspector

You can directly modify Media Pool clips in the Inspector, before you edit those clips into a timeline. This allows you to change the parameters of source media so that clips that are subsequently edited into a timeline carry those new settings with it. For example, you can prepare your material prior to editing by changing the clip's file and RAW settings, adjusting the audio levels and EQ, or assigning it a specific lens correction, etc. Once modified, any part of that clip would have the correct Inspector parameters already in place when you edited them into your timeline.

To adjust Media Pool clips in the Inspector:

1. Select one or more clips in the Media Pool Panel of either the Media, Cut, Edit, or Fairlight pages.
2. Open the Inspector panel, and adjust any parameters in the Video, Audio, Image and File tabs.

   These parameter changes are stored with the Media Pool clip, and will be carried over when any part of that clip is edited into the Timeline. Of course, each clip's Inspector parameters can be further modified once it's in the Timeline, and those Timeline parameters are independent from the Media Pool Inspector settings. This means that any further adjustments you make to the clip in the Timeline do not affect that same clip's adjustments already in the Media Pool.

Video

The Video Panel of the Inspector exposes a vast array of controls designed to manipulate the size, speed, and opacity of your clips.

Transform

The Transform group includes the following parameters for resizing and repositioning your clips:

The Transform section of the Video Inspector panel

- **Zoom X and Y:** Allows you to blow the image up or shrink it down. The X and Y parameters can be linked to lock the aspect ratio of the image, or released to stretch or squeeze the image in one direction only.
- **Position X and Y:** Moves the image within the frame, allowing pan and scan adjustments to be made. X moves the image left or right, and Y moves the image up or down.
- **Rotation Angle:** Rotates the image around the anchor point.
- **Anchor Point X and Y:** Defines the coordinate on that clip about which all transforms are centered.
- **Pitch:** Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values stretch the image more extremely.
- **Yaw:** Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and push the right of the image forward. Higher values stretch the image more extremely.
- **Flip Image:** Two buttons let you flip the image in different dimensions.

  Flip Horizontal control: Reverses the image along the X-axis, left to right.

  Flip Vertical control: Reverses the clip along the Y-axis, turning it upside down.

Cropping

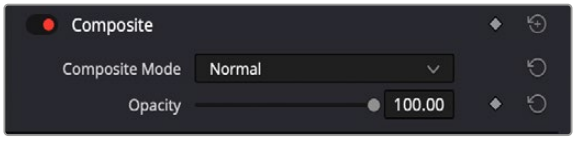
The Video Inspector controls the image's cropping parameters:

The Cropping section of the Video Inspector panel

- **Crop Left, Right, Top, and Bottom:** Lets you cut off, in pixels, the four sides of the image. Cropping a clip creates transparency so that whatever is underneath shows through.
- **Softness:** Lets you blur the edges of a crop. Setting this to a negative value softens the edges inside of the crop box, while setting this to a positive value softens the edges outside of the crop box.
- **Retain Image Position:** Clicking this checkbox will lock the crop parameters in place when you resize the image using the Transform tool above. Unchecking this box will scale and position the crop as well as the image.

Dynamic Zoom

The Dynamic Zoom controls, which are off by default, make it fast and easy to do pan and scan effects to zoom into or out of a clip. Turning the Dynamic Zoom group on activates two controls in the Inspector that work hand-in-hand with the Dynamic Zoom onscreen adjustment controls.



The Dynamic Zoom section of the Video Inspector panel

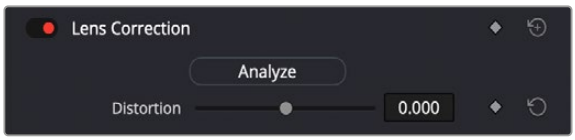
- **Dynamic Zoom Ease:** Lets you choose how the motion created by these controls accelerates. You can choose from Linear, Ease In, Ease Out, and Ease In and Out.
- **Swap:** This button reverses the start and end transforms that create the dynamic zoom effect.

> For more information on using the Dynamic Zoom controls, jump to this chapter: Compositing and Transforms in the Timeline.

Composite

Composite modes can be used to combine clips that are superimposed over other clips in the Timeline.

The Composite section of the Video Inspector panel



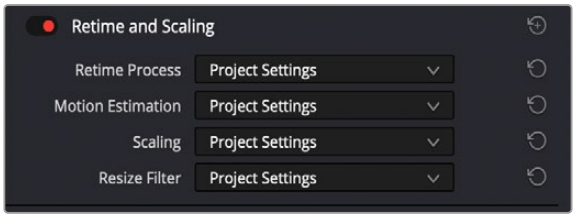
- **Composite Mode:** This selects the type of composite mode to combine the superimposed clips. The default “Normal” means no compositing mode is applied.

> For more information on Composite Modes, jump to this chapter: Compositing and Transforms in the Timeline.

- **Opacity:** This slider makes a clip more or less transparent in addition to compositing already being done.

Lens Correction

The Lens Correction group (only available in Resolve Studio) has two controls that let you correct for lens distortion in the image, or add lens distortion of your own.



The Lens Correction section of the Video Inspector panel

- **Analyze:** Automatically analyzes the frame in the Timeline at the position of the playhead for edges that are being distorted by wide angle lens. Clicking the Analyze button moves the Distortion slider to provide an automatic correction. If you're analyzing a particularly challenging clip, a progress bar will appear to let you know how long this will take.
- **Distortion:** Dragging this slider to the right lets you manually apply a warp to the image that lets you straighten the bent areas of the picture that can be caused by wide angle lenses.
  If you clicked the Analyze button and the result was an overcorrection, then dragging this slider to the left lets you back off of the automatic adjustment until the image looks correct.

Retime and Scaling

The Retime and Scaling group has four parameters that affect retiming quality and clip scale:

The Retime and Scaling section of the Video Inspector panel

- **Retime Process:** Lets you choose a default method of processing clips in mixed frame rate timelines and those with speed effects (fast forward or slow motion) applied to them, on a clip-by-clip basis. The default setting is "Project Settings," so all speed-effected clips are treated the same way.

  There are three options: Nearest, Frame Blend, and Optical Flow, which are explained in more detail in the Speed Effect Processing section, jump to this chapter: Speed Effects.

- **Motion estimation mode:** When using Optical Flow to process speed change effects or clips with a different frame rate than that of the Timeline, the Motion Estimation pop-up lets you choose the best-looking rendering option for a particular clip. Each method has different artifacts, and the highest quality option isn't always the best choice for a particular clip. The default setting is "Project Settings," so all speed-effected clips are treated the same way. There are several options. The "Standard Faster" and "Standard Better" settings are the same options that have been available in previous versions of DaVinci Resolve. They're more processor efficient and yield good quality that are suitable for most situations. However, "Enhanced Faster" and "Enhanced Better" should yield superior results in nearly every case where the standard options exhibit artifacts, at the expense of being more computationally intensive, and thus slower on most systems.

- The “Standard Faster” and “Standard Better” settings are the same options that have been available in previous versions of DaVinci Resolve. They’re more processor efficient and yield good quality that are suitable for most situations. However, “Enhanced Faster” and “Enhanced Better” should yield superior results in nearly every case where the standard options exhibit artifacts, at the expense of being more computationally intensive, and thus slower on most systems.
- The Speed Warp setting is available for even higher-quality slow motion effects using the DaVinci Neural Engine. Your results with this setting will vary according to the content of the clip, but in ideal circumstances this will yield higher visual quality with fewer artifacts than even the Enhanced Better setting.
- AI Speed Warp Metal (macOS only) is a specifically enhanced version of Speed Warp that takes advantage of Mac hardware. It should dramatically speed up the DaVinci Neural Engine Speed Warp operations.

- **Scaling:** Lets you choose how clips that don’t match the current project resolution are handled on a clip-by-clip basis. The default setting is “Project Settings,” so that all mismatched clips use the same method of being automatically resized.

  However, you can also choose an individual method of automatic scaling for any clip. The options are Crop, Fit, Fill, and Stretch; for more information see the 2D Transforms sectionm, jump to this chapter: Sizing and Image Stabilization.

- **Resize Filter:** For clips that are being resized in any way, this setting lets you choose the filter method used to interpolate image pixels when resizing clips. Different settings work better for different kinds of resizing. There are four options:

  Sharper: Usually provides the best quality in projects using clips that must be scaled up to fill a larger frame size, or scaled down to HD resolutions.

  Smoother: May provide higher quality for projects using clips that must be scaled down to fit an SD resolution frame size.

  Bicubic: While the Sharper and Smoother options are slightly higher quality, Bicubic is still an exceptionally good resizing filter and is less processor intensive than either of those options.

  Bilinear: A lower quality setting that is less processor intensive. Useful for previewing your work on a low-performance computer before rendering, when you can switch to one of the higher quality options.

  Other Resize Methods: A selection of specific resize algorithms is available if you need to match them to other VFX workflows.

Super Scale

For instances when you need higher-quality upscaling than the standard Resize Filters allow, you can now enable one of the “Super Scale” options in the Inspector. Unlike using one of the numerous scaling options in the Edit, Fusion, or Color pages, Super Scale actually increases the source resolution of the clip being processed, which means that clip will have more pixels than it did before and will be more processor-intensive to work with than before, unless you optimize the clip (which bakes in the Super Scale effect into the optimized media) or cache the clip in some way.

The Super Scale parameters

For more detailed information on Super Scale, jump to this chapter: Image Sizing and Resolution Independence.

Using Super Scale in the Inspector is functionally equivalent to setting the same controls for the media clip in the Clip Attributes. This means that changing this setting affects all of the additional edits referencing the selected media as well.

The Super Scale group has the following parameters that affect the quality and clip scale:

- **Super Scale:** Lets you choose the amount of scaling required. The options are 2-3-4x and 2-3-4x Enhanced.
- **Sharpness:** Lets you choose the amount of detail in the scaling. This is limited to Low, Medium, or High, unless the Super Scale mode is set to Enhanced, which allows you to apply variable sharpness. You will want to balance this setting against Noise Reduction.
- **Noise Reduction:** Lets you choose the amount of noise reduction in the scaling. This is limited to Low, Medium, or High, unless the Super Scale mode is set to Enhanced, which allows you to apply variable noise reduction. You will want to balance this setting against Sharpness.

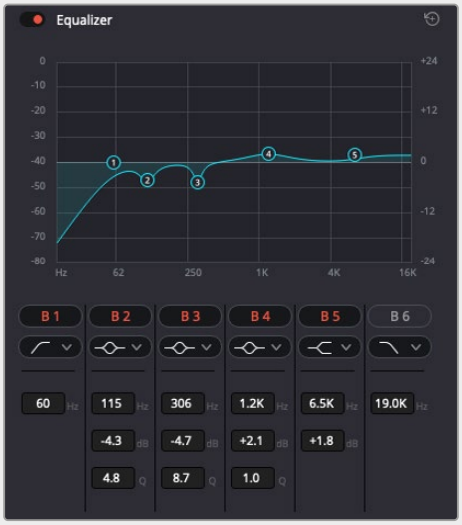
Audio

The Audio Inspector parameters

The Audio tab contains four commonly used audio controls for video editing purposes, including Clip Volume, Clip Pan, Clip Pitch, and Clip Equalizer.

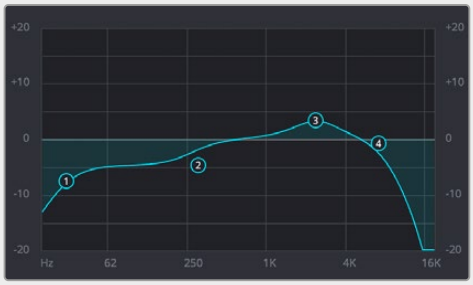
- **Clip Volume:** Each clip has a single volume control that corresponds to the volume overlay over each audio clip.
- **Clip Pan:** (Only exposed for clips) A simple Pan slider that controls stereo panning.
- **Clip Pitch:** Lets you alter the pitch of a clip without changing the speed. Two sliders let you adjust clip pitch in semi tones (large adjustments, a twelfth of an octave) and cents (fine adjustments, 100th of a semi tone).

Equalizer



This six-band parametric equalizer has both graphical and numeric controls for boosting or attenuating different ranges of frequencies within that clip, before it even gets to the EQ built into the Mixer. Each band has controls for the filter type (Bell, Lo-Shelf, Hi-Shelf, Notch), Frequency, Gain, and Q-factor (sharpness of the band), with the available controls for each band of EQ changing depending on the filter type.

TIP: Clip EQ settings can be copied and pasted from one Clip EQ to another, and between Clip EQ and Track EQ instances.



Master EQ Controls

The Equalizer window has the following overall controls located in the upper right and left corners:

- **Enable button:** Turns the overall EQ effect off and on, without resetting the controls.
- **Reset button:** Resets all controls of the EQ window to their defaults.

Clip EQ in the Audio Inspector

The Clip EQ graph with user-draggable handles

Clip EQ Graph

This graph displays the current EQ curve with handles that correspond to each enabled EQ band listed below. You can drag any numbered handle to boost or attenuate the range of frequencies governed by that band, using whatever type of equalization that band has been set to..

Dragging the numbered handles on this graph in turn modifies the parameters of the corresponding band, and changing each band's parameters will also alter the EQ graph, which serves the additional purpose of providing a graphical representation of the equalization being applied to that track.

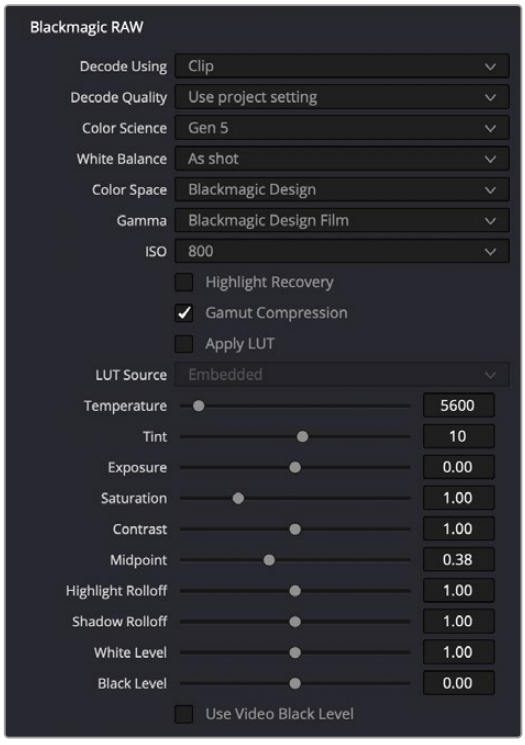
Bands 1 and 6

The outer two sets of band controls let you make high-pass and low-pass adjustments, if necessary.

- **Band enable button:** Turns each band of EQ on and off.
- **Band filter type:** Bands 1 and 6 can be switched among five specific filtering options for processing the lowest or highest frequencies in the signal.

  For Band 1, these include (from top to bottom): Lo-Shelf, Bell, Notch, Hi-Shelf, and Hi-Pass.

  For Band 6, the options are (from top to bottom): Lo-Pass, Lo-Shelf, Bell, Notch, and Hi-Shelf.
- **Freq:** Adjusts the center frequency of the EQ adjustment.
- **Gain:** Adjusts the amount by which the affected frequencies are impacted. Negative values attenuate those frequencies, while positive values boost those frequencies.
- **Q Factor:** This parameter adjusts the width of affected frequencies and appears whenever the Bell option is selected. Lower values include a wider range of frequencies; higher values include a narrower range of frequencies.



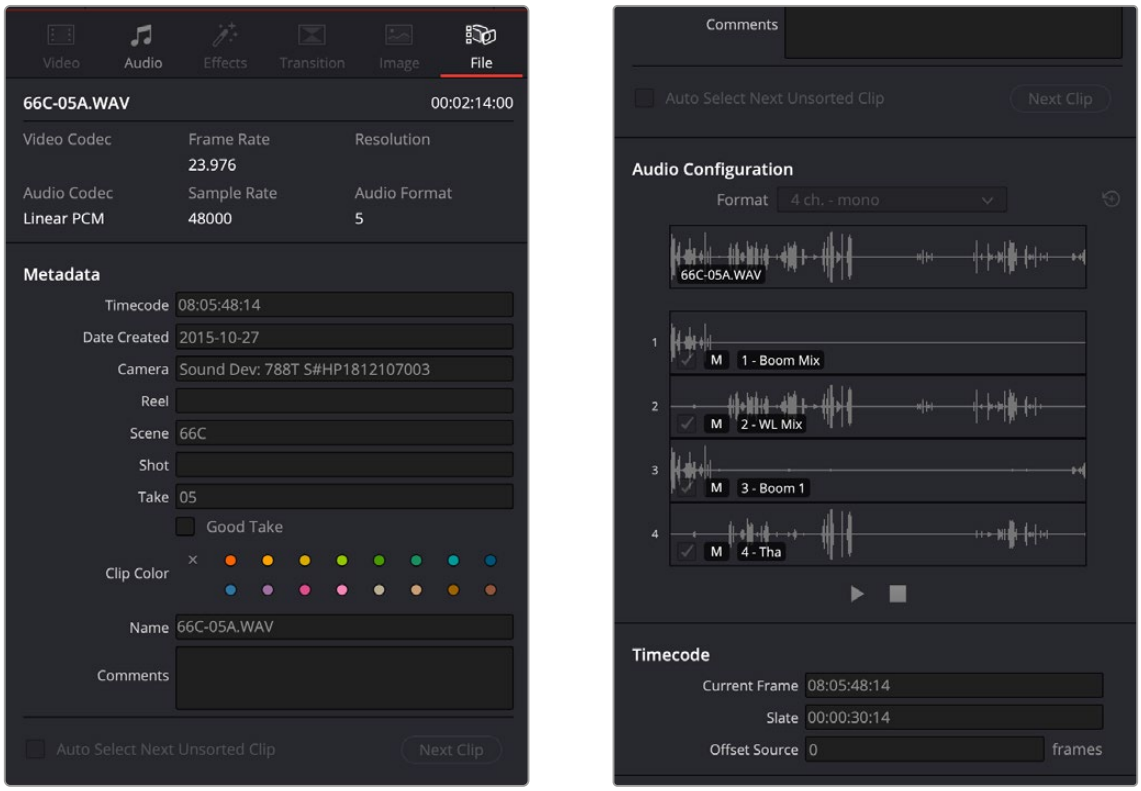
Bands 2 through 5

These band controls let you make a wide variety of equalization adjustments.

- **Band enable button:** Turns each band of EQ on and off.
- **Band filter type:** These Bands offers four filtering options (from top to bottom): Lo-Shelf, Bell, Notch, and Hi-Shelf.
- **Frequency:** Adjusts the center frequency of the EQ adjustment.
- **Gain:** Adjusts the amount by which the affected frequencies are altered. Negative values attenuate those frequencies, while positive values boost those frequencies.
- **Q Factor:** This parameter appears when the Bell setting is selected. It adjusts the width of affected frequencies. Lower values include a wider range of frequencies; higher values narrow the range of frequencies.

NOTE: There are many more refined plugins and effects for audio clips in the Audio FX library. If you apply any of these, the controls will appear in the Inspector's Effects tab Audio section, instead of here.

Image



The Image Inspector controµls for BRAW footage

The Image panel contains groups of parameters that correspond to every camera raw media format that's supported by DaVinci Resolve. Using these parameters in the Image panel, you can override the original camera metadata that was written at the time of recording and make simultaneous adjustments to camera raw media throughout your project.

For a detailed explanation of each of the RAW camera parameters supported by DaVinci Resolve, jump to this chapter: Camera Raw Settings.

File

The File Inspector controls

Metadata

The File panel of the Inspector provides a consolidated way to view and edit a subsection of a clip's most commonly used media file metadata. It's easily accessible in the Inspector across the Media, Cut, Edit, and Fairlight pages.

The tab is composed of the following parts:

- **Clip Details:** Presents data about the clip's data format (codec, resolution, frame rate, etc.).
- **Metadata:** Presents a reduced set of common metadata fields for quick user entry.

  Timecode: The start timecode of the clip. This field is editable if you want to manually change the clip's starting timecode.

  Date Created: The date that the clip was created. This field is editable if you want to manually change the clip's creation date.

  Camera: Sets the Camera # metadata.

  Reel: Sets the Reel/Card ID.

  Scene: The Scene number of the clip.

  Shot: The Shot letter/number of the clip.

  Take: The Take number of the clip.

  Good Take: This checkbox indicates if the clip is a good or circled take.

  Clip Color: Assign a specific color to a clip that is reflected in the Timeline.

  Name: This can be entered manually and changes a clip's name in that specific timeline only.

Comments: Add a text description to the clip.

Auto Select Next Unsorted Clip: When this box is checked, the next clip in the Media Pool is selected when you hit the Return button after entering a metadata field, and the cursor is automatically placed in the same field. This allows rapid sequential metadata entry without having to manually click to load each individual clip in the Media Pool. The Next Clip button will select the next clip in the Media Pool, regardless of the checkbox status.

Audio Configuration

The File tab in the Inspector now has an Audio Configuration pane that handles the controls that were formerly handled by Clip Attributes in the Media Pool (though that option is still available). The Audio Configuration pane provides a more intuitive and visual way of changing the track properties of an audio clip. Simply click on an audio clip in the Media Pool or Timeline, and then on the File Inspector to reveal this interface.

The pane features a per-channel waveform display for all tracks within a multichannel audio file. If the tracks have been named in the audio recorder, these names will appear over their respective tracks as well. The Audio Configuration panel can preview up to 36 tracks of audio.

At the top of the pane, a composite waveform is shown of all the tracks and is updated depending on the mute status of individual tracks. By default this composite is heard when the Play button is activated, and all channels are audible.

The Audio Configuration panel. Track 3 has been muted and Track 5 has been disabled.

A format menu allows you to choose common configurations for your source audio file without cumbersome manual re-routing. Custom routing can still be accommodated by choosing custom in the drop-down, which brings up the older clip attributes for situations that require less common configurations.

Audio for a selected source or timeline clip can be played or skimmed by moving the cursor along the waveform, and the specific track is solo'ed when skimming or playing. The play position or track being monitored can also be switched dynamically during playback. For example, you can start playback on track one, then simply click on track two, and the playback continues from that position. These controls let you quickly skim through and identify exactly what audio is on which track for further adjustment.

Each track has two adjustments that can be made, an Enable/Disable checkbox and a Mute button.

Enable/Disable: Enabling a track makes that track available for use in editing operations. Disabling a track removes that track from use in editing operations. For example, if you disable Track 2 of a 4-track audio file, when you drag that audio file from the Media Pool into the timeline, only 3 tracks (1, 3, and 4) will come over.

These adjustments can only be made on Media Pool clips; audio clips already in the timeline will have these options disabled.

Mute: Clicking this icon will mute the track so it is unheard but leave the actual track in place when used in editing operations and dragged into the timeline. Option clicking a mute button on a channel will allow you to solo by muting all other channels.

Underneath the track layout is a simple transport control comprised of Play and Stop buttons to start and stop audio playback.

Adjusting Trim Levels of Individual Channels in a Source File

The level of individual source clip channels in the audio inspector can be be adjusted via a trim control. This allows source clip audio in one channel to be brought up in level or brought down in level, as needed.

The trimmed level is internal to source clip in the Media Pool and will be inherited whenever that source clip configuration is used on a timeline, unless it is changed.

NOTE: The trim level is totally separate from clip gain in the timeline. Be aware that trimmed levels can clip if you move them too high.

You can adjust the trim levels of individual audio channels in a multichannel clip.

Using the Trim slider

1. Select one or more channels in the Audio Configuration section of the File Inspector
2. Adjust the Level slider at the bottom to the desired audio level.

The waveform will adjust dynamically to the level value and will display a trimmed value in dB in the channel itself. If you have multiple lanes selected, all channels will be trimmed together. Relative levels are not stored, so if you adjust one, it will then force any others in the selection to match. When no channel lanes are selected, the Level control is grayed out.

Multiple Clip Selection and Adjustments

You can select multiple audio clips and adjust their properties in the Audio Configuration pane. For example, you can select a group of audio files and remove Track 2 from all of them at once. However, the following should be noted:

- In a multiple clip selection, only the last selected clip will appear in the track layout of the Audio Configuration pane. However the top composite waveform will be named “Multiple Clips” to let you know that more than one clip has been selected.
- Any adjustments, like muting or enabling/disabling a track will be applied to all the selected clips at once.

Timecode

The File tab in the Inspector now has a Timecode pane that handles the types of controls that were formerly handled by Clip Attributes in the Media Pool (though that option is still available). Here you can override the timecode details for a clip or clips in the Media Pool.

- **Current Frame:** Lets you assign a new time for the timecode at the currently viewed frame of the clip.
- **Slate:** In situations where source media comes from a shoot where a timecode slate was used during the shoot, then you can assign the slate timecode as a second timecode track that can be used for various operations, without changing the primary timecode of the clip, which may already be in use for program sync.

  To set appropriate Slate timecode, select a clip in the Media Pool with a visible timecode slate, and move the playhead to a frame where the timecode in the slate is clearly readable. Then, open the Timecode panel of the Clip Attributes window, and type the timecode value you see in the image into the Slate Timecode field.
- **Offset Source:** If an entire set of clips has timecode that’s merely offset, you can correct the timecode offset for as many selected clips as you like.

Chapter 20

Syncing Audio and Video

When you're working on a program where the production audio was recorded separately from the production video (often referred to as "dual-system recording), DaVinci Resolve provides tools for syncing the audio and video together in a variety of ways to create media that you can edit easily. The process of syncing audio and video together is often referred to as "syncing dailies."

Syncing Audio to Video

If you're editing a shoot that used dual-system recording, where audio is recorded to a separate device than video, you can synchronize and merge the production audio files with the video clips in DaVinci Resolve either manually or automatically.

Auto Sync Audio

While manually syncing together hundreds of separate audio and video files can build character, it's generally not the most efficient use of your time. DaVinci Resolve has an Auto Sync Audio feature that can take the tedious process of syncing and fully automate it using a variety of methods. Each of these methods though requires some initial setup.

The Auto Sync Dialog

In order to Auto Sync you first need to organize your audio and video files. You can do this by placing all the audio and video clips you want to sync in the same bin, or you can have separate video and audio bins that you then multi-select by command-clicking them. For the best results, you will want to have only the video and audio clips that need to be synced (i.e. dialog, live music, etc.) isolated from the media flies that don't (i.e. b-roll, room tone, MOS shots, etc.).

Auto Sync Audio to Video Using Timecode

Ideally, if the sound recordist on set was highly organized, and the camera and audio recorder both used synchronized timecode, you can use a single command to automatically sync every clip in a timeline to a bin of Broadcast .wav files that have matching timecode.

To batch sync audio to video using timecode:

1. Right-click the bin(s) containing the matching audio and video clips, and choose Auto Sync Audio from the contextual menu.
2. In the Synchronize Using selector, choose Timecode.
3. Optionally you can choose to retain the original audio files and video metadata.

   Retain embedded audio: Adds new channels in addition to the audio channels that were previously in the media file. The newly waveform-synced channels are added to an additional track, so when edited into the timeline, a clip that's synced this way appears with one video clip and two audio clips that occupy two different audio tracks, so you can edit the camera original audio independently from the synced audio.

   Every clip in the selected bin for which there was an accompanying Broadcast .wav file with matching timecode is immediately synced with an audio track. If multiple audio files overlap with matching time code, each file will be synced and a new audio track added to the resulting clip to accommodate each audio file. You can modify this behavior to only sync the single best matching file and ignore others by checking the "Limit media pool audio sync to first timecode match" box in the Editing panel of the User section in the DaVinci Resolve Preferences.

   Retain Video Metadata: Default is off, which means that video files that are synced to audio files inherit metadata (e.g., scene and take) from the audio file. When this option is checked, the video file's metadata is retained and not overwritten instead.
4. Press Sync.

   All synced clips appear with an audio icon at the bottom left in the Media Pool when Thumbnail view is selected. Now that the clips are synced, you can edit them in the Edit page or use the Deliver page to export offline dailies or online media with embedded sync audio for use in other applications.

Auto Sync Audio to Video by Matching Waveforms

If you don't have matching timecode in the audio and video source clips you're syncing, but you had the foresight to record camera audio at the same time as the dual source production audio you want to sync to, DaVinci Resolve can use waveform syncing to compare the audio waveforms of your audio and video source files, and sync the ones that match.

To batch sync dailies using waveform syncing:

1. Organize the media you want to sync. For example, it's not a bad idea on multi-day shoots, to organize the audio and video files so that it's easy to select all of a single day's clips at once so that you can sync your files in smaller batches. Even organizing your clips by scene can make waveform syncing go faster by reducing the number of files that need to be compared at once.
2. Right-click the bin(s) containing the matching audio and video clips, and choose Auto Sync Audio from the contextual menu.
3. In the Synchronize Using selector, choose Waveform. This analyzes and compares the waveforms of each of the selected clips, and replaces each video clip's previous audio channels with the newly synced .wav files.
4. Choose from the following options.

   Use channel number: Lets you choose which audio track to perform the waveform analysis on. With "Auto," DaVinci Resolve automatically picks the channels most suited for waveform comparison. With "Mix," DaVinci Resolve compares waveforms from the mixdown audio from all available channels. This can be useful when audio may not be present on long sections of one or channels. Users can also specify individual channels to avoid noisy audio.

   Retain embedded audio: Analyzes and compares the waveforms of each of the selected clips, and adds new channels in addition to the audio channels that were previously in the media file. The newly waveform-synced channels are added to an additional track, so when edited into the Timeline, a clip that's synced this way appears with one video clip and two audio clips that occupy two different audio tracks, so you can edit the camera original audio independently from the synced audio.

   Retain Video Metadata: Default is off, which means that video files that are synced to audio files inherit metadata (e.g., scene and take) from the audio file. When this option is checked, the video file's metadata is retained and not overwritten instead.

5. Press Sync.

   A progress bar dialog appears, showing you how long the syncing operation will take. When it's complete, your clips will be synced.

Progress dialog for syncing dialog using waveforms

TIP: After syncing, you may be notified via a dialog that one or more clips could not be synced. Note these clips, as it may be possible to use waveform syncing more successfully on just the selected pair of audio and video items that belong together.

Auto Sync Audio to Video by In/Out Points and Markers

If you don't have matching timecode in the audio and video source clips you're syncing, and there is no camera audio to sync by waveform, you can also sync audio by In/Out Points and by Markers. This is still mostly a manual process, and it requires someone to have previously marked each audio and video clip at a point that they know the clip is in sync before they use this function. It can also only be used on one audio/video pair at a time.

To batch sync dailies using In/Out Points or Markers:

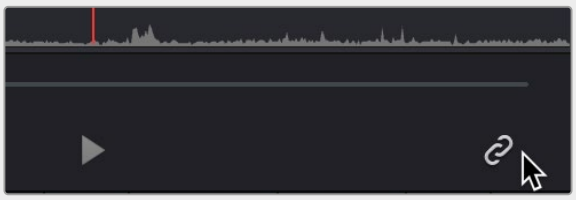
1. Place the audio and video clip you wish to sync in the same bin.
2. Identify a sync point on the video clip, for example the point where someone clapping their hands hits together.
3. Place an In Point, Out Point, or Marker at this position.
4. Identify a sync point on the audio clip, for example the spike on the waveform where you hear the sound of the hand clap.
5. Place an In Point, Out Point, or Marker at this position.
6. Select both the matching audio and video clips in the bin, right-click on one of them and choose Audio Sync > Auto Sync Audio from the contextual menu.
7. In the Synchronize Using selector, choose either In, Out, or Marker depending on which one you used to mark both the clips. Both clips need to have the same type of point marked on them.
8. Choose from the following options.

   Retain embedded audio: Analyzes and compares the waveforms of each of the selected clips, and adds new channels in addition to the audio channels that were previously in the media file. The newly waveform-synced channels are added to an additional track, so when edited into the Timeline, a clip that's synced this way appears with one video clip and two audio clips that occupy two different audio tracks, so you can edit the camera original audio independently from the synced audio.

   Retain Video Metadata: Default is off, which means that video files that are synced to audio files inherit metadata (e.g., scene and take) from the audio file. When this option is checked, the video file's metadata is retained and not overwritten instead.
9. Press Sync.

Manually Syncing Audio to Video

If you have a collection of WAV or AIFF audio files with video source media that lacks matching timecode, you need to manually sync each pair of media files together, one-by-one, using a sync reference such as the clap of a clapperboard or any other sharp sound with a distinct audio/visual correspondence.



To manually sync audio to video:

1. Create a new project, and import the video media you need to sync into the Media Pool. If a dialog appears asking whether or not you want to update the project to match the media, click OK.
2. If you want to stay organized, create a second bin in the Media Pool, named Audio Clips, and import the matching Broadcast .wav files into it. The name of the bin is not important, and having all the audio in one bin is simply a matter of convenience.
3. Click the Waveform button at the top of the Audio Panel, which lets you view and scrub along the waveform of audio clips you select in the Media Pool.
4. Select a video clip to sync, and move the Viewer playhead to line up with the first visual sync point in the first clip. This could be the clap of a clapperboard, the red flash of a tablet computer's slate app, a hand clap, or any clear visual cue to which there is a corresponding audible sound.
5. Now, select whichever audio clip corresponds to the current video clip in the Viewer, to open its waveform into the Audio Panel.
6. Use the Audio Panel transport controls and scrubber bar in the Source Viewer to move the playhead to the audio sync point that corresponds to that video sync point. This may be a clap, a beep, or some other staccato sound that's easy to sync to. As you play through the clip, the bottom half of the Viewer shows a zoomed out waveform for the entire clip, while the top half of the Viewer shows a zoomed in section of the waveform that immediately surrounds the playhead. Hopefully, the sync point you're looking for is a distinct, loud spike somewhere towards the beginning or the end (in the case of a tail slate) of the audio clip.

Aligning video and audio sync points with the Audio Panel set to show the Waveform panel

7. When you've found the audio sync point that matches the video sync point, click the Link/Unlink Audio button at the bottom right of the Audio Panel to embed the now synced audio into the video clip.

Clicking the sync link button to lock sync

The audio and video items are linked. At this point, you can use the newly synced clips in the Edit page, and use the Deliver page to export offline or online media with embedded audio for editing.

Retaining Video Metadata and Embedded Audio when Syncing Audio Manually

When syncing audio to video manually in the Media page, you can choose whether to include the original camera audio tracks in the synced file, or whether to retain the camera scene/take metadata, rather than have the audio file scene take metadata overwrite it as normal.

In the Media page > Audio > Waveform tab, the option (3 dot) menu now offers 2 choices:

The Audio > Waveform tab (3 dot) option menu lets you choose to retain embedded audio and/or video metadata.

Retain embedded audio

When enabled, embedded camera audio tracks are included with any newly synced audio during the manual linking process (using the link icon on this pane).

Retain video metadata

Default is off, which means that video files that are synced to audio files inherit metadata (e.g., scene and take) from the audio file. When this option is checked, the video file's metadata is retained and not overwritten instead.

Offsetting the Sync of Previously Synced Clips

If you need to offset the audio (or stereo 3D) sync of the items that make up a clip later on, you need only select the synced clip you want to resync in the Media Pool, then click the Waveform button at the top of the Audio panel to show the clip's audio waveform, turn off the linked clip button, change either the audio or video sync points, and turn the linked clip button back on again.

You can also use two sets of commands for slipping the sync of any clip:

- **Trim > Slip Audio > Slip Audio One Frame Forward/Reverse:** (Option-Period and Option-Comma) Slips the audio/video sync of any clip in whole frame increments.
- **Trim > Slip Audio > Slip Audio One Subframe Forward/Reverse:** (Option-Right Arrow and Option-Left Arrow) Slips the audio/video sync of any clip in 1/10th frame increments.
- **Trim > Slip Eye > Slip Eye One Frame Forward/Reverse:** (Command-Option-Period and Command-Option-Comma) Slips the sync relationship between the eyes within a stereo clip in whole frame increments.

Finding Synced Audio Files

When you've synced dual-system audio and video clips together in DaVinci Resolve, you can find the audio clip that a video clip has been synced to using the following procedure.

To find the audio clip that a video clip has been synced to:

- Show the Media Pool in List view, and reference file name in the Synced Audio column.
- Right-click a video clip that's been synced to audio, and choose Audio Sync > Reveal synced audio in Media Pool from the contextual menu. The bin holding the synced audio clip is opened and that clip is selected.

Displaying Synced Audio File Names on the Timeline

For certain workflows you may wish to see the name of the original audio file used in a synced dual system audio pair on the timeline tracks, rather than the name of the video clip its attached to.

To display the filename of the original audio file used in a synced pair in the timeline:

1. Choose View > Show File Names. You cannot see synced audio file names unless you've set DaVinci Resolve to display the original file names.
2. Choose View > Overlay Synced Audio File Names. You should now see the names of the synced audio files superimposed on the audio clips in the Timelines, and the names of the video files superimposed on the video clips in the Timelines, even when they're synced.

Viewing the synced audio file names in the Edit page Timeline

Detach Synced Audio from Video

Occasionally it can be necessary to separate the synced audio from their respective video clips. This is useful for workflows to prepare the timeline for sound post using either media management or .drt exports of the sound only without the video files. This action can be triggered from the Edit page to replace all the synced audio elements with the original source audio media in the media pool. You can find this option in Timeline > Audio > Detach Synced Audio from Video.

Chapter 21

Modifying Clips and Clip Attributes

Once you've added clips to the Media Pool, you may find you have to make some changes to prepare it for use in your project.

This chapter covers diverse tasks that include redefining the clip attributes associated with each source clip to reinterpret video and audio attributes, timecode values, and clip names, converting LTC timecode recorded on an audio track into usable timecode, chopping long clips into more manageable subclips, and creating stereo clips from left and right eye media.

Adjusting Media Pool Clips in the Inspector

You can directly modify Media Pool clips in the Inspector, before you edit those clips into a timeline. This allows you to change the parameters of source media so that clips that are subsequently edited into a timeline carry those new settings with it. For example, you can prepare your material prior to editing by changing the clip's file and RAW settings, adjusting the audio levels and EQ, or assigning it a specific lens correction, etc. Once modified, any part of that clip would have the correct Inspector parameters already in place when you edited them into your timeline.

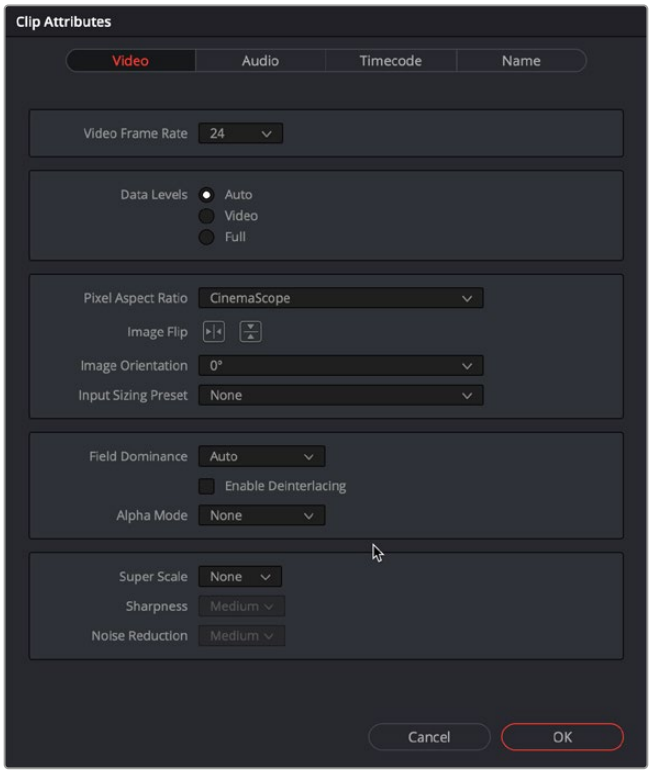
For more information about using the Inspector in the Media Pool, jump to this chapter: Using the Inspector in the Media Page.

Changing Clip Attributes

Using the Clip Attributes window, you can alter additional attributes for multiple clips all at once. This window has some overlap with other clip attributes that are editable directly from submenus within the Media Pool clip contextual menu.

To edit the attributes of one or more clips in the Media Pool of any page:

1. Select one or more clips in the Media Pool by Shift-clicking, Command-clicking, or dragging a bounding box around them.
2. Right-click one of the selected clips, and choose Clip Attributes.
3. Click to open the panel of the attributes you want to edit. If you've selected multiple clips, then making your alterations automatically checks the box of the attributes being changed.
4. When you're finished, click OK to accept the changes.



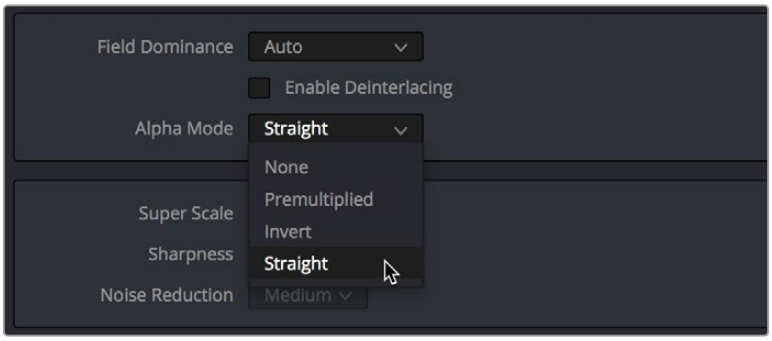
You can also edit select clip attributes for clips that have been edited into the Timeline.

To edit the attributes of one or more clips in the Timeline of the Cut, Edit, or Color pages:

1. Select one or more clips in the Timeline by Shift-clicking, Command-clicking, or dragging a bounding box around them.
2. Right-click one of the selected clips, and choose Clip Attributes.
3. Click to open the panel of the attributes you want to edit. If you've selected multiple clips, then making your alterations automatically checks the box of the attributes being changed.
4. When you're finished, click OK to accept the changes.

Video Attributes

These affect individual clip frame rate, geometry, and data levels.



The Video panel of the Clip Attributes Window

- **Video Frame Rate:** In cases where a clip's frame rate was specified incorrectly by another application or recording device, or if there is no frame rate metadata available at all, you can change what DaVinci Resolve considers the frame rate of the source clip to be by either using this menu to choose a frame rate from 1 to 120 fps, or choosing Custom and entering a value from 1 to 32,000 fps (to accommodate high-speed and specialty format video). Changing a clip's Video Frame Rate will change its duration and relative playback speed in DaVinci Resolve. A clip's audio, however, will be unaffected. Please note, just because extremely high frame rate media is supported, do not expect real time performance at excessively high frame rates, and understand that what performance your workstation is capable of depends on its configuration and the speed of your storage.
- **Data Levels:** In certain circumstances, you may find that you need to manually choose appropriate data levels for clips that are not being interpreted correctly, choosing between Auto, Video, and Full.

> For more information on this setting, and how it affects the image data in your project, jump to this chapter: Data Levels, Color Management, and ACES.

- **Pixel Aspect Ratio:** In projects using a mix of media with different frame sizes, you can assign specific pixel aspect ratios using this drop-down menu. You can also change the Pixel Aspect Ratio to a manual value to adjust and compensate for various motion picture capture technologies. Select Custom from the Pixel Aspect Ratio menu, and then enter a numeric value in the box below. The value is the X in the 1:X ratio. For example, you would type in 1.6 to get a pixel aspect ratio of 1:1.6.

- **Horizontal and Vertical Image Flip:** Modifies the horizontal and vertical image flip camera metadata for r3d clips, which is useful for stereoscopic 3D projects shot with a mirrored camera rig that reverses the media from one eye, or in cases where steadicam rigs result in upside-down clips. These settings are different from the Flip Image controls in the Sizing palette of the Color page.
- **Image Orientation:** For media that has an orientation setting, this lets you change the rotation of that media so that it's correctly oriented. Four settings let you adjust by 0°, 90° right, 180°, and 90° left.
- **Input Sizing Preset:** You can use this panel to assign a Sizing palette preset to select clips. For example, if you have a special Input Format Preset for standard definition PAL widescreen clips that you've edited into a high definition project, you can do a sort in the Media Pool to isolate them, and then select them all and apply this preset.
- **Field Dominance:** By default, the Auto setting enables DaVinci Resolve to automatically determine whether a particular clip is Upper- or Lower-field dominant. If this automatic determination is wrong, you can choose Upper or Lower to manually override this.
- **Enable Deinterlacing:** (only available in Studio version) This checkbox is only enabled if "Enable video field processing" is turned off in the Master Settings panel of the Project Settings. Turning the Enable Deinterlacing checkbox on sets DaVinci Resolve to deinterlace clips using the Deinterlace quality setting that's located in the Image Scaling panel of the Project Settings. Normal is a high-quality deinterlacing method that is suitable for most clips, while High is a more processor-intensive method that can sometimes yield better results, depending on the footage. The DaVinci Neural Engine option uses advanced machine learning algorithms to reconstruct the frame, which will ideally give even better results than the High setting.
- **Alpha Mode:** The options presented here depend on the format of the clip you've selected, since only certain formats (such as ProRes 4444, QuickTime Animation, OpenEXR, TIFF sequences, and so on) are capable of containing alpha channels. If you've imported clips with embedded alpha channels, this panel lets you enable or disable their use in DaVinci Resolve (by choosing None), choose the type of alpha channel (Premultiplied or Straight), or invert the alpha channel. If you select a clip that doesn't contain an alpha channel, then most of these options don't appear.

The Alpha Mode options that are available when a clip has an embedded alpha channel

- **Super Scale High Quality Upscaling:** For instances when you need higher-quality upscaling than the standard Resize Filters allow, you can now enable one of three "Super Scale" options in the Video panel of the Clip Attributes window for one or more selected clips. Unlike using one of the numerous scaling options in the Edit, Fusion, or Color pages, Super Scale actually increases the source resolution of the clip being processed, which means that clip will have more pixels than it did before and will be more processor-intensive to work with than before unless you optimize the clip (which bakes in the Super Scale effect into the optimized media), or cache the clip in some way.

The Super Scale drop-down menu provides the options of 2-3-4x and 2-3-4x Enhanced, as well as Sharpness and Noise Reduction options to tune the quality of the scaled result. Most of the Super Scale parameters are in fixed increments, however the Enhanced modes let you apply Super Scale in variable amounts. Selecting one of these options enables DaVinci Resolve to use advanced algorithms to improve the appearance of image detail when enlarging clips by a significant amount, such as when editing SD archival media into a UHD timeline, or when you find it necessary to enlarge a clip past its native resolution in order to create a closeup.

You may find that, depending on the source media you're working with, setting Sharpness to Medium yields a relatively subtle result that can be hard to notice, but setting Sharpness to high should be immediately more preferable, while also sharpening grain and noise in the image to an undesirable extent at the default settings. However, while raising Noise Reduction will ameliorate this effect, it will also diminish the gains you obtained by raising Sharpness. In these cases, it's worth experimenting with keeping Sharpness at Low or Medium so that Super Scale sharpens all aspects of a clip, but then using the Noise Reduction tools of the Color page (with their additional ability to be fine-tuned) to diminish the unwanted noise.

Super Scale options in the Video panel of the Clip Attributes window

TIP: Super Scale, while incredibly useful, is an extremely processor-intensive operation, so be aware that turning this on will likely prevent real-time playback. One way to get around this is to create a string-out of all of the source media you'll need to enlarge at high quality, turn on Super Scale for all of them, and then render that timeline as individual clips, while turning on the "Render at source resolution" and "Filename uses > Source Name" options.

Real-Time 3:2 Pulldown Removal

If you have 29.97fps interlaced material that was encoded with a 3:2 pulldown, DaVinci Resolve can reconstruct the original footage's progressive frame rate in real time. For example, if you have source media from a film camera (24fps progressive) that has been telecined to NTSC video (29.97fps interlaced), DaVinci Resolve can pull the original 24 discrete film frames out of the various interlaced fields that make up the NTSC signal.

To remove 3:2 pulldown in real time:

1. Select one or more 29.97 fps interlaced clips in the Media Pool.
2. Right-click one of the selected clips and select Clip Attributes.
3. In the Video tab, turn on the Remove 3:2 Pulldown checkbox.
4. Set the Frame where the 3:2 cadence started in the "First Frame of Clip" drop-down (this is usually the "A" frame).
5. Click OK.

   The footage will now behave like a 24fps progressive clip.

Telecine footage with 3:2 pulldown removed; the scrambled number (mix of the numbers 1 and 2) at the end of the KeyKode is a field indicator, showing that this A frame was created properly from fields 1 and 2 of the interlaced signal.

Audio Attributes

The Audio panel lets you alter the channel format and channel assignments for one or more clips. These settings affect what appears in the audio tracks of the Timeline when you edit a clip into a program. When you first import clips into the Media Pool, you can use the Audio Attributes panel to define which embedded audio channels can be exposed as tracks in the Edit and Fairlight page timelines for editing, and how they will appear.

The Audio panel of the Clip Attributes window

Add Track Controls

A set of controls at the top of the Track/Channel list lets you add additional tracks to a clip. Adding additional tracks to a clip lets you remap that clip's available channels to appear in the Timeline when you edit it.

- **Format:** A drop-down that lets you choose a format for new tracks that you add. The setting you choose here affects how many channels appear in the Channel Assignments list below, as well as what kind of Timeline audio track will be required to expose all channels of that clip. If you choose a Channel Format with fewer channels than are embedded in a clip, all extraneous channels will be disabled. The available options are:

  Mono: Appropriate for single-channel clips

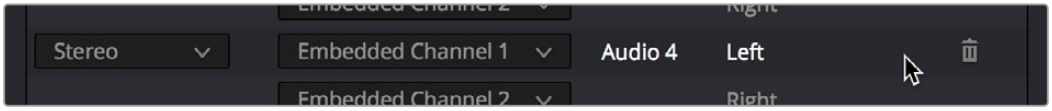
  Stereo: Appropriate for clips with two-channel left/right audio

  5.1: Appropriate for 5.1 surround mixes

  7.1: Appropriate for 7.1 surround mixes

  Adaptive: Appropriate for multiple-mono production audio, such as multi-channel recordings where a boom microphone, two separate lavaliere microphones, and a mixdown track are recorded simultaneously.

- **Tracks:** Lets you adjust how many tracks you want to add to the current clip or clips. Each track you add will result in an additional linked audio item being edited into an additional audio track when this clip is edited into the Timeline. For example, if you have a multi-channel production recording with four different microphones, you can add 3 mono audio tracks, and then assign each channel to a separate track to expose each channel as an individual audio clip in the Timeline for purposes of editing each microphone separately.
- **Add button:** Lets you add the tracks you've specified to the current clip or clips.
- **Reset:** Clicking on the Reset icon will reset the audio clip attributes to their original state.

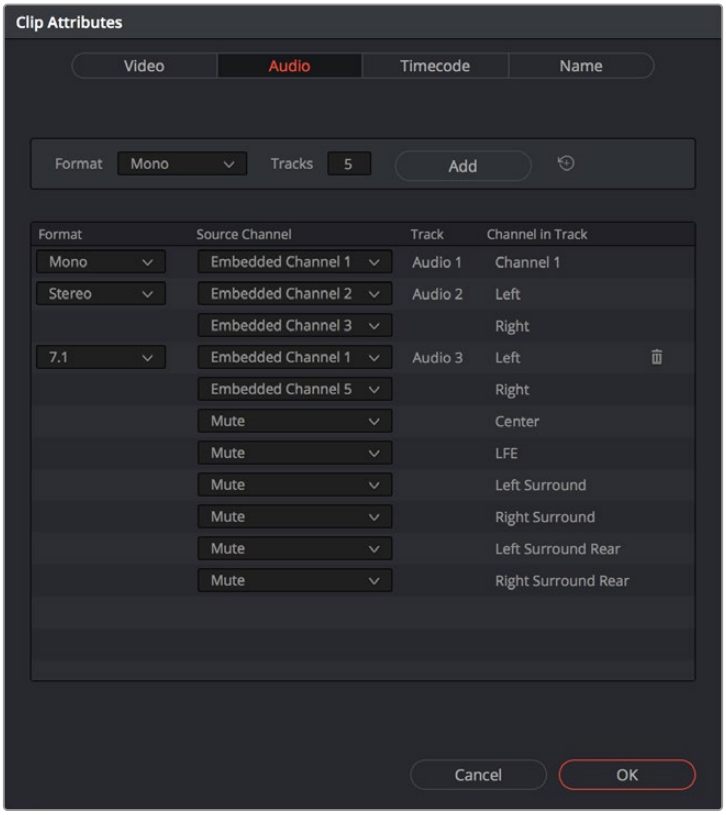


A clip with a single track of two-channel stereo audio at left, compared to a clip with two tracks of single channel mono audio at right

Audio Track and Channel List

The list below the Add Track controls show an entry for each track defined within the currently selected clip or clips. Pop-ups within this list let you redefine and map how that clip's channels are spread across the differently mapped tracks you've created.

- **Format:** The format of each audio track. Can be Mono, Stereo, 5.1, 7.1, or Adaptive.
- **Source Channel:** Each track lists however many channels the specified format requires. A Stereo track has two source channels, a 7.1 track has eight source channels. Channels appear hierarchically underneath the track they belong to. If you wish to remove a specific channel from the clip, you can choose <none> from the list.
- **Track:** The name of each track in a clip.
- **Channel in Track:** The name of each channel in that track.
- **Delete Track button:** Hovering the pointer over a track reveals a trashcan icon you can click to delete that track.

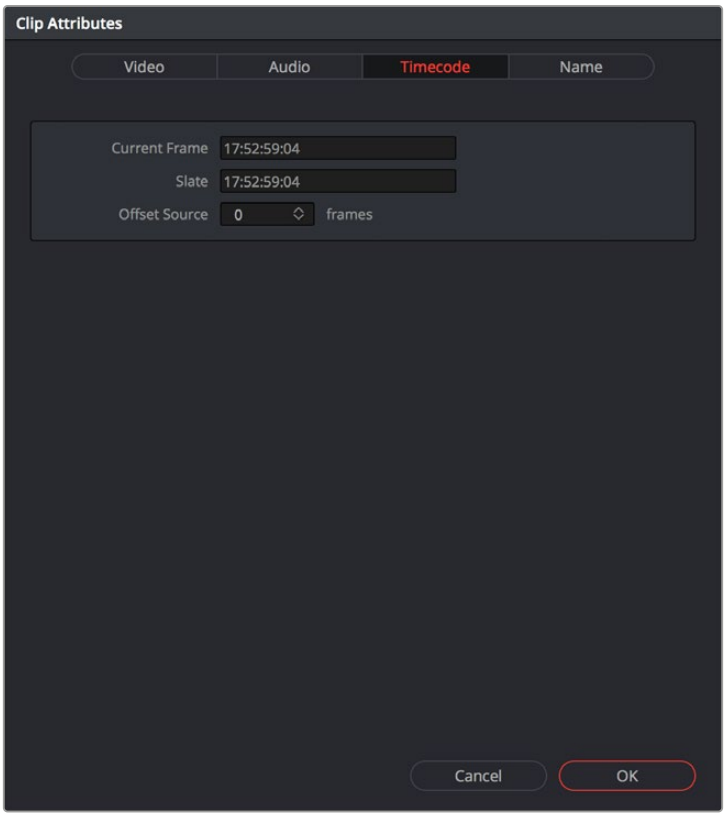


A trashcan button you can use to delete an audio track within Clip Attributes; it only appears when you hover the mouse over a track

Support for Mixed Audio Track Formats from Source Clips

DaVinci Resolve also supports media with multiple audio tracks that have differently formatted channels embedded within them. For example, a clip with one stereo track, one 5.1 surround track, and six mono tracks can all be appropriately set up in the Audio panel of Clip Attributes after that clip has been imported.

The Audio panel of Clip Attributes now has controls over what format (Mono, Stereo, 5.1, 7.1, Adaptive) the channels embedded within a particular clip should be configured as. This means that you can set up clips with multiple tracks, each one using potentially different formats of audio employing different combinations of clips, which is handy for mastering.



Clip Attributes now lets you assign channels among different tracks with different channel assignments

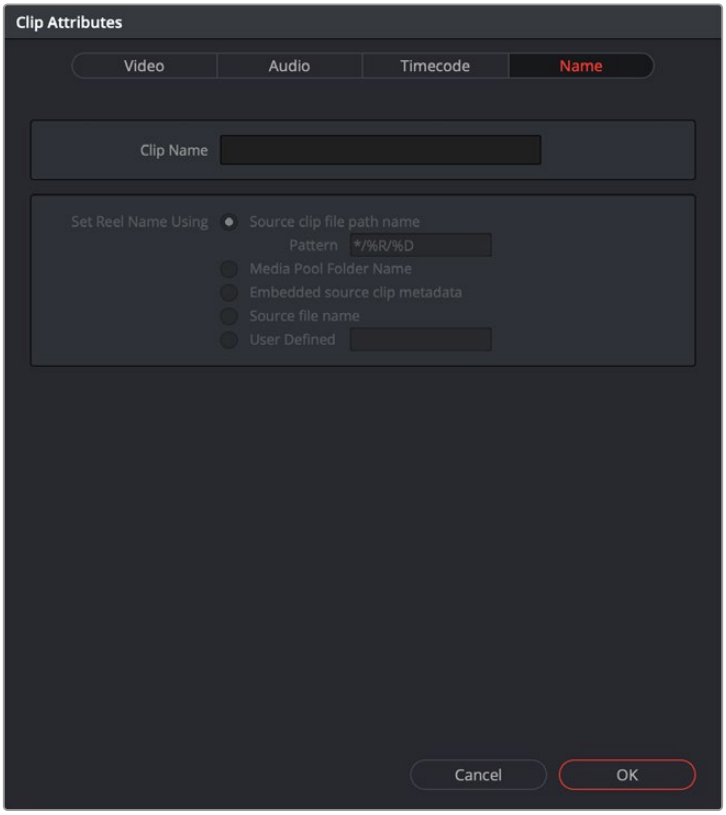
Timecode Attributes

If you find yourself dealing with clips that have incorrect timecode, or timecode with an incorrect relationship to the EDL, XML, or AAF project you've been given, you can use these attributes to modify the timecode and reel name of clips in the Media Pool. None of these tools alter the source media on disk. They simply change the timecode metadata in your DaVinci Resolve project, which by extension affects the timecode of any media you render.

- **Current Frame Timecode:** Lets you assign a new time for the timecode at the currently viewed frame of the clip.
- **Slate Timecode:** In situations where source media comes from a shoot where a timecode slate was used during the shoot, then you can assign the slate timecode as a second timecode track that can be used for various operations, without changing the primary timecode of the clip, which may already be in use for program sync.

  To set appropriate Slate timecode, select a clip in the Media Pool with a visible timecode slate, and move the playhead to a frame where the timecode in the slate is clearly readable. Then, open the Timecode panel of the Clip Attributes window, and type the timecode value you see in the image into the Slate Timecode field.
- **Offset Source Timecode:** If an entire set of clips has timecode that's merely offset, you can correct the timecode offset for as many selected clips as you like.

The Timecode panel of the Clip Attributes window



Reel Name Attributes

The "Assist using Reel Names" checkbox in the General Options panel of the Project Settings is an extremely important setting for controlling how the conform process works. By default it's turned off, and Reel Names are left blank. This is fine for conform workflows where all you need is the file path or file name and source timecode to successfully identify which media files correspond to what clips. However, if you need more information than that to reconform the clips in your project, you can turn on the "Assist using Reel Names" checkbox to enable DaVinci Resolve to use one of four different methods to automatically define reel names for every clip in the Media Pool.

Using the Clip Attributes dialog, you also have the option of manually defining how one or more selected clips in the Media Pool have their Reel Names defined. This is useful when there are certain clips in a project that need to use a different method of reel name extraction, or manually entered

reel names. Once you've used Clip Attributes to change the reel names of clips, those clips no longer automatically update when you change the "Assist using Reel Names" options in the Project Settings.

You must first turn on "Assist using Reel Names" in the General Options of the Project Settings, and choose a Reel Assist setting, for the reel name attributes in the Clip Attributes window to be editable.

The Reel Name panel of the Clip Attributes Window

- **Source clip file pathname:** Obtains the reel name by extracting it from each media file's path. This makes it possible to extract a reel name from all or part of the file name, or from all or part of the name of any folder in the path that encloses that file. This extraction is defined using the Pattern field.
- **Pattern:** A code that defines how a reel name should be extracted from the source clip pathname. More information about creating patters appears later in this chapter.
- **Media Pool bin name:** The reel name is obtained from the name of the bin in the Media Pool that encloses that clip. For example, in a stereoscopic workflow you might want to export offline stereo media with the "Left" and "Right" bin names in which they're organized as reel names. Another example would be organizing VFX being incrementally processed in individually named bins, such as "VFX_Tuesday_10-12."
- **Embedding in Source clip file:** Useful for file formats where the reel name is embedded within the media file itself. CinemaDNG and other digital cinema cameras, QuickTime files created by Final Cut Pro, and DPX frame files are formats that can contain reel name header data.
- **Source clip filename:** If there is no defined reel number, often it's easy to just use the Source clip filename.
- **User Defined:** This option is only available when you manually alter the reel name for one or more selected clips in the Media Pool using the Clip Attributes dialog. Choosing User Defined lets you type any string of text you like to use as the reel name.

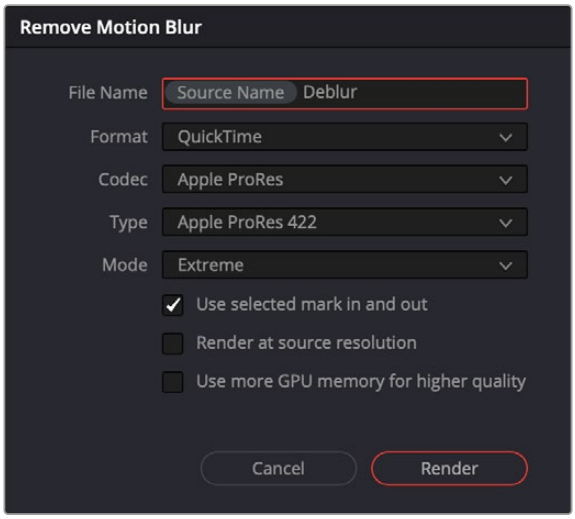
Motion DeBlur (Studio Version Only)

Motion DeBlur is an AI tool that removes common motion blur artifacts, including softness from a clip. This results in crisper, more in-focus images from footage that was shot at slow shutter speeds.

To start, download the Motion DeBlur model from DaVinci Resolve > Extras Download Manager.

Motion DeBlur renders new media clips to your workstation, and adds them to your media pool. It does not replace the original footage.

The original footage with motion blur as the model turns.



The crisper footage after the Motion DeBlur operation.

To apply Motion DeBlur to a clip:

1. Select one or more clips in your media pool.
2. Right-click on any one of them and select AI Tools > Remove Motion Blur.
3. Adjust the file name, codec, and mode from the Remove Motion Blur dialog.
4. Click Render.

NOTE: Motion DeBlur is a resource-intensive operation and can take up to 60 seconds to analyze every 1 second of footage.

The Remove Motion Blur dialog box.

The Remove Motion Blur dialog lets you choose the following parameters:

- **File Name:** Choose the file name for the new DeBlurred media clip.
- **Format:** Select the video format for the new DeBlurred media clip.
- **Codec:** Select the video codec for the new DeBlurred media clip.
- **Type:** Select the video codec type for the new DeBlurred media clip.
- **Mode:** Choose the amount of blur to remove from the clip, either standard or extreme depending on the amount of motion blur you start with.
- **User selected mark in and out:** To keep render times manageable, check this box to render only the media between the set In and Out points of the clip. Uncheck this box to render the entire clip.
- **Render at source resolution:** Check this box to render the new DeBlurred media clip at its source resolution. Uncheck this box to render it at the timeline resolution.
- **Use more GPU memory for higher quality:** Check this box to increase the amount of GPU ram used in the operation, for higher quality results.

Some tips for better results from Motion DeBlur:

- In general, MotionDeblur is tolerate of moderate motion blur caused by slow camera panning.
- Videos with noticeable camera shake can yield decent results, provided the main subject is visible in every frame. For better results, use footage where the subject stays near the

center of the frame throughout the clip. Small variations in framing are acceptable and may still produce good results—such as recording a city scene while walking slowly or standing still with slight handheld motion.

- Clips that contain at least some sharp frames usually yield better deblurring results. For instance, a video may contain brief blur during a step or sudden movement, while the remaining frames stay relatively clear.
- In more challenging cases, higher frame rates can improve results. Extreme motion blur might still be beyond the model's capabilities.
- Avoid rapid camera movements, especially when the subject moves quickly across the frame—such as from one point to another within a few seconds.

Update Timecode from Audio – LTC

Some cameras do not offer the ability to sync to an external timecode source. Their recorded timecode may be time of day or free run timecode, but it would not be frame accurately synced to other cameras, the dual system audio recorder or the digital slate. This makes multi-cam or dual sound system syncing a time consuming manual operation.

DaVinci Resolve offers a solution to this problem if, by connecting an externally generated timecode to the camera audio input, the video that's recorded by the camera has a timecode reference recorded on the audio track during the shoot.

Select this clip, or clips, in the media pool, then right-click on one of the highlighted clips and select "Update timecode from audio - LTC." DaVinci Resolve automatically and instantly updates the clip timecode using the LTC it finds on the audio tracks. You can now use the clips as though they were synced on set.

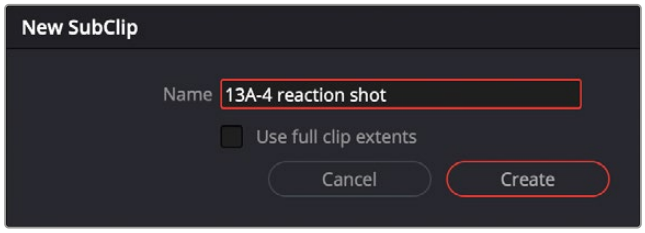
Changing Clip Thumbnails in the Media Pool

When the Media Pool is in Thumbnail mode, each clip is represented by a small image that defaults to the first frame of that clip. You can scrub the thumbnail of any clip to view its contents using the pointer after hovering over it for a moment. However, when you're done scrubbing, moving the pointer away from any clip returns its thumbnail to the first frame of media, which may or may not be representative of its contents. You can change this, if you like.

To customize the thumbnail of any clip:

1. Move the pointer over a clip you want to customize the thumbnail of.
2. Hover for a moment, then scrub to a representative frame.
3. Right-click that clip, and choose Set Poster Frame, or press Command-P.

To clear the custom poster frame of any clip:



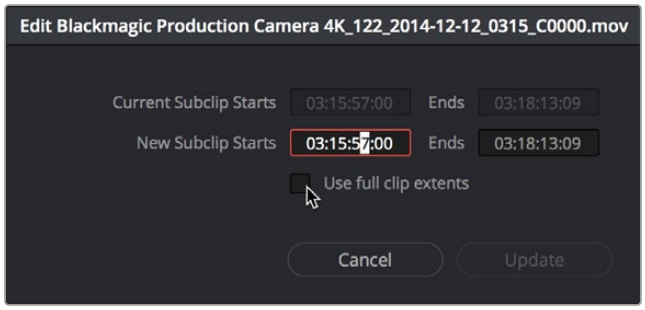
- Right-click a clip, and choose Clear Poster Frame, or press Option-P.

Creating Subclips

Subclips give you another way of organizing media in the Media Pool, letting you break excessively long clips into shorter ones. For example, if the director of a project is fond of “rolling takes” where multiple takes are all recorded within a single clip, you can break these takes up by making them into subclips.

To create a subclip:

1. Select any clip in the Media Pool to open it into the Viewer.
2. Set In and Out points to define the section you want to turn into a subclip.
3. Do one of the following:
   - Right-click the jog bar and choose Make Subclip.
   - Drag a clip from the Viewer or Source Viewer into the Media Pool.
4. A new subclip dialog appears, allowing you to name the subclip and decide to use its full extents by turning on the checkbox.



The New SubClip dialog

Once created, subclips appear and work like any other clip in DaVinci Resolve. You can also create subclips in the Media page while performing other organizational tasks there.

Removing or Changing Subclip Limits

Once created, you can right-click any subclip in the Media Pool or a timeline and choose Edit Subclip to open a dialog in which you can turn on a checkbox to use the subclip’s full extents, or to change the start or end timecode of the subclip via timecode fields, before clicking Update to modify the subclip.

The Edit Subclip dialog

Organizing Stereo 3D Media

When working with stereo media in DaVinci Resolve, one of the first tasks you must perform is that of syncing each stereo pair of clips to act as a single clip. This is easily accomplished so long as you're careful about how you organize your media in the Media Pool.

Each set of right- and left-eye media should always be organized into separate left-eye bins and right-eye bins, to facilitate later syncing of these clips using the Stereo 3D Sync command in the Media Pool contextual menu.

For more information on setting up media for stereo workflows, jump to this chapter: "Stereoscopic Workflows.

Camera Raw Decoding

Camera raw media formats are so named because they capture raw color space data directly from the sensor of whatever digital cinema camera did the recording. Raw image data is not human readable, and must be debayered or demosaiced to convert the original raw data into image data that can be handed off to DaVinci Resolve's image processing pipeline.

There are four ways you can control how camera raw media is debayered into a useful, "normalized" image for adjustment or output:

- The Camera Raw panel of the Project Settings contain groups of parameters that correspond to every camera raw media format that's supported by DaVinci Resolve. Using these parameters in the Camera Raw panel, you can override the original camera metadata that was written at the time of recording, and make simultaneous adjustments to all camera raw media throughout your project.
- The Image Panel in the Inspector also contains the controls for every raw media format that's supported by DaVinci Resolve. Allowing you to select all, some, or individual clips for raw debayering.
- The Camera Raw palette in the Color page lets you individually adjust Camera Raw parameters for individual clips in the Timeline.
- When you use Resolve Color Management (RCM) in a project that uses Camera Raw formats, color science data from each camera manufacturer is used to debayer or demosaic each camera raw file to specific color primaries with linear gamma, so that all image data from the source is preserved and made available to DaVinci Resolve's color managed image processing pipeline. As a result, the Camera Raw project settings and Camera Raw palette of the Color page are disabled, because RCM is controlling the debayering of all camera raw clips, and all image data from the raw file is available for conversion to the Timeline Color Space you choose to work with as you grade.

For more information about each of the Camera Raw formats that can be adjusted in DaVinci Resolve, jump to this chapter: Camera Raw Settings.

Chapter 22

Importing and Conforming Timelines

Generally speaking, “conforming” a project describes the process of importing a project exchange file from another post-production application, and automatically relinking each clip in the imported timeline to the high-quality media files each clip corresponds to.

If you need to continue editing, color correct, or finish a project that was put together in another application, you can import via the EDL, AAF, or XML project exchange formats. When you go through the process of conforming a project, you use the imported project data to arrange the clips in the Media Pool into a timeline that constitutes the program that’s about to be graded.

This chapter walks you through the process of preparing timelines in other applications prior to moving them into DaVinci Resolve and covers which effects have counterparts in the DaVinci Resolve timeline. It ends with instructions on how to set up to compare a reference movie to the Timeline.

Preparing to Move Your Project to DaVinci Resolve

When you're preparing to move a project from another NLE to DaVinci Resolve, there are a few steps you can take to make your work more organized.

Move Clips to the Lowest Video Track

Editors often use the multiple tracks NLEs offer for simple clip organization in the edit of a scene. While this is convenient for offline editorial, it is less convenient when you're trying to conform, grade, finish, and render the media used by a project as quickly and efficiently as possible.

For this reason, it's a good idea to move all clips that are not stacked or superimposed as part of a compositing operation down to track V1 of the Timeline in your NLE. This produces a simplified edit that has many advantages. The project becomes smaller to move because there's less media in the Timeline, and consequently becomes faster to render. Furthermore, the colorist is spared confusion because this eliminates "hidden" media that is nonetheless connected to other clips that can be seen.

It's also helpful, once you've reorganized the Timeline, to eliminate any empty tracks that are left. This can be done from within DaVinci Resolve, but doing it in your NLE further simplifies the project import process.

Organize Unsupported Media Files

Depending on your workflow and on the NLE you're working with, there may be clips using formats that are unsupported in DaVinci Resolve. Unsupported generators, media formats, and other effects constructs may simply not be seen in DaVinci Resolve, and will consequently appear as unlinked clips.

If you know this in advance, you can move all such clips into dedicated tracks where they can be isolated, and the track can be turned off to hide the unsupported clips, simplifying timeline navigation. This also saves the colorist from the need to worry about why there are offline clips in the Timeline at 3 o'clock in the morning, immediately before starting a render.

Creating an Offline Reference Movie

Even though the colorist in any given workflow is likely to be building new grades from scratch, it can be valuable to have a reference movie showing any color corrections, filters, or effects that the offline editor applied during the editing process. This offline reference can be imported into a DaVinci Resolve project, and used as a split-screen reference whenever there's some question about a look or effect from the offline edit.

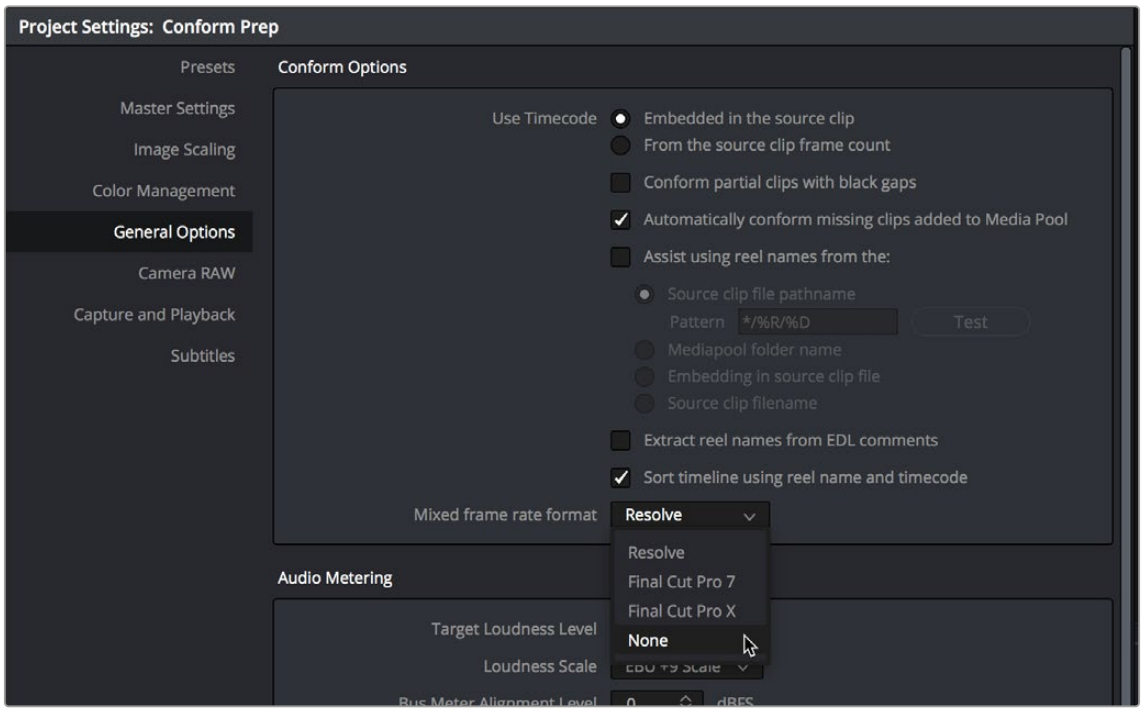
Offline reference movies also serve as a useful tool when conforming a project in the Edit page. After project conform, you can compare the project as seen in the Record Viewer with the synchronized offline movie as seen in the Source Viewer set to Offline mode. This makes it easy to scrub through a project to make sure that each clip has imported correctly and is in sync.

More information about using offline reference movies appears later in this chapter.

Mixed Frame Sizes and Mixed Codecs

Most NLEs can freely mix media using different frame sizes, different codecs, and different frame rates. DaVinci Resolve deals with these combinations in different ways, depending on what settings you've selected in the Project Settings.

Mixing Frame Sizes: Mixed frame sizes are easily handled. The Set Timeline Resolution To parameter in the Project Settings panel of the Project Settings dictates the current resolution of the project. Any clips with a frame size that doesn't match the project is resized according to the option selected in the Image Scaling panel of the Project Settings. You can, of course, always manually readjust the sizing of any clip if you want to make a specific adjustment. All resizing is done using the optical-quality resizing algorithms in DaVinci Resolve.



For more information, jump to this chapter: Sizing and Image Stabilization.

Mixing Codecs: Mixed codecs are also not a problem, as long as the different codecs used by the media in the project you're importing are compatible with the list of codecs and formats that DaVinci Resolve supports. For more information about the currently supported list of codecs and formats, check the Blackmagic Design support page for DaVinci Resolve. This list is updated often with newly supported formats.

Mixed Frame Rates

DaVinci Resolve also supports mixed frame rates, although there is a setting you must choose to ensure the best results for the NLE you're importing from. By default, mixed clip frame rate support is enabled via the "Mixed frame rate format" pop-up menu that appears either in the Master Project Settings, or in the Import AAF or XML dialog.

The different options available in the "Mixed frame rate format" pop-up are available to let you conform projects using the method of mixed frame rate calculation used by the NLE a project was originally edited in; different NLEs have different ways of mixing frame rates, and that used by Final Cut Pro 7 is different from that used by Final Cut Pro X or Avid Media Composer. If you need to change this setting, you must do so before you import any media into the Media Pool; once the Media Pool is populated, this setting can no longer be changed.

Mixed frame rate format selection

This Mixed frame rate format pop-up menu is also found in the Load AAF and Load XML dialogs. DaVinci Resolve automatically chooses a setting from the “Mixed frame rate format” pop-up menu that corresponds to the project file you’re importing, but in some cases you can override this setting if necessary. For projects sent from Final Cut Pro, you can choose either “Final Cut Pro 7” or “Final Cut Pro X” to match the type of project you’re importing. On the other hand, you should choose “Resolve” for projects imported from Premiere Pro, Smoke, Media Composer, or other NLEs.

When “Mixed frame rate format” is set to anything but None, DaVinci Resolve conforms and processes all clips in the Timeline to play at the project’s frame rate. For example, 23.98, 29.97, 30, 50, 59.94, and 60 fps clips will all play at 24 fps if that’s what “Timeline frame rate” is set to in the Master Project Settings. Clips with different source frame rates will be retimed to match the Timeline conform frame rate.

The Retime process that’s used to render clips with differing frame rates can be changed for individual clips via the Retime Process parameter in the Edit page Inspector, or it can be changed project-wide using the Retime Process parameter found in the Frame Interpolation panel of the Master Project Settings.

For more information on how each of the three available options work, jump to this chapter: System and User Preferences.

If you choose “None,” then clips with frame rates that aren’t equal to the Timeline frame rate will ignore their original frame rate and will play at the Timeline rate, resulting in either faster or slower motion, depending on the difference between the original and Timeline frame rates.

NOTE: Because DPX files often either lack or have incorrect frame rate information in the header data, you may need to select None when conforming a project using image sequences to make sure your media is not incorrectly interpreted.

How clips in mixed frame rate timelines are rendered depends on whether the Render Settings are set to render individual source clips or one single clip. When you render the Timeline as ”Individual Source Clips,” then all clips are rendered individually at their original frame rate. If you select ”Single Clip,” then all clips are converted to the “Timeline frame rate” frame rate setting, and rendered as a single media file.

Importing Effects when Conforming Edits

DaVinci Resolve is capable of translating a subset of the effects exported within XML, AAF, and EDL project files into their DaVinci Resolve equivalents. The following chart illustrates which effects are supported, and for which project import formats.

Unsupported effects are neither imported nor displayed in DaVinci Resolve. However, the majority of unsupported effects are preserved internally, and are reinserted into exported XML or AAF files so that those effects will reappear in your NLE once the project is reimported.

	EDL	FCP 7 XML	FCP X XML	AAF
Color Corrections	No	No	Yes	No
Composite Modes	No	Yes	Yes	Overlay only
Multiple Tracks	No	Yes	Yes	Yes
Video Transitions	Yes	Yes	Yes	Yes
Audio Transitions	No	No	No	Yes
Opacity Settings	No	Yes	Yes	Yes, via 3D Warp or Superimpose
Position, Scale, Rotation	No	Yes	Yes	Yes, via 3D Warp
Flip and Flop	No	No	No	Yes, via Flip, Flop, or Flip-Flop effects
Pitch and Yaw	No	No	No	Yes, via 3D Warp
Linear Speed Effects	Yes	Yes	Yes	Yes
Variable Speed Effects	No	Yes	Yes	Yes
Still Image Clips	No	All supported formats in Resolve	All supported formats in Resolve	All supported formats in Resolve
Freeze Frames	No	No	No	Yes
Nested Sequences	No	Yes	Yes	No
Linked Clip Audio	Yes	Yes	Yes	Yes
Mixed Frame Rates	No	Yes	Yes	Yes
Text Generators	No	Yes	Yes	No

Effects supported with imported AAF, XML, and EDL

About Supported Color Corrections

At the time of this writing, only Final Cut Pro X XML projects are capable of exporting color correction data that can be imported as primary grades in DaVinci Resolve. For obvious reasons, color correction import is a one-way street, and imported color corrections cannot be output back to Final Cut Pro. Imported Final Cut Pro X color adjustments appear in the Color page as primary corrections.

Other workflows for importing color correction information from other applications are available using ColorTrace to import grade data from CDLs (Color Decision Lists).

For more information, jump to this chapter: Copying and Importing Grades Using ColorTrace.

About Supported Transitions

EDLs are the most restrictive when it comes to transition support in DaVinci Resolve, as only Cross Dissolves will be read. Any other transitions appearing in an EDL will be automatically converted to a Cross Dissolve of the same duration when it's imported into DaVinci Resolve.

On the other hand, DaVinci Resolve supports the import of ten different transitions when importing XML project files from Final Cut Pro X and legacy Final Cut Pro 7, or nine different transitions when importing AAF files from Avid Media Composer or Symphony.

	EDL	FCP XML	AAF
Clock Wipe	No	Yes	Yes
Center Wipe	No	Yes	Yes
Cross Dissolve	Yes	Yes	Yes
Additive Dissolve	No	Yes	No
Dip to Color Dissolve	No	Yes	Yes
Edge Wipe	No	Yes	Yes
Venetian Blind Wipe	No	Yes	Yes
Cross Iris	No	Yes	Yes
Diamond Iris	No	Yes	Yes
Oval Iris	No	Yes	Yes

Supported transitions for imported EDL, XML, and AAF

Transition Names

To help you prepare projects for export, note that the names of transitions vary between XML and AAF project files. Here are the supported transitions as they appear in Avid Media Composer and Symphony.

Dip to Color Dissolve	Dip to Color effect in the Blend category
Edge Wipe	Horizontal/Vertical/Lower Left/Lower Right/Upper Left/Upper Right Diagonal effects in the Edge Wipe category
Center Wipe	Horizontal Open and Vertical Open effects in the Edge Wipe category
Clock Wipe	Clock effect in the Shape Wipe category
Venetian Blind Wipe	Vertical Blinds and Horizontal Blinds effects in the Shape Wipe category
Cross Iris	4 Corners effect in the Shape Wipe category
Diamond Iris	Diamond effect in the Shape Wipe category
Oval Iris	Circle effect in the Shape Wipe category

About Supported Opacity, Position, Scale, and Rotation Settings

When importing XML project files from Final Cut Pro X, Premiere Pro, or legacy Final Cut Pro 7, DaVinci Resolve supports the import of Opacity, Position, Scale, and Rotation settings. Imported Composite and Transform settings for any given clip appear in the Inspector of the Edit page, or in the Edit Sizing mode of the Sizing palette in the Color page. If these settings have been keyframed, the animation will appear in DaVinci Resolve.

When importing AAF files from Media Composer or Symphony, DaVinci Resolve supports the import of Opacity, Resize, and 3D Warp effects, which are converted into Pan, Tilt, Zoom, and Rotate settings in DaVinci Resolve, located in the Edit page Inspector or the Edit Sizing mode of the Sizing palette in the Color page.

About Flip and Flop Support

When importing AAF project files from Media Composer or Symphony, Flip, Flop, and Flip-Flop effects are converted into the equivalent horizontal and vertical Flip toggles in DaVinci Resolve, located in the Edit page Inspector or the Edit Sizing mode of the Sizing palette in the Color page.

Pitch and Yaw

When importing AAF files from Media Composer or Symphony, DaVinci Resolve supports the import of Pitch and Yaw 3D Warp effects, which are converted into equivalent Pitch and Yaw settings in DaVinci Resolve, located in the Edit page Inspector or the Edit Sizing mode of the Sizing palette in the Color page.

About “Ken Burns Effect” and Dynamic Zoom

If you import a project from Final Cut Pro X with clips that use the Ken Burns effect for creating pan and scan animation, then the Dynamic Zoom parameters (found in the Edit page Inspector when a clip is selected) for each affected clip will be populated with an equivalent animated effect.

About Speed Effects

DaVinci Resolve supports the import of speed effects from different applications, but different project formats have different speed effect support.

- **EDL:** DaVinci Resolve only supports the import of linear speed effects when importing EDLs.
- **XML:** DaVinci Resolve supports the import of both linear and variable speed effects when importing XML project files from Premiere Pro, Final Cut Pro 7, and Final Cut Pro X. As of DaVinci Resolve version 11.1, XML from Final Cut Pro X can also provide information about whether frame blending or optical flow is used, as well as information about the Bezier curve transitions of speed effects.
- **AAF:** DaVinci Resolve supports the import of both linear and variable speed effects when importing AAF files from Media Composer or Symphony that use Timewarp effects.

DaVinci Resolve has high-fidelity conversion of variable-speed speed effect data from other applications, accomplished by creating one speed keyframe per frame for each affected clip. However, you may see small variations between the resulting speed effect in DaVinci Resolve and an offline reference movie exported from the original NLE if you haven’t set the Retime Process setting to the same type of speed interpolation that the original NLE was using.

In other words, if you created a Timewarp speed effect in Media Composer that uses FluidMotion to create smooth slow motion effects, then you’ll want to make sure to change either the project-wide or clip-specific Retime Process setting to Optical Flow so that the speed effects in DaVinci Resolve best match those in Media Composer.

For more information on speed effects in DaVinci Resolve, jump to this chapter: Speed Effects.

About Nested Sequences and Compound Clips

DaVinci Resolve supports the import of compound clips from Final Cut Pro X and of nested sequences from legacy Final Cut Pro 7. Both appear within DaVinci Resolve as compound clips, in both the Timeline and the Media Pool. Compound clips with mixed frame rates are supported, as well as multi-cam and A/V synchronized clips from Final Cut Pro X, which are represented in DaVinci Resolve as compound clips.

For more information on creating and using compound clips in DaVinci Resolve, jump to this chapter: Take Selectors, Compound Clips, and Nested Timelines.

About Supported Composite Modes

When importing XML project files from Final Cut Pro 7, Premiere Pro, and Final Cut Pro X, DaVinci Resolve supports the import of eight different composite modes. When importing AAF files from Media Composer, the Overlay composite mode is supported when the source AAF file has a Superimpose effect applied to it.

	FCP 7/X XML	AAF
Add	Yes	No
Subtract	Yes	No
Difference	Yes	No
Multiply	Yes	No
Screen	Yes	No
Overlay	Yes	Yes
Lighten	Yes	No
Hardlight	Yes	No
Softlight	Yes	No
Darken	Yes	No

Supported composite modes with imported XML and AAF

About Supported Still Image Formats

DaVinci Resolve supports the import of greater-than-one-frame-in-duration TIF, JPG, PNG, DPX, TGA, and DNG still image files that appear in Final Cut Pro X, Final Cut Pro 7, and Premiere Pro XML files, and AAF files exported from Media Composer. These clips appear as ordinary clips in the DaVinci Resolve Timeline. Export of still images is limited to Final Cut Pro 7 and Final Cut Pro X XML formats.

About Supported Alpha Channels

Media with embedded alpha channels is supported for any project as long as it's in a media format that DaVinci Resolve supports; this includes TIFF, OpenEXR image sequence formats, and four-channel QuickTime formats such as ProRes 4444, DNxHR 444, and QuickTime Animation. Alpha channels are automatically enabled, and can be used for compositing directly within the DaVinci Resolve Timeline.

Alpha channels can be exported in round-trip workflows when rendering individual source clips. However, when rendering a program as a single clip, all composited effects are rendered together to produce a single output media file.

For more information on rendering clips with alpha channels, jump to this chapter: Delivery Effects Processing.

About Imported Text Effects

DaVinci Resolve supports the import of text generators when importing XML project files from both Final Cut Pro X and Final Cut Pro 7. All imported text effects appear in the DaVinci Resolve Timeline as Basic text generators. Some, but not all, formatting parameters are imported, depending on the project file format being imported.

About Imported Audio in AAF Projects

Any combination of audio track types, channel map order, MXF and QuickTime files, and rendered or unrendered clips should import without problems.

NOTE: When exporting an AAF project, DaVinci Resolve is capable of writing mono media in stereo tracks.

Preparing Unsupported Clips and Effects You Want to Grade

If there is an unsupported effect within your NLE of choice that you want to move into DaVinci Resolve for grading (for example, clips with effects filters that are native to a particular NLE), here's a simple workflow to follow.

To "bake" an effect into a clip you're sending to DaVinci Resolve:

1. Export that clip as a self-contained media file using whatever DaVinci Resolve-compatible mastering codec you prefer.
2. Reimport the resulting media file into your project.
3. Edit it into your project's timeline to replace the original effects clip.
4. Export a version of the resulting sequence for use in DaVinci Resolve.

This is a good way of prepping the titles and effects of projects that you want to finish in DaVinci Resolve. If you create self-contained media files for all title clips and effects, then these elements will import cleanly and easily, and you can export a complete, texted version of your program out of DaVinci Resolve.

Additionally, if a composited clip is using unsupported effects (for example, a filtered still image with animated position that's superimposed using the Overlay composite mode and set to 70% opacity), an ideal way to prep this clip for XML export to DaVinci Resolve is to set the composite mode to Normal, set Opacity to 100%, and then export the resulting clip as a self-contained QuickTime movie. Reimport the result, edit it back into the Timeline to replace the original superimposed clip, and then set its composite mode to Overlay and its Opacity to 70% to match the original settings. Now the unsupported effects are "baked" into the clip, but the effects that DaVinci Resolve does support are still live, and can be readjusted in context while grading.

Verifying Imported Timelines Using Offline References

DaVinci Resolve has a specific interface for comparing two versions of a program. This eliminates the need to edit a rendered version of a timeline as a superimposed clip within your timeline and provides many other features to aid this comparison without cluttering your timeline.

By setting the Source Viewer in the Edit page to Offline mode, you can compare an Offline Reference Clip or Timeline to a currently open timeline, with both playheads ganged together, either side by side, or as a split screen, a box wipe, or difference operation, all of which will be visible via your video output device. As you play the Timeline, the Offline Reference Clip or timeline plays as well, making it easy to spot differences between the two.

IMPORTANT: You need to make sure that the media you've imported or are using as an Offline Reference Clip has a valid timecode track with a start time that matches the timecode of the Timeline you're comparing to, otherwise there will be an offset between the Timeline and offline reference that will make a comparison difficult to impossible. Small offsets can be corrected via an offset field in the Source Viewer while in offline mode, but large offsets will be impractical to correct.

Why Set Up An Offline Comparison?

However you set up an offline reference, this is a convenient way of comparing two versions of a program. There are several reasons for comparing an Offline Reference Clip to a timeline:

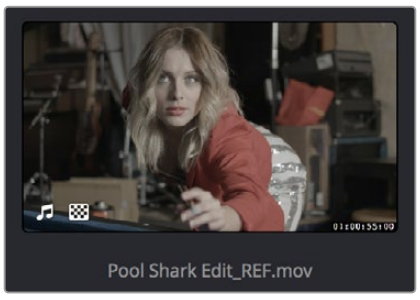
- **Verifying the clip order:** If you're unsure whether or not you've properly resolved reel conflicts or other problems that occurred while you were conforming a timeline, you can compare each edit to the offline version of the program to spot problems and identify the proper media that should correspond to any clip.
- **Recreating effects:** If there are offline effects, such as temporary grades made in the NLE, or pan and scan transforms that you want to check, the Offline reference mode lets you split-screen your current grade against the Offline Reference Clip in the Color page.
- **Comparing two versions of a timeline:** You can make a visual comparison a timeline with another version of that timeline to spot differences for evaluation.
- **Filling holes in timelines with missing or unlinked clips:** Two options found in the Preferences > User > Editing > General settings, "Show offline clips through conform gaps," and "Show offline clips through missing clips," let you set DaVinci Resolve to display Offline Reference Clip media to fill gaps in the Timeline or replace the contents of unlinked clips. This is typically done to resolve emergency situations when you need to proceed with a screening or review session despite the fact that you're missing media for whatever reason.

For more information, jump to this chapter: System and User Preferences.

NOTE: Typically, the flattened version of the program you're given uses a low-quality codec, and contains effects and color correction that's not final, which is why it's called an Offline Reference Clip.

Assigning a Clip or Timeline for Offline Comparison

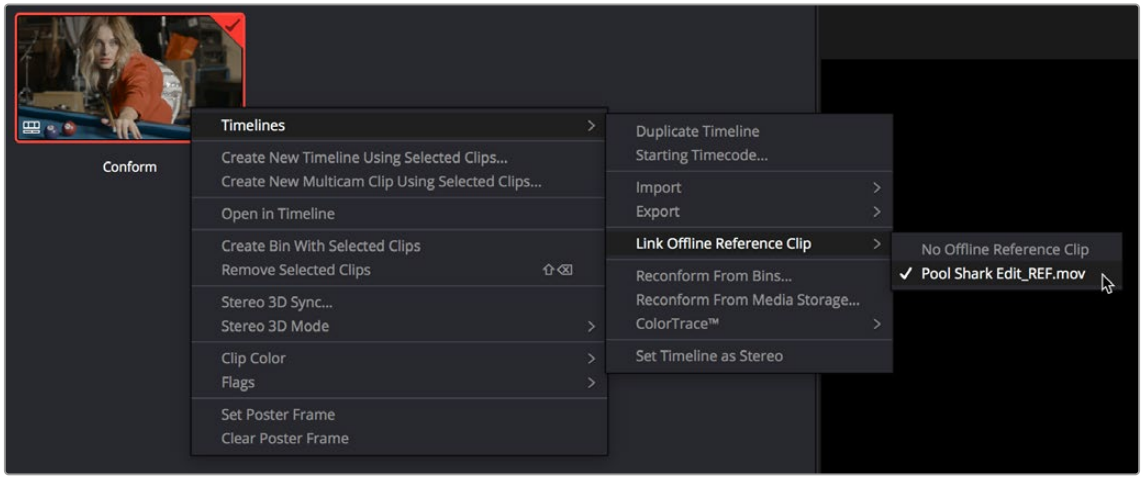
There are two ways you can assign an Offline Reference Clip or Timeline to a particular timeline for comparison. The easiest and most flexible way is to open a timeline, and then drag and drop a clip or timeline with matching timecode that you want to compare to from the Media Pool onto the Source Viewer in Offline mode.



To assign any clip or timeline to a specific timeline for comparison:

1. Open the timeline you want to make the assignment to in the Edit page.
2. Set the Source Viewer to Offline mode.
3. Drag a clip or timeline with matching timecode that you want to assign onto the Source Viewer. The clip or timeline you dragged is immediately assigned to the open timeline as an Offline Reference Clip, and synced via timecode.
4. In the Media Pool, right-click the Timeline you want to review against the Offline Reference Clip, and choose the reference clip or timeline you assigned from the Timelines > Link Offline Reference Clip submenu of that timeline's contextual menu.

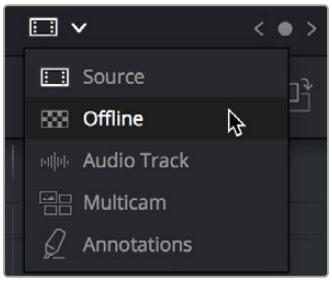
   You can also add a clip to the Media Pool specifically as an Offline Reference Clip, making it easy to associate such a clip with a particular timeline by right-clicking that timeline in the Media Pool and choosing it from the Link Offline Video submenu. The idea is that if you or your client exports a flattened version of their edited sequence at the same time as they export the EDL, AAF, or XML project file they want graded, then you can compare the project data that's imported into DaVinci Resolve to the actual video of the offline edit.



To assign an imported Offline Reference Clip to a specific timeline for comparison:

1. Open the Media page, and use the Media Storage browser to find the flattened Offline Reference Clip that you want to use for comparison.
2. Right-click the Offline Reference Clip file and choose Add as Offline Reference Clip.
3. That clip appears with a small checkerboard badge in its icon in the Media Pool.

Checkerboard indicating an offline video



4. Open the Edit page, right-click the timeline you want to review against the Offline Reference Clip, and choose the offline clip you imported from the Timelines > Link Offline Reference Clip submenu.

Selecting the offline video to link to the current Timeline.

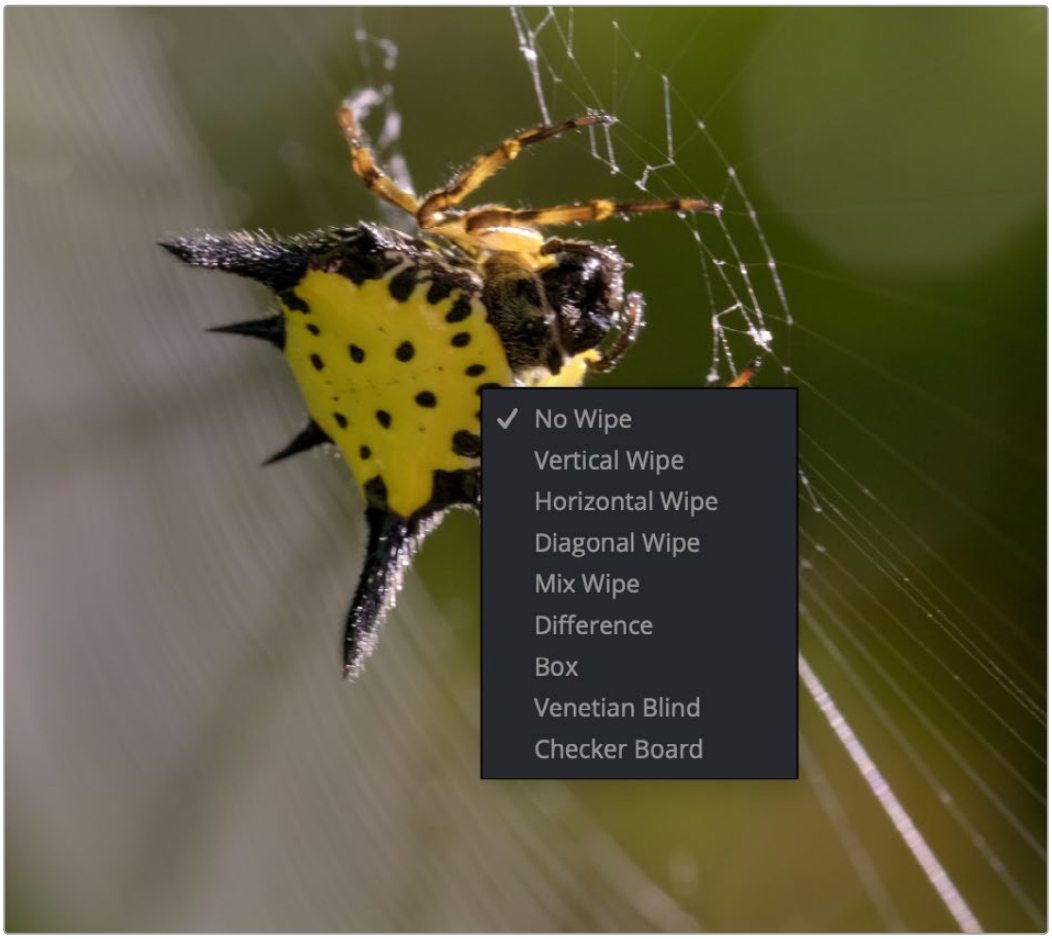
Setting Up an Offline Reference/Timeline Comparison

Once you've assigned a clip or timeline as an Offline Reference Movie, it's easy to see a comparison.

Selecting the Offline video in the Source Viewer

To view an offline reference comparison:

1 Open the Source Viewer's Mode pop-up menu and choose the checkerboard icon indicating Offline Reference.



The Offline Reference Clip you assigned previously now appears within the Offline Viewer, and plays back in sync with the Timeline. If your clips have sizing applied, have Fusion or other effects, or are graded, you can see a side-by-side comparison between the state of each clip in the Offline Reference Clip, and the graded Timeline clip.

The Edit page in Offline/Timeline mode

2 If the currently selected Offline Reference is out of sync (which can be confirmed via the position of a slate, two-pop, title, or other known shared sync point at the beginning of the program), you can use the sync field at the upper left-hand corner of the Source Viewer in Offline mode to slip the sync of the reference by whatever number of frames you need.

3 If you like, you can optionally choose other ways of comparing clips, by right-clicking anywhere within the Timeline Viewer and choosing Vertical Wipe, Horizontal Wipe, Diagonal Wipe, Mix Wipe, Difference (a Composite mode), Box (wipe), Venetian Blind, or Checkerboard. These modes offer you different ways of quickly and directly comparing the content, sizing, color, and alignment of the Offline Reference Movie to the clips in your timeline.

Different viewing options for comparing the Offline Reference Movie to the Timeline are available in the Timeline Viewer contextual menu

If you choose a wipe or difference comparison, that comparison will also be visible on the display connected to your video output interface, and dragging anywhere within the Timeline Viewer will adjust the ratio and position of the wipe.

4 To turn an offline comparison viewer mode off, simply right-click the Timeline Viewer again and choose No Wipe.

5 When you're done doing this offline comparison, choose Source from the Source Viewer's Mode pop-up menu, and the Source Viewer is ready for viewing clips from the Media Pool, as normal.

Conforming and Relinking Media

DaVinci Resolve has tools for managing the relationship between clips in the Media Pool, clips in timelines, and the links between each clip and its corresponding media file on disk. These tools support a variety of project workflows, and can help to resolve issues that may arise when importing projects of different formats and sources.

This section covers the available methods for conforming clips and relinking media. More information on the clip metadata that's used to match clips with their source media is covered later in this chapter.

Conforming and Relinking During Project Import

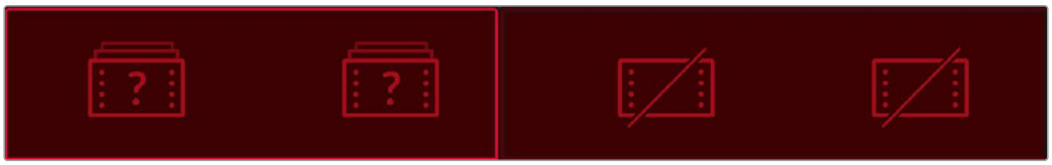
When you import an AAF or XML file, DaVinci Resolve automatically relinks the imported clips in the Media Pool to their corresponding source media files on disk. At the same time, the imported timeline is conformed to those clips in the Media Pool. The result is a populated media pool, and a timeline containing the arranged clips.

Because these steps typically happen together, it's easy to overlook the distinction between a timeline's relationship to clips in the Media Pool, and each clip's relationship to its source media file on disk.

The workflow for importing an EDL makes this distinction more explicit. You'll start by importing the required clips into the Media Pool, ensuring they have the correct reel names and timecode. This establishes the link between the Media Pool clips and the source media on disk. You'll then import the EDL, which creates a timeline that attempts to conform itself to the media pool clips using reel name and timecode information.

Conforming and Relinking Existing Timelines and Clips

Sometimes, you may need to reconform or relink media after editing or grading has begun. For example, you might start a project using placeholder VFX or stock footage clips, then replace these with final versions of the same shots. Or, you may choose to edit using transcoded versions of camera raw media files, and later switch to the original camera media for grading and finishing.



To support these workflows, DaVinci Resolve has a wide variety of tools for reconforming timelines and relinking media throughout the life of a project.

The Difference Between Conforming and Relinking

While the terms are often used interchangeably, conforming generally refers to matching clips in a timeline to the appropriate source clips in the Media Pool, and relinking refers to matching source clips in the Media Pool to their corresponding media files on disk. This recent change reflects the expanded relinking and conforming workflows available in DaVinci Resolve, so the author offers his apologies if these terms are used more loosely elsewhere in this manual.

The Difference Between Unlinked and Missing Clips

When it comes to the relationship between clips in the Media Pool and clips in a timeline, there's an important distinction between clips that are unlinked, and clips that are missing. While both of these "offline" clip states look different in the timeline, their differences aren't just cosmetic.

A missing clip in the Timeline (left) compared to an unlinked clip in the Timeline (right).

An unlinked clip is one that exists in the Media Pool, but has lost its connection to the corresponding media file on disk. However, because the unlinked clip and its metadata remain in your project's timelines, it can be easily relinked to matching media with the Relink command (described later), or reconformed to previously imported or newly imported clips in specific bins of the Media Pool with the Reconform From Bins command (also described later).

A missing clip doesn't exist in the Media Pool, but might still appear in the timelines of your project. If there isn't a corresponding source clip in the Media Pool, its metadata is unavailable in the Metadata Editor, and any remote grades associated with that source clip are also lost.

For more information about remote grades, jump to this chapter: Grade Management.

You can fix missing clips in a timeline in one of two ways:

- If the "Automatically conform missing clips added to Media Pool" setting is enabled in the Project Settings > General Options panel, simply reimport the corresponding source clips into the Media Pool. Any missing clips with matching timecode and file names in the timeline will be reconformed. Note that this only occurs at the time of import, and doesn't apply to matching clips that are already in the Media Pool. This setting must be disabled if you use collaborative workflows.
- If the "Automatically conform missing clips added to Media Pool" setting is disabled in the Project Settings > General Options panel, reimport the missing media. Then either manually reconform them individually to the missing timeline clips with the Conform Lock with Media Pool Clip command, or use the Reconform From Bin(s) or Import Additional Clips With Loose/Tight Filename Match commands to simultaneously reconform multiple clips.

When you reconform the missing clips, you won't get back the original remote grades or manually edited metadata, unless you previously exported them—in which case, you can reimport them and apply these in separate steps.

Duplicate Clips Are Considered Separate Sources

In DaVinci Resolve, duplicate clips are treated as separate from the original Media Pool or Timeline clips you duplicated them from.

For example, if you import five clips into Media Pool Bin 1, edit them into a timeline, then drag those timeline clips into Media Pool Bin 2, the clips in Bin 1 and Bin 2 would not be intrinsically linked.

This means that if you select the original clips in Bin 1 and choose Unlink Selected Clips, any instances of those clips used in the timeline will be unlinked—but the duplicate clips in Bin 2 would be unaffected.

Summary of Methods for Conforming and Relinking

Because timelines, source media and Media Pool clips are managed autonomously, there are several methods for conforming and relinking media. The most appropriate method depends on your chosen workflow.

- **Conforming clips during XML and AAF import:** When importing a project via AAF or XML, you can use the embedded file paths to import referenced media into the Media Pool and automatically reconform the clips in the imported timeline. If the original media has been moved, DaVinci Resolve will prompt you to locate it. Alternatively, you can ignore the AAF or XML file's embedded file paths and instead conform the timeline using different media files that share the same file names and timecode.
- **Importing clips before importing an EDL, AAF, or XML:** For EDL workflows, you must import the media before the EDL itself. The same approach applies to AAF and XML import workflows. When you import clips into the Media Pool before importing an AAF or XML, DaVinci Resolve automatically reconforms the clips in the imported timeline to those in the Media Pool first. It then identifies the media on disk for missing clips. This behavior depends on the options selected in the Import AAF/EDL/XML dialog.
- **Conforming missing clips by importing their source media into the Media Pool:** When the "Automatically conform missing clips added to Media Pool" setting is enabled in the Project Settings > General Options panel, DaVinci Resolve automatically matches newly added Media Pool clips with missing clips in your project timelines. This applies whether you add clips to the Media Pool by importing, copying and pasting, or creating duplicates. For example, importing a clip with a matching file name and timecode into the Media Pool can automatically restore a missing timeline clip. This setting must be disabled if you use collaborative workflows.
- **Using the Import Additional Clips commands:** You can automate the process of importing media for missing clips in a timeline. Simply right-click a timeline in the Media Pool and go to Timelines > Import > Additional Clips With Loose Filename Match or Additional Clips With Tight Filename Match. This searches the selected directory and its subfolders for media that matches the offline clips in that timeline. The Loose Filename Match command ignores file extensions and lets you conform to alternate media formats, while the Tight Filename Match command requires file extensions to match.

- **Reconforming online clips by importing new media into the Media Pool:** When the "Automatically conform missing clips added to Media Pool" setting is enabled in the Project Settings > General Options panel, DaVinci Resolve attempts to update the conformed relationship between the clips you're adding to the Media Pool, and the clips whose Conform Lock Enabled setting has been disabled. This applies whether you add clips to the Media Pool by importing, copying and pasting, or creating duplicates.

  By default, clips in imported or new timelines have Conform Lock Enabled turned on (unless the source media goes missing). This option means that a particular clip in a timeline will only consider the source clip in the Media Pool to which it's currently conformed as the correct match. All other clips are ignored, regardless of matching file names and overlapping timecode.

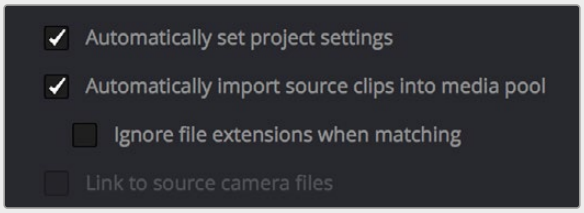
  If you right-click a clip in the timeline that has multiple potential matches in the Media Pool, then disable Conform Lock Enabled, a "clip conflict" icon appears, with a red <!> badge beside its name. Double-click the indicator to view all matching Media Pool clips, from which you can choose your desired source.

  > **NOTE:** The "Auto conform clips with media added into Media Pool" setting must be disabled if you use collaborative workflow.

- **Using Conform Lock commands to force a timeline clip to conform itself to a clip in the Media Pool:** A manual command that conforms a selected timeline clip to a selected Media Pool clip. It's useful when none of the automatic conforming methods don't produce the desired result.
- **Using the Relink command on clips or bins in the Media Pool:** If there are unlinked clips in the Media Pool of your project, use the Relink Media, Relink Selected Clips, or Relink Clips in Selected Bins commands to relink clips to the corresponding source media on whatever storage volume it's on. At the same time, any timeline instances of those clips are automatically updated. You can also use these commands to force clips to relink to alternative media. The Relink command searches all subfolders in the selected directory, making it useful when your media has moved. Note that if you're searching large SAN volumes, choosing a directory that's too high in the folder hierarchy may result in longer search times.
- **Using the Change Source Folder command:** This command updates the directory structure of each selected clip's file path into a new file path, based on the parent directory you select. It's useful when media has been moved, but retains its original subdirectory structure. This makes it a safe and fast command to use when relinking to a structured collection of media on a SAN volume.
- **Using the Reconform From Bin(s) command:** If you have multiple versions of the same clips (with identical file names, overlapping timecode, or other matching criteria) separate Media Pool bins, you can disable Conform Lock Enabled for every clip in a timeline you want to reconform—then use the Reconform From Bin(s) command to reconform timeline clips to Media Pool clips in one or more specific bins. You can also choose the matching criteria used during reconforming. DaVinci Resolve will only reconform timeline clips that can be matched to media in your chosen bins; timeline clips without a match remain unchanged.
- **Using the Reconform From Media Storage command:** This command reconforms timeline clips directly to media located in a selected file-system directory that hasn't been imported into the Media Pool. You can also choose the specific criteria used during reconforming to match timeline clips with clips in the selected bins. Only clips with a valid match are updated, while timeline clips without a match remain unchanged.
- **Overwriting clips on disk that are linked to in a DaVinci Resolve project:** When a media file has been overwritten on disk, DaVinci Resolve automatically updates relinked clips—provided the replacement clip has the same file name, timecode, and reel name (if used).

The following sections detail each of these methods of conforming and relinking media.

Conform Multiple Selected Timelines



To conform multiple timelines from the same source media simultaneously, simply select the timelines you wish to conform in the Media Pool by Option-clicking or Shift-clicking them. Right-click on one of the selected timelines, then select Timelines Reconform from Bins or Reconform from Media Storage.

Unlinking Clips

To unlink media pool clips, select the clip(s) to unlink, right-click any of them, then choose Unlink Selected Clips.

Conforming Clips During XML and AAF Import

For AAF and XML workflows where DaVinci Resolve relinks imported clips to media on disk or reconforms them to clips already in the Media Pool, the clip metadata used for reconforming depends on two settings in the Load AAF or XML dialog: “Automatically import source clips into media pool”, and “Ignore file extensions when matching”.

The most important settings for conforming media in the Load dialog.

These two checkboxes interact in a complex manner to let you decide how media is conformed to an imported AAF or XML file. Here are the rules:

When Importing Clips With File Extensions Matching Those in the AAF or XML File

Turn “Automatically Import” on and “Ignore file extensions” off.

This default setting is useful when the AAF or XML file you’re importing has references to media you want to add to the Media Pool for use.

- If there are already clips in the Media Pool, DaVinci Resolve will conform as many of them as possible by matching the file paths in the AAF or XML file to the stored file paths of each clip in the Media Pool.
- The software will then import as many remaining missing clips as possible into the Media Pool from any storage volumes that are visible to DaVinci Resolve, using the file paths from the XML or AAF.
- For all remaining clips not found, DaVinci Resolve executes a clip name match in the Media Pool.
- If there are still missing clips, DaVinci Resolve attempts a timecode match (along with a reel name match, if this is enabled) of media pool clips.
- Finally, for all remaining clips that still aren’t found, you’ll be prompted to manually choose another folder to search.

When Importing Clips With Different File Extensions

Turn on both “Automatically import”, and “Ignore file extensions”.

Enabling both these options is useful when the sequence you’re importing was edited using offline quality media, and you want to conform to high-quality online media in a different format—possibly in the Media Pool, or on another disk.

For example, if you’ve edited using QuickTime proxies and wish to conform the edit back to its original camera RAW files for color grading, you should enable both “Automatically import source clips into media pool”, and “Ignore file extensions”. This imports and relinks the RAW files in a single operation.

- If there are already clips in the Media Pool, DaVinci Resolve attempts to conform as many of these clips as possible by matching clip names.
- For all remaining clips not found, the user is prompted to choose another folder to search, and DaVinci Resolve imports as many clips as possible by matching clip names, ignoring file extensions.
- For all remaining clips that still aren’t found, DaVinci Resolve attempts a timecode match (and reel name match, if this is enabled in the Project Settings > General Options panel) of clips that are already within the Media Pool.
- Finally, if there are still remaining clips not found, the user is prompted to manually choose another folder to search.

Turn on both “Automatically import”, and “Link to source camera files”.

The “Link to source camera files” checkbox only appears when you import AAF files. When automatically importing media, enabling this option relinks the imported project to the original camera source files, which Media Composer/Symphony track using the Source Name metadata in the AAF file.

When You’re Only Relinking to Clips Already in the Media Pool

Turn “Automatically import” off.

Disable the “Automatically Import source clips into media pool” setting when you want to conform an imported AAF or XML to clips in the Media Pool. This is most useful if you’ve already imported the original camera media—for example, when reconforming an edited AAF or XML to dailies created earlier in DaVinci Resolve.

- If there are already clips in the Media Pool, DaVinci Resolve attempts to conform as many clips as possible by matching the file paths in the XML or AAF to the file paths stored for each clip in the Media Pool.
- For all remaining clips not found, DaVinci Resolve tries a clip name match of clips that are already in the Media Pool.
- For all remaining clips that still aren’t found, DaVinci Resolve attempts a timecode match (and reel name match if this is enabled) of clips that are already within the Media Pool. In this case, the file name is not used.

Beware When Choosing a Volume or Folder to Search

When prompted to choose a folder to search, you can optionally choose an entire volume. DaVinci Resolve always searches through all subdirectories, and all media on that volume will be found. However, the operation time depends on the size and number of files on the selected volume—so you can expect long wait times on a SAN volume, for example.

Importing Clips Before Importing an EDL, AAF, or XML

When importing media prior to importing an EDL, DaVinci Resolve follows a specific set of rules to determine which Media Pool clips correspond to clips in the resulting timeline. These rules also apply when you've imported media prior to importing an AAF or XML file, and want to prioritize specific media over the file paths embedded in those imported timeline formats.

The following sections elaborate on these rules, and how to use them to your advantage.

Essential Clip Metadata for Easy Conforming and Relinking

When conforming projects in DaVinci Resolve, the accuracy and integrity of clip metadata is critical for a successful result. Keep this criteria in mind when preparing your media for use in DaVinci Resolve:

- **Accurate timecode:** Each clip requires a valid timecode track, and that timecode should match all other instances of that media file within a project. If there are problems with a clip's timecode, you can edit or offset timecode inconsistencies with DaVinci Resolve tools. By default, the "Use Timecode" project setting is set to Embedded in the Source Clip—which means that timecode is read from the embedded timecode track within a QuickTime or MXF file, or from the header data of a DPX frame file. However, you can also enable the "From the source clip frame count" option, which lets you read the timecode from the source clip's frame count for image sequences.
- **File names:** When "Assist using reel names from the" in Project Settings > General Options panel is disabled (the default setting), DaVinci Resolve conforms clips using file names when importing XML and AAF projects. File names can only be only used when conforming XML or AAF files, or when importing a DaVinci project. They're never used when conforming EDLs.
- **Reel Name:** This is only used for conforming if "Assist using reel names from the" is enabled in Project Settings > General Options panel. Assigning reel names to your media is recommended but not essential; it can ease media management for certain operations, especially in EDL workflows. However, if you experience problems conforming clips when the "Assist using reel names from the" option is enabled, try disabling it.

The way that DaVinci Resolve matches media files to clips in an imported project depends on how you're importing that project.

Defining Clip Metadata When Adding Media to the Media Pool

The rules on defining clip metadata before conforming are different, if your workflow involves any of the following: Manually adding media files when editing from scratch in DaVinci Resolve, preparing to process dailies, or as a separate step before importing EDL, XML, or AAF project files and reconforming them to a higher quality set of media than what was used in the original edit.

- **Timecode:** Calculated using the "Timeline Frame Rate" setting in the Project Settings > Master Project Settings panel.
- **Reel Names:** Determined by enabling or disabling the "Assist using reel names from the" checkbox in the Project Settings > General Options panel, and depending on your selected option. Reel names can be extracted dynamically, and changing this setting will update your Media Pool with the revised reel names. Reel names can also be defined manually if you set different methods of reel name extraction per clip.
- **Clip Names:** Read and stored, used for AAF and XML imports, but not used for imported EDLs.

How Reel Names Are Identified

The "Assist using reel names from the" checkbox in the Project Settings > General Options panel is a crucial setting for controlling the conform process. By default, it's disabled, and reel names are left blank. This is fine for conform workflows that only require the file path or file name and source timecode to successfully identify which media files correspond to which clips.

However, if you need more information to reconform the clips in your project, you can enable the "Assist using reel names from the" checkbox, which triggers DaVinci Resolve to use one of four methods to automatically define reel names for every clip in the Media Pool.

Automatically Defining Reel Names

When you use the "Assist using reel names from the" options in the Project Settings > General Options panel, reel names are extracted dynamically. If you change the method of reel name extraction in the project settings, the reel names of all media pool clips will automatically reflect that change. These are viewable in the Reel Name column of the Media Pool (when in List view).

> For example, if you change the "Assist using reel names" options from "Source clip file pathname" to "Mediapool folder name," the contents of the Reel Name column are updated. This is useful when you're importing a project for which all clips use the same method of determining their reel name.

Manually Choosing Reel Name Definitions for Individual Clips

You can also manually select the criteria for how your media pool clip(s) have their reel names defined, using the Clip Attributes dialog. This is useful for project clips that require a different method of reel name extraction, or require manually entered reel names.

To manually define reel names for one or more clips:

1. Select one or more clips in the Media Pool.
2. Right-click one of the selected clips, and choose Clip Attributes.
3. Open the Reel Name panel of the Clip Attributes dialog, choose a new option, and click OK.

Once you've used Clip Attributes to change the reel names of clips, those clips no longer automatically update when you change the "Assist using reel names from the" options in the Project Settings > General Options panel.

For more information on using Clip Attributes, jump to this chapter: Using Clip Metadata.

Methods of Defining Reel Names

There are five options that automatically determine how reel names are extracted from the source media when you enable "Assist using reel names from the". One option is the Clip Attributes Reel Name panel, which lets you manually define reel names. The use of reel names is critical in EDL and AAF workflows, but less so in XML-centric workflows.

- **Source clip file pathname:** Obtains the reel name by extracting it from each media file's path. This means you can extract a reel name from all or part of the file name, or from all or part of the name of any folder in the path that encloses that file. This extraction is defined using the Pattern field.
- **Pattern:** A code that defines how a reel name should be extracted from the source clip pathname. More information about creating patterns appears later in this chapter.
- **Mediapool folder name:** The reel name is obtained from the name of the bin in the Media Pool that encloses that clip. For example, in a stereoscopic workflow, you might want to export offline stereo media with the "Left" and "Right" bin names in which they're organized as reel names. Another example would be organizing VFX so that it's incrementally processed in individually named bins, such as "VFX_Tuesday_10-12."
- **Embedding in source clip file:** Useful for file formats where the reel name is embedded within the media file itself. Blackmagic RAW and other digital cinema cameras, QuickTime files created by Final Cut Pro, and DPX frame files are formats that can contain reel name header data.
- **Source clip filename:** If there is no defined reel number, often it's easy to just use the source clip filename.
- **User Defined:** This option is only available when you manually alter the Reel Name for one or more selected clips in the Media Pool using the Clip Attributes dialog. To customize the reel name, choose User Defined.

An additional checkbox is also available in the Project Settings > General Options panel, titled "Extract reel names from EDL comments." This is useful for legacy workflows when you wish to conform an EDL exported from Final Cut Pro 7 to camera original R3D media.

Extract reel names from EDL comments: Some media file formats, such as R3D, have their reel names obtained from file names that exceed the eight-character limit allowed in a standard EDL. This option lets DaVinci Resolve extract reel names from appropriately formatted EDL comments, such as those output from Final Cut Pro 7.

Using the Pattern Field

If you're using the Pattern option to extract the reel name from a clip's source file pathname, you can create a search pattern that triggers DaVinci Resolve to extract the reel name in highly specific ways to accommodate more unusual workflows.

Extraction patterns are interpreted from right to left, deciphering each clip's file path element by element starting with the file name, and then considering each enclosing directory's name to the left. Each extraction pattern has a series of text characters and "wild card" operators in unique combinations corresponding to the length and names used in the file path.

Here are a series of search characters that may be used:

Extraction Pattern Operators	
?	Looks for matches of any single character. Add as many question marks as there are characters you want to match. ?? matches two characters such as 02, while ???? matches four characters such as 0002.
*	A wildcard that creates matches for any sequence of zero or more characters.
%R	Specifies the reel name's actual location. Reel names may contain any character, but should not contain a directory separator (forward slash).
%_R	Extracts the reel name and strips out the R3D file name underscores found in EDLs from Final Cut Pro 7 or earlier.
%D	Matches any directory name or file name. When this is the last operator in a pattern, do not add a forward slash.
/	Used to separate any two operators

If you're trying to create a new extraction pattern for a unique workflow, use this test dialog before applying them to your project.

To test the extraction path:

1. Turn on "Assist using reel names from the" and click the Test button next to the current Pattern in the Project Settings > General Options panel. The "Specify Reel Extraction Pattern" dialog opens.
2. Type the extraction patten you want to test into the Pattern field.
3. Using your preferred method, locate the file path of the media file that you want to test the extraction pattern on, then copy or type it into the Sample Path field.
4. Click Test.
5. If the reel name that appears below is correct, click Apply to copy the extraction pattern into the Pattern field of the Project Settings > General Options panel. If the reel name that appears is incorrect, modify the extraction pattern and try again.

Examples of Reel Name Extraction Patterns

To better understand how this process works, the following examples show the various methods of reel name extraction. The "/" is used as a separator between control parameters.

Example 1:

This example shows the reel name stored within the parent folder name of the clip.

- **Pattern:** */%R/%D
- **File path:** vol0/MyMovie/Scans/004B/Frame[1000-2000].dpx
- **Reel name:** 004B

  Parsing starts from right to left. To analyze this pattern, start from the right. In this case, the %D matches the file name FrameNNNN.dpx, where NNNN is the frame number in each file of the clip. Moving to the left of the file name, the /%R/ section of the string specifies that the reel name will be the entire name of the parent directory immediately above the file. Finally, the * at the start of the string says to match any pathname in front of the directory name that has the reel name. This string will find the parent directory, regardless of how many levels deep it is nested within the directory path.

Example 2:

Here, the reel name is stored in the parent folder name of the clip and prefixed with the reel name.

- **Pattern:** */????%R/%D or alternatively */Reel%R/%D
- **File path:** /vol0/MyMovie/Scans/Reel1234/Frame[1000-2000].dpx
- **Reel name:** 1234

  In this example, both extraction patterns produce the same result. They are also similar to the first example. The reel name is still in the parent directory name, but in this case, the fixed characters “Reel” are prefixed before the reel name. The first pattern with ???? would match any 4 characters in front of the reel name. The second pattern is more specific, and would only match the word “Reel” in the directory name.

Example 3:

This example shows the reel name stored within the parent folder name two directory levels up.

- **Pattern:** */%R/%D/%D
- **File path:** /vol0/MyMovie/Scans/004B/134500-135000/Frame[1000-2000].dpx
- **Reel name:** 004B

  This example is again similar to Example 1—but a key difference is that the reel name is the directory name two levels above the clip (versus one level up, in Example 1).

Example 4:

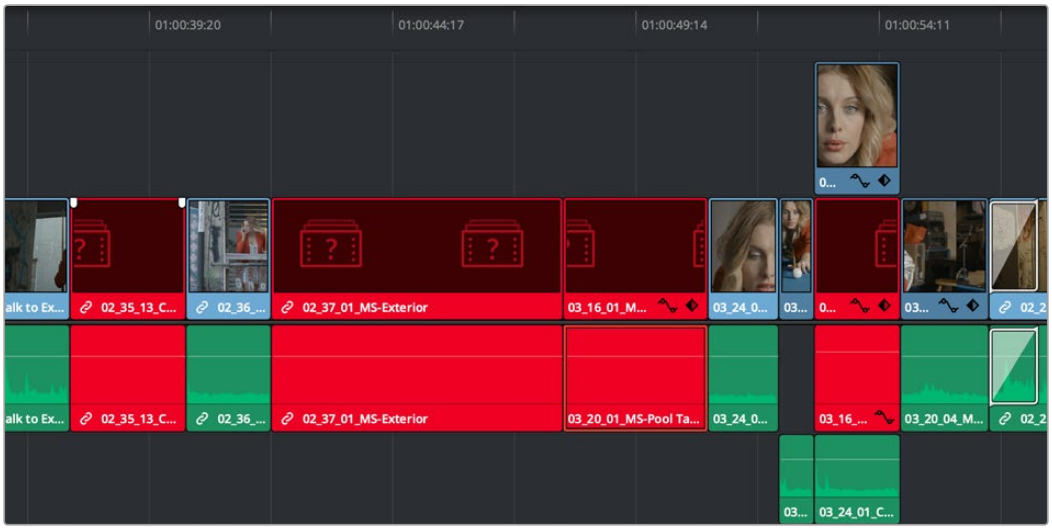
Finally, we see the reel name that is embedded within the clip name of the material.

- **Pattern:** */Reel%R_*
- **File path:** /vol0/MyMovie/Scans/Reel004B_[1000-2000].dpx
- **Reel name:** 004B

  This example shows a method for extracting the reel name from the file name of the clip. Again, starting from the right, the two pattern characters _* match any series of characters, up to the first _ character. In this case, it picks up the file extension (.dpx) and the frame number portion of the file name. Next, the /Reel%R characters indicate the reel name is the characters between the /Reel and _ character. The * at the beginning of the pattern will match a file path any number of directories deep in front of the file name.

Conform Missing Clips by Importing Their Source Media

If your timeline has one or more missing clips, the relationship between that clip in the timeline and the Media Pool has been lost. If you manually import clips into the Media Pool that correspond to those missing clips, your next steps are determined when you go to Project Settings > General Options panel and enable “Automatically conform missing clips added to Media Pool”. If you use collaborative workflow, this setting must be disabled.



If you enable the “Auto conform clips with media added into Media Pool” setting when importing additional clips, DaVinci Resolve updates the conformed relationship between clips that you add to the Media Pool, and missing clips in the various timelines of your project. At the same time, it also updates the conform relationship of all other timeline clips that have disabled the Conform Lock Enabled option.

If you disable the “Auto conform clips with media added into Media Pool” setting when importing additional clips, DaVinci Resolve will not attempt to reconform anything automatically. Instead, it relies on you to manually reconform offline or missing clips. Some methods you could use are Reconform From Bins, or Conform Lock With Media Pool Clip.

For more information on manually adding clips to the Media Pool, jump to this chapter: Adding and Organizing Media with the Media Pool.

Using the Import Additional Clips Command

If there are many missing clips in the timeline and no corresponding Media Pool clips, one easy fix is to automate the process of gathering a list of what’s missing, so that you can import and conform missing clips at once. This only works for missing clips, and not unlinked clips. (In the latter case, use the Relink command in the Media Pool).

The conformed Timeline with missing clips.

To import missing clips and reconform them to the Timeline:

1. In the Edit page, right-click a timeline in the Media Pool that has missing clips, and choose one of the following commands from the Timelines > Import submenu:

   Timelines > Import > Additional Clips With Loose Filename Match: Searches the timeline for all missing clips, and prompts you to specify a directory of media with which to conform them, adding only the media that's necessary to the Media Pool. The Loose Filename Match command ignores file extensions, which lets you replace offline media with online media in a different format.

   Timelines > Import > Additional Clips With Tight Filename Match: Searches the timeline for all missing clips, and prompts you to specify a directory of media with which to conform them, adding only the media that's necessary to the Media Pool. The Tight Filename Match command searches only for media with identical file extensions.

2. Choose the directory with the remaining media to be conformed in the dialog, and click OK.

   If the conditions are met for matching the media files in the directory you selected to the missing clips in the current Timeline, the necessary clips are automatically added to the Media Pool and conformed to the timeline.

Using Conform Lock As a Command

If an unlinked clip in a timeline won't conform to a clip in the Media Pool even though it's there, use the Conform Lock with Media Pool Clip command. This forces a clip in the timeline to conform to a clip in the Media Pool of your choosing. It also automatically suspends the Conform Lock Enabled setting of a target clip, ignoring file names and reel names, in favor of conforming the target clip to your manually selected clip. At the same time, the timecode is still used to align the clip being conformed with the original clip in the timeline.

To conform lock a clip in the Timeline to another clip in the Media Pool:

1. Select a clip in the Media Pool. For the Force Reconform command to be successful, the clip must be equal in length or longer than the selected clip in the Timeline.
2. Right-click an unconformed clip in the timeline, and choose Conform Lock with Media Pool Clip. This conforms the clip you selected in the Media Pool to the selected clip in the Timeline:

   If the selected Media Pool clip has timecode matching the selected Timeline clip: The new clip is perfectly conformed to match the original clip.

   If the selected Media Pool clip doesn't have timecode matching the selected Timeline clip: The new clip is conformed such that the first frame of the Media Pool clip is aligned with the first frame of the reconformed clip in the Timeline, and occupies the same duration.

3. If you right-click that clip again, you'll see that Conform Lock Enabled is enabled, showing you that the clip has successfully conformed to media for which it wasn't originally a match.

Relinking Clips to Media Files on Disk

The best method for relinking clips in your project that have either gone offline or are not properly linked is to use either the Relink Media or Relink selected clips command. Note, the Relink command only works for unlinked clips, and not missing clips—since the latter would not have corresponding clips in the Media Pool.

The Relink command is the most flexible method of relinking the Media Pool clips from your project with clips in a file system directory of your choice, using file name and timecode as the primary criteria for re-creating the correspondence between each clip and its corresponding media file on disk. This command is useful for relinking media that's been moved to another location, or reorganized using another file structure on disk.

To relink all unlinked media:

1. Select the orange Relink icon in the page's Media Pool.
2. Select the Locate button next to the specific volume(s) that are missing, and choose a directory where the missing files are located.
3. If the quick search initiated by the Locate buttons doesn't find the media (even though you know it's there), you can initialize an exhaustive deep disk search for the media by clicking on the Disk Search button.
4. If there are still other clips that can't be found, you're prompted to either choose another directory altogether to continue searching, or quit.

To relink selected clips:

1. Select one or more offline clips to relink, or select a bin in the Media Pool bin list that contains clips you want to relink, then right-click one of the selected clips or the selected bin, and choose Relink Selected Clips from the contextual menu.
2. When the Relink File dialog opens, choose a directory to look for the files you want to relink to, and click OK. DaVinci Resolve attempts to find every clip with a matching file name in the subdirectories of this directory, using the original file paths of the clips being relinked. By first looking for the clips in their originally located directories, relinking can be quite fast.
3. If there are clips that couldn't be found in Step 2, you're prompted with the option to do a "deep search". If you click Yes, then DaVinci Resolve will look for each clip inside every subdirectory of the directory you selected in Step 2. This may take significantly longer, but should be successful so long as the media that's required is within the selected directory structure.
4. If there are still other clips that can't be found, you're prompted to either choose another directory altogether to continue searching, or quit.

Using “Change Source Folder” to Relink Clips

If you’ve used your file system to move media that’s associated with a DaVinci Resolve project—but haven’t changed the directory structure with which it’s organized—you can use the Change Source Folder command to quickly relink selected clips in the Media Pool to the new file path of the media on disk, using the original file paths as a guide. This is a good relinking method for projects on a SAN. It also avoids the long search times that sometimes result from using the Relink command to examine a nested hierarchy of folders in a more flexible way.

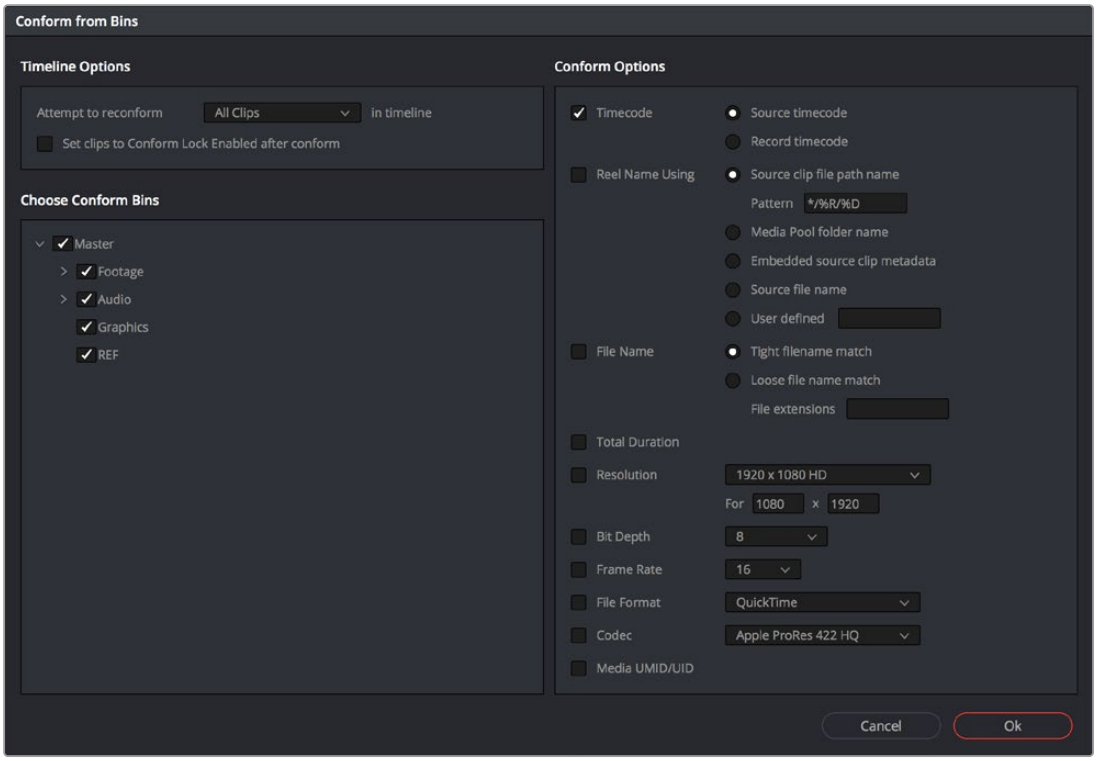
To relink your Media Pool clips to a new location:

1. Select your clip(s) in the Media Pool, then right-click one of the selected clips, and choose Change Source Folder. The Relink Media window will now display the original path for the material, with controls for choosing a new directory.
2. To the right of the Change To field, click Browse, then use the file navigation dialog to find the new location of the media file. Select it and click Open.
3. If you succeeded in finding the appropriate media file, click Change. Otherwise, click Cancel.

Using the “Reconform From Bins” Command

The Reconform From Bins command lets you simultaneously reconform multiple clips in a timeline to a specific bin (or bins) of clips with matching metadata. To use this command, select the clips you want to reconform in a timeline and disable Conform Lock Enabled. Then use the Reconform From Bin command to manually choose another bin of clips in the Media Pool that you want to reconform to.

An important aspect of the Reconform From Bins command is that DaVinci Resolve only reconforms timeline clips that can be matched to source clips in selected Media Pool bins. All timeline clips that cannot be matched are left as is. This makes the command ideal for when you’ve imported a subset of clips to the Media Pool that you need to reconform to clips found throughout an existing timeline.



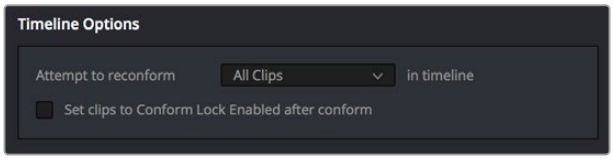
For example, you could use this method to:

- Replace transcoded versions of clips in a timeline with the original camera raw clips.
- Replace the previous versions of VFX clips in a timeline with new versions.
- Replace the offline-quality media you’ve been working with so far with online-quality media.
- Replace your temp clips with rescanned or recaptured stock footage.

Before using Reconform From Bins, ensure your clips are well-organized in the Media Pool. Ideally, they should be in a self-contained bin, or bins separate from the other media used by that timeline. It can be a sub-bin, but it must be separate.

Here’s a simple example: If the media you edited or originally imported is in Bin 1, then import the updated versions of all clips that need to be reconformed into Bin 2. Using Reconform From Bins, you can now decide which bin your timeline clips should be conformed to—because only timeline clips for which there is a valid match are reconformed, while all other timeline clips are ignored.

DaVinci Resolve lets you choose custom conform options to control which metadata is used when matching timeline clips to source clips in the Media Pool. This means you aren't restricted to only using Timecode, Reel Name, and File Name. You could also use any combination of Total Duration, Resolution, Bit Depth, Frame Rate, File Format, Codec, and/or Media UMID/UID to control how clips are conformed, depending on your needs and what you're solving for.

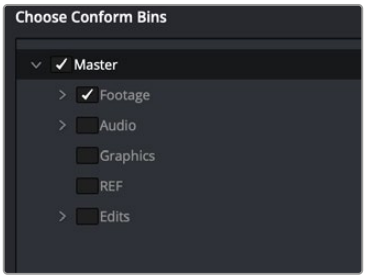


The Reconform from Bins dialog.

However, if your selected criteria doesn't match, the Reconform From Bins operation will fail. You can either try again with other conform criteria, or manually replace the necessary clips in the Timeline.

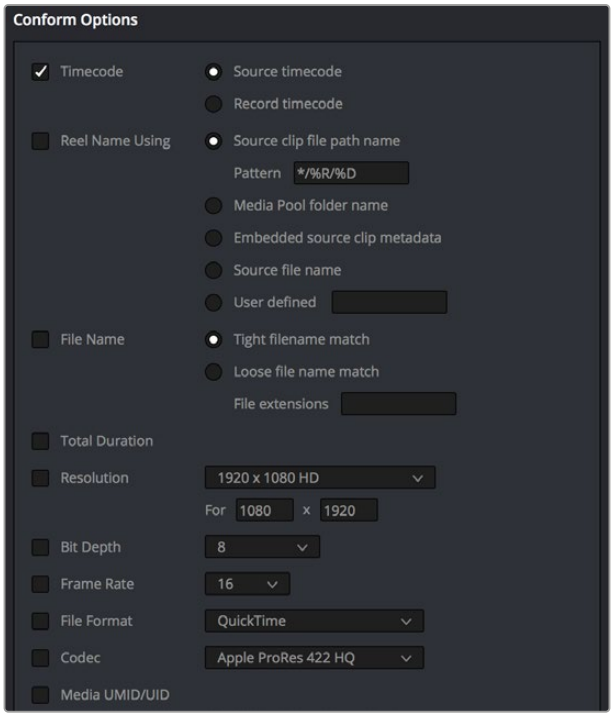
Here's a step-by-step workflow:

To reconform a timeline to clips within a specific Media Pool bin:



1. Go to the Timeline you want to reconform, and double-click to open it.
2. Either individually select the specific clips for reconforming, or—to select and reconform all clips in the timeline—press Command-A.
3. Right-click one of the selected clips, and disable Conform Lock Enabled. Repeat this step for all the clips you want to reconform. This helps DaVinci Resolve to consider all possible conform matches, particularly in cases where there may be multiple clips with overlapping timecode in the Media Pool.
4. Right-click the current Timeline in the Media Pool, and choose Timelines > Reconform From Bins. The Conform Options dialog appears, with Timeline Options and Choose Conform Bins list to the left, and the Conform Options panel to the right.
5. From the Timeline Options section, choose whether to conform to All Clips or to Selected Clips from the dropdown. To set clips to Conform Lock Enabled after conforming, enable the checkbox.

Choose which clips in the Timeline to attempt to reconform.



6 In the Choose Conform Bins section, click the disclosure triangle to the left of the Master bin to reveal the sub-bins.

7 Enable the checkboxes for the bins with media you want to conform the Timeline to, and disable the checkboxes for bins with media that you want to ignore.

Select folders for reconform.

8 Next, choose the conform options you want to be considered when matching timeline clips to Media Pool clips in the selected bins. By default, Timecode is enabled. You can select additional criteria on how your clips should be reconformed, or change the criteria if you need to use other metadata to get better results for clips that you're struggling to conform.

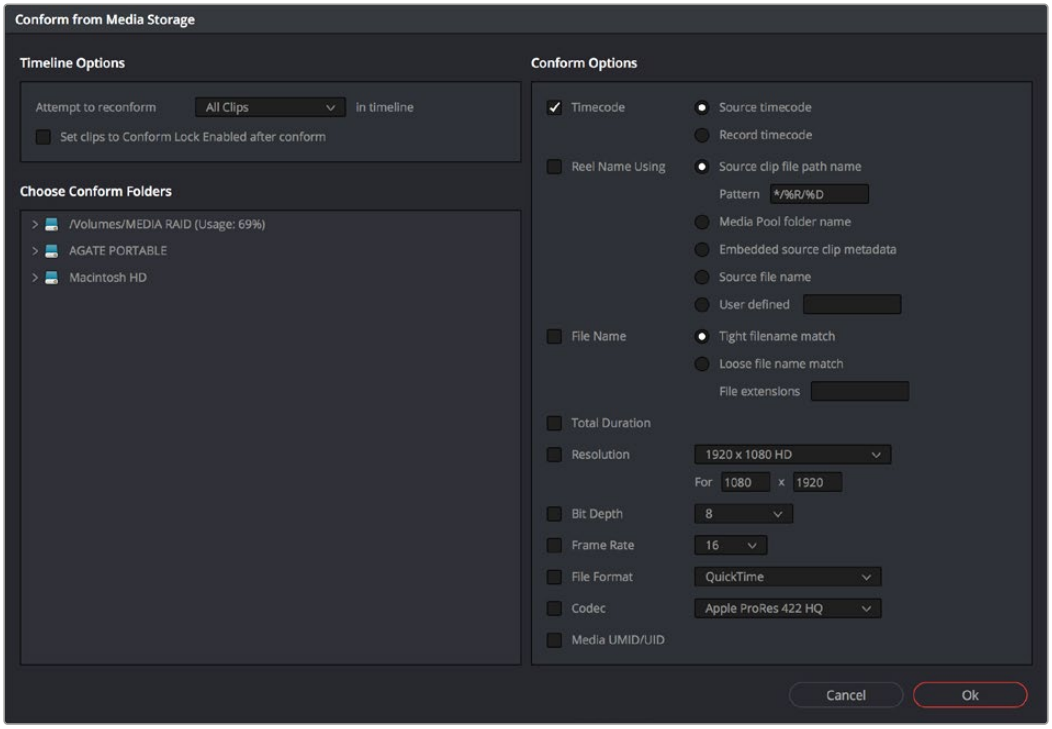
Select criteria to guide the reconform.

TIP: Choose Custom from the top of the pop-up menu to view various editable fields for File Extensions, File Format, and Codec. You can enter multiple options and possibilities, separated by commas, for higher chances of a successful match.

The order in which you enter these options is important. DaVinci Resolve will attempt to conform clips starting with the first format/codec at the left, moving to the next format/codec to the right if no match is found, until every entry in your list has been checked.

9 Click OK. Where necessary, the Timeline automatically updates to conform to the media contained within the bins you checked.

10 After you've used Reconform From Bins, any reconformed timeline clips that now contain timecode and reel names/file names that match two or more source clips in the Media Pool will display a clip conflict badge in the Timeline. To eliminate these warnings, you can select either just the clips that were conformed, or all clips in the Timeline, right-click them, and choose Conform Lock Enabled.



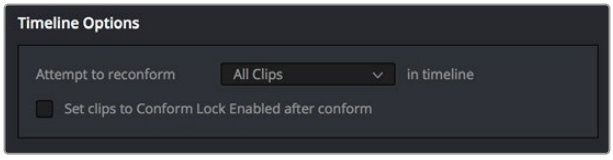
Using Reconform From Media Storage

Starting in version 14, DaVinci Resolve introduced another reconform method that lets you conform clips in a timeline to clips in a specific File System directory (including all subdirectories) using the Reconform From Media Storage Folders command. This means you can simultaneously reconform multiple clips in a timeline to matching source media files on disk without first importing those clips to the Media Pool. All clips that can be conformed according to the specified conform criteria will be automatically imported as necessary.

An important aspect of the Reconform From Media Storage command is that DaVinci Resolve will reconform all timeline clips that can be matched to source media files on disk in the selected Media Storage directories, but all Timeline clips that cannot be matched are left as is. This makes Reconform From Media Storage an ideal command in the following situations:

- When you need to reconform clips that are found throughout an existing timeline to a smaller subset of media in a specific directory on disk, such as updated VFX or motion graphics from a third-party application.
- When you need to quickly reconform missing timeline clips throughout an imported timeline, and especially when you need to use custom conform criteria to successfully reconform those clips. (Unlinked clips can only be reconformed with this command if you select them and disable Conform Lock Enabled.)

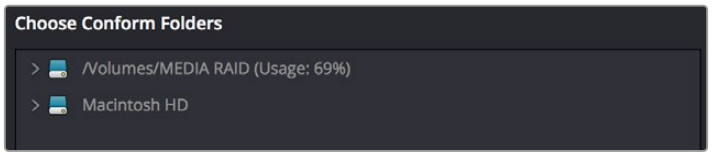
Similar to the Reconform From Bins command, you can specify the combination of conform criteria you want to use to match clips in the timeline with clips in the Media Pool. This means you aren't restricted to only using Timecode, Reel Name, and File Name. You could also use any combination of Total Duration, Resolution, Bit Depth, Frame Rate, File Format, Codec, and/or Media UMID/UID to control how clips are conformed, depending on your needs and what you're solving for.



The Reconform From Media Storage dialog.

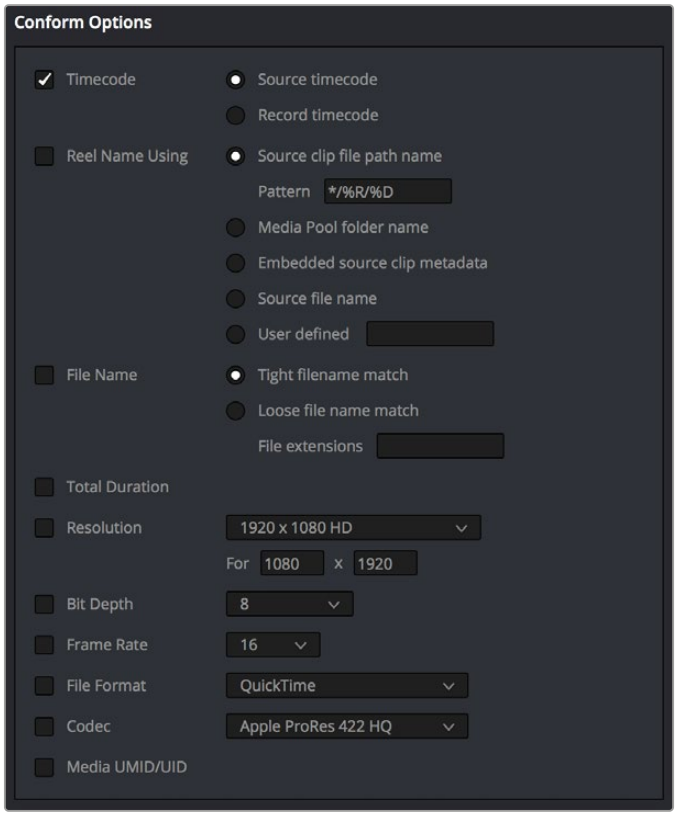
This is the ideal method, especially if the only way to feasibly conform a timeline to your required media involves using a specific combination of metadata that's different from the rules that DaVinci Resolve defaults to.

For example, you have a jumble of 8-bit and 10-bit versions of the same clips on your hard drive, but only wish to conform a given timeline to the 10-bit media in preparation for finishing. Using the Reconform from media storage folders command lets you be specific with which media to use.



To use "Reconform from media storage folders" to reconform a timeline:

1. Go to the Timeline you want to reconform, and double-click to open it.
2. Either individually select the specific clips for reconforming, or—to select and reconform all clips in the timeline—press Command-A.
3. Right-click one of the selected clips, and disable Conform Lock Enabled. Repeat this step for all the clips you want to reconform. This helps DaVinci Resolve to consider all possible conform matches, particularly in cases where there may be multiple clips with overlapping timecode in the Media Pool.
4. Right-click the timeline you want to reconform, and choose Timelines > Reconform from media storage folders. The Import From dialog appears, with a File System browser to the left, and an Options panel to the right.
5. From the Timeline Options section, choose whether to conform to All Clips or to Selected Clips from the dropdown. To set clips to Conform Lock Enabled after conforming, enable the checkbox.



Choose which clips in the Timeline to attempt to reconform.

6 From the Conform Folders section, choose a directory containing the media you want to reconform to.

Select a directory that has media you want to conform to.

7 Next, choose the conform options you want to be considered when matching timeline clips to source media files in the selected directory. By default, Timecode is enabled. Choose additional criteria to be even more selective about which clips will be reconformed, or choose different criteria to use other metadata for better results.

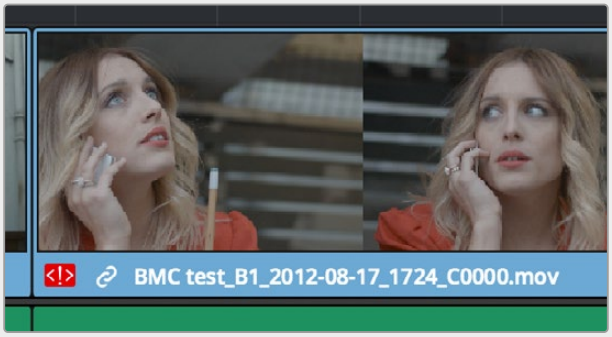
Select criteria to guide the reconform.

TIP: Choose Custom from the top of the pop-up menu to view various editable fields for File Extensions, File Format, and Codec. You can enter multiple options and possibilities, separated by commas, for higher chances of a successful match.

The order in which you enter these options is important. DaVinci Resolve will attempt to conform clips starting with the first format/codec at the left, moving to the next format/codec to the right if no match is found, until every entry in your list has been checked.

8 Click OK. Where necessary, the Timeline automatically updates to conform to the media in your selected directory. All source media files that were conformed will now be in your Media Pool.

9 After you've used Reconform From Bins, any reconformed timeline clips that now contain timecode and reel names/file names that match two or more source clips in the Media Pool will display a clip conflict badge in the Timeline. To eliminate these warnings, you can select either just the clips that were conformed, or all clips in the Timeline, right-click them, and choose Conform Lock Enabled.



Understanding, Fixing, and Using Reel Conflicts

If the Auto conform clips with media added into Media Pool setting is enabled in the Project Settings > General Options panel, the same dynamic relationship between clips in the Media Pool and timeline are maintained, no matter if they're linked or unlinked. However, this means if you have two different versions of the same clip in the Media Pool, or even two different clips with the same file name (or reel name) and the same overlapping timecode, then DaVinci Resolve is capable of automatically conforming to either clip.

Let's say you have both the camera raw version of a clip, and a ProRes or MXF transcoded version imported into the Media Pool at the same time. Both clips share the same content, file name, and range of frames.

These factors could cause a "clip conflict". You might not notice this at first, since the Conform Lock Enabled setting is enabled by default. In this state, all clips in a timeline only consider the current clip in the Media Pool to which they're conformed as the valid clip. In effect, all other clips with file names and overlapping timecode that would otherwise make them a valid match are ignored.

However, if you right-click such a clip in the Timeline and disable Conform Lock Enabled, a "clip conflict" icon may appear, indicated by a red <!> conflict icon beside its name in the timeline.

The red <!> conflict icon, indicating at least two clips have matching conform parameters.

Clip conflicts are not always considered an error. They can be a problem if your imported project from a separate application contains media that was added with timecode but no reel identifier (for example, when shots from multiple unidentified reels all start at 0 hour).

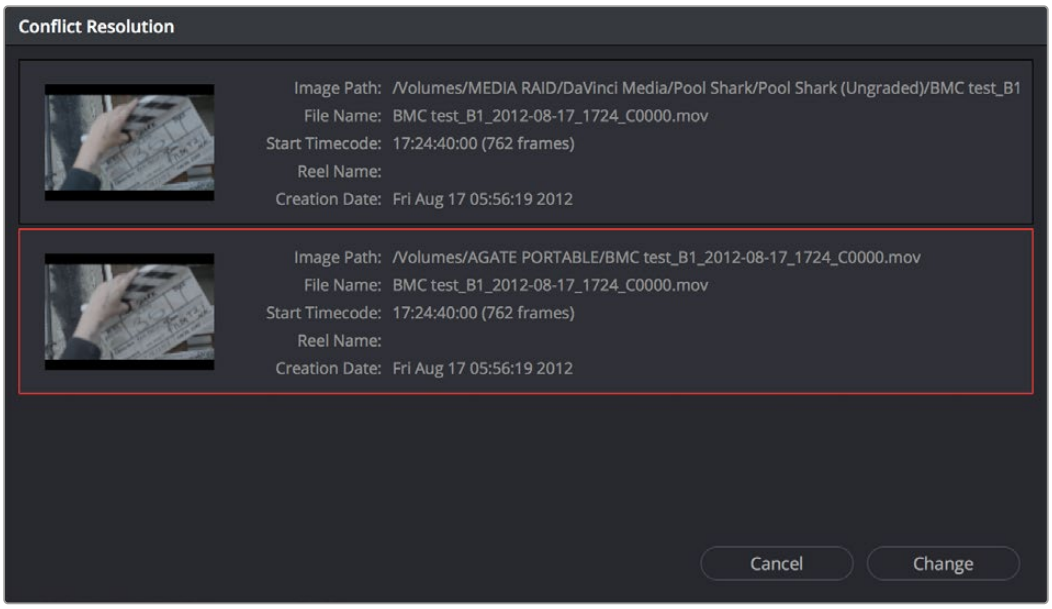
TIP: Overlapping timecode is common in the normal course of work, but should be managed by altering each clip's embedded reel name, or by organizing media in different bins.

Using Clip Conflicts as a Conform Tool

On the other hand, clip conflicts can be a desirable solution for workflows that require switching between versions of a particular clip. If you had an edited timeline comprising of transcoded QuickTime versions of camera raw original media, and you only had the transcoded clips in the Media Pool, then all is well.

However, let's assume that you find yourself in need of the resolution or additional color latitude of the camera raw version of a particular clip. If you import the camera raw version of that clip, nothing changes. But if you right-click that clip in the Timeline and deselect Conform Lock Enabled, the red <!> conflict badge appears beside the clip name in the Timeline. This means the clip in the Timeline is accurately seeing the relationship between it and the now two simultaneously named clips with timecode overlap in the Media Pool.

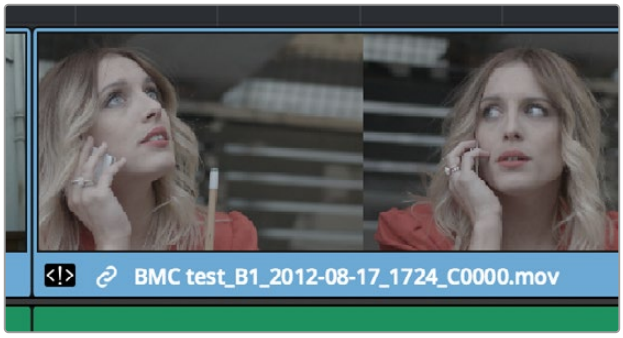
The current relationship between this timeline clip and the one to which it is conformed doesn't change; this badge simply indicates there is a second clip in the Media Pool to which you could conform this clip in the Timeline. You can now select your preferred clip by double-clicking the badge and following the below steps.



Resolving Clip Conflicts

Clip conflicts are easy to resolve. In fact, this feature is the very basis for the name of our software.

To resolve a reel conflict by relinking a clip's media:



1 Double-click the red <!> conflict badge beside the clip name in the Timeline.

The Conflict Resolution window appears with a list of files in the Media Pool (of any format) that have identical file names or reel names and overlapping timecodes with the clip you right-clicked. Each item in this list has a thumbnail of the clip, the file path of the media on disk, the file name, starting timecode, reel name (if any), and creation date. These will help you decide which clip to use.

The Conflict Resolution window shows which other clips have overlapping timecode and reel information.

2 Choose the clip that you want to conform to, then click Apply. The clip in the Timeline now reflects your selected media, and the red <!> conflict badge is replaced with a black “resolved” badge. To change which Media Pool clip you want to conform to, simply double-click the “resolved” badge. It remains a dynamic relationship.

A “resolved” badge shows that the conflict was resolved.

Re-editing Media Directly to the Timeline

If none of the above methods work, try replacing the problem clip. For example, you may need to replace an old version of an effects shot with a newer one—or replace an offline version of a stock footage shot with a higher quality one. The problem occurs when you have a mismatched filename and/or timecode, no reel name, and the files are in different formats, frame sizes, and durations.

In this case, it’s a good thing that DaVinci Resolve has such excellent editing tools.

When fixing conform problems with manual editing, the replace edit is your friend. For example, you could use a replace edit to match a new incoming clip’s timing to the old one. Or you could use a three-point edit, a place on top edit, or even a simple drag and drop edit to update the clip in the Timeline.

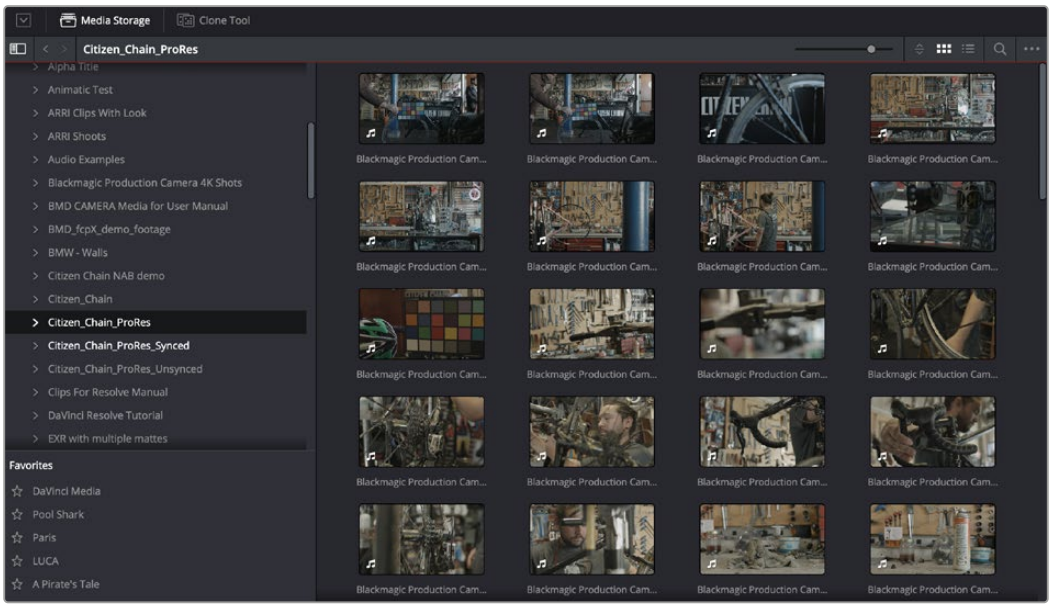
For information on the different edit types in DaVinci Resolve, jump to this chapter: Editing Basics.

How Grades Are Linked to Multiple Timelines

If your project uses Remote versions, clips that reference the same file in the Media Pool are linked and share their Remote grades.

For example, two close-up shots clips taken from the same source file will share the same remote grades, since they reference the same media. This behavior applies across multiple timelines. If clips in different timelines reference the same Media Pool clip, they share the same Remote grades.

This is why you can grade one timeline, and then import a re-edited version via EDL, AAF, or XML, and have the new timeline automatically inherit the existing grades from the previous timeline.

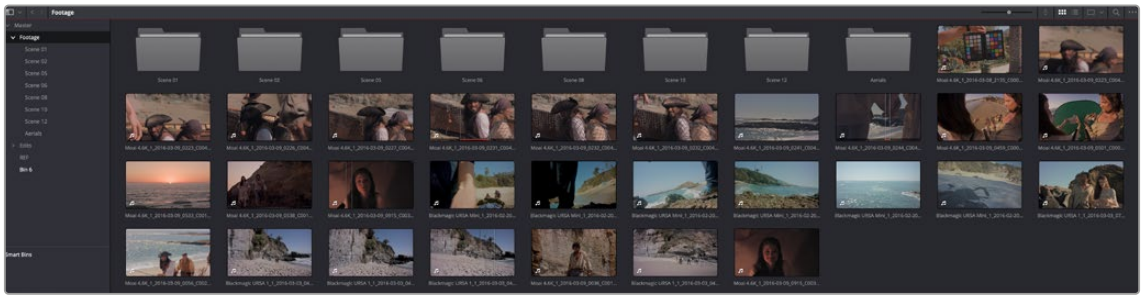


To independently grade a timeline, first select it, then open the Color page > right-click any clip in the Thumbnail timeline > choose Copy Remote Grades to Local. All grades are copied to Local versions, and changes will only affect that timeline.

For more information on Local and Remote versions, jump to this chapter: Grade Management.

Creating Digital Dailies for Round Trip Workflows

Step 1–Ingest Media and Add/Edit Metadata



You don't need to export a project file from an NLE before working in DaVinci Resolve. The Media Storage browser on the Media page lets you access any available storage volume, and import compatible media directly into the Media Pool.

The Media Storage browser with scrubbable clip thumbnails.

The Media Pool is DaVinci Resolve's project library for all media used in the current project. You can organize clips in into multiple bins, and use the Metadata Editor to add descriptions, notes, scene and take information, flags, shooting days and dates, program and episode details, and more. This data can populate metadata tags when exporting ALE lists to move the metadata to a compatible NLE.

For more information on ingesting media in the Media page, jump to this chapter: Adding and Organizing Media with the Media Pool.

The Media Pool.

Step 2–Sync Audio to the Dailies

If your video format contains embedded audio, DaVinci Resolve can pass that audio through when rendering from the Deliver page. If your production uses dual-system audio recording, there are various ways to sync it in the Media page.

You can also import timecoded Broadcast WAV. files into the same bin as the accompanying video clips—or into a sub-bin, if preferred—before syncing the dailies in DaVinci Resolve. Once you've imported the video and audio media you want to sync into the Media Pool of the Media page, right-click the enclosing folder and choose Auto-Sync Audio Based on Timecode. This syncs every timecode-matched pair of audio and video media clips within the same folder. Alternatively, to add the synced audio tracks to audio tracks already present in the video clips, choose Auto-Sync Audio Based on Timecode and Append Tracks.

TIP: For the best results, use different folders for each day's audio and video clips.

If you don't have synced timecode, but your video clips contain separately recorded audio (e.g. via an on-camera microphone) that matches the dual-system audio recordings, you can instead use waveform syncing.

Import your separately recorded audio files into the same bin as the accompanying video clips, or into a sub-bin. Then right-click the enclosing folder and choose Auto-Sync Audio Based on Waveform. This syncs every timecode-matched pair of audio and video media clips within the same folder.

Alternatively, to add the synced audio tracks to any audio tracks already present in the video clips, choose Auto-Sync Audio Based on Waveform and Append Tracks.

TIP: For the best and quickest results during waveform syncing, use different folders for each day's audio and video clips—or even different folders per scene. This reduces the number of waveforms that need to be compared each time.

Open the video clip in the Media page viewer, click the Waveform button in the Audio panel, then select the corresponding audio clip to display its waveform. Position the Viewer and Audio panel playheads on the matching sync points, then click the Audio panel's Link button to lock the audio and video together.

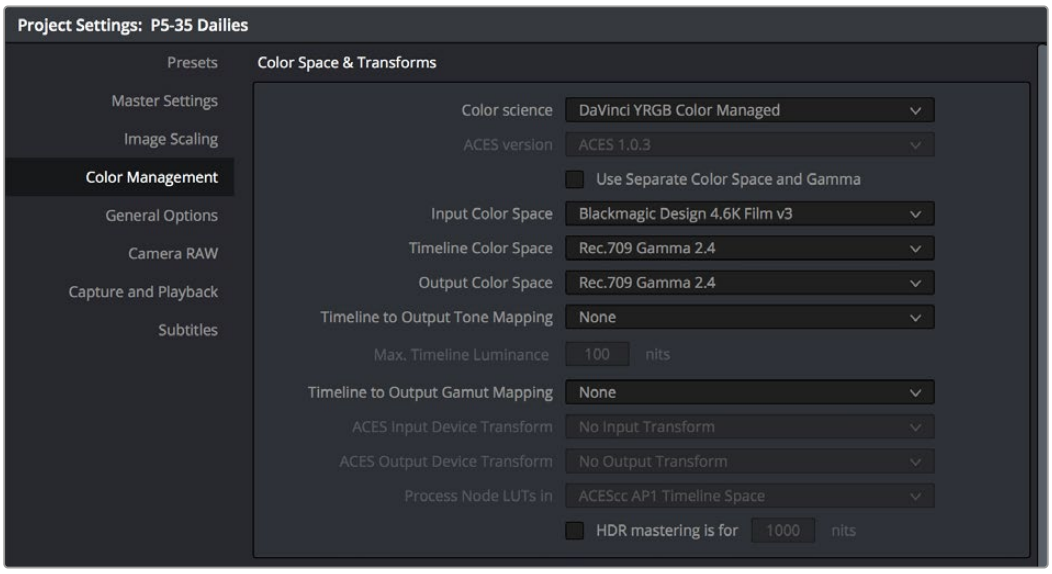
If neither timecode nor waveform matching is available, you can manually sync audio using a clapboard or any other visual sync point. Select a video clip to open in the Media page viewer, click the Waveform button in the Audio panel, then select the corresponding audio clip to display its waveform in the audio panel. From here, you can drag the Viewer and Audio panel's playheads to the video and audio sync points, and click the Audio panel's Link button to lock the audio and video together.

For more information on syncing audio and video in the Edit page, jump to this chapter: Modifying Clips and Clip Attributes.

Step 3–Do Whatever Grading is Necessary

Many productions choose not to record camera raw media, instead electing to record a log-encoded or "flat" image to ProRes or DNxHD media files. This preserves the most image data for grading without clipping highlights or shadows, and can be accomplished using in-camera settings that record log-encoded QuickTime or MXF media—or via external video recorders such as the Blackmagic Video Assist. Depending on the camera you shoot with, the recorded media will use one of a variety of log-encoded gamma curves such as Log-C, S-Log, S-Log2, S-Log3, BMD Film, CanonLog, Panasonic VLog, or REDlog Film, among others.

In other workflows, raw video formats are recorded then debayered as log-encoded clips, which preserves the maximum amount of debayered data for grading, or in preparation for transcoding.

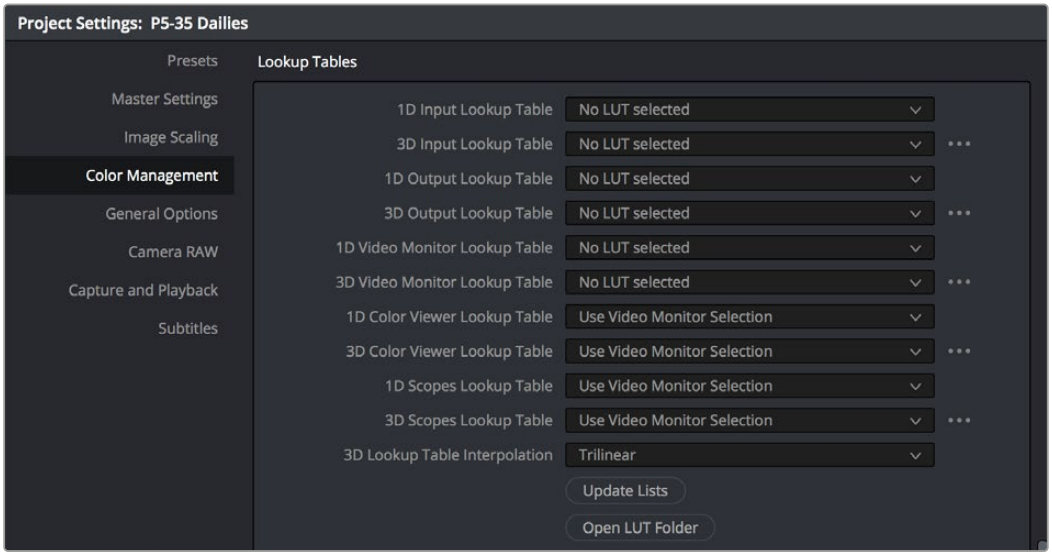


If you're outputting high-quality media files that will later be used for finishing, then you may want to simply pass the source image data through unaltered. But if you're creating offline media for editors, directors, and producers to watch for the next three months, there are ways of grading this data for a more pleasing output that's been "normalized" to look closer to what was monitored on-set during the shoot.

There are many ways of normalizing log-encoded media in DaVinci Resolve. If you're working with one or more raw formats, you can debayer all clips straight to Rec. 709 in the Project Settings > Camera Raw panel.

But if you're working with log-encoded ProRes or DNxHD media, you'll have to use other methods to normalize these clips.

One such way is with DaVinci Resolve Color Management. To start, access the Project Settings > Color Management panel and set the Color science setting to DaVinci YRGB Color Managed. Then, right-click each clip or group of clips in the Media Pool, and choose the appropriate setting for each media type from the Input Color Space submenu (you can define the Input Color Space of multiple selected clips at once).



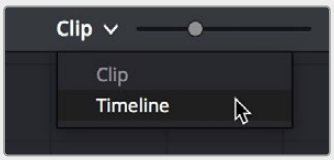
For more information on using DaVinci color management, jump to this chapter: Data Levels, Color Management, and ACES.

Enabling DaVinci Resolve Color Management via the Project Settings.

Alternatively, you can also normalize log-encoded media using one or more Lookup Tables (LUTs). Simply apply a LUT to the entire project to normalize the particular log characteristics of the media you're processing. Project-wide LUTs can be applied in the Project Settings > Color Management panel.

For more information, jump to this chapter: System and User Preferences.

Project-wide LUT table settings are located in the Project Settings > Color Management > Lookup Tables.



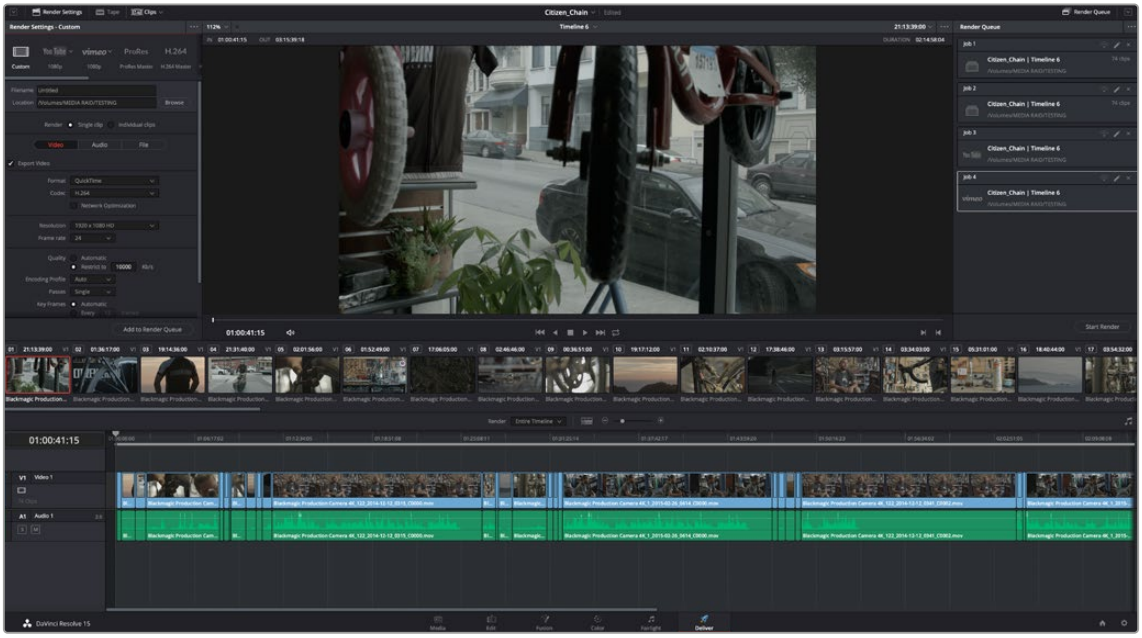
In the case of LUT-managed shooting workflows—where a variety of LUTs have been custom-designed to monitor different scenes—you can manually apply individual LUTs to one or more selected clips from each scene using the Media Pool's contextual menu.

You can also edit each scene's clips into timelines, and apply separate LUTs to each clip by going to the Color page's Node Editor and selecting Clip mode. Alternatively, you can apply a single LUT to an entire timeline going to the Color page's Node Editor and selecting Timeline mode.

For more information on using LUTs as part of grades, jump to this chapter: Node Editing Basics.

Alternately, if on-set color correction from the shoot been provided via a CDL-compliant EDL exported from one of several on-set grading solutions that are available, you can use the ColorTrace™ from CDL command to batch-import grading information from an external application.

For more information on CDL import workflows, jump to this chapter: Copying and Importing Grades Using ColorTrace.

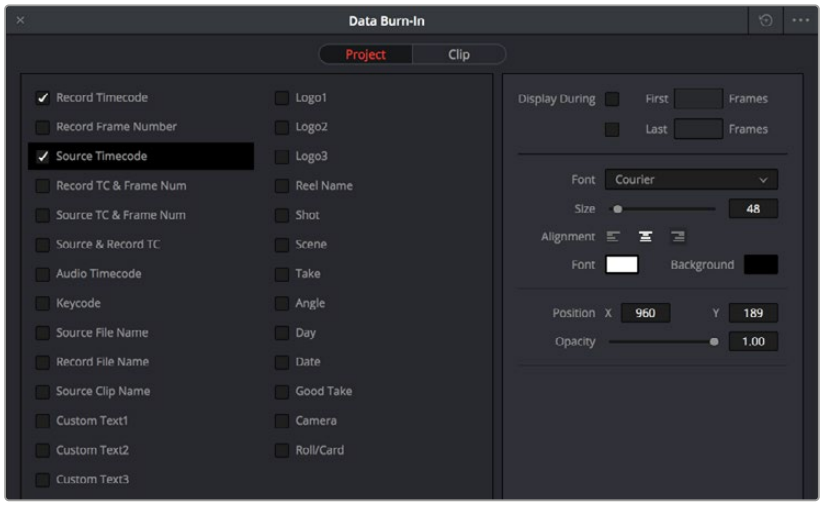


Selecting Timeline in the Node Editor.

If your project's workflow requires starting out with even higher quality dailies, you can also manually grade individual clips, as you would with any project. To create a fast "one-light" adjustment for every clip in the Master Timeline simultaneously, go to the Color page's Node Editor and use the Timeline mode to apply a single correction simultaneously to every clip in the current timeline. This is particularly useful as you can readjust the Timeline grade as much as you like. The changes are automatically applied to every clip in the timeline.

For more information, jump to this chapter: Node Editing Basics.

Step 4–Export Media Suitable for Editing



Once you've organized your clips, synced the dailies, and applied any necessary grading, go to the Deliver page to set up the format, file naming convention, and organization of the media you're outputting for editing or finishing.

The Deliver page, with several jobs set up for rendering.

Additionally, to apply a window burn, watermark or logo to the media you're processing, go to the Workspace > Data Burn-In > Project panel. Window burns can be formatted with great flexibility, and are written out to media that's either rendered or output to tape.

For more information, jump to this chapter: Data Burn-In.

Choosing metadata to display onscreen in the Data Burn-in window.

After selecting the appropriate render settings and window burn options, you can output one or several versions of the media, to accommodate jobs where you need to provide several media deliverables.

For more information on setting up and using the Deliver page, jump to this chapter: Using the Deliver Page.

Step 5–Reconform Media to an EDL, AAF, OTIO, or XML Project File

Once the offline media you've delivered has been edited in whichever NLE is used for the project, you can easily reimport the edited project via an AAF, XML, OTIO, or EDL file, depending on which is most suitable to your application. This edit data can be used to reconform the media you originally imported into the Media Pool, so that you can immediately access the graded adjustments you made to create the offline media, as applied to the source media.

Importing AAF, XML, OTIO, or EDL files in the Edit page creates new timelines. If you find yourself grading a project that is in progress editorially, you can also import multiple subsequent Timelines to accommodate changes that have been made to the edit.

Depending on how you set up your grades, you can also use remote versions which will automatically ripple to follow each clip when you import a re-edited version of the program as a new timeline, saving you the trouble of recreating your work.

For more information on using remote versions, jump to this chapter: Grade Management.

Step 6–Output Final Media for Finishing

With your final grade complete, you can again use the controls in the Deliver page to render the program's final media, either as individual clips for a round-trip workflow, or as a single media file or image sequence for delivery as a digital master.

Conforming XML Files

DaVinci Resolve can import projects that were exported to the Final Cut Pro 7 or Final Cut Pro X XML formats. Adobe Premiere Pro and Autodesk Smoke and Flame Premium are also capable of using the Final Cut Pro XML project exchange format to accommodate round-trip workflows. However, for the best results you need to make sure that you're exporting XML from Premiere Pro version 5.5.1 or newer; ideally you want to export from the latest version of Premiere Pro that's available.

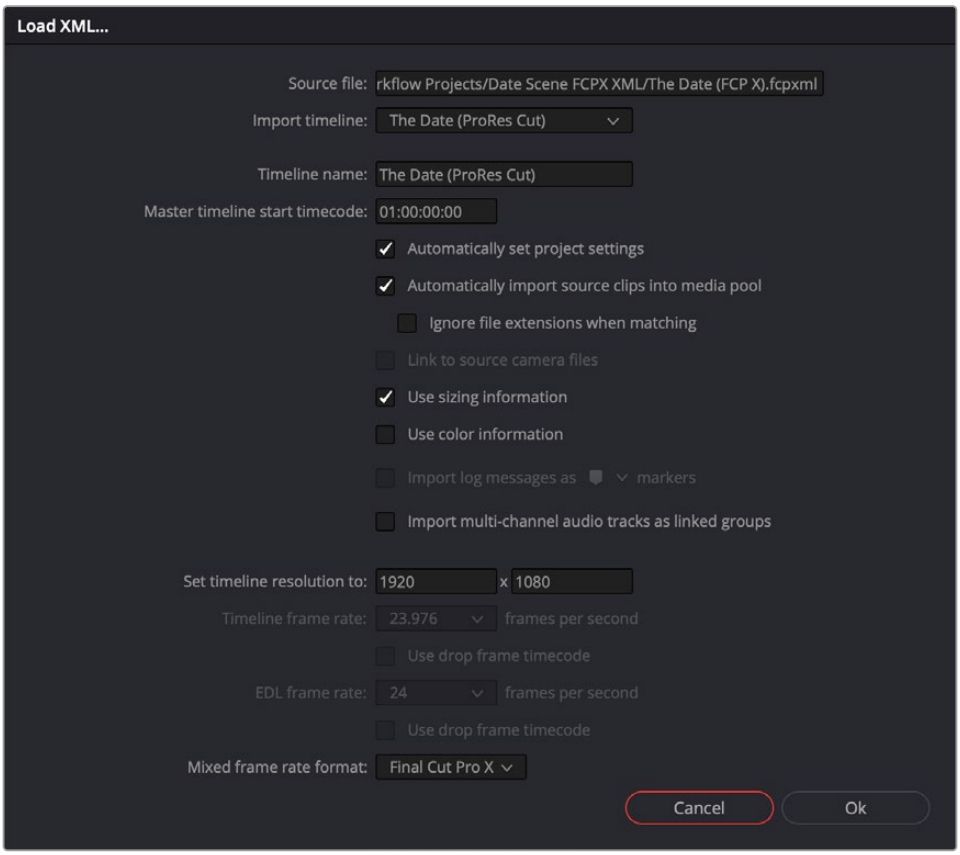
Exporting XML for use by DaVinci Resolve is straightforward: There aren't any settings you need to tweak before exporting, other than the version of XML you wish to export. For this reason, it's best to do whatever timeline and/or media management you need to before XML export.

Manage Your Media Before Exporting an XML

In workflows using imported XML or AAF projects (or even EDLs), it's easy to relink and conform to the accompanying media files if they're located in a single directory path. Having media sorted into multiple directories is fine, as long as they're located in a single main directory that you can select at the appropriate stage of project import.

Importing XML Project Files

This section details the Import AAF/EDL/XML dialog. One procedure lets you accomplish any of the following workflows:



- Importing an XML file and automatically conforming to and importing the media it's linked to.
- Importing an XML file and manually choosing another set of media, presumably in a different format or resolution, with identical metadata, to conform to instead.
- Importing an XML file that's linked to offline media derived from a camera original format, and automatically conforming it to and importing the camera original media.

Each of these workflows is possible if you choose the correct combination of options, as detailed in the following procedure.

You can select multiple XML, AAF, FCP XML, or EDL timelines (or any combination thereof) simultaneously with the Timeline Import dialog. The selected timelines will import sequentially, pausing after each time the OK button is pressed. This lets you adjust separate Import Settings per timeline.

To load an XML file and automatically link to its referenced media:

1. Do one of the following:
   - From any page, choose File > Import Timeline (Shift-Command-I).
   - Open the Edit page, right-click anywhere in the Media Pool, and choose Timelines > Import > AAF/EDL/XML/DRT/ADL/OTIO.
2. Using the file dialog that appears, select the project file you want to import, then press the Open button. The Load OTIO window appears, depending on your selection.

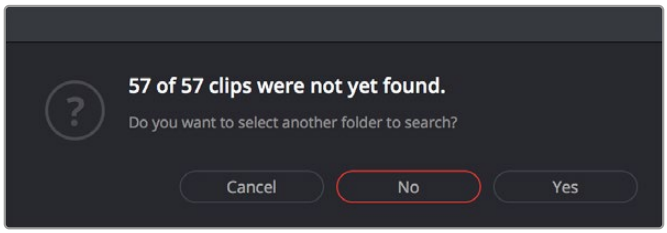
Options when importing an XML file.

3 Choose the options that are applicable to your particular project. By default, these options are based on metadata within the file you selected.

- **Source file:** The file you selected in the previous step.
- **Import timeline:** If there are multiple sequences within the selected XML source file, this pop-up menu lets you choose which sequence to import as a DaVinci Resolve timeline.
- **Timeline name:** The name of the Timeline you're about to create. This defaults to the name of the sequence that was exported, but you can change it if you like.
- **Master timeline start timecode:** The timecode at which the imported timeline will start. This automatically matches the start timecode of the selected Import Timeline.
- **Automatically set project settings:** Leave this option enabled to automatically apply the frame size and frame rate settings shown in this window to the Project tab of the Config page. You can still import timelines with frame rates that differ from the project's frame rate.
- **Automatically import source clips into media pool:** Leave this checkbox enabled to automatically import the media referenced by the selected XML file into the Media Pool using the embedded file paths. If DaVinci Resolve can't locate the media at those locations, you'll be prompted to manually select a directory where the clips are located.

  Ignore file extensions when matching: Enable this checkbox to manually choose a different directory of media to link to. For example, if the XML you're importing links to ProRes Proxy media, and you wish to relink to another directory of corresponding ProRes 4444 or camera raw media.
- **Use sizing information:** Lets you import position, scale, and rotation transforms from the originating NLE via the imported XML project file. These transforms are stored in each clip's settings in the Edit page Inspector.
- **Use color information:** For Final Cut Pro X XML files only. This option lets you import a subset of color correction data from the Final Cut Pro X color board controls.
- **Import multi-channel audio tracks as linked groups:** Turn on this checkbox if you want to import multi-channel audio, such as stereo, 5.1, and 7.1 audio into individual mono timeline tracks that are linked together in the Fairlight page.

For more information on Linked Groups, jump to this chapter: Setting Up Tracks, Busses, and Patching.

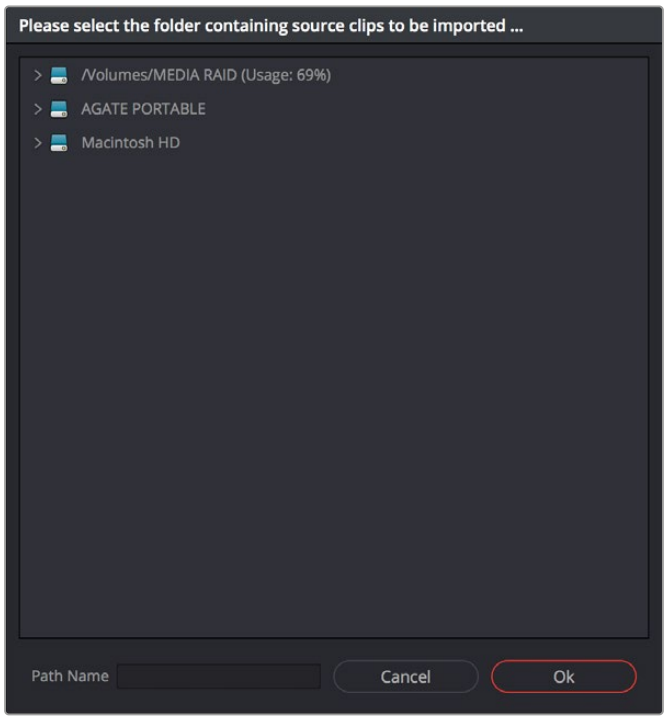


If this checkbox is disabled, multi-channel audio will be imported into multi-channel audio tracks in the Timeline.

- **Set timeline resolution to:** Two fields let you specify the width and height of the frame size you want to work at in DaVinci Resolve. By default, this is derived from the resolution specified in the XML file being imported.
- **Timeline frame rate:** By default, this is derived from the frame rate of the XML file being imported. If you're importing an XML file into a project that already has media in the Media Pool, the Timeline frame rate is locked and cannot be changed.
- **Use drop frame timecode:** By default, this is derived from the XML file being imported.
- **EDL frame rate:** By default, this is derived from the frame rate of the selected file.
- **Use drop frame timecode:** By default, this is derived from the frame rate of the selected file.
- **Mixed frame rate format:** From this pop-up menu, choose the method used to conform mixed frame rates for rendering and playback. You can choose the Final Cut Pro 7 or Final Cut Pro X methods of conform. For projects imported from Media Composer, Premiere Pro, Smoke, or other NLEs, you should leave this set to DaVinci Resolve. This pop-up menu also appears in the Load XML dialogs when you import a project.

4 After choosing all necessary settings, click OK.

5 Assuming you left “Automatically import source clips into media pool,” turned on, if the media linked to by the XML file is not in the expected disk location, or if you turned on the “Ignore file extensions when matching” checkbox, then another dialog appears prompting you to choose the folder within which the media for this project is stored. Do one of the following:



- **To try to relink to media in another disk location:** Click Yes, and then navigate to the folder containing your media (all subfolders will be automatically traversed as well), select it, and click OK.
- **To just import the Timeline with all offline clips:** Click No.

A prompt appears if all the media was not found.

IMPORTANT: It’s always possible to choose the top level of any volume to automatically find all media in any directories located within. But it can be an extremely time-intensive process if the volume is large and filled with multiple folders and documents.

6 If you clicked Yes to selecting another folder, use the folder selection dialog to navigate to another folder, and click Ok. You can repeat this process as many times as needed.

Selecting the source folder for your XML imported clips

The XML file is imported. A new Timeline and the referenced media files appear in the Media Pool, and you'll be able to view the open Timeline and its contents. Clips that are offline and unlinked will appear in red in both the media pool and timeline.

TIP: You can open the Edit Index and choose Filter Offline Clips from the option menu to see a list of all offline clips in the current Timeline.

Conforming AAF Files

AAF (Advanced Authoring Format) is a project exchange format that was originally developed by the Advanced Media Workflow Association (AMWA). Commonly used video applications that export project data in the AAF format include Avid Media Composer, Avid Symphony, Autodesk Smoke and Flame Premium, and Adobe Premiere Pro.

Supported Media Types in AAF Workflows

Media Composer supports several methods for ingesting and managing media. The formats suitable for a one-way or round-trip project between Media Composer and DaVinci Resolve depends on whether the media format is compatible with DaVinci Resolve.

Not every format is compatible with every media management operation in Media Composer. You should carefully tailor your workflow around the media formats you're using, and the operations they support.

Transcoding to DNxHD or DNxHR Always Works

Because DNxHD and DNxHR are Media Composer's core codecs, the simplest and most reliable workflow for round-tripping between Media Composer and DaVinci Resolve is to transcode media to MXF-wrapped DNxHD/DNxHR before editing.

DaVinci Resolve supports both MXF-wrapped and QuickTime-wrapped DNxHD/DNxHR media.

Linking to Media Using AMA and Consolidating

Avid Media Access (AMA) lets you directly link clips to media files in Media Composer without transcoding them to MXF-wrapped DNxHD/DNxHR files, or copying them to an Avid MediaFiles directory. While convenient, AMA-based workflows require additional planning.

Not all AMA-compatible media formats can be consolidated in Media Composer, which limits your ability to create a smaller, more portable media package for use in DaVinci Resolve. Since Media Composer can only consolidate formats that it can write, the media format of an AMA-linked clip determines if it can be consolidated. For example, since Media Composer cannot write R3D media, R3D clips cannot be consolidated.

Similarly, not all AMA-compatible media formats are supported by DaVinci Resolve. The ability to edit a format in Media Composer does not guarantee that it can be used in DaVinci Resolve. The following table lists the media formats that can be AMA-linked in Media Composer, the formats that can be consolidated, and which ones can be used in DaVinci Resolve.

If your sequence contains a mixture of media formats, including some that can be consolidated and others that can't, you should transcode all clips that aren't compatible with consolidation to an Avid-native codec before consolidating media and exporting the AAF to DaVinci Resolve.

Codec	Can be Natively AMA-Linked	Can be Consolidated	DaVinci Resolve Compatible
ARRI ALEXA Raw	Non-native support	No	Yes
AVCHD	Yes	No	Yes
AVC-Intra and Long GOP	Yes	Yes	Yes
Blackmagic RAW	Non-native support	No	Yes
Canon XF	Yes	Yes	Yes
Cine (Phantom)	Yes	Yes	Yes
CinemaDNG	No	No	Yes
DVC PRO P2	Yes	Yes	No
QuickTime (ProRes)	Yes	Yes	Yes
R3D (RED)	Non-native support	No	Yes
Sony F65 Raw	Yes	No	Yes
Sony HDCAM SR (SStP)	Non-native support	No	Yes
Sony XAVC	Yes	Yes	Yes
Sony XDCAM	Yes	Yes	Yes

Compatible AMA-linked formats

Fast Imported Media

Media Composer also supports a media ingest method called Fast Import, which quickly copies imported media is into the Avid MediaFiles directory by wrapping the original image data using the original codec into an MXF wrapper. While this is a fast and efficient way to import media into Media Composer, the resulting files are not typically compatible with DaVinci Resolve.

On the other hand, any media format that supports Fast Import can also be consolidated. If you're planning to round-trip a sequence containing Fast Imported media, you should either transcode those clips to DNxHD prior to AAF export—or conform your exported AAF project to the original camera media in DaVinci Resolve instead.

TIP: Whenever your project contains media formats that aren't compatible with DaVinci Resolve, you can enable the Transcode Video To checkbox in the Export As dialog when exporting an AAF project. This automatically transcodes any incompatible media into a compatible format. An important note: Some non-standard frame sizes can't be transcoded in Avid, and will return an unsupported resolution error.

Logged Errors When Importing AAF

When you enable the Import log messages as markers checkbox in the Load AAF dialog, markers (with error message notes) will be added to your Timeline, alerting you to issues with the AAF import. You can choose your preferred marker colors to store this information when enabling the checkbox.

The following messages will create markers:

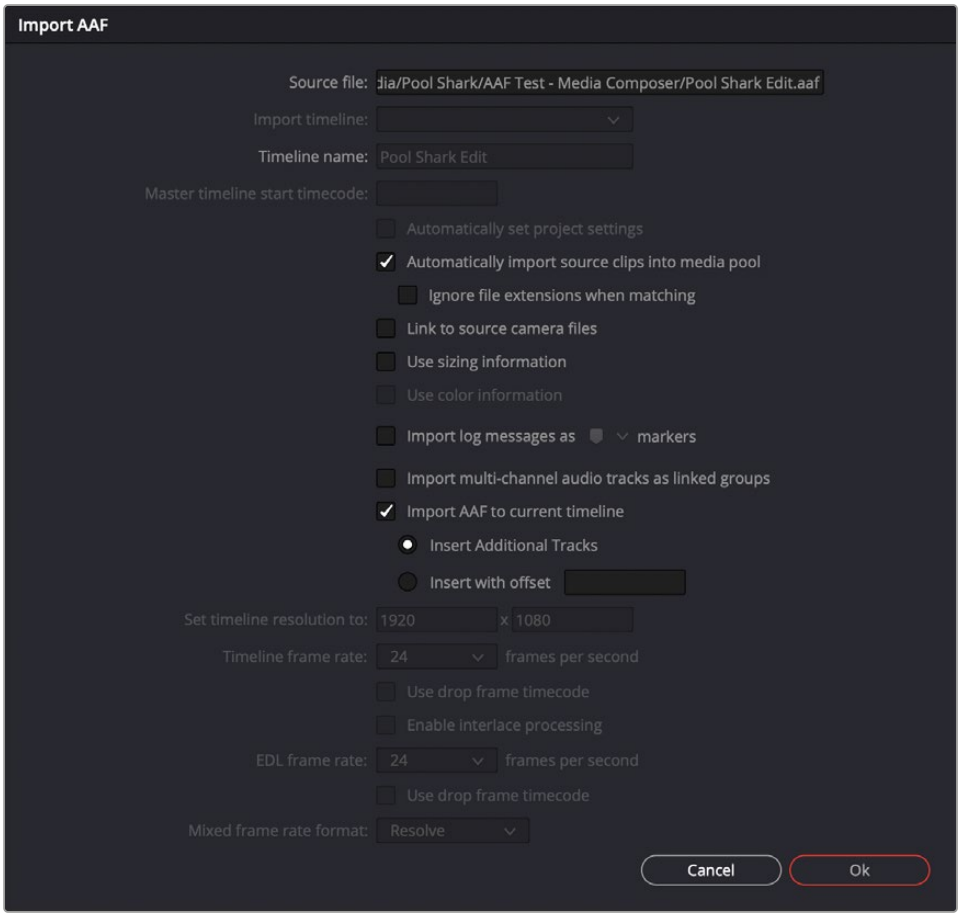
- Transition type 'XXXX' is not supported in this release. A Cross Dissolve will be inserted.
- Effect type 'XXXX' is not supported in this release. Plain clips will be imported.
- SMPTE Wipe Transition type 'XXXX' is not supported in this release. A Cross Dissolve will be inserted.
- Interpolation type 'XXXX' is not supported in this release. Linear interpolation will be used.
- The clip 'XXXX' failed to link because the timecode extents do not match any clip in the Media Pool.
- Mismatch between specified target timecodes 'XXXX' and located file timecodes 'YYYY.'
- No overlap between specified target timecodes 'XXXX' and located file timecodes 'YYYY.'
- Clip 'XXXX' in track 'XXX' at timecode 'UNKNOWN', with reel name 'XXXX' and filename 'XXXX.'
- Clip 'XXXX' in track 'XXX' at timecode 'UNKNOWN', with reel name 'XXXX' and filename 'XXXX.'
- File not found in search directories.

At the time of writing, this feature is only available when importing AAF files.

Simple AAF Import

This section details the Import AAF, EDL, XML dialog. One procedure lets you accomplish any of the following workflows:

- Importing an AAF file and automatically conforming to and importing the media it's linked to.
- Importing an AAF file and manually choosing another set of media, presumably in a different format or resolution, with identical metadata, to conform to instead.
- Importing an AAF file that's linked to offline media derived from a camera original format, and automatically conforming it to and importing the camera original media.



You can select multiple XML, AAF, FCP XML, or EDL timelines (or any combination thereof) simultaneously with the Timeline Import dialog. The selected timelines will import sequentially, pausing after each time the OK button is pressed. This lets you adjust separate Import Settings per timeline.

Each of these workflows is possible if you choose the correct combination of options, as detailed below.

To load an AAF file and automatically link to its referenced media:

1. Do one of the following:
   - From any page, choose File > Import Timeline (Shift-Command-I).
   - Open the Edit page, right-click anywhere in the Media Pool, and choose Timelines > Import > AAF/EDL/XML/DRT/ADL/OTIO.

2 Using the file dialog that appears, find the project file you want to import, and click the file to open it. The Load AAF window appears, depending on your selection.

Options when importing an AAF file.

3 Choose the applicable options for your particular project. By default, these options are based on metadata within the file you selected.

- **Source file:** The file you selected in the previous step.
- **Import timeline:** If there are multiple sequences within the selected AAF source file, this pop-up menu lets you choose which sequence to import as a DaVinci Resolve timeline.
- **Timeline name:** The name of the Timeline you're about to create. This defaults to the name of the sequence that was exported, but you can change it.
- **Master timeline start timecode:** The timecode at which the imported timeline will start. This automatically matches the start timecode of the selected Import Timeline.
- **Automatically set project settings:** Leave this option enabled to automatically apply the frame size and frame rate settings shown in this window to the Project tab of the Config page. You can still import timelines with frame rates that differ from the project's frame rate.
- **Automatically import source clips into media pool:** Leave this checkbox enabled to automatically import the media referenced by the selected XML file into the Media Pool using the embedded file paths. If DaVinci Resolve can't locate the media at those locations, you'll be prompted to manually select a directory where the clips are located.

  Ignore file extensions when matching: Enable this checkbox to manually select a different directory of media to link to. For example, if the OTIO you're importing links to ProRes Proxy media, and you want to relink to another directory of corresponding ProRes 4444 or camera raw media.

- **Use sizing information:** Lets you import position, scale, and rotation transforms from the originating NLE via the imported AAF project file. These transforms are stored in each clip's settings in the Edit page Inspector.
- **Import log messages as COLOR markers:** Enable this checkbox to choose a marker color from the accompanying dropdown menu. These markers will be placed in the Timeline with notes describing import errors that you might want to revisit.
- **Import multi-channel audio tracks as linked groups:** Enable this checkbox to import multi-channel audio, such as stereo, 5.1, and 7.1 audio into individual mono timeline tracks that are linked together in the Fairlight page.

> For more information on Linked Groups, jump to this chapter: Setting Up Tracks, Busses, and Patching.
>
> If this checkbox is disabled, multi-channel audio will be imported into multi-channel audio tracks in the Timeline.

- **Import AAF to current timeline:** Imports the AAF to the currently loaded Timeline, instead of creating a new timeline in the media pool.

  Insert Additional Tracks: Automatically assigns new tracks to the Timeline, so the AAF referenced media does not overwrite current clips on the existing timeline.

  Insert with offset: Overwrites the AAF referenced media on the Timeline and offsets it by the amount set in timecode format.

- **Set timeline resolution to:** Two fields let you specify the width and height of the frame size you want to work at in DaVinci Resolve. The default is derived from the resolution specified in the AAF file being imported.
- **Timeline frame rate:** By default, this is derived from the frame rate of the AAF file being imported. If you're importing an AAF file into a project that already has media in the Media Pool, the Timeline frame rate is locked and cannot be changed.
- **Use drop frame timecode:** By default, this is derived from the AAF file being imported.
- **EDL frame rate:** By default, this is derived from the frame rate of the selected file.
- **Use drop frame timecode:** By default, this is derived from the frame rate of the selected file.
- **Mixed frame rate format:** This drop-down menu lets you choose the method used to conform mixed frame rates for rendering and playback. You can choose the Final Cut Pro 7 or Final Cut Pro X methods of conform. For projects imported from Media Composer, Premiere Pro, Smoke, or other NLEs, you should leave this set to DaVinci Resolve. This drop-down menu also appears in the Load AAF dialogs when you import a project.

4. After choosing all necessary settings, click OK.
5. Assuming you left Automatically import source clips into media pool enabled, if the media linked to by the AAF file is not in the expected disk location, or if you enabled the "Ignore file extensions when matching" checkbox, then another dialog appears prompting you to choose the folder within which the media for this project is stored. Do one of the following:

   - **To try to relink to media in another disk location:** Click Yes, and then navigate to the folder containing your media (all subfolders will be automatically traversed as well), select it, and click OK.
   - **To just import the Timeline with all offline clips:** Click No.

A prompt appears if all the media was not found

IMPORTANT: It's always possible to choose the top level of any volume to automatically find all media in any directories located within. But it can be an extremely time-intensive process if the volume is large and filled with multiple folders and documents.

6 If you clicked Yes to selecting another folder, then use the folder selection dialog to navigate to another folder, and click Ok. You can repeat this process as many times as needed.

Selecting the source folder for your AAF imported clips

The AAF file is now imported. A new Timeline and the referenced media files appear in the Media Pool, and you'll be able to view the open Timeline and its contents. Simple nested clips should also come through. Clips that are offline and unlinked will appear in red in both the media pool and timeline.

TIP: You can open the Edit Index and choose Filter Offline Clips from the option menu to see a list of all offline clips in the current Timeline.

Supported AAF Timeline Features

The following additional AAF timeline information will automatically be imported to DaVinci Resolve:

- **Timeline Markers:** Any timeline markers within the AAF will be imported. Timeline markers can also be exported from DaVinci Resolve to AAF for round-trip workflows.
- **Nested Clips:** DaVinci Resolve will import AAF files with simple nested clips.
- **Boris Continuum FX:** Boris Continuum FX effects and settings will be imported along with a timeline via AAF export. You'll need to have the same Continuum suite of effects installed on both machines (OFX version for DaVinci Resolve, AVX for Avid). When importing an AAF, Boris Continuum effects that were used in the original NLE will appear on each affected clip in the resulting DaVinci Resolve timeline, with all previously applied parameters available in the Inspector. The Sapphire and Mocha suites are not available for AAF import at this time.

Performing an AAF Avid Round Trip

This section walks you through the workflow for creating a project in Media Composer, transferring it to DaVinci Resolve for grading, then rendering and sending the finished project back to Media Composer.

The following workflows are covered:

- Ingesting high quality MXF-wrapped DNxHD, then round-tripping from Media Composer to DaVinci Resolve.
- Importing and editing Resolve-compatible AMA-linked media, then round-tripping from Media Composer to DaVInci Resolve.
- Transcoding AMA-linked media files into offline-quality DNxHD clips for editing, then exporting an AAF file and reconforming it in DaVinci Resolve to the original high-quality camera media.

  Media Composer can ingest media and output AAF projects in many ways. Before continuing with your project, be sure to familiarize yourself with the following procedures.

Step 1–Create a Project in Media Composer

1 Create a new project in Media Composer, ensuring the image format details match those in DaVinci Resolve. In particular, set the image format (e.g. 1080p/24), raster dimensions (e.g. 1920 × 1080) and mastering format accordingly. If you plan to send ingested or transcoded media to DaVinci Resolve for grading, set the color space to RGB 709.

> **NOTE:** This information can also be found in the Avid Project Format tab.

2 Open your project and ingest all required media into a new bin using one or both of the following methods:

Transcode media for editing: The simplest workflow for AAF import and round-trip workflows is to ingest transcoded, native MXF-wrapped DNxHD media using the Import command.

Import AMA-linked clips: You can also import AMA-linked clips, provided the media format is compatible with DaVinci Resolve. Keep in mind that not all AMA-compatible formats can be consolidated in Media Composer. To use this workflow, import AMA-linked media into a new bin using the Link to AMA File(s) command, then edit as you normally would.

Once you've ingested all required media, edit your project as usual, keeping in mind which effects are compatible with DaVinci Resolve.

For more information on effects in Media Composer to DaVinci Resolve round trips, jump to this chapter: Importing and Conforming Timelines.

Step 2–Exporting an AAF for DaVinci Resolve

When you're finished editing, export an AAF to conform the .mxf media you used in Media Composer to a DaVinci Resolve timeline. The export configuration depends on whether DaVinci Resolve and Media Composer are installed on the same system.

1. Select the sequence you want to export, then choose File > Output > Export to File.
2. In the Export As dialog, enter a name for the AAF file.
3. Choose where to save the AAF. You can save it anywhere, but if you're transferring the project to another workstation, it's recommended to save it to a folder on a removable hard drive where you store your AAF and XML files. This location can also be used to store any exported media that accompanies the AAF.
4. Click the Options button to open the Export settings.
5. Enable the AAF Edit Protocol checkbox. This exports a simplified AAF file that has better compatibility with project exchange workflows between applications.
6. Choose an option from the Export Method pop-up menu based on your workflow:

   If Media Composer and DaVinci Resolve are on the same system: Choose Link to (Don't Export) Media to export an AAF file that references the existing media in its current location. Then open the Audio Details tab and choose Link to (Don't Export) Media from the Export Method pop-up menu.

   If Media Composer and DaVinci Resolve are on different systems: Choose one of the two following export methods:

   - **Copy All Media:** Copies the entire source media file for every clip used in the sequence. This preserves each clip's relationship to its original source media file. However, using this option could potentially export a lot of media.
   - **Consolidate Media:** Copies only the media used in the sequence, making it a more efficient option for finished projects. You can specify additional handles, in frames, using the Handle Length field. If any media and handle ranges overlap, they will be combined into a single exported media file.
7. (Optional) If you're using a combination of media formats in your project that aren't compatible with DaVinci Resolve, enable the Transcode Video To checkbox and choose a compatible format from the adjacent menu. Any incompatible media in the sequence is automatically transcoded to the selected format.
8. If you're copying or consolidating media to another drive, choose Folder from the Media Destinations Video/Data pop-up menu. Enable the Use Same Folder As AAF File checkbox to save the exported media to the same folder you selected in Step 3. If you leave this checkbox disabled, click Select Folder to choose a different location.
9. Click Save, and when you return to the Export As dialog, click Save again.

   When the export is complete, Media Composer creates a duplicate sequence and duplicate media in your bin. The exported sequence is given the suffix .Exported, while each media clip is given the suffix .new. In the file system, the export folder contains the AAF file, and an Avid MediaFiles folder that contains the exported media.

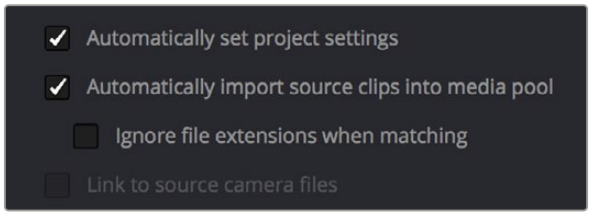
Step 3–Conforming Your AAF in DaVinci Resolve

1 Open DaVinci Resolve and create a new project.

2 You should first set DaVinci Resolve to properly read the timecode and reel number information from the AAF files that Media Composer creates. On the lower right-hand side of the DaVinci Resolve window, click the gear button to access the Project Settings > General Options > Conform Options, then do the following:

- Make sure that Use Timecode is set to Embedded in the source clip.
- Enable the Assist using reel names from the checkbox, and choose Embedding in source clip file.

Conform assistance, with reel names embedded in the source clip.



3 Click Save

4 Do one of the following:

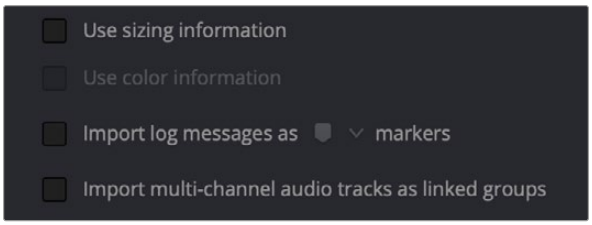
- From any page, choose File > Import Timeline > Import AAF, EDL, XML (Shift-Command-I).
- Open the Edit page, right-click anywhere in the Media Pool, and choose Timelines > Import > AAF/EDL/XML.

5 When the File Selection window opens, select the AAF file you exported from Media Composer, and click Open.

6 When the Load AAF dialog appears, the settings you choose determine which media files the AAF will be conformed to:

The Load AAF window conform options.

To conform to the transcoded or AMA-linked media files you edited: Leave the “Automatically import source clips into media pool” checkbox enabled.



To conform to a different set of camera original media files: Enable both the “Automatically import source clips into media pool” and “Link to source camera files” checkboxes. These will reference the Source Name metadata that Media Composer/Symphony embeds in exported AAF files to track the correspondence in file-naming between transcoded and camera original media.

To conform to a directory of media of your choosing: Enable both the “Automatically import source clips into media pool” and “Ignore file extensions when matching” checkboxes.

To conform to media that’s already in the Media Pool: Disable the “Automatically import source clips into media pool” checkbox. There must be clips in the Media Pool for this to work.

7 Additionally, ensure that the “Automatically set project settings” checkbox enabled.

8 There are three other options that are relevant to AAF import:

Load AAF window conform options

Use Sizing Information: (Optional) Enable this checkbox to import position, scale, and rotate transform data from the original Media Composer project into DaVinci Resolve.

Import log messages as COLOR markers: Enable this checkbox to assign colored markers along the Timeline, with notes describing import errors that may need troubleshooting at a later stage.

Import multi-channel audio tracks as linked groups: Enable this checkbox to import multi-channel audio, such as stereo, 5.1, and 7.1 audio into individual mono timeline tracks that are linked together in the Fairlight page.

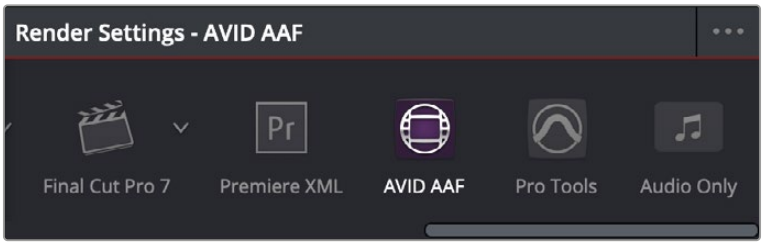
> For more information on Linked Groups, jump to this chapter: Setting Up Tracks, Busses, and Patching.
>
> If this checkbox is disabled, multi-channel audio will be imported into multi-channel audio tracks in the Timeline.

9 Click OK.

If the media is in the same location as when you exported it from Media Composer, the timeline and all its media should import.

If the location of the media files you’re conforming to has changed, you’ll need to first identify the location of the media via an additional dialog. For example, if you’ve copied the media from the portable hard drive it was originally conformed to into a faster storage volume, a file dialog will prompt you to choose the folder containing the media used by your project. If prompted, do so and click OK.

Once import is complete, the Media Pool fills with the source media used by the imported project, and the edit appears as the current Timeline in the Edit page.



Step 4–Continue Editing, Grading, and Finishing the Project

Edit the Timeline in the Edit page and grade each clip in the Color page as you would any other. If you've made editorial changes to the timeline using tools from the Edit page, your export options will change later on:

- **If you don't make editing changes:** You can use DaVinci Resolve to generate an updated version of your Avid AAF file. This preserves audio and all other unsupported effects, so that they reappear when you export a new AAF back to Media Composer. If you use this option, ensure the original AAF file you import remains in the same location.
- **If you do make editing changes:** You can use the Generate New AAF command to export an AAF of the re-edited Timeline from DaVinci Resolve back to Media Composer. This newly generated AAF file will exclude any effects that are not supported by DaVinci Resolve.

Step 5–Render Graded Media and Export a New AAF

1. When you're ready to send a graded project back to Media Composer, select the Timeline you graded and open the Deliver page.
2. Choose Avid AAF from the Presets at the top of the Render Settings to load its settings.

Selecting the Avid AAF setup for round-trip.

3. In the Format section, choose the MXF codec you want to render to.
4. In the File section, choose your file destination path for the rendered media. The location you choose depends on whether Media Composer and DaVinci Resolve are on the same computer.

   If Media Composer and DaVinci Resolve are on the same computer: Create a new folder in your Avid MediaFiles folder (Avid MediaFiles/MXF/) named with a number. Make sure you choose a previously unused number.

   If DaVinci Resolve is on a different computer using different storage: Select any directory on the same portable hard drive you'll be using to bring the media back to the Media Composer workstation from which it came.
5. You can add handles for your rendered output in the Video tab > Advanced Settings. When making changes to the File render settings, enable the Render Clip with Unique Filename checkbox so that every rendered clip has a different file name (especially since these clips may come from the same source clip).
6. In the Timeline, click Select Entire Timeline to select the entire Timeline for delivery. Go to the bottom of the Render Settings > click Add to Render Queue.
7. Click Start Render at the bottom of the Render Queue to initiate rendering.
8. The project renders, and an AAF will be exported to the same directory as the media you've rendered.

Step 6–Copy the Graded Media to Avid MediaFiles

1. For workflows where DaVinci Resolve and Media Composer are on separate workstations, locate the folder containing the media files rendered by DaVinci Resolve on the portable hard drive that was used to transfer the project, then copy it into the Avid MediaFiles/MXF/ directory.
2. Rename the directory in number format. Be sure to choose an unused number.

Step 7–Import the Graded AAF

1. Reopen the original project in Media Composer. If the media in the new directory of the Avid MediaFiles folder is in a compatible format, it will automatically be added to the internal database of media.
2. Create a new bin to contain the graded sequence you're about to import.
3. Open the new bin, then choose File > Input > Import Media, select the graded AAF file that you exported from DaVinci Resolve, and click Open.
4. As long as the media is available in the Avid MediaFiles directory, the new bin you've created should automatically fill up with the clips that were rendered out of DaVinci Resolve, and a new sequence should appear.
5. Double-click the sequence you've imported to open it into the Record monitor and Timeline, fully conformed with the color corrected clips from DaVinci Resolve. This sequence is now ready for finishing in Media Composer.

Relinking Transcoded Media to AMA Media

This workflow is useful if you've been editing transcoded, offline versions of processor- or bandwidth-intensive media, but want to send the original high-quality source media (such as ALEXA or RED raw files) to DaVinci Resolve for grading. In some situations, it may be better to reconform your sequence to the original AMA-linked media files in Media Composer before you round trip from Media Composer to DaVinci Resolve.

Step 1–Relink Your Transcoded Media to AMA-Linked Source

1. Edit a sequence using media that you've transcoded within Media Composer.
2. When you're finished, open the bin that contains your project's camera original media, and select the AMA-linked clips that correspond to the transcoded clips you've been editing.
3. Right-click the edited sequence in its bin, and choose Relink from the contextual menu.
4. When the Relink dialog appears, turn on Select items in ALL open bins. Select Tape Name or Source File Name under the Source Name settings, and leave the Create new sequence checkbox turned on.

   A new sequence is created that is now linked to the AMA-linked camera originals.

Step 2–Export an AAF File

1. Select the new sequence that was created, and choose File > Output > Export to File.
2. Type a new name, choose a location for the file, and click Options.
3. Choose AAF from the Export As menu, and choose Link to (Don't Export) Media from the Export Method menu.
4. Click Audio Details, and choose Link to (Don't Export) Media from the Export Method pop-up menu.
5. Click Save to exit the Export Settings dialog, and then click Save again to export the file.

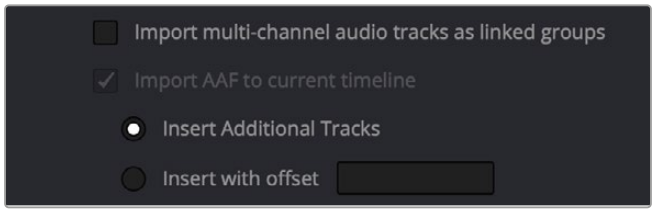
Step 3–Import the AAF, Grade, Render, and Export

1. Open DaVinci Resolve, and import the AAF file you exported into the Edit page. You'll need to manually select the media in a second dialog.
2. Grade the project as you would any other.
3. When you're done grading, use the AAF Round Trip option in the Deliver page to render the graded media into a new (numbered) directory in the Avid MediaFiles directory.
4. Open the Edit page, select the original AAF timeline you imported, right-click it, and choose Export AAF/XML. Pick a location for the file and click Save.

Step 4–Reimport the AAF into Media Composer/Symphony

Open Media Composer, and import the AAF you exported from DaVinci Resolve. Your graded sequence is now ready for finishing.

Audio AAF Import from Pro Tools



The workflow for importing audio AAF timelines from Pro Tools (or any DAW software capable of exporting AAF) is similar to that of importing a video AAF from Media Composer, as detailed at the start of this chapter. However, there are two methods you can use:

Import AAF, EDL, XML

Use the File > Import Timeline > Import AAF, EDL, XML command (Command-Shift-I) and select a Pro Tools AAF. You're presented with all the same import options as a Media Composer AAF, but will end up with an audio-only timeline, to which you can add a reference video if needed.

Import AAF to Current Timeline

Use the File > Import Timeline > Import AAF to Current Timeline command to import an audio AAF to the currently open timeline.This command triggers similar import options, along with two additional options.

Additional options available when you use the "Import AAF to current timeline" command.

When the Import AAF to current timeline checkbox is enabled, you have two options:

- **Insert Additional Tracks:** Lets you import the audio tracks starting at the beginning of the current timeline, placing them underneath the lowest track with existing audio in the Timeline.
- **Insert with offset:** Lets you import the audio tracks with a specified offset from the beginning of the Timeline.

Conforming EDL Files

DaVinci Resolve supports the CMX 3600 format for EDL import and export. The universality of EDLs is the result of their simplicity and longevity: different EDL formats have been used for decades. In DaVinci Resolve, EDLs refer to a narrow range of editorial information including clip arrangement, clip name (via embedded comments), video transitions (cuts or dissolves), and linear speed settings (percentage of fast forward or slow motion).

One limitation is that EDLs only support a sequence of shots on a single video track. To move projects with multiple tracks of audio and video: Export each track as a separate EDL from the originating application, right-click the timeline you want to import them into in the Media Pool, then use Timelines > Import > EDL to New Track to import each EDL into a new track of a single timeline in DaVinci Resolve. This is also detailed later in this chapter.

NOTE: While the EDL format supports a variety of SMPTE-defined video transition codes, all EDL transitions are turned into cross dissolves of identical duration in DaVinci Resolve.

If you're not familiar with the EDL format, each edit appears as a numbered event that contains the reel number, edit type, source timecode (In and Out points), and record timecode (In and Out points). Here's a sample of a simple four event EDL:

```
TITLE:   Pool Shark Edit
FCM: NON-DROP FRAME
001  REEL_ONE AA/V  C        10:59:23:01 10:59:28:16 01:00:00:00 01:00:05:15
002  REEL_ONE AA/V  C        11:39:48:15 11:39:51:13 01:00:05:15 01:00:08:13
003  REEL_ONE AA/V  C        13:16:30:21 13:16:34:19 01:00:08:13 01:00:12:11
004  REEL_ONE AA/V  C        14:09:43:16 14:09:44:20 01:00:12:11 01:00:13:15
```

Since DaVinci Resolve was originally designed to work by importing and exporting EDLs, you have several methods for importing projects using EDLs. In all cases, you must first add the media referenced by that EDL to the Media Pool before you can import its EDL.

The three primary workflows are:

- **Conforming EDLs to individual media files:** Importing an EDL that references a collection of discrete media files that have already been imported into DaVinci Resolve.
- **Preconforming, or "notching," a "flattened" master media file using an EDL:** Importing an EDL that references a "flattened" master media file. Flattened master media files are created when an entire sequence is exported from an NLE as a single self-contained media file.
- **Importing an EDL directly to a new track of an existing edit:** If you're importing a multi-track video project and the only means of doing so is using EDLs, you should first export each track of the source project as an individual EDL, and then import each EDL into DaVinci Resolve directly into additional tracks of the same timeline. This is also useful for workflows where effects clips are being managed on a separate track assembled elsewhere, that you can then import directly into a graded timeline to place many new effects clips all at once.

You can select multiple XML, AAF, FCP XML, or EDL timelines (or any combination thereof) at the same time using the Timeline Import dialog. The selected timelines will import sequentially, pausing each time the OK button is pressed. This lets you adjust separate Import Settings for each timeline.

The following section explores the different ways that EDLs can be used in DaVinci Resolve.

EDL Export of a Project and Its Media

When using EDL workflows, you must ensure that every clip in your edited sequence—and every source media file it's linked to—has an appropriate reel number/reel name, and true timecode written into that file. When conforming EDLs, DaVinci Resolve requires reel names and accurate timecode to successfully conform the imported EDL timeline to media in the Media Pool.

To export an EDL that can be easily conformed by DaVinci Resolve, each NLE has particular settings that you should use. The primary supported format is CMX 3600, although DaVinci Resolve also supports the DEDL format exported by both Smoke and Flame. Also, most editing applications let you choose which video and audio tracks you want to export, and how to handle the start timecode for the selected sequence of clips you're exporting. In general, ensure that the exported start timecode matches that of your sequence timeline.

There are other details that vary by application. For example, when exporting an EDL from Media Composer via Tools > List Tool, you should ensure that the Active Setting is set to Default EDL, and that the Output Format is set to CMX_3600.

When exporting an EDL from Premiere Pro, you can choose to enable Use Source File Name and Include Transitions. When exporting an EDL from the legacy Final Cut Pro 7, ensure you set Reel Conflicts to Generic Edits, and enable the File Names checkbox.

Most applications provide optional settings, such as including EDL notes—but for a cleaner, more readable EDL, we recommend disabling these settings.

Conforming EDLs to Individual Media Files

One advantage of working with discrete media files is that they are the “purest” version of the media, without any effects (such as dissolves or superimpositions) “baked” into the visuals that complicate the grading process.

1 Before importing media, go to the Project Settings > Master Settings panel > Timeline frame rate pop-up menu and ensure you set a frame rate that matches your project and media. Otherwise, the EDL’s timecode will be misinterpreted.

2 Open the Media page and use the Media Storage browser to locate the media to add to the project. Then add it to the Media Pool by right-clicking the enclosing directory and choosing one of the following commands:

Add Folder into Media Pool: Adds all compatible media files within that folder to the Media Pool. Subfolders are not traversed.

Add Folder and SubFolders into Media Pool: Adds all compatible media files from that folder, and all subfolders within that folder, to the Media Pool.

Add Folder Based on EDLs into Media Pool: Prompts you to choose an EDL. Only media referenced by that EDL is imported, and only the selected folder is searched for that media.

Add Folder and SubFolders Based on EDLs into Media Pool: Prompts you to choose an EDL. Only media referenced by that EDL is imported, and the selected folder and all subfolders are searched for that media.

> **TIP:** Use the “Add Folder...Based on EDLs” command to add exactly what you need to the Media Pool. This helps you to avoid instances where terabytes of unmanaged source media go unused.

3 Do one of the following:

- From any page, choose File > Import Timeline (Shift-Command-I).
- Open the Edit page, right-click anywhere in the Media Pool, and choose Timelines > Import > AAF/EDL/XML/DRT/ADL/OTIO.

A window appears, prompting you to Select a file to import.

4 Navigate to the EDL file you want to use, select it, and click Open. The Load EDL window appears.

5 Choose the options that are applicable to your particular project. Greyed out options are not editable—either because they’re not applicable, or are not defined by the Project Settings that are currently applied. The options you can set include:

Source File: The file you selected in the previous step.

Timeline name: The name of the timeline you’re about to create. This defaults to the name of the EDL file you selected, but you can change it—for example, if this is a new version of the edit, and you’d like to add the import date.

Automatically set project settings checkbox: Enable this option to overwrite the frame size setting in the Project Settings > Master Project Settings panel. You can’t overwrite the timeline frame rate when importing an EDL.

Set timeline resolution to: Two fields let you specify the width and height of the frame size you want to work at in DaVinci Resolve. This defaults to your project settings, but can be overridden by enabling the Automatically set project settings checkbox.

EDL frame rate: Choose the frame rate of the sequence that you exported as an EDL. If you set the timeline frame rate to 24 frames per second (fps) and the EDL frame rate to 30 fps, you can use this option to convert the EDL frame rate from 30 fps to 24 fps. This is useful when an offline edit is done at 30 fps with media using 3:2 pulldown. Note that 25 fps to 24 fps conversion is not supported.

Use drop frame timecode checkbox: Only enabled if the EDL frame rate pop-up menu is set to 30 fps. Turn this on if your EDL uses drop-frame timecode.

6 Once you're done choosing your options, click OK.

The EDL is imported, a new timeline appears highlighted in the Media Pool—and if you're in the Edit page, its corresponding sequence of clips appears in the Timeline Editor. Clips that could not be linked to a corresponding file in the Media Pool appear with a red thumbnail to indicate that they're unconformed.

Preconforming "Flat" Media Files to EDLs

Preparing an edited sequence for grading alongside the individual clips of each media file is time-consuming work, especially for effects-intensive projects. (And if your project has no effects, this might well be an unnecessary step.)

In such cases, it's simpler and quicker to export a flattened master media file that can be split into its individual clips in DaVinci Resolve. This workflow is similar to a more traditional tape-to-tape workflow, except that you're working from a digital master instead of a tape-based master.

To get started , use the Preconform button in the Edit page to split a single master file that you've imported into the Media Pool back into individual clips in a new timeline.

To preconform a flattened master media file to an EDL:

1 Open the Media page, use the Media Storage browser to navigate to the flattened master media file that you exported containing the entire program, and double-click to add it into the media pool.

2 Right-click anywhere in the background of the media pool, and choose Timelines > Import > Preconformed EDL.

3 In the Select an EDL file dialog, navigate to the EDL that matches the flattened master media file you had exported, select it, and click Open.

4 In the Parse preconform options dialog, give the new timeline a name, and click OK.

A new Timeline appears in the Media Pool list, and opening it in the Edit page shows the flattened media file with edits added to its video track that correspond to those from the selected EDL, ready for further editing and grading. The audio is left uncut, on the premise that you're probably focused on grading the visuals in this workflow, and not on re-editing the audio.

Override Input Color Space of Clips in Preconform Workflows Using Color Management

When you preconform a flattened master media file using an EDL with the File > Import Timeline > Pre-conformed EDL command, and your project has Resolve Color Management or ACES enabled, you can now independently change the Input Color Space of each clip in the resulting Timeline.

To do so, open the Color page, right-click the clips you want to customize, and choose an option from the Input Color Space submenu of the contextual menu.

This is useful in workflows where you've received a flattened media file that was output with clips in different color space. One example is mixing Rec. 709 media with log-encoded clips of different kinds.

Conforming "Flat" Media Files Using Split and Add

The second method of conforming an EDL to a flattened file is by using the Split and Add command in the Media page. This splits one or more master media files into individual clips that match those of an EDL. You can then import the EDL itself in the Edit page.

This method is useful if you have clips in different folders or volumes that need to be conformed to a single EDL. For example, the majority of the first reel of a program may have been exported as a single flattened file, but the corresponding EDL may require an additional folder of effects clips be added to the Media Pool to be fully conformed.

To split a flat media file in the Media page and import its EDL in the Edit page:

1. Before you import any media, go to the Project Settings > Master Settings panel > Timeline frame rate pop-up menu, and ensure you set a frame rate that matches your project.
2. Open the Media page and use the Media Storage browser to navigate to the flattened master media file that contains the entire program.
3. Select the flattened media file, right-click it, and choose Split and Add into Media Pool.
4. In the Select EDL files for splitting clips dialog, navigate to the EDL that matches the flattened master media file, select it, and click Open.
5. Select the frame rate of the project from the File Conform Frame Rate dialog. This frame rate should be identical to the Timeline frame rate you set in Step 1.
6. Choose the appropriate options in the Enter handle size for splitting dialog:

   Handle size in number of frames: Enter a number of frames to be added as handles to the first and last frame of the clip. This is useful if you're using the Split and Add into Media Pool command to import only the referenced sections of a directory of individual media files.

   Split Unreferred Clips: Useful if the referenced media files include segments that aren't "referred to" by any events within the EDL used to split them. Enabling this checkbox adds all such unreferred clip segments to the Media Pool as separate clips for later use (if needed).

7. Click Split & Add. The Media Pool is then populated with individual segments of the flattened master media file, each of which matches an event in the EDL you used to split it.

8 To import the corresponding EDL to create a timeline with this media, do one of the following:

- From any page, choose File > Import AAF, EDL, XML (Shift-Command-I).
- Right-click anywhere in the background of the media pool, and choose Timelines > Import > AAF/EDL/XML.

9 In the Choose a file to import dialog, navigate to the EDL that matches the flattened master media file, select it, and click Open.

10 Choose whatever options are necessary from the Load EDL dialog (the default settings should work fine), and click OK.

The Master Timeline and your newly imported timeline will appear in the media pool. At the same time, the Conform EDL list will update with the events from the imported EDL, and the Timeline editor shows the edited clips, ready for grading. Clips that could not be linked to a corresponding file in the Media Pool appear with a red x to indicate that they're unconformed.

Importing an EDL to a New Track

This last procedure describes how to add an EDL as an additional video track to an existing timeline, instead of an individual new timeline. There are many reasons you might want to do this. For example, if you use multiple EDLs to move a multi-track project from an application that can't export AAF or XML files supported by DaVinci Resolve, you can export each track of the source project as a separate EDL, then import each one into the same timeline as an additional track.

This workflow is also useful when effects clips are being managed on a separate track assembled elsewhere. You can import them directly into a graded timeline, making it easy to add multiple effects clips at once.

To import an EDL to a new track of an existing timeline:

1 Either import the media referenced by the EDL into the Media Pool before importing the EDL, or add the media after the EDL has been imported.

2 Open the Edit page, select a timeline in the Media Pool, then right-click it and choose

3 Timelines > Import > EDL to New Track. You'll be prompted to Choose a file to import.

4 Navigate to the EDL file you want to use, select it, and click Open.

5 A new video track is created above the existing tracks, and events from the selected EDL are added based on their record timecode positions. If you imported the required media at the start of this procedure, that media should be automatically conformed. Otherwise, import the required media files into the Media Pool to conform the clips.

Conforming OTIO Files

DaVinci Resolve supports the Open Timeline IO (OTIO) format for importing and exporting timelines between applications. OTIO is an open source media and timeline interchange format created by the Academy Software Foundation. It's application- and platform-agnostic, so you can pass your timeline and its media assets between programs with more compatibility than AAF or XML.

Exporting OTIO for use by DaVinci Resolve is straightforward, and there really aren't any settings you need to manage when exporting an OTIO file other than deciding if you want to export the Timeline only (.otio), or the Timeline and all its associated media (.otioz).

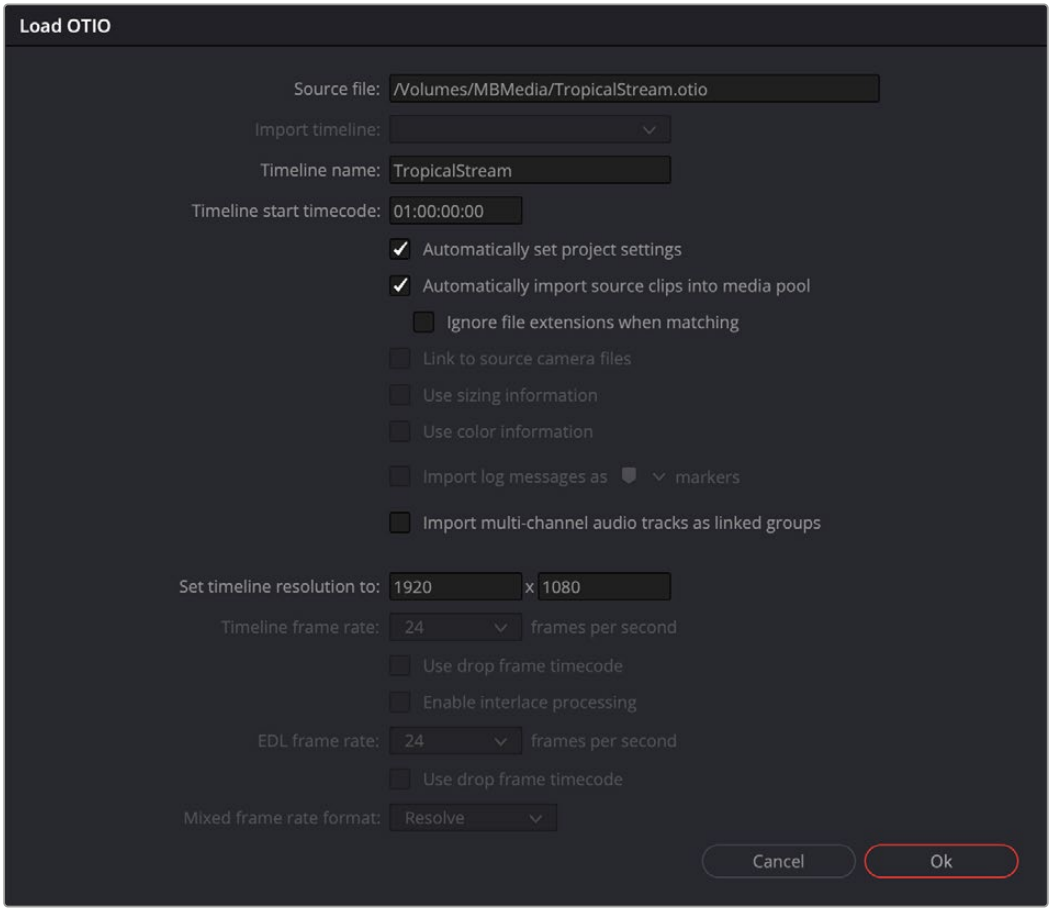
There are two different OTIO formats supported by DaVinci Resolve.

.otio: These files contain just the metadata about the timeline and no associated media. They are small, portable, and require the end user to link the Timeline to their own copies of the media.

.otioz: These bundle files contain both the Timeline metadata and all of the Timeline's media assets zipped together into one file. As a result this file can be very large, as it contains the full length media files of all assets used in the Timeline. However, it assures that whoever imports the file has all the media needed and is linked automatically to replicate the Timeline on their machine.

Importing OTIO Project Files

This section covers the Import OTIO dialog in much more detail. One procedure lets you accomplish any of the following workflows:



- Importing an .otioz file automatically and its associated media.
- Importing an .otio file and automatically conforming to and importing the media it's linked to.
- Importing an .otio file and manually choosing another set of media, presumably in a different format or resolution, with identical metadata, to conform to instead.
- Importing an .otio file that's linked to offline media derived from a camera original format, and automatically conforming it to and importing the camera original media.

  You can select multiple XML, AAF, FCP XML, or EDL timelines (or any combination thereof) simultaneously with the Timeline Import dialog. The selected timelines will import sequentially, pausing each time the OK button is pressed. This lets you separately adjust the Import Settings per timeline.

  Each of these workflows is possible if you choose the correct combination of options, as detailed below:

To load an OTIO file and automatically link to its referenced media:

1. Do one of the following:
   - From any page, choose File > Import Timeline (Shift-Command-I).
   - Open the Edit page, right-click anywhere in the Media Pool, and choose Timelines > Import > AAF/EDL/XML/DRT/ADL/OTIO.
2. Using the file dialog that appears, select the project file you want to import, then press the Open button. The Load OTIO window appears, depending on your selection.

Options when importing an .otio file.

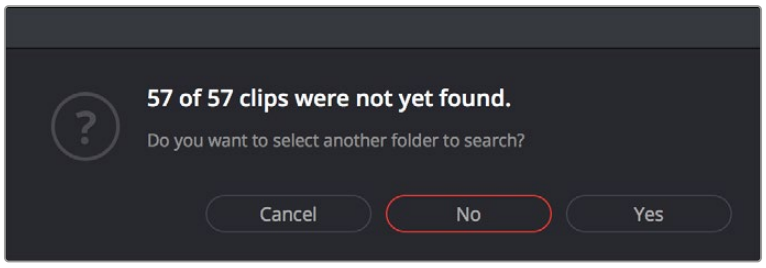
3 Choose the options that are applicable to your project. By default, these options are based on metadata within the file you selected.

- **Source file:** The file you selected in the previous step.
- **Timeline name:** The name of the Timeline you're about to create. This defaults to the name of the sequence that was exported, but you can change it.
- **Timeline start timecode:** The timecode at which the imported timeline will start. This automatically matches the start timecode of the selected Import Timeline.
- **Automatically set project settings:** Leave this option enabled to automatically apply the frame size and frame rate settings shown in this window to the Project tab of the Config page. You can still import timelines with frame rates that differ from the project's frame rate.
- **Automatically import source clips into media pool:** Leave this checkbox enabled to automatically import the media referenced by the selected XML file into the Media Pool using the embedded file paths. If DaVinci Resolve can't locate the media at those locations, you'll be prompted to manually select a directory where the clips are located.

  Ignore file extensions when matching: Enable this checkbox to manually select a different directory of media to link to. For example, if the OTIO you're importing links to ProRes Proxy media, and you want to relink to another directory of corresponding ProRes 4444 or camera raw media.

- **Import multi-channel audio tracks as linked groups:** Enable this checkbox to import multi-channel audio, such as stereo, 5.1, and 7.1 audio into individual mono timeline tracks that are linked together in the Fairlight page.

For more information on Linked Groups, jump to this chapter: Setting Up Tracks, Busses, and Patching.

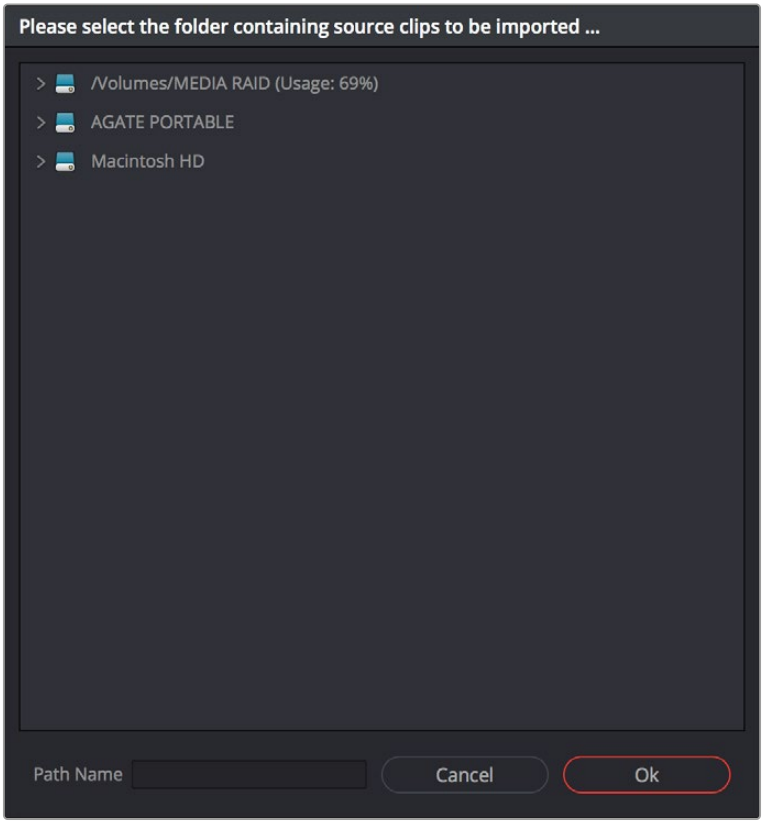


If this checkbox is disabled, multi-channel audio will be imported into multi-channel audio tracks in the Timeline.

- **Set timeline resolution to:** Two fields let you specify the width and height of the frame size you want to work at in DaVinci Resolve. By default, this is derived from the specified resolution in the OTIO file being imported.
- **Timeline frame rate:** By default, this is derived from the frame rate of the OTIO file being imported. If you're importing an OTIO file into a project that already has media in the Media Pool, the Timeline frame rate is locked and cannot be changed.
- **Use drop frame timecode:** By default, this is derived from the OTIO file being imported.
- **EDL frame rate:** By default, this is derived from the frame rate of the selected file.
- **Use drop frame timecode:** By default, this is derived from the frame rate of the selected file.
- **Mixed frame rate format:** From this pop-up menu, choose the method used to conform mixed frame rates for rendering and playback. You can choose the Final Cut Pro 7 or Final Cut Pro X methods of conform. For projects imported from Media Composer, Premiere Pro, Smoke, or other NLEs, you should leave this set to DaVinci Resolve. This pop-up menu also appears in the Load OTIO dialogs when you import a project.

4 After choosing all necessary settings, click Ok.

5 Assuming you left Automatically import source clips into media pool turned on, and the media linked to by the OTIO file is not in the expected disk location—or you enabled the Ignore file extensions when matching checkbox—another dialog will prompt you to choose the folder within which the media for this project is stored. Do one of the following:



- **To try to relink to media in another disk location:** Click Yes, and then navigate to the folder containing your media (all subfolders will be automatically traversed as well), select it, and click OK.
- **To just import the Timeline with all offline clips:** Click No.

A prompt appears if all the media was not found.

IMPORTANT: It's possible to choose the top level of any volume to automatically find all media in any directories located within. But it can be an extremely time-intensive process if the volume is large and filled with multiple folders and documents.

6 If you clicked Yes to selecting another folder, then use the folder selection dialog to navigate to another folder, and click Ok. You can repeat this process as many times as needed.

Selecting the source folder for your OTIO imported clips.

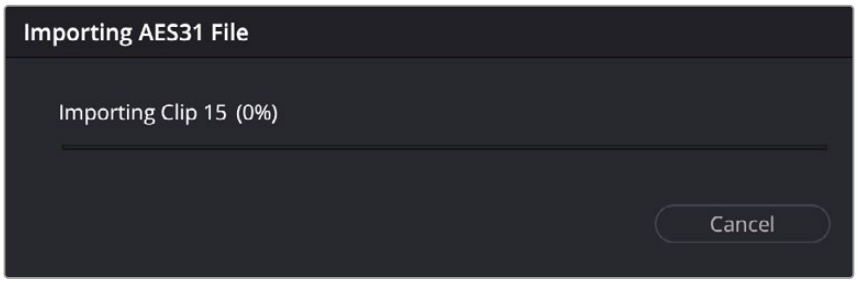
The OTIO file is now imported. A new Timeline and the referenced media files appear in the Media Pool, and you'll be able to view the open Timeline and its contents. Clips that are offline and unlinked will appear in red in both the media pool and timeline.

TIP: To view a list of all offline clips in the current Timeline, open the Edit Index and choose Filter Offline Clips from the Option menu.

Importing .otioz Files

The process for importing .otioz files is the same as above, with one difference:

If an .otioz file was selected for import, the media assets will unzip themselves into the same folder as that .otioz file, and automatically link themselves. Ensure you have enough storage space for this.



Conforming ADL Files

DaVinci Resolve supports the AES31 Audio Decision List (.adl) format for import. ADL is a timeline interchange format created by the Audio Engineering Society. It's designed to be application- and platform-agnostic, letting you transfer your timeline and its media assets between digital audio workstations.

At the time of writing, DaVinci Resolve does not export ADL files.

Importing ADL Project Files

This section covers the import of ADL files with one simple procedure.

The AES31 Audio Decision List (.adl) import progress dialog box.

To import and Audio Decision List (.adl) file and automatically link to its referenced media:

1. Do one of the following:
   - From any page, choose File > Import Timeline (Shift-Command-I).
   - Open the Edit page, right-click anywhere in the Media Pool, and choose Timelines > Import > AAF/EDL/XML/DRT/ADL/OTIO.
2. Using the file system dialog that appears, find the .adl project file you want to import, select the file, and press the Open button.
3. DaVinci Resolve will import the timeline, and proceed to import all the associated .wav files with the ADL. An Import AES31 File dialog box will show you the progress of the import.

   Unlike other Timeline Import formats, there are no additional controls for importing an ADL file. The timeline and associated media are imported directly to the open bin in the Media Pool.

Chapter 23

Using Scene Detection

If you have a program that someone has delivered as a single media file, with no accompanying EDL with which to split it up, you can use DaVinci Resolve's Scene Detect window to automatically find the cut points and split it into individual clips, ready for grading.

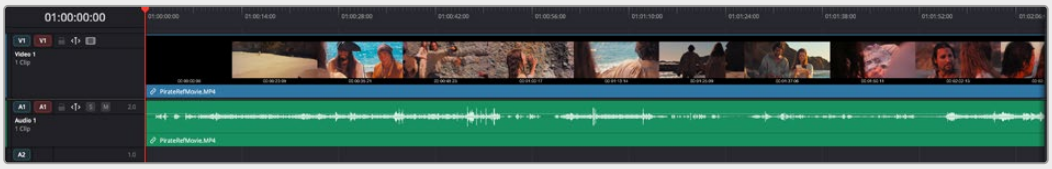
Scene Cut Detection on the Timeline (Studio Version Only)

If you need to break down a previously edited video into its component clips for re-editing or color correction, you can now do so directly in an Edit or Cut page Timeline. Using the DaVinci Neural Engine, DaVinci Resolve can automatically analyze and split up an edited video into individual clips.

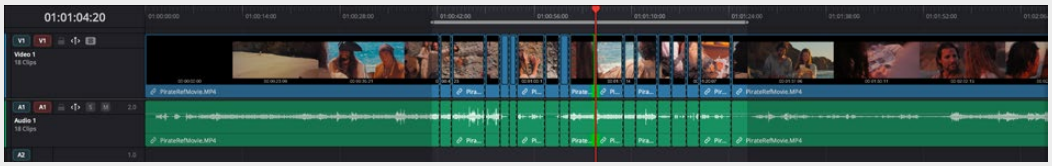
If you prefer, you can continue to use the original Scene Cut Detection tool found in the Media Pool and described later in this chapter.

To use Scene Cut Detection on the Timeline:



1. Put one or more clips you want to split on the Timeline. If you have clips on more than one video track, you can selectively lock/unlock tracks to limit the scene detection to specific video tracks. Additionally, you can limit Scene Cut Detection to just a portion of a clip by setting In and Out points on the Timeline around the section you want to analyze.
2. Choose Timeline > Detect Scene Cuts.

   A dialogue box appears, “Detecting scene cuts in clips x of x.” This process can take some time, depending on the length, number, and complexity of the clips you’ve selected. When the Scene Cut Detection has finished, the clip you selected will be broken up into a number of through edits that now can be used as independent clips.



Checking and Fixing Your Results

If the Neural Engine has made an error, you can fix it manually by navigating to the cut using the Up and Down Arrow keys to go back and forth in the Timeline, and by then doing one of the following:

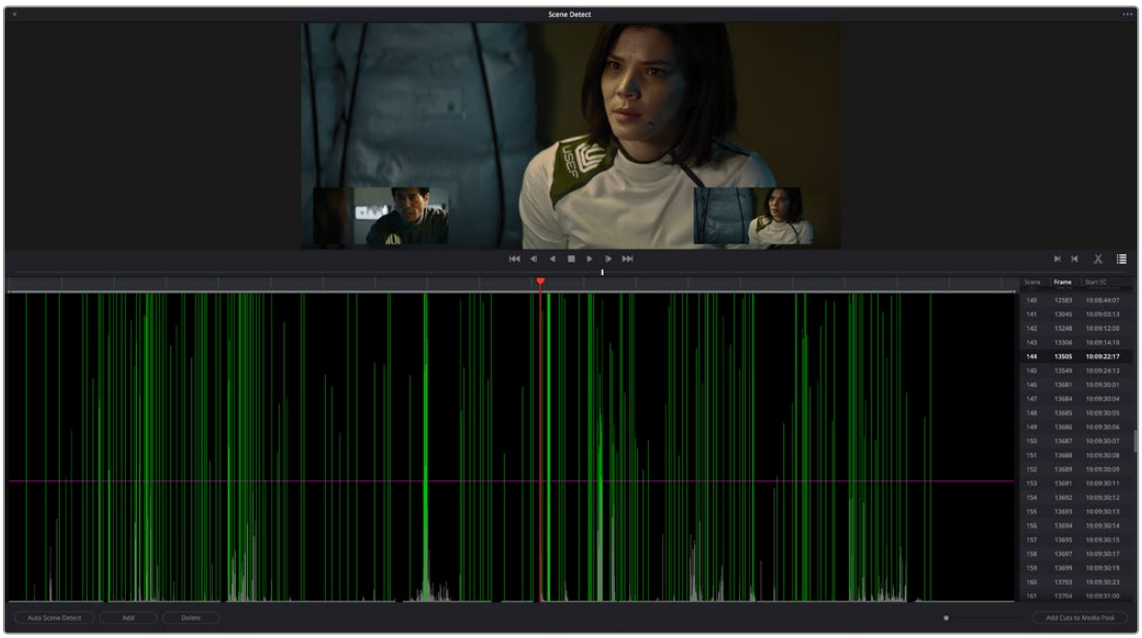
- **To remove a Cut:** Click the through edit to select it, and press the “Delete” key.
- **To make a New Cut:** Place the timeline indicator at the cut point, and choose Timeline > Split Clips (Command-\).

A single clip of a finished edit, consisting of multiple cuts before the Detect Scene Cuts command

Multiple individual clips extracted from the edited clip via Detect Scene Cut; the operation has been contained by the In and Out points, and one of the resulting through edits has been highlighted in green.

Scene Detection in the Media Page

You can still perform automatic scene detections using the original tools in the Media page. When using the original Media page Scene Detection, it's important to note that the analysis and splitting of the selected clip is done in the Media Storage panel, before the clip is added to the Media Pool.



To open a clip into the Scene Detect window:

1. Open the Media page, and use the Media Storage browser to find and select the clip you need to split apart. Do not add a clip you want to use scene detection on to the Media Pool first. You need to use Scene Detection before the clip has been imported.
2. Right-click the file and choose Scene Cut Detection.
3. The Scene Detect window opens up, containing the clip you selected.
4. Press the Auto Scene Detect button in the lower left of the interface.

   DaVinci Resolve scans through the selected scene and analyzes the media for possible cut points.

The Scene Detect Window Interface

The Scene Detect window is divided into three main areas, the viewers, the Graph, and the Cut List. Together, these controls let you analyze the movie, examine the automatically found cuts, and manage the Cut List in preparation for sending back to your project.

Scene Detect window

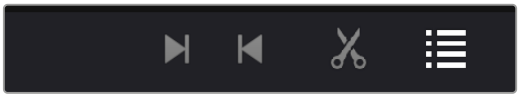
The Scene Detect Viewers

A set of three viewers appear at the top of the Scene Detect window, one main viewer and two smaller picture-in-picture (PiP) viewers. These three viewers are designed to make it easy to test whether the playhead in the Scene Detect Graph is on a cut point or not. The leftmost PiP viewer is the last outgoing frame of a detected cut point. The main viewer shows the first incoming frame of that cut point, and the rightmost PiP viewer shows the second incoming frame of that cut point.

If the playhead in the Scene Detect Graph is directly on top of an edit point, the leftmost viewer should show a completely different frame than the center and rightmost viewers, which should be very similar to one another. If this is the case, you have found a correct cut point. This can be seen in the following example.

The Scene Detect viewers show the last frame of the outgoing clip, and the first two frames of the incoming clip. If the left viewer is significantly different than the main and right viewers, this indicates a correct cut point.

If all three viewers appear to display a continuous series of frames, then you're not looking at a cut point.



No scene cut here as all images are almost the same

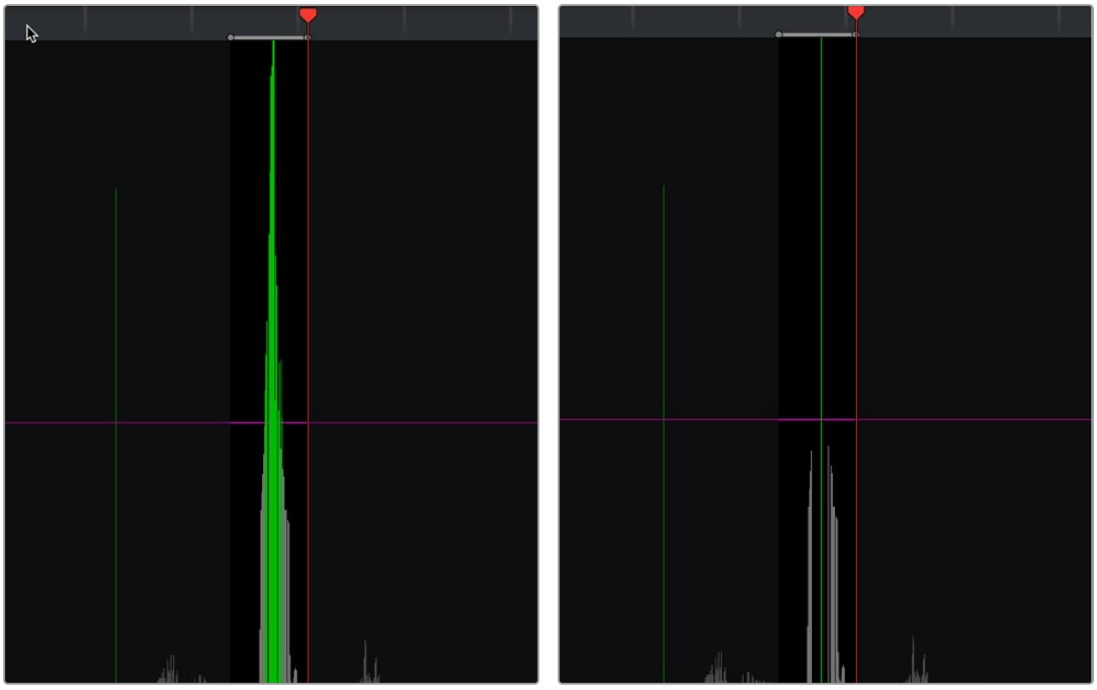
Underneath the viewers are a series of controls.

The Scene Detect viewer transport controls

The In, Out, Prune, and Show Cut List controls

- **Transport controls:** A set of seven transport controls include first frame, step back, play reverse, stop, play forward, step forward, and last frame.

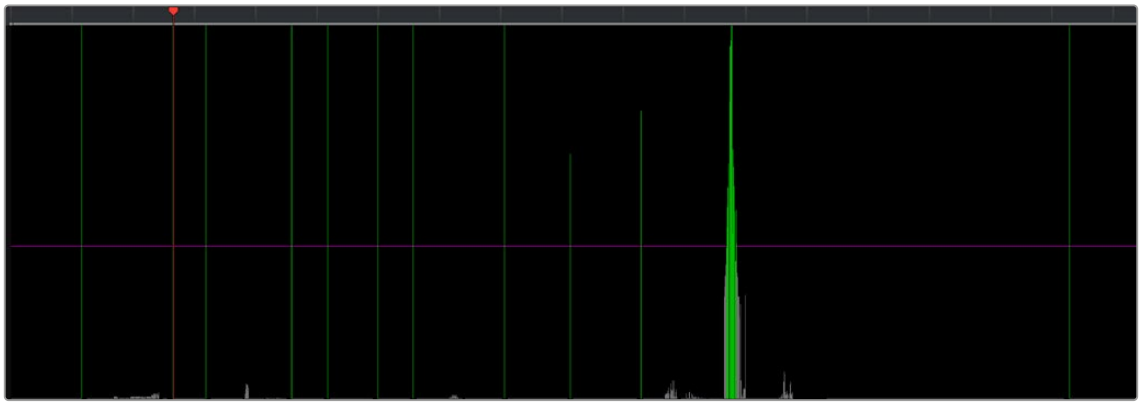
In: Lets you set an In point, with which to define a range of the Scene Detection Graph to prune.



Out: Lets you set an Out point, with which to define a range of the Scene Detection Graph to prune.

Prune: If you've identified a large number of false positive scene cuts (for example, a cluster of cuts corresponding to a dissolve from one shot to another), use the In and Out buttons to surround the undesirable range of scene cuts in the Scene Detect Graph, and then click Prune to eliminate all scene cuts between these points that are within one frame of another scene cut. Within the group of identified cuts, the highest probability cut will remain while the other cuts are deleted.

Show Cut List: Shows and hides the Cut List, which shows the currently detected scene cuts.



(Left) Isolating scene cuts to prune with In and Out points, (Right) The result of clicking the Prune button to eliminate all unwanted scene cuts but one

The Scene Detect Graph

The majority of the bottom half of the Scene Detect window, to the left, consists of the Scene Detect Graph, which shows the scene detect analysis results after you've clicked the Start button.

Frames that DaVinci Resolve thinks are cut points appear as green vertical "scene cuts" of various heights. The height of each scene cut corresponds to the likelihood that frame is really an edit point, and not a swish pan, sudden jump in the motion of the frame, or abrupt change in color or lighting, all of which can fool the scene detection algorithm.

A horizontal magenta confidence bar lets you choose the threshold of confidence required for scene cuts to be added to the Cut List. If you drag this bar up above any shorter scene cuts of low confidence, those lines turn gray and are omitted from the Cut List.

Detection graph displays potential scene cuts

NOTE: Dissolves and other transitions are not automatically detected, although dissolves most often appear as a triangular cluster of lines peaking in the middle.

Four controls appear underneath the graph.

Auto Scene Detect: This initiates the scene cut detection process.

Add: Lets you manually add a scene cut at the current position of the playhead. Sometimes two adjacent clips with similar color and lighting will appear to be a single clip to the scene detection algorithm. This lets you add scene cuts at frames where they weren't initially found.

Delete: Lets you manually delete a scene cut located at the position of the current frame indicator within the graph.

Zoom slider: Lets you zoom into and out of the Scene Detect Graph to see more or less detail as you examine the results.

Cut List

At the lower right of the Scene Detect window, the Cut List displays one entry for each of the scene cuts that intersect the confidence bar.

Three columns show each cut's order number, frame number, and timecode value. You can select items in the Cut List to evaluate each cut using the three viewers above. Whenever you select a new item in the Cut List, the playhead jumps to that frame in the Scene Detect Graph.

To select items in the Cut List:

- Click any item in the Cut List.
- Press N (next) or the Down Arrow to select the next item down.
- Press P (previous) or the Up Arrow to select the next item previous.

As you move up and down the list, you can delete items that you can confirm aren't real cuts using the viewers above. If it's a long list and you don't have time to check it all at once, it can be saved for later recall using commands found in the Scene Detect Options drop-down menu.

Once you're finished checking the list and are satisfied that each cut is accurate, you can use it to split the media file into individual clips in the Media Pool by clicking "Add Cuts to Media Pool," located immediately below.

The Cut List shows all currently detected cuts

The Scene Detect Options Drop-down Menu

The Options drop-down menu, located at the upper right-hand corner of the Scene Detect window, contains a variety of commands.

- **Reset Zoom:** Sets the zoom level of the Scene Cut Graph such that the entire clip fits within the current width.
- **Reset Marks:** Clears the current In and Out points you've set.
- **Prune Scene Cuts:** If you've identified a large number of false positive scene cuts (for example, a cluster of cuts corresponding to a dissolve from one shot to another), use the In and Out buttons to surround the undesirable range of scene cuts in the Scene Detect Graph, and then click Prune Scene Cuts to eliminate all scene cuts between these points that are within one frame of another scene cut. Within the group of identified cuts, the highest probability cut will remain while the other cuts are deleted.
- **Save Scene Cut:** Saves the current scene cut detection information, including the probability metadata, to disk. Scene Cut files use the file extension .sc and can be reimported later to continue working on a lengthy scene detection task.
- **Load Scene Cut:** Imports an existing .sc file into the Scene Detect window. You must first open the media file you're working on into the Scene Detect window before you can load a Scene Cut file.

- **Save EDL:** Exports the Cut List as a CMX-style EDL.
- **Load EDL:** Loads a CMX-style EDL into the Cut List, letting you use the cut information from the EDL during the Scene Cut Detection process.
- **Auto Cue:** When enabled, the playhead jumps to each new scene cut as it's detected when you initiate scene detection. This lets you evaluate each scene cut as it's found using the three viewers above.

An Example Scene Detect Workflow

This section describes an ideal workflow for using scene detection without an EDL.

To scene detect a media file:

1. Locate a media file to scene detect using the Media Storage browser of the Media page.
2. Verify its frame rate and if it uses drop-frame timecode, and make sure that the "Timeline frame rate" matches the "Use drop frame timecode" parameter in the Master Settings panel of the Project Settings. These parameters are not automatically set if the project already has media in the Media Pool, and you may have problems if they don't match your media.
3. Right-click the media file, and choose Scene Cut Detection.
4. When the Scene Detect window appears, click the Options drop-down menu and choose Auto Cue (it should be on by default, but it's always good to check), then click Auto Scene Detect.

   Scene detection initiates, and you can evaluate each scene cut as it's found. If any scene cut looks wrong (three sequential frames in a row), note its place in the list for future evaluation.
5. When DaVinci Resolve has finished scene detection, move the playhead to some of the shorter scene cuts, and verify if they're actual cuts by checking the three viewers above. If the frames being displayed are "different-same-same," then it's a genuine cut.

   If the frames being displayed are "same-same-same" (actually three sequential frames), then these aren't cuts.

   TIP: Fast camera motion such as whip pans, sudden changes in lightness such as camera flashes, or even film coming up to speed causing the shutter to "flash" can confuse the analysis, which looks for large changes in the image.
6. If there are numerous low-confidence scene cuts that you've verified aren't cuts, drag the magenta confidence bar so that the low-confidence scene cuts fall below it to automatically remove them all from the list.
7. Next, you may want to move down the Cut List, evaluating each scene cut to verify that it's correct. Click the first scene cut in the list, check it, then press the keyboard Down Arrow key to select the next list item down, check it, and repeat until you've checked every item in the list. If you need to move back up the list, you can press the Up Arrow key to select the previous list item. If any item is not a cut point, click the "Delete" button at the bottom left corner of the Scene Detect window to eliminate that scene cut.
8. If there are sections in the Scene Detect Graph with dense groups of spikes, these are probably frames with types of motion that confused the Scene Cut Detector. To delete this unwanted "noise" in the data, use the In and Out buttons to isolate the data, and then click "Prune" to delete these unwanted scene cuts.

9 If there's a gap between any two scene cuts that you're positive should have another scene cut, then scrub the playhead or use the transport controls to find the missing cut, and click the "Add" button at the bottom left corner of the Scene Detect window to add another scene cut.

> **TIP:** Adjacent shots with very similar ranges of color and contrast may sometimes go undetected by the scene detection algorithm. If you know of scenes in the media you're analyzing that are like this, you may want to scrub through them a bit more carefully to make sure you're not missing anything. However, if you find you've missed a cut later, you can always use the Split Clip control in the Edit page timeline to add a new edit point.

10 When you're confident that the Cut List is accurate, split the media file into individual clips in the Media Pool by clicking "Add Cuts to Media Pool."

11 When the Conform Settings dialog appears, click OK if you checked your settings in step 2.

12 Close the Scene Detect window.

> The individually cut up clips of the media file you analyzed now appear in the Media Pool, and you can edit the entire sequence of clips into a new Timeline in order, ready for grading.

Chapter 24

Ingesting From Tape

DaVinci Resolve is capable of capturing media from tape using a compatible video input device, such as a Blackmagic Design UltraStudio or DeckLink card. Device control is supported.

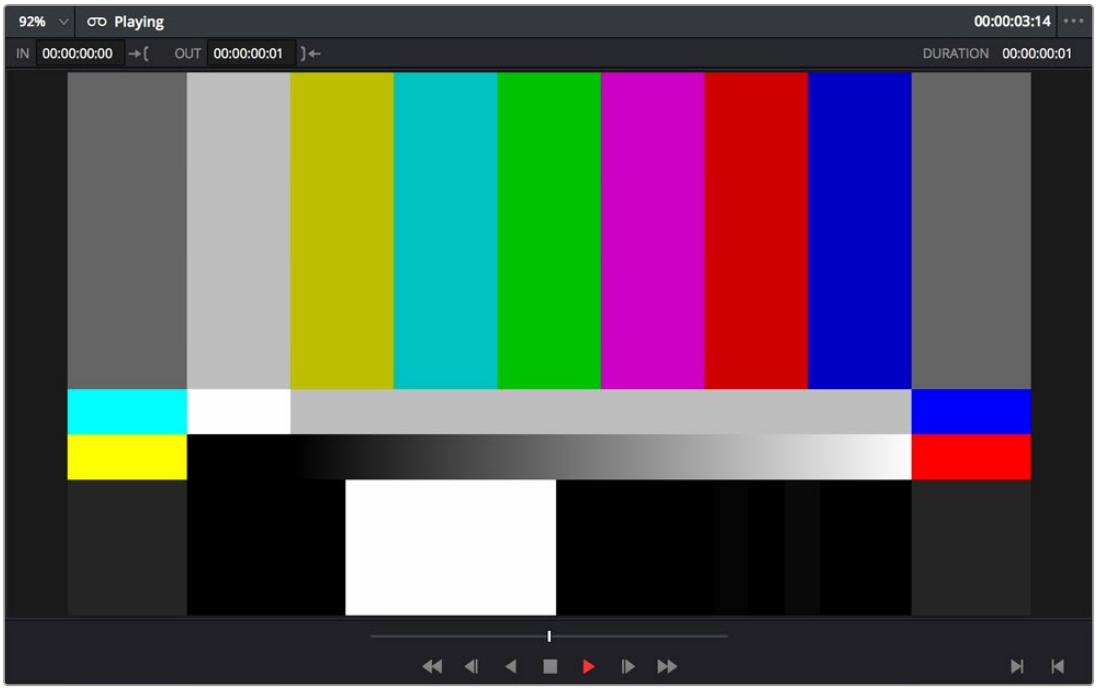
Logging and Capturing Multiple Clips 562
Batch Capture Via EDL 563

Tape Ingest

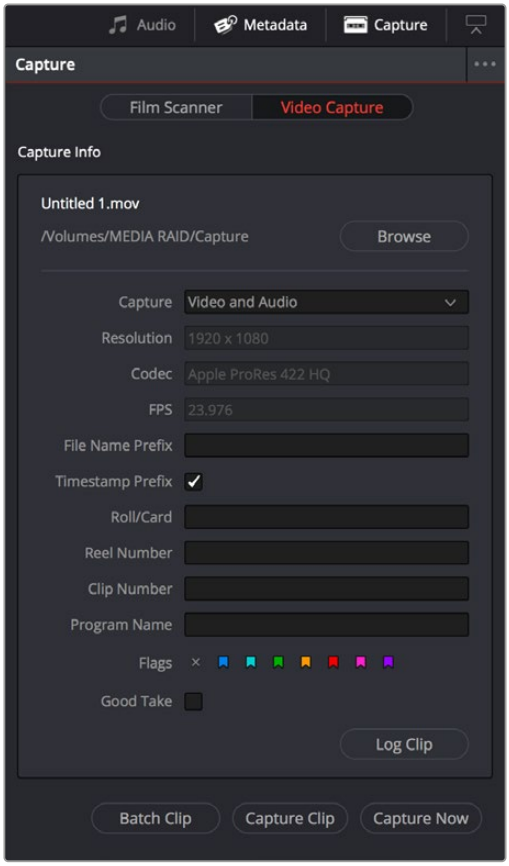
This chapter covers how to capture media from tape directly into the Media Pool in DaVinci Resolve. Whether you need to capture a handful of clips to incorporate into an existing project, or you need to recapture every clip corresponding to the events of an EDL, you can use the Media page in Capture mode to capture from any device-controllable deck via a compatible video interface.



To switch to tape capture in the Media page:

- Click the Capture button, located to the left of the Interface toolbar at the top of the Media page.

  The Media page updates to reflect the relevant controls for editing to tape, and the Audio panel is replaced by a dedicated set of capture metadata and controls to help you track the resulting clips.



The Tape Capture Interface

While in Capture mode, the Media page is used to control the VTR, in order to establish In and Out points for logging or capturing a selected range of the tape.

Tape Capture viewer in the Media page

- **Transport controls:** The transport controls, while similar in appearance to those used when simply playing through selected clips in the Media page, now work to control the VTR.
- **Shuttle control:** A shuttle control appears in what was formerly the scrubber bar, which lets you shuttle through the range of reverse and forward speeds compatible with the connected deck.
- **In and Out controls:** In Capture mode, the In and Out buttons to the right of the transport controls define a range of the tape from which to capture.
- **Capture panel:** The panel automatically switches to the Capture panel, with tape-specific metadata and capture controls. Populating File Name Prefix updates the file name preview that's shown above in the Header, that also shows the Capture directory, Resolution, and Frame Rate specified in the Capture and Playback panel of the Project Settings.

Editable capture metadata

Setting Up to Capture From Tape

Before you begin capturing from tape, you need to adjust a variety of settings in the Capture and Playback panel of the Project Settings. Two groups of settings, in particular, need to be defined.

Deck Settings

These settings affect both capture and playback when using the Tape Ingest options of the Media page, or the Tape Output options of the Deliver page.

- **Video capture and playback:** You can choose the video format (frame size and frame rate) with which to output to tape from this drop-down menu. HD timelines can be downconverted to SD, and SD timelines can be upconverted to HD using the format conversion of your DeckLink card.
- **Use left and right eye SDI:** A checkbox that enables the Blackmagic Design DeckLink HD Extreme 3D+ to ingest and output muxed stereoscopic video when used with supported VTRs, such as HDCAM SR decks with 4:2:2 x 2 mode. (When muxed stereoscopic signals are ingested, each eye is separated into individual left-eye and right-eye image files.)
- **Video connection operates as:** Selects between the available signal options: Use 4:4:4 SDI and Enable Single Link. Which options are available depend on which video capture card you are using.
- **Data Levels:** Lets you specify the data range (normally scaled or full range) that's used when ingesting from or outputting to tape. This option switches the data range of the signal output by your video capture card, but only during capture from tape in the Media page, or output to tape in the Deliver page. When capture or output is not currently occurring, your video capture card goes

back to using the identically named data range setting in the Master Settings panel of the Project Settings pane, which governs how you monitor the signal being output on an external broadcast display or projector.

- **Video bit depth:** 10-bit is the only available option.
- **Use deck autoedit:** If supported by your video deck, this is the best method to record video to the deck, as it enables the deck to roll the edit using the specified preroll, and control the edits via serial device control. If this checkbox is turned off, a basic edit On/Off mode is used by the deck, with the potential for frame inaccuracies if the "Non auto edit timing" setting is not properly adjusted.
- **Non auto edit timing:** Adjusts the edit synchronization of the connected deck when auto edit is turned off.
- **Deck preroll:** Sets the number of seconds for preroll. How much is appropriate depends on the performance of your deck.
- **Video output sync source:** When using a DeckLink card this is set to Auto. Other capture cards may require you to set the sync source to "Reference" for playout and "Input" for ingest. This setting is only available if you have the DVS card installed on your system.
- **Add 3:2 pulldown:** Inserts or removes the 3:2 pulldown required to record or play 23.98 fps media to or from a 29.97 tape format.

Capture

These settings are used when you use the Capture mode in the Media page to capture clips from tape into the Media Pool, or when controlling the Cintel Film Scanner to scan film of different formats.

- **Capture:** Lets you choose whether to capture both Video and Audio, or Video only.
- **Video Format:** The format captured media will be saved to. When capturing from tape, the available options are DPX and QuickTime.
- **Codec:** The codec used to write captured media. When capturing from tape, these include the various type of Apple ProRes, 8- and 10-bit YUV 422, 10-bit RGB, and the various types of DNxHD.
- **Save clips to:** A field that displays the directory path to which media files captured from tape are written. You want to choose a volume that's fast enough to accommodate the data rate of the media format you're capturing.

  Browse: Click this button to choose a directory to write captured media to. The directory you choose appears in the field above.

- **Save in this folder path:** A series of checkboxes lets you specify what other information to use to define the directory hierarchy that will hold the captured media. Every checkbox you turn on adds an additional directory with a name defined by that checkbox's metadata. You can choose any or all of the following: Program name, Clip number, Reel number, Roll/Card.
- **Apply reel number to:** Lets you choose how to write the reel name. Two checkboxes let you write the reel name to the file's name, and/or to the Header data.
- **Use prefix:** A field lets you type in a prefix to be used in the media file's name. This lets you add text identification that will make the media more easily identifiable and searchable.
- **Apply prefix to:** Two checkboxes let you choose to use the prefix you typed in the file name, and/or in the folder name.
- **Use frame number with:** When capturing to image sequences, you can choose how many digits to use when writing the frame number into the name of each frame file.
- **Set batch ingest handles to:** Lets you add additional frames of handles to the beginning and end of each scanned clip when batch capturing with the scanner.
- **Input:** A drop-down that lets you choose how many tracks of audio to capture, from 2 to 16.

The Three Methods of Capture

Once you've set up all relevant settings in the Project Settings window, including at minimum "Video Capture and Playback," "Capture Clips Saved to," and Apply Reel Name to" settings, then you're ready to start capturing. Depending on your workflow, there are three methods of capturing from tape that you can use.

For all capture methods, media can be ingested as QuickTime Movies or DPX image sequences.

Using Capture Now

If you simply need to capture a section of tape quickly, you can use the Capture Now command.

To Capture Now:

1. Use the transport controls and the In button to identify what you want to capture.
2. Enter all relevant information into the various fields of the Metadata Editor. The Header updates to show a preview of the file name that will be saved.
3. Use the transport controls to start playback, and then click the Capture Now button at the bottom of the Metadata Editor.
4. When the section of tape you wanted to record has finished, click Capture Now again to stop capture.

A new clip appears in the Media Pool, automatically placed in a new folder in the Media Pool with a name defined by the timecode value converted into a frame count, based on the ingest frame rate. For example, 00086400.dpx is the file name of a clip captured at timecode 01:00:00:00.

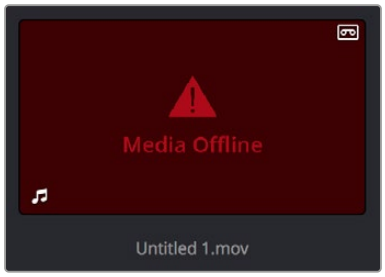
Logging and Capturing Individual Clips

If you're capturing an exact range of tape, or multiple sections at once, you can also work by logging each section of tape you want to capture in advance, before using the Capture Clip or Batch Clips commands in a second step.

To capture a single clip using device control:

1. Use the transport controls to find the beginning of the section of tape you want to record, and click the In button. Then, find the end of the section of tape you want to record, and press the Out button.
2. Enter all relevant information into the various fields of the Metadata Editor. The Header updates to show a preview of the file name that will be saved.
3. When you're finished, click Capture Clip.

Deck control is automatically used to play through the specified range of tape and capture that clip. When capture is complete, the new clip appears in the Media Pool.



Logging and Capturing Multiple Clips

For efficiency's sake, you can also log multiple clips at once, from multiple tapes if necessary, and then batch capture them all at once.

To log one or more clips:

1. Use the transport controls to find the beginning of the section of tape you want to record, and click the In button. Then, find the end of the section of tape you want to record, and press the Out button.
2. Enter all relevant information into the various fields of the Metadata Editor. The Header updates to show a preview of the file name that will be saved.
3. When you're finished, click Log Clip.

   That clip is added to the Media Pool as an offline tape clip, indicated by a black icon with a tape badge.

Logged clip in the Media Pool prior to capture

To batch capture one or more logged clips:

1. (Optional) Put the Media Pool into List view, and click the Reel No column header to sort the Media Pool clips by reel number. This makes it easier to select a range of clips to capture from a particular reel.
2. Select one or more offline tape clips in the Media Pool that come from a particular reel.
3. Click Batch Clips, at the bottom of the Metadata Editor. To interrupt capture at any time, click Batch Clips again.

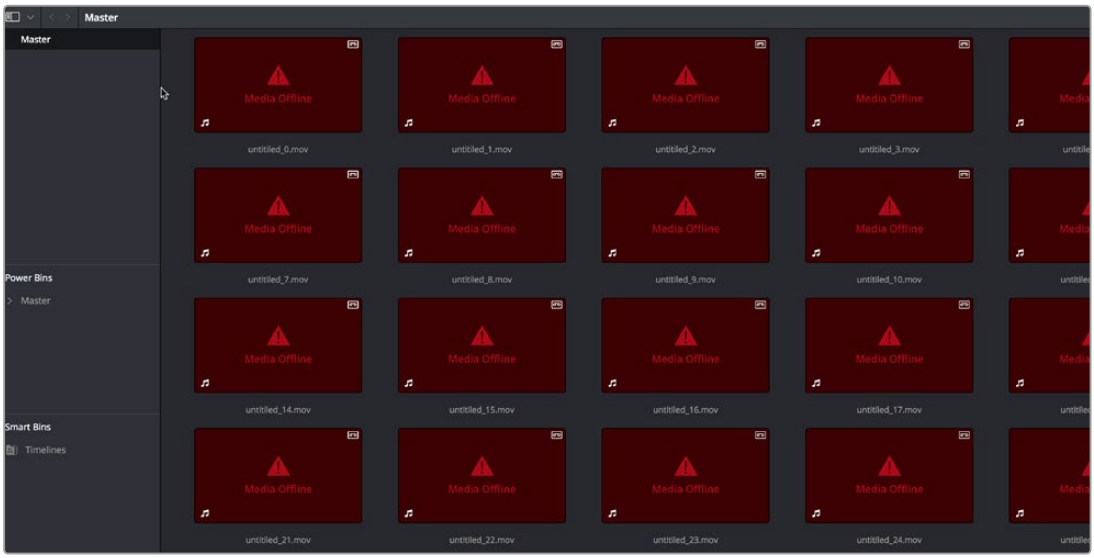
   Deck control is automatically used to play through the current tape in the VTR and capture every logged clip you've selected that can be found on that tape, starting with the clip with the lowest timecode value and ending with the clip having the highest timecode value. A progress bar with accompanying text shows how much longer to go until capture is complete. As each clip is captured, its corresponding logged clip in the Media Pool updates with a thumbnail reflecting the captured media.

   When DaVinci Resolve finishes capturing all clips from a particular reel, Batch Capture stops.

Batch Capture Via EDL

You can also use an EDL to create offline tape clips, one for each event in the EDL, with which to batch capture all the media necessary to conform a project from tape.

To import an EDL as a batch capture list:



1. Open the Project Settings, click Master Panel in the sidebar, and make sure of the following:
   - Set "Timeline frame rate" to the frame rate of your EDL.
   - Turn on "Use drop frame timecode" if your EDL requires it.
   - Make sure "Use Timecode" is set to "Embedded in the source clip."
   - Turn on "Assist using reel names from the."
2. Choose File > Import Batch List From EDL.

3 When a Conform Settings dialog appears asking you to confirm the current Project Settings, click OK if the settings are good.

4 Use the controls of the Select EDL files dialog to select one or more EDLs, then click Open. If you select multiple EDLs, then every event in each EDL is imported at once.

5 In the dialog that appears next, choose a frame rate to conform the EDL at, and click OK.

Each event in the EDL now appears as offline tape clips in the Media Pool, ready for capturing. If you load an EDL and there are already clips in the Media Pool that have the same reel name and start timecode as events in the EDL, DaVinci Resolve will not create new offline tape clips for those.

A set of logged clips imported from an EDL

6 (Optional) Put the Media Pool into List view, and click the Reel No column header to sort the Media Pool clips by reel number. This makes it easier to select a range of clips to capture from a particular reel.

7 (Optional) If there are any offline clips that you don't need to capture, you can remove them from the Media Pool by right-clicking them and choosing Remove Selected Clips.

8 Select which of the offline tape clips you want to capture. It's best to select ranges of clips that come from the same reel.

9 Click the Capture mode button to the left of the transport controls, and then click Batch Clips to begin capture. To interrupt capture at any time, click Batch Clips again. Deck control is automatically used to play through the current tape in the VTR and capture every logged clip you've selected that can be found on that tape, starting with the clip with the lowest timecode value and ending with the clip having the highest timecode value. A progress bar with accompanying text shows how much longer to go until capture is complete. As each clip is captured, its corresponding logged clip in the Media Pool updates with a thumbnail reflecting the captured media.

When DaVinci Resolve finishes capturing all clips from a particular reel, Batch Capture stops.

Chapter 25

Capturing From the Cintel Film Scanner

This chapter details how to ingest scanned film using DaVinci Resolve settings and workflows to control the Cintel film scanner.

Contents

Controlling the Cintel Film Scanner 566
The Cintel Scanner Interface 567
Film Controls 567

Color Space and Sizing 587

Controlling the Cintel Film Scanner

The Blackmagic Cintel film scanner is a compact, easy to use, real time film scanner capable of converting 35mm, 16mm, and 8mm (with separately purchased gates) positive and negative film formats into Cintel Raw Image (CRI) digital files that can be organized, edited, and graded using DaVinci Resolve, delivered to any format DaVinci Resolve can output, and archived for later use.

The Cintel scanner

DaVinci Resolve can control any Blackmagic Cintel film scanner that's connected to your computer via Thunderbolt or PCIe. Once connected, the Film Scanner controls in the Media page can be enabled, which let you choose the film type to be scanned, align the film frames to the sensor, adjust the scanner's light source for optimal exposure and color, and choose whether to use the scanner's hardware-based Automatic Perf Detection to perform image stabilization.

NOTE: This chapter of the DaVinci Resolve manual describes the use of a Cintel film scanner connected to DaVinci Resolve for the purpose of ingesting scanned film. For other operational inquiries, please see the documentation that accompanies the scanner itself, or visit the Blackmagic Design support page on the web to download it.

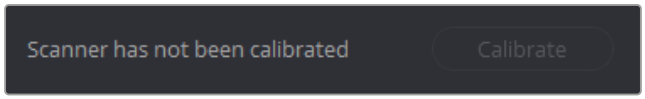
This section of the manual shows you how to use settings and features in DaVinci Resolve's film scanner panel to control your scanner. For example calibrating your scanner, adjusting the light source strength and color temperature, setting image stabilization, and more. You can even set how gentle your Cintel scanner handles film which may have become delicate with age.

TIP: DaVinci Resolve saves all scanner settings in your current project.

The Cintel Scanner Interface

Click on the ‘capture’ button in the UI toolbar at the top of the DaVinci Resolve screen to set the media page to control your Cintel scanner. Open DaVinci Resolve’s film scanner panel to set up, calibrate, and choose options for logging or scanning a selected range of the currently spooled roll of film. If you want more room for viewing the Cintel scanner controls, click the full height button that’s all the way to the right of the UI toolbar, and turn off the ‘metadata’ panel.

Cintel scanner controls in the Media page



Transport Controls: The transport controls under the viewer, while similar in appearance to those used while in playback mode, now work to control the Cintel scanner. Additional controls appear for moving forward or backward a frame at a time.

In and Out Controls: In Cintel Scanner mode, the In and Out buttons to the right of the transport controls define a range of the film roll from which to capture.

The following groups of settings appear to the right of the Media page viewer when in Cintel Scanner mode to scan clips from film into the Media Pool.

Film Controls

The film controls provide options to calibrate the scanner’s optics, select the film type, adjust the frame alignment, scan speed and spool wind direction, choose the reel type, and turn the focus assist feature on or off.

The calibration button can be used to help remove dust or small blemishes from the optics of your Cintel scanner.

Calibration

This option lets you calibrate the optics of the scanner to eliminate optical blemishes or dust that cannot be removed. Please note that this feature does not remove dust from the film itself.

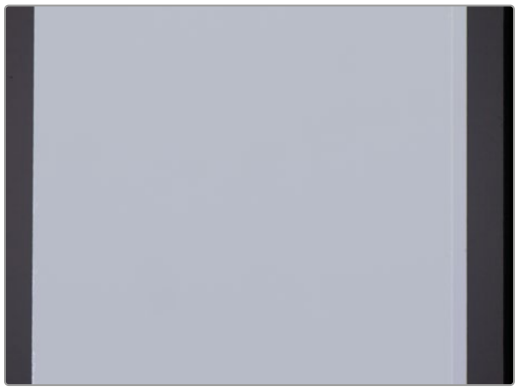
While it's recommended to "spray dust" the optics before scanning new material, it's possible over time for some blemishes on the optics to be unremovable, in which case using the calibrate button will eliminate them from the scanned image.

Calibrate the optics with the skid plate installed and correctly aligned, as this assists with image stabilization and offers the best image quality.

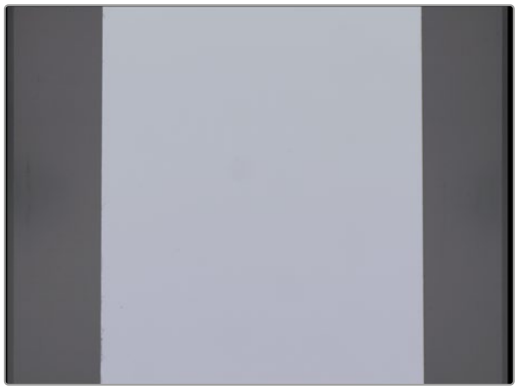
To support small gauge film types, the calibration button also analyzes the gate fitted and adjusts the captured image to a datum reference. To permit this, the calibration process should be run on every gate swap with no film in the gate to ensure optimum performance.

If you are using the 8mm HDR gate or 16mm HDR Gate and have adjusted the aperture shutters to switch to a different film gauge, you will need to repeat the calibration process to avoid a 'ghost image' of the previous calibration.

Incorrect calibration shows Super 8mm film with a Standard 8mm calibration



Incorrect calibration shows Standard 8mm film with a Super 8mm calibration

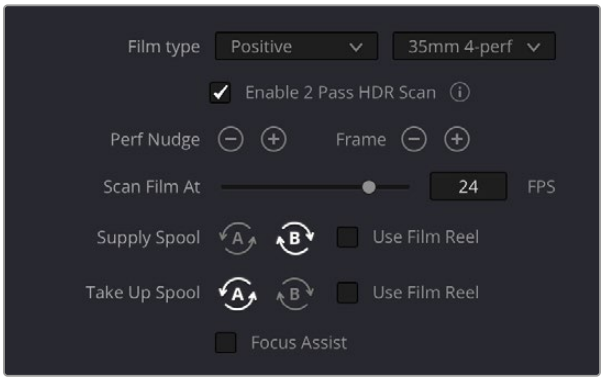


Correct calibration of Standard 8mm film

Incorrect

Incorrect

Super 16mm poss correct

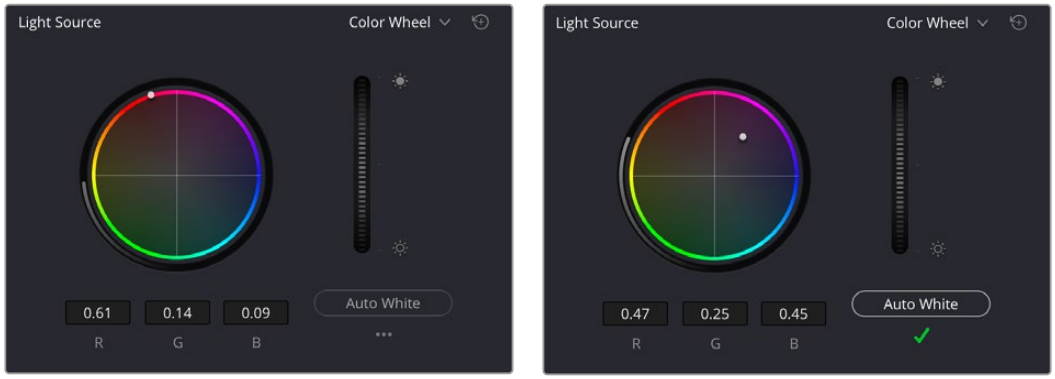


Standard 16mm neg correct

Film Type

Lets you choose what type of film you're scanning. For color as well as black and white film, the choices are positive, negative, interpositive, and internegative. HDR scanning offers an improvement for all these film types. Select the film type you're scanning from 35mm 2, 3, and 4 perf, 16mm, Super 8mm, and 8mm. The scanner automatically detects whether the film is 35mm, 16mm, or 8mm. For 8mm scanning, the default is set to Super 8mm. When scanning regular 8mm, you will need to manually set your scanner for that specific film type.

When scanning interpositive and internegative film on Cintel Scanner and Cintel Scanner G2, the increased density of the film requires slightly extended pulse durations from the light source. Normally, this does not affect the scan, however, a slight reduction in resolution may occur when scanning at above 12 frames per second. If you do notice a difference in resolution, simply reduce your scanning speed to 12 frames per second or less.



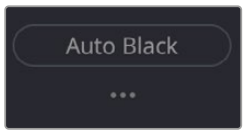
Film Type controls in the Media page

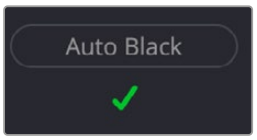
- **Enable 2 Pass HDR Scan:** Enables high dynamic range multi pass capture. It is important to perform an ‘auto black’ or ‘auto white’ on a frame with a wide dynamic range as it determines the high and normal exposure levels from your selected frame.
- **Perf nudge:** Used for making fine adjustments of the perf position relative to the scanner gate aperture. Command-J nudges up, while Command-L nudges down.
- **Frame:** These buttons are push and hold to activate. When on, the film is slowly advanced to move the frame up or down and when released the film stops in place. This is useful for aligning the film frame with the scanner’s sensor. Using the ‘perf nudge’ and ‘frame’ buttons, you want to align the visible film frame so the bottom of the previous frame and the top of the next frame are just visible at the top and bottom of the viewer, and the current frame is centered vertically.

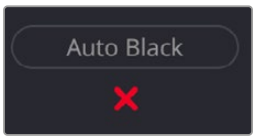
  It’s important to make sure the image in the viewer is not zoomed in when you do this. Command-Left Arrow on your keyboard moves the frame up, while Command-Right Arrow moves the frame down.
- **Scan Speed:** With adequate disk performance, you should be able to scan at 30 fps. However, if you’re scanning to a slow hard drive, you can reduce the scanning speed to a frame rate that’s suitable for your workstation without dropping frames.
- **Supply:** Sets the wind direction of the left-hand side feed spool. While auto-detection will prevent incorrect operation, you should manually configure the reel winding direction based on how each film roll is wound.
- **Take up:** Sets the wind direction of the right-hand side take up spool. While auto-detection will prevent incorrect operation, you should manually configure the reel winding direction based on how each film roll is wound.
- **Use Film Reel:** Small film reels have a different weight and inertia compared to large film spools, and this can affect the transport system. Tick this box to switch to settings that offer improved stability for small film reels.
- **Focus Assist:** Enables luminance peaking on your scanner’s HDMI monitor output, plus the viewer inside DaVinci Resolve’s film scanner panel, which makes it easy to obtain optimum focus adjustments.

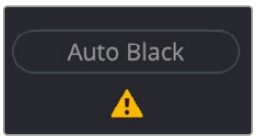
Adjusting the Light Source

These controls let you adjust your Cintel Scanner’s light source to calibrate the optimal Dmin density minimum. The Dmin density minimum is the minimum scanned value, plus the color temperature of the scanned material. Adjusting the light source settings correctly will ensure the best quality scans and make sure you are not clipping image data during the scanning process. It’s a good idea to check your light source settings when changing film to ensure the quality of your capture.









Light Source controls in the Media page showing the default uncalibrated status of the light source (left), and the status when calibration is successful (right)

Use the built in software scopes in DaVinci Resolve to help you set your light source to its optimal level settings. The scopes can be opened in the Media page by choosing Workspace > Video Scopes > On.

- **Light Source master wheel:** The vertical light source master wheel is located next to the color wheel and adjusts the intensity of the light source used to illuminate the film, raising or lowering the RGB channels all at once. For typical negative film, this lets you adjust the black point of the film image, which is the darkest part of the image. In negative film, this in fact corresponds to the highlights of the film image. Adjust the light intensity to sit just above the typical Dmin value of 95, as measured on the histogram of the video scopes, which guarantees that the highlights won't be clipped by a Cineon-style LOG conversion. For positive film, simply adjust the master wheel so that no part of the signal is being clipped.
- **Auto Black and Auto White button:** Analyzes the current frame displayed in the Viewer and does an automatic adjustment to set the black point for negative and internegative using the framing bar area. For print and interpositive film it uses the brightest highlight in the image area to set the white point, so key selection of the frame is important. Alternatively, for positive film types you can use a punch hole frame for maximum white to ensure all subsequent frames are compliant. For positive film types, the 'auto black' button changes to 'auto white'.

Light Source Status Indicators

These indicators under the 'auto' button let you know if the auto black or auto white light source calibration has been successful or if there are items to address. They also provide a helpful reminder to recalibrate the LED light source to ensure the highest quality scans.

			
Light source calibration has not yet been performed.	Light source calibration has performed successfully.	Light source calibration failed. Verify you have the correct film type selected, the light path is not obstructed and a suitable reference frame is selected. If required, try advancing film and selecting an alternate reference frame.	Light source calibration has successfully balanced colours but not at desired levels. As a solution, you can accept the balanced scan and optimize the image in DaVinci Resolve's color page or select an alternate reference frame for calibration with a wider dynamic range.

- **RGB controls:** By default, a color balance control lets you adjust all three color channels by varying amounts to alter the color temperature of the light source used to illuminate the film, while the adjusted R, G, and B values are displayed in three fields below. Optionally, you can choose to put this control into 'color bars' mode using the mode pop-up to the right of the 'light source' title bar, which changes this control to three vertical red, green, and blue color channel sliders.Image Stabilization

NOTE: The light source calibration is saved when you change rolls. This allows you to scan multiple rolls with a single light source calibration in both SDR and HDR modes. The last light source calibration will be saved until a new calibration is performed, or until your Cintel scanner is power cycled.

These controls let you enable and disable as well as control image stabilization to eliminate vertical film hop and horizontal weave

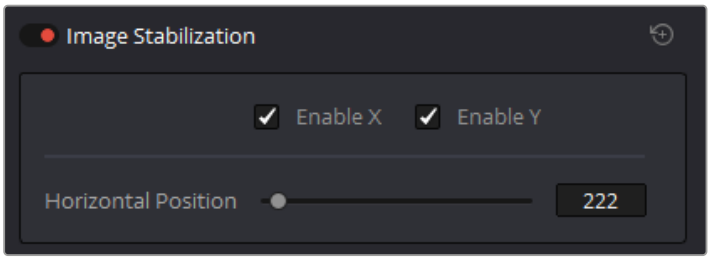


Image Stabilization controls in the Media page

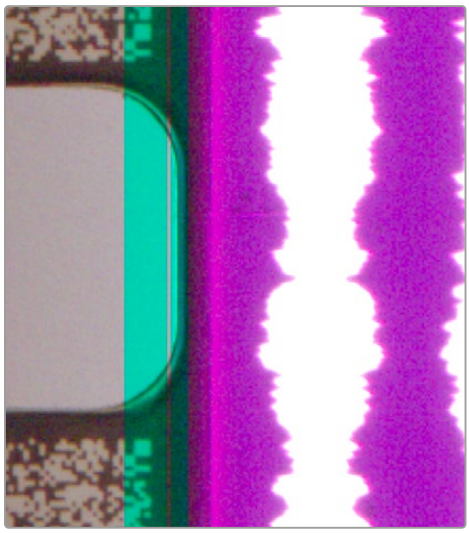
- **Image Stabilization enable/disable control:** The dot to the left of the 'image stabilization' title bar lets you enable or disable your scanner's hardware-based image stabilization altogether. While hardware stabilization is typically desirable when you have high quality perforations, you may want to turn this option off if the condition of the perforations is poor and you decide to use DaVinci's software based stabilization instead.

  When image stabilization is enabled, a horizontal X axis detection overlay is displayed in the viewer, highlighting the edge of the film perforation that will be used as the reference for stabilization. This overlay is automatically hidden when recording. Image stabilization is enabled by default.

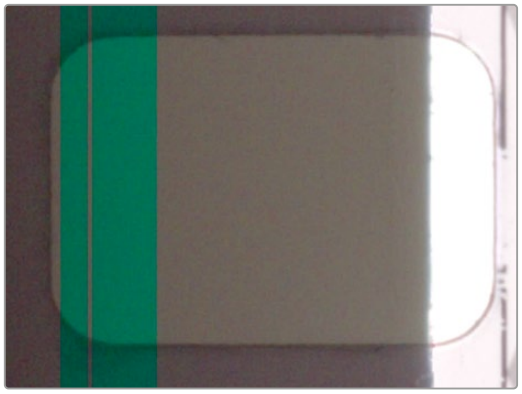
- **Enable X and Y checkboxes:** Enable X and enable Y lets you choose whether to use hardware image stabilization to fix horizontal gate weave and vertical gate hop respectively. If the results are unsatisfactory with both axes enabled, you can turn off the axis that's causing issues with stabilization and utilize DaVinci Resolve's software-based stabilization tools instead.
- **Horizontal Position slider:** Your Cintel scanner attempts to automatically place the stabilization detection overlay at the best location, with reference to the perforation shown on the currently loaded frame, for the best stabilization result.

You will notice a thin transparent line in the blue alignment overlay. For optimum stabilization, this line should touch the edge of the perforation. If the automatic positioning is not ideal, you can manually move the overlay to a more ideal position, either by dragging it in the viewer with your mouse, or by using the horizontal slider.



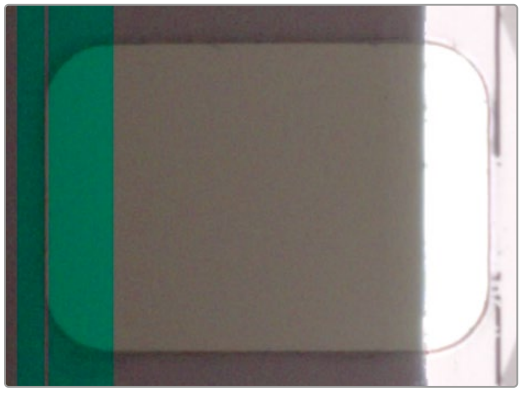
Ideal placement of the stabilization overlay should position the clear line in the alignment overlay on the edge of the perforation, as shown in the example image. With the overlay correctly positioned, this enables hardware stabilization of gate weave along the X axis.

Image stabilization automatically manages vertical gate hop when you select the 'enable y' checkbox. It needs no further adjustment and works in conjunction with horizontal stabilization.



Incorrect 35mm setup.

Adjusting the horizontal position of the stabilization overlay. The overlay is not aligned to the edge of the perforation.

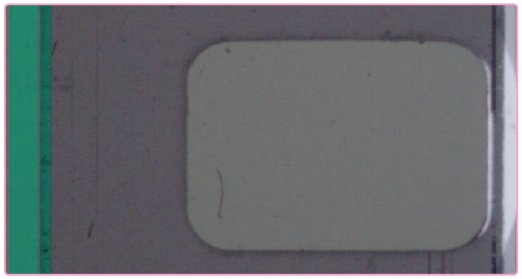


Correct 35mm setup.

The hardware stabilization control correctly positioned over a perforation in the viewer. The transparent stripe in the stabilization overlay touches the edge of the perforation.

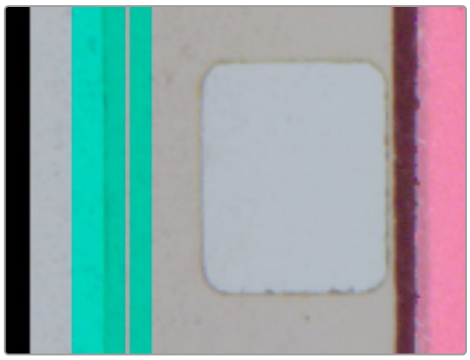
Incorrect 16mm perf setup.

The overlay is not aligned to the edge of the perforation. With the 16mm HDR skid plate installed, the stabilizer aligns automatically to the other side of the perforation to avoid interfering with the film image and improve horizontal stability. When using a 'non-HDR' 16mm skid plate, it functions the same as the 35mm skid plate.



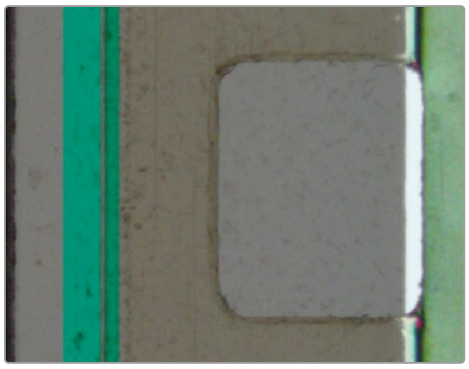
Correct 16mm perf setup.

For the stabilization overlay, the default alignment position is for the left edge of the perforation as this is not affected by image content. The transparent stripe in the stabilization overlay touches the edge of the perforation correctly.



Incorrect 16mm film edge setup.

The overlay is not aligned to the edge of the film reference edge.

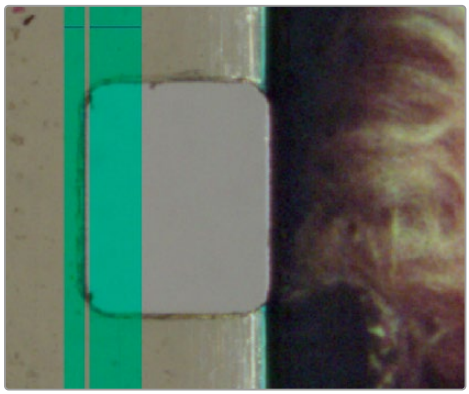


Correct 16mm film edge setup.

The overlay is aligned to the edge of the film reference edge. The transparent overlay touches the film ref edge correctly.

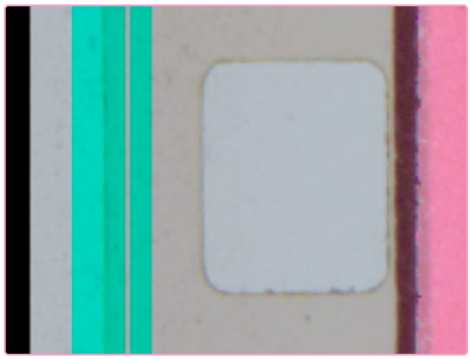
Incorrect 8mm setup.

The overlay is not aligned to the edge of the film.



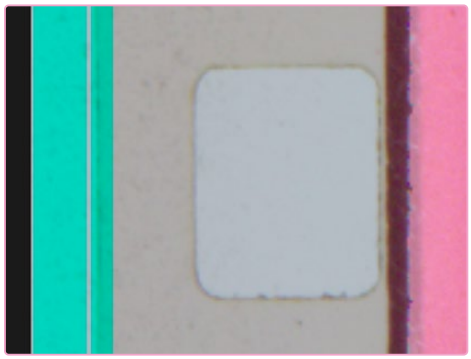
Correct 8mm setup.

For the stabilization overlay, the transparent stripe in the overlay is within the film base area.



Incorrect 8mm perf setup.

The overlay is not aligned to the edge of the perforation.



Correct 8mm perf setup.

For the stabilization overlay, the default alignment position is for the left edge of the perforation as this is not affected by image content. The transparent stripe in the stabilization overlay touches the edge of the perforation correctly.

Incorrect 8mm film edge setup.

The overlay is not aligned to the edge of the film reference edge. The overlay is not aligned to the edge of the film reference edge.

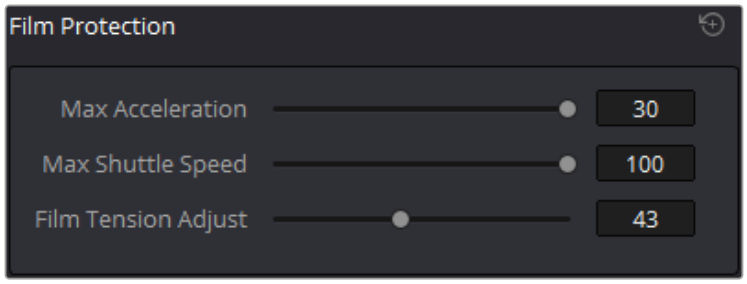
Correct 8mm film edge setup.

The overlay is aligned to the edge of the film reference edge. The transparent overlay touches the film ref edge correctly.

To closely check the results of your stabilization settings before capturing, set the Viewer to full resolution and zoom into the perforation region to allow fine adjustment. Simply click on the options settings at the top right corner of the Viewer and select ‘full resolution preview’ from the menu, click on the zoom scalar at the top left-hand corner of the Viewer and select ‘100%’. This setting does not affect the stabilization feature but enables the best possible preview so you can monitor how well it is performing.

Full resolution preview is very GPU intensive and may result in some frame lag. For best performance, turn full resolution off after checking stabilization. It is worth mentioning that the overlay position will be saved within the project settings and not the clip settings, therefore may require individual adjustment for multiple rolls.

Resetting the detection overlay to its default position for a given film type can be achieved via the Stabilization pane Reset button.



Audio and Synchronization

The Audio and Synchronization palette contains settings for the optional Cintel Audio and KeyKode Reader.

For more information, refer to the ‘optional Audio and KeyKode Reader’ section of the Blackmagic Cintel manual .

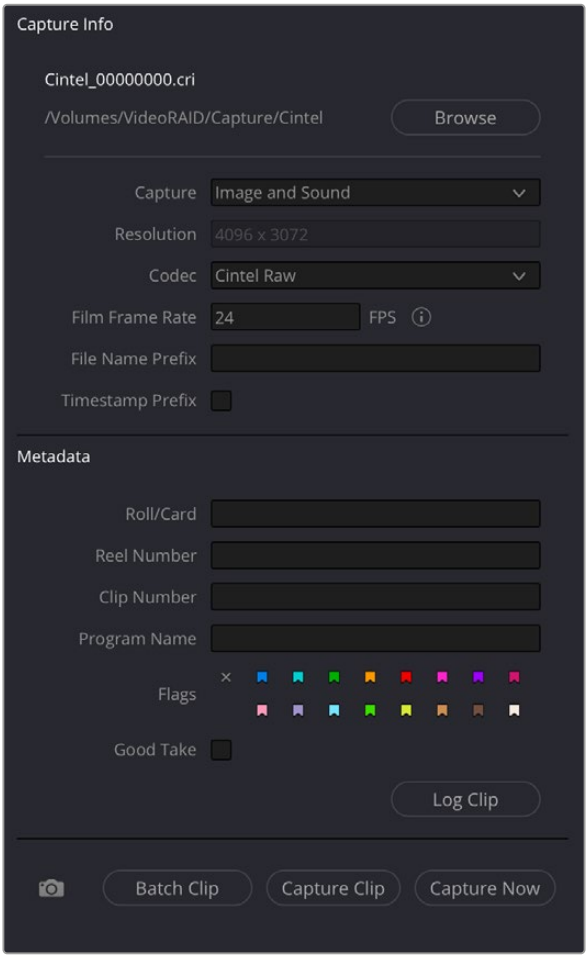
Film Protection

These controls are intended to allow delicate film to be handled gently by the Cintel Scanner. Fast acceleration and shuttle speeds can be hard on archival footage, so it’s recommended to lower both of these sliders from their defaults whenever you’re scanning older film.

The ‘Acceleration’ and ‘Shuttle Speed’ sliders should be lowered when scanning older, delicate archival film.

NOTE: The ‘Film Tension Adjust’ slider is present when using Cintel scanners with sprockets.

- **Max Acceleration:** Sets the maximum change in speed to increase or decrease by 5-30 fps per second.
- **Max Shuttle Speed:** Changes the speed of shuttling from one section of film to another between 1–100 frames per second for 35mm film, and between 1–200 frames per second for 16mm film.
- **Film Tension Adjust:** If your Cintel Scanner has sprocket wheels, this setting gives you the ability to adjust the amount of tension applied to 35mm film. For example, when loading delicate archival film, or compensating for film shrinkage. There is no possible way you can damage the film with



the ‘film tension adjust’ setting. The adjustment values are very small and only gentle changes are all that’s required to prevent sprocket picking.

If your Cintel Scanner has capstans, sprocket picking cannot occur, so this setting is disabled or not present.

Editing Capture Info Metadata

When DaVinci Resolve is used in conjunction with Cintel Scanner, a set of capture metadata fields appears at the bottom of DaVinci Resolve’s film scanner panel. The ‘capture info’ panel has editable metadata fields that describe capture properties such as where to save files, the type of codec, frame rate, and the format of file names. This metadata is attached to your clips and can be read on the media page.

Before you begin scanning, you may want to adjust some of the project settings.

The ‘capture info’ panel lets you specify metadata for your scanned clips.

- **Capture Location:** Before you begin a film scanning session, scroll down to the ‘capture info’ section of DaVinci Resolve’s film scanner panel to make sure the scanned files are being saved to the directory and volume where you want them. Click the ‘browse’ button and choose a location from the file destination dialog. It’s good to do this first, as this step is easy to forget.
- **Capture:** When you have a Cintel Audio and KeyKode Reader fitted, this menu gives you options for ‘audio only’ so no images will be captured, or ‘image and sound’. Alternatively, you can capture ‘image only’ if audio is not important.

- **Resolution:** The resolution of the capture files depends on the source film format so this field cannot be edited.
- **Codec:** DaVinci Resolve selects the 'Cintel Raw' codec for lossless compression by default, or you can choose 'Cintel Raw 3:1' for even smaller file sizes.
- **Film Frame Rate:** Specify the frame rate that the film was originally shot at. DaVinci Resolve automatically adjusts the timeline frame rate based on this value. This setting is unrelated to capture or transport speeds.

  When using the optional Audio and KeyKode Reader accessory to scan audio, the reader will automatically adjust for frame rate to maintain an overall sample rate of 48kHz. Timecode output is supported for 16, 24, 25, and 30 fps, and for other frame rates no timecode signal is outputted.
- **File Name Prefix:** Prefix to help identify the scan. This can be the name of your project, such as the title of the film you are scanning.
- **Timestamp Prefix:** Select this checkbox to prefix your scans with a timestamp as well as the 'file name prefix' you specified. Your clips will be saved to independent sub-folders in the destination folder. This checkbox is selected by default.

  If you want to save all your clips together in one master destination folder without the timecode in the file name, simply deselect the checkbox.

  NOTE: If you don't make capture names unique with the timestamp prefix and the files go into the same location, this could potentially overwrite files.
- **Roll/Card, Reel Number, Clip Number, and Program Name:** These are ways to identify the clip with metadata.
- **Flags:** You can use these color coded flags to tag clips.
- **Good Take:** Corresponds to 'circled take' metadata in the media pool.
- **Log Clip:** Adds a clip to the media pool. After you mark 'in' and 'out' points for a section you want to scan, confirm the metadata is correct, and then click 'log clip'. For more information, refer to the 'Logging and Capturing Individual Clips' and 'Logging and Capturing Multiple Clips' sections in the DaVinci Resolve manual.
- **Batch Clip, Capture Clip, Capture Now, and Snapshot:** These scanning buttons offer different methods to capture clips. For more information about scanning buttons, refer to the 'Scanning One or More Sections of Film' section of this manual.

Film Scanning Workflows

The following sections describe how to scan film using DaVinci Resolve and to control the Cintel scanner. Throughout, the features outlined in the previous section are presented in the order in which you'll perform each step of the scanning process.

Before You Begin

Before turning your scanner on and loading film, you should first dust the gate to make sure your scans are as clean as possible. This can be accomplished using compressed air, but if the gate is extremely dirty, you can remove it to give it a more thorough cleaning. Once that's finished, turn on the Cintel Scanner, open DaVinci Resolve and create the project you'll be using to scan film, and then click the 'Cintel scan' button on the media page. Now click the 'Film Scanner' tab to select DaVinci Resolve's film scanner panel.

Before you load film into the scanner or do anything else, click the ‘calibrate’ button at the bottom left of the film scanner panel. While you should always dust the gate of the scanner before loading a new reel of film, clicking the calibrate button eliminates any unremovable blemishes in your scanner’s optics from the scans you’re about to make.

Load and Align the Film

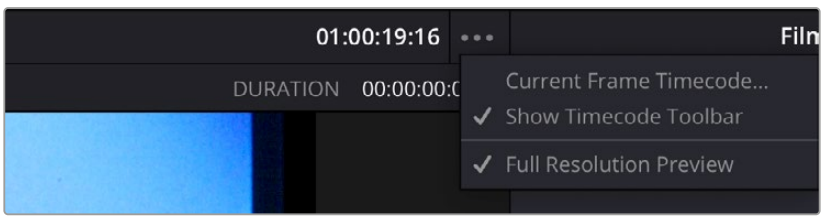
Load the film you want to scan. In the presence of an image the scanner will automatically align a frame. You should note that the image may be framed incorrectly if you first load blank film leader.

Next, choose the film type. If necessary, use the ‘perf nudge’ and ‘frame’ buttons to manually improve the alignment of the framing bar to the scanner’s sensor such that the bottom of the previous frame and the top of the next frame are just visible at the top and bottom of the viewer, and the current frame is centered vertically. It’s important to make sure the image in the viewer is not zoomed in when you do this.

Focus the Scanner

Just as you need to focus the lens on a camera, you’ll need to focus the projected film image on your scanner’s sensor. To achieve perfect focus, turn on the Focus Assist checkbox in the Film Scanner capture settings of DaVinci Resolve. This superimposes a focus peaking overlay over the Ultra HD image that’s output from the scanner’s HDMI output, and is also displayed in DaVinci Resolve’s capture window. For the best results, connect an Ultra HD display to your Cintel scanner so that you can monitor at the maximum available resolution while you focus.

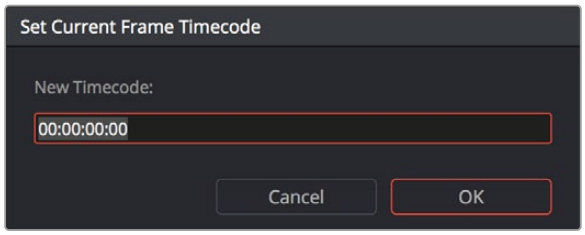
With Focus Assist turned on, focus peaking will detect the film grain of the scanned image whenever the film plane is in perfect focus. This enables the operator to focus the scanner even if the film image is out of focus. Simply monitor the Ultra HD output of the scanner while you turn the Cintel scanner’s focus wheel. Your image will be in focus when the grain running throughout the image displays peaking outlines.



You can verify the focal adjustments you’ve made by checking the edges of your film’s perforations. When these are sharp, your film will be in focus.

Reset the Timecode

To set the timecode for the roll of film you’re about to scan, you need to locate the zero frame for that roll. It’s standard practice to punch a small physical hole within the frame before the first frame of necessary film on a roll, to use as a permanent reference for whenever that roll is scanned. This is referred to as the marker frame, lab roll hole, or head punch. By always setting the first frame of timecode to match the marker frame, subsequent film scans will have the same frame count as previous scans, making it possible to rescan and reconform the same material whenever necessary.



To reset scanned timecode at the marker frame of a new film roll:

1. Use the transport controls under the viewer to locate the marker frame.
2. Click the ‘viewer’ option menu and choose ‘current frame timecode.’

Choosing Current Frame Timecode from the Viewer Option menu

3 Enter a timecode value in the dialog box that appears. For example, if you're scanning the first roll of a project, you can enter 01:00:00:00.

The Set Current Frame Timecode dialog

4 When you're done, click OK.

Timecode cannot be a negative value, so don't set the start frame to zero. Another common organizational technique is to change the hour number whenever you change rolls, to coincide with the film roll's number, which makes it easy to identify a scanned clip with the corresponding source roll and frame range.

Your Cintel Scanner has built in 'Options Interface' ports for adding optional hardware in the future. This offers the ability to add optional features such as reading KeyKode from the camera negative, or optical/magnetic audio.

For more information, see the 'Optional Audio and KeyKode Reader' section in the Blackmagic Cintel manual .

Choose a Location to Save the Scanned Frames

Once all this is done, scroll down to the 'capture info' controls in DaVinci Resolve's film scanner panel, and click the 'browse' button to choose a location for the scanned files. You can use the other fields in this section to set what prefix you want to add to the name of the scanned files and enclosing folders. The 'file name prefix' updates the file name preview that's shown at the top in the header. The header also shows the file path, resolution, frame rate, duration, and the format. Specify what roll, reel, clip, and program information you want associated with the scanned media. The 'timestamp prefix' checkbox in the 'Capture info' controls is selected by default and will save your clips to independent sub-folders within the destination folder, together with a timecode prefix in the file name.

If you want to save all your clips together in one master destination folder, simply deselect the checkbox.

When you capture an HDR clip, the scanner completes a high exposure scan and saves it in a hidden folder named .HDR inside the same folder as the standard scan. If you delete the .HDR folder, the scan converts to a normal clip after refreshing it in the media storage and re-importing the clip into media pool. This is useful if there is a problem with the HDR portion of the scan, as you can easily convert it to a regular CRI clip.

Check the Codec

DaVinci Resolve selects the 'Cintel Raw' codec by default, or you can choose 'Cintel Raw 3:1'.

The Cintel Raw Format

The Cintel Raw Format Bayer pattern of each film frame scanned with your Cintel scanner's sensor is saved with embedded scanner metadata as a 12-bit linear Cintel Raw Image, or CRI, image sequence. When grading in DaVinci Resolve, CRI images are automatically debayered as 12-bit log encoded image data.

The logarithmic encoding is similar, but not identical to Cineon encoding. For example, negative film is encoded using a Gamma of 2.046 for density, while print film is encoded using a full range Gamma 2.2 curve to ensure that no image data is clipped. Both of these logarithmic encodings can be converted to a linear color space using the 'Cintel to Linear' 1D LUT, before converting to other color spaces you may want to work in.

The film is scanned using the full sensor area of 4096x3072 to keep the audio waveform visible for optical audio and to accommodate perforation visibility for stabilization. The image is then cropped and the resolution of the capture files depends on the source film format after overscan for perforations and the audio area are removed.

For more information on scanning resolutions for different types of film, see the 'specifications' section.

The Cintel scanner creates Cintel Raw files with variable bitrate lossless compression by default. This is visually lossless compression and achieves approximately 3:2 reduction in file size depending on image content. However, Cintel Raw 3:1 uses lossy compression with a ratio of approximately 3:1. This is still very high quality but may not always be visually lossless.

For example, files for 35mm 4 perf are approximately 12.5MB with Cintel Raw and approximately 6.3MB with Cintel Raw 3:1. Files for 16mm are approximately 4MB with Cintel Raw and approximately 2MB with Cintel Raw 3:1.

CinemaDNG Quality Settings

To control the quality of CRI files, use the 'decode quality' and 'play quality' CinemaDNG settings located in the Camera Raw panel of the project Settings. These settings are 'full' by default. On computers with low processor or memory resources, these settings may be lowered but this will affect the quality of the final render.

Set the Timeline Resolution

DaVinci Resolve displays and renders the output from the scanner using the same resolution as the timeline. For example, for 35mm 4 perforation film, a custom resolution of 4096x3072 would be required for maximum resolution.

NOTE: If your timeline is set for HDR with the desired deliverable at Ultra HD, a loss of resolution may occur.

For more information on the cropped image area resolutions for all film gauges, refer to the 'effective resolutions' in the 'specifications' section. Alternatively, for the full native resolution of the captured clip, access the 'clips attributes' in DaVinci Resolve.

Adjusting the Color of the Scanner

DaVinci Resolve's film scanner panel gives you control over the exposure and color temperature of the light used to illuminate the film for scanning. You can adjust these via the light source master wheel and RGB controls, in order to maximize the amount of information you're extracting from each frame, while preventing any part of the image from being irretrievably clipped. While it's true that CRI is a raw image format, there's no latitude beyond the internal data range used by DaVinci, so be mindful that if you're clipping data in the built in video scopes while scanning, it might be clipped permanently in the scanned media.

How often you'll adjust the color and exposure of scanned shots depends on how much variety there is in the scenes on a particular film roll. For example, some rolls may have many takes of the same scene, all of which have the same lighting and which can share the same adjustments.

Meanwhile, other rolls may have a variety of different scenes with widely different lighting in each one, necessitating you to make individual adjustments for each scanned clip to maximize data quality.

This is important because the light source master wheel and RGB controls cannot be automatically changed between scanned clips in a log and capture workflow. This means that the current light source settings will be used for all clips you scan until you manually change those settings again, even for clips that you've logged from different parts of a film roll. This means that the log and capture style of working is only advisable in situations where it makes sense to log multiple clips that share the same light source master wheel and RGB control adjustments.

Otherwise, it's recommended you make lighting adjustments on a clip by clip basis, as you scan each clip, in situations where you need maximum image quality for finishing. Keep in mind that the goal for these adjustments is to maximize image data from the scan, not to create the final look of the clips, which you'll accomplish later in the grading phase of work using the controls of the 'color' page.

To adjust the light source settings, find a typical image for the section of roll or for the first series of shots you're going to scan, and adjust the light source while viewing the built in video scopes.

Adjust the light source master wheel to set the intensity of the light source used to illuminate the film, raising or lowering the level of the R, G, and B channels all at once. For a typical camera negative, this lets you adjust the black point of the film image. In a negative print, the darkest part of the image corresponds to the highlights of the film image. Set the light source master wheel to sit just above the typical Dmin value of 95, as measured on the histogram of the video scopes, which guarantees that the highlights won't be clipped by the Cineon LOG conversion that DaVinci uses to debayer the CRI image for grading. For positive film, manually adjust the light source levels so that no part of the highlights or shadows of the signal is being clipped; typically 1000 in 10-bit or 4000 in 12-bit.

You can turn on 'show reference levels' in the waveform, RGB parade, or histogram scopes, and set the 'low' value to indicate the digital Dmin value of 95.

Once that's accomplished, adjust the RGB controls to rebalance all three color channels by varying amounts to alter the color temperature of the light source used to illuminate the film, to produce the most useful, or neutral, color balance in the scanned result.

Scanning One or More Sections of Film

After you've adjusted the light source, it's a good idea to stay organized as you scan each clip by entering all relevant metadata into the metadata editor as you go. The 'capture info' group of metadata fields contains information for defining the file name prefix, roll, reel number, clip number, program name, flags, and whether a particular take is good. If you populate these fields before scanning a clip, that metadata will be written into the clip.

At the bottom of the 'capture info' panel, you will see four buttons for film scanning.

With all of this accomplished, you can scan the film in one of four ways:

- **Capture Now:** Use the capture now button to capture long sections of a reel all at once. Clicking 'capture now' begins scanning near the current frame, ending whenever you click 'stop'.

  If 'Enable 2 Pass HDR Scan' is selected, click 'Capture HDR' after the capture has begun to let DaVinci Resolve know you've reached the end of your desired clip so it can now proceed to capture the high exposure pass. If you scan the entire reel without clicking 'Capture HDR', the scanner automatically proceeds with the high intensity scan from where you started it until the end of the reel.

- **Capture Clip:** A more controlled means of scanning specific sections of film. After you've used the transport controls and the In and Out button to define a section of film, clicking 'capture clip' scans that one clip and then stops.

  If 'Enable 2 Pass HDR Scan' is selected, the high intensity HDR scan uses the same In and Out points as the initial scan.

- **Batch Clips:** A way you can log multiple clips in advance of scanning them all at once using the current light source settings in DaVinci Resolve's film scanner panel. Log each clip in advance by setting In and Out points for each section of film you want to scan, and click the 'log clip' button to save that frame range as an unscanned clip in the media pool. When you click 'batch clips', all unscanned clips will be scanned one after the other until the job is complete. You can also select one or more unscanned clips, and only the selected clips will be scanned. Furthermore, you can import an EDL that corresponds to a particular film roll, and use the resulting logged clips for scanning.

  > **NOTE:** When you click the 'log clip' button, Cintel Scanner applies the same project settings to all clips in the batch, and uses the newest project settings at the time of capture. You are advised to confirm the scanner settings before starting the batch capture.

  If 'Enable 2 Pass HDR Scan' is selected, the high intensity HDR scan uses the same sets of In and Out points as the initial batch of scans.

  > For more information on batch capture workflows, jump to this chapter: Ingesting From Tape.

- **Snapshot:** Capture a single frame with normal exposure and current scanner settings.

  Once scanning, if DaVinci Resolve detects that your storage bandwidth is too low to capture at the selected speed, the scan speed will automatically adjust to ensure the capture is successful. If you are using the optional Audio and KeyKode Reader accessory, the audio sample rate will also be adjusted to maintain your chosen audio quality.

Extracting Audio

If the film you're scanning also contains an optical sound track, you can extract the audio in a separate step. There is a standard image frame to audio frame offset of 26 frames for 16mm and 21 frames for 35mm that DaVinci automatically aligns when extracting the audio. Select all of the clips that have an optical sound track, then right-click one of the selected clips and choose 'extract audio'. Resolve analyzes the overlapping optical track area of each frame and automatically generates a matching audio track, synchronized with the scanned image sequence.

Each clip's audio will be automatically extracted, embedded in the clip and saved to the same directory the scanned frames have been written to. A small audio icon will appear on the corner of your clip's thumbnail so you know there is a corresponding audio file.

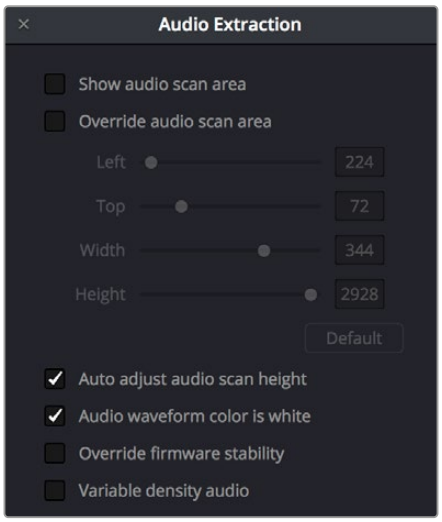
To make extraction easier, you can filter the clips in the media storage by name, resolution, date modified or by film clips only. Filtering your clips makes it easier for you to find and select exactly what you need. You can also make a large selection and extract audio from multiple clips at once by right clicking on your selection and choosing 'extract audio...' from the menu. During audio extraction, an information box indicates the progress. You can click the 'stop' button any time to stop the extraction.

You can filter the contents in the media storage to make it easier to manage them.

If the 'timestamp prefix' checkbox was deselected in the 'capture info' section when your clips were scanned, and you want to have extracted audio automatically embedded in your clips, always remember to extract audio from the clips inside the media pool.

Audio Extraction Settings

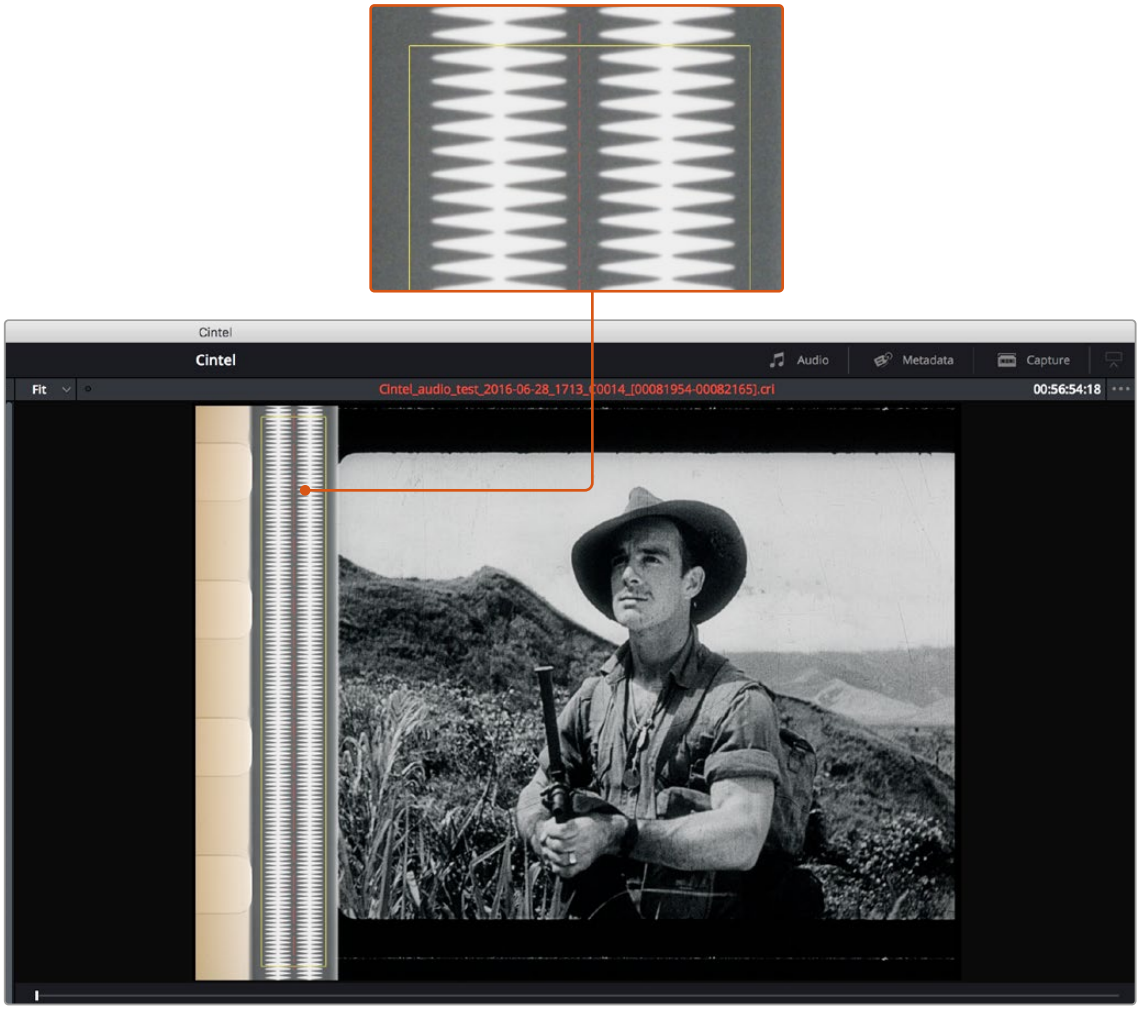
Normally, once you have selected the film type, the automatic features in DaVinci Resolve will extract your optical audio perfectly. However, the condition of the optical track can vary with the condition of the film being loaded and in some instances this can confuse the automation. If this happens, you can bypass the automatic features and make adjustments manually.



For manual adjustments, simply open the 'Audio Extraction' settings window by clicking on 'Show Cintel Audio Settings' in the inspector options near the top right of the viewer.

Audio extraction settings let you make the following manual adjustments:

Show audio scan area



This checkbox turns the audio scan area guides on or off. The guides are displayed as a box on the side of the frame covering the optical audio scan area and shows what optical information will be used during extraction. The position of the guides will conform to the film type you have selected. However, you can change the position manually if you need to. The audio scan area guides are also great indicators to show you what is happening during the extraction process so you can identify any potential troubles and make manual adjustments.

The Audio Extraction settings let you make manual adjustments, if needed.

Inside the box is a thin red line. This line is the mid point detector which detects the separation between stereo audio channels. When mono sound is detected during audio extraction, the mid point detector disappears and the guides will adjust automatically to suit the width of the mono optical track.

TIP: If you need a closer inspection of the audio scan area guides, you can zoom into the viewer and move the viewer position up or down, and left or right. Simply choose the amount of zoom from the sizing options at the top left corner of the viewer, then click and drag the viewer with your mouse or track pad.

When ‘show audio scan area’ setting is turned on, the audio area guides will be visible so you can see exactly what information is being used and monitor the extraction process.

Override audio scan area

This setting provides sliders for adjusting the horizontal and vertical positioning, width, and height of the audio scan area guides.

These settings include:

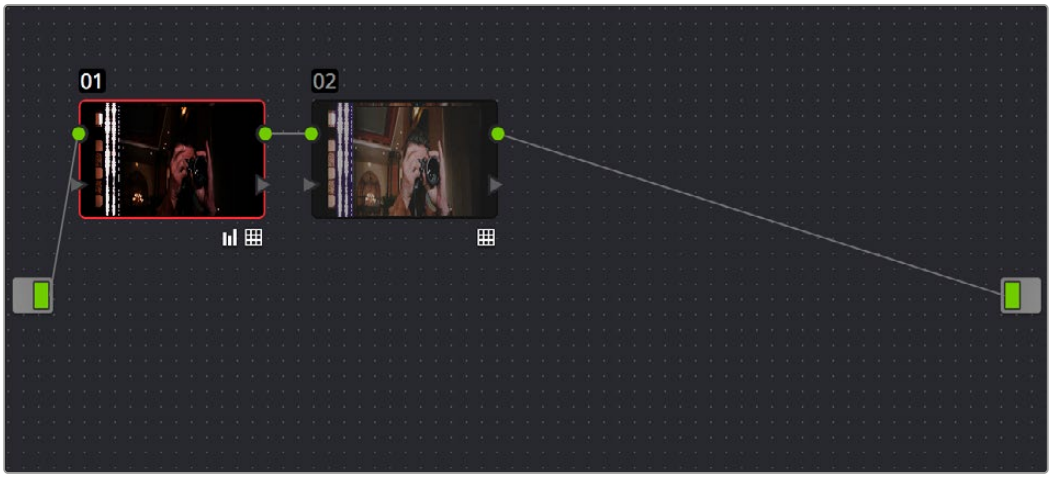
- **Left and Width:** If your film type is such that audio appears on the right side of the frame, you can simply adjust the 'left' slider to move the guide box to the right. Normally, this will happen automatically if you have the corresponding film type selected, but the setting gives you more flexibility for adjustments if you need it. Similarly, the 'width' setting is used to adjust the width of the scan area.

  These are helpful tools for making subtle adjustments to the side edges of the guide box if there are unwanted elements inside the film's optical audio area. This can happen due to perforation wear and tear, or varying print qualities, and can sometimes interfere with the quality of the audio extraction. You can help avoid this by making a subtle movement to the side edges to keep the stray elements outside of the guide box.

- **Top:** This setting adjusts the vertical position of the guide box.
- **Height:** Sometimes film frames on older rolls of film may be slightly smaller than normal due to shrinkage over time. When making manual adjustments to the guide box, you can make adjustments for film shrinkage using the 'height' slider.
- **Auto adjust audio scan height:** This setting is on by default and automatically adjusts the guide box height to align with the audio waveform at the top of each frame. The automatic feature works well for normal audio conditions, however, if during extraction you notice the box moving randomly and the quality of the extraction is affected, it may be due to similar features in the audio track overlapping between frames. If this occurs, deselect the checkbox and try the extraction again.

  If deselecting the 'Auto adjust audio scan height' checkbox, make sure the 'height' setting places the guide box at the optimal position for the frame. Making manual adjustments can help if you need them, but don't forget to turn the automatic features back on afterwards!

> **TIP:** If deselecting the 'Auto adjust audio scan height' checkbox, make sure the 'height' setting places the guide box at the optimal position for the frame. Making manual adjustments can help if you need them, but don't forget to turn the automatic features back on afterwards!



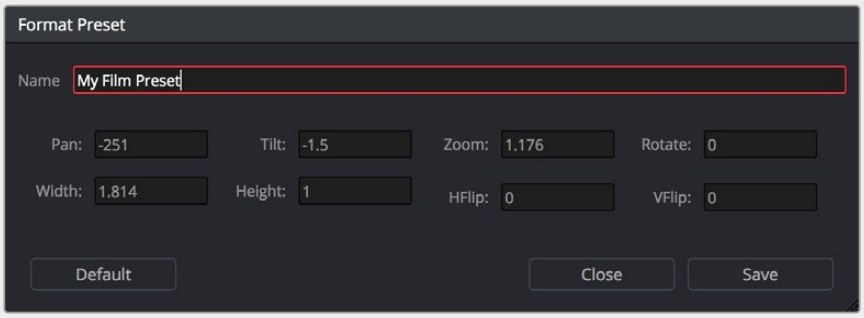
- **Audio waveform color is white:** Depending on the scanned film type, the audio waveform may be black or white. If the waveform is white, make sure the corresponding checkbox is enabled. This will ensure the white information in the waveform is used during audio extraction. If the waveform is black and the surrounding audio area is white, disable the checkbox so DaVinci knows to use the black information in the waveform. Other automatic features, such as mid point and mono detection, also rely on this setting being set correctly.
- **Override firmware stability:** In rare instances, the condition of the film may have created large movements in the frame due to the internal firmware stabilization. This can cause the audio extraction guide box to misalign with the optical track. If this occurs, enabling 'override firmware stability' lets the audio extraction guide box track the film perforations independently and adjust its positioning for potentially better results.
- **Variable density audio:** If your film contains variable density audio, make sure you select the 'Variable density audio' checkbox so DaVinci Resolve knows the type of audio to extract. The default state is set to 'off' for variable area audio soundtracks.

  If you haven't used variable density audio before, you can visually identify it as a tight sequence of shaded lines, similar to a bar code with the lines squeezed closer together. By comparison, 'variable area' soundtracks appear as an audio waveform.

Color Space and Sizing

A pair of 1D LUTs, ‘Cintel Negative to Linear,’ and ‘Cintel Print to Linear,’ have been provided to help you convert scanned media to a color space in which you can do further work. You can apply these LUTs via a node in the ‘color’ page to convert the original scans to a Linear color space. However, if you want to convert the image to Rec. 709 or to Cineon for further adjustment, you’ll want to apply a second LUT in a second node. The default color space for print is a 2.2 gamma standard log curve, and all others are 2.046 film density log gamma.

In general for negative film, it’s best to “color invert” after the second LUT is applied. Furthermore, normally some grading is required on the Linear data to remove black offsets, due to Dmin, for proper conversion into the destination color space. There are a variety of VFX IO LUTs available in the 3D LUT submenu of each node’s contextual menu that let you convert an image from Linear color space to any other color space you want to work within.



Using three nodes to convert a film scan using LUTs; node 1 converts from Negative or Print to Linear, node 2 converts from Linear to Rec. 709, and node 3, if required, inverts the color

NOTE: Applying a LUT within a node will clip any image data falling below 0 and above 1. To prevent clipping, you can use the Lift/Gamma/Gain controls within any node with a LUT applied to adjust your image levels prior to the transform applied by the LUT within that node.

The format of the film you’re scanning and the way the material was originally shot both affect the framing. You can adjust the final framing of your scanned clip by resizing, zooming, stretching, panning, tilting, and more. On the ‘Color’ page, open the ‘Sizing’ palette and use the ‘Input Sizing’ mode to create the necessary framing. To save your sizing preferences as a preset, open the menu, select ‘save as new preset’ and enter a name for your preset.

Once you’ve created an appropriate sizing preset for a given type of media, you can apply that preset to multiple film scans all at once, in either the Color page or in the Media Pool using the ‘change input sizing preset’ command, found in the contextual menu of selected clips.

For more information on sizing, jump to this chapter: Sizing and Image Stabilization

Creating a sizing preset in the Sizing palette of the Color page

The Photo Page

The Photo page is primarily a photo editing application—but with deep integration into the rest of DaVinci Resolve's effects and toolset, it opens up more creative possibilities than still-image editing. Using Photo Albums, you can pass full resolution stills into the Cut, Edit, Color, and Fusion pages for additional processing.

The Photo Page.

The Photo page features a full-image management pipeline including tagging, favorites, ratings, and photo album collections. In addition, you can tether your camera to the Photo page, and capture images and control your camera settings live. The new Intellisearch feature helps to analyze your images and search for them based on content, objects, people, colors, and more. The Photo page includes an extensive, built-in effects library with some of the most powerful Resolve FX and Fusion FX ready to use.

With the addition of the Photo page to DaVinci Resolve, you can move fluidly between photos, video editing, color grading, VFX and audio post, all in real time.

The Interface Toolbar

At the very top of the Photo page is a toolbar with buttons that let you show or hide different parts of the user interface. These buttons are as follows, from left to right:

The Photo Page Toolbar.

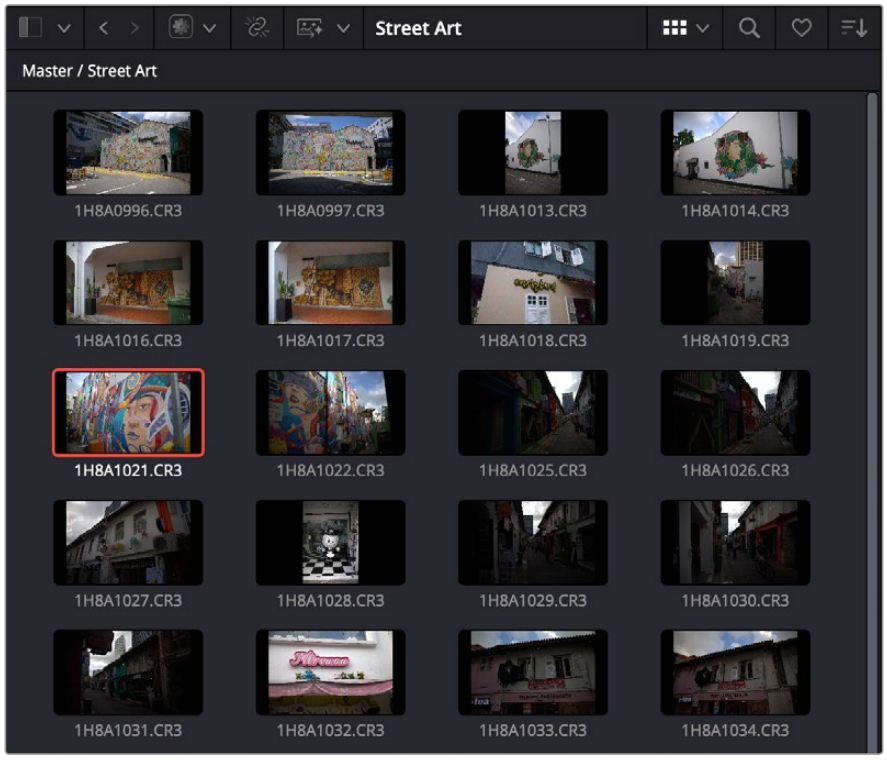
Media Pool: Opens or hides a smaller version of the full Media Pool page, allowing access to all the images used in the project.

Effects Library: Opens or hides the repository of all transitions, generators, and effects that are available for use in the Photo page.

Photo Album: Opens the Photo Album at the bottom of the interface.

Quick Export: Opens the Quick Export Dialog to deliver an export of your photos.

Metadata: Shows or hides the Metadata Editor.

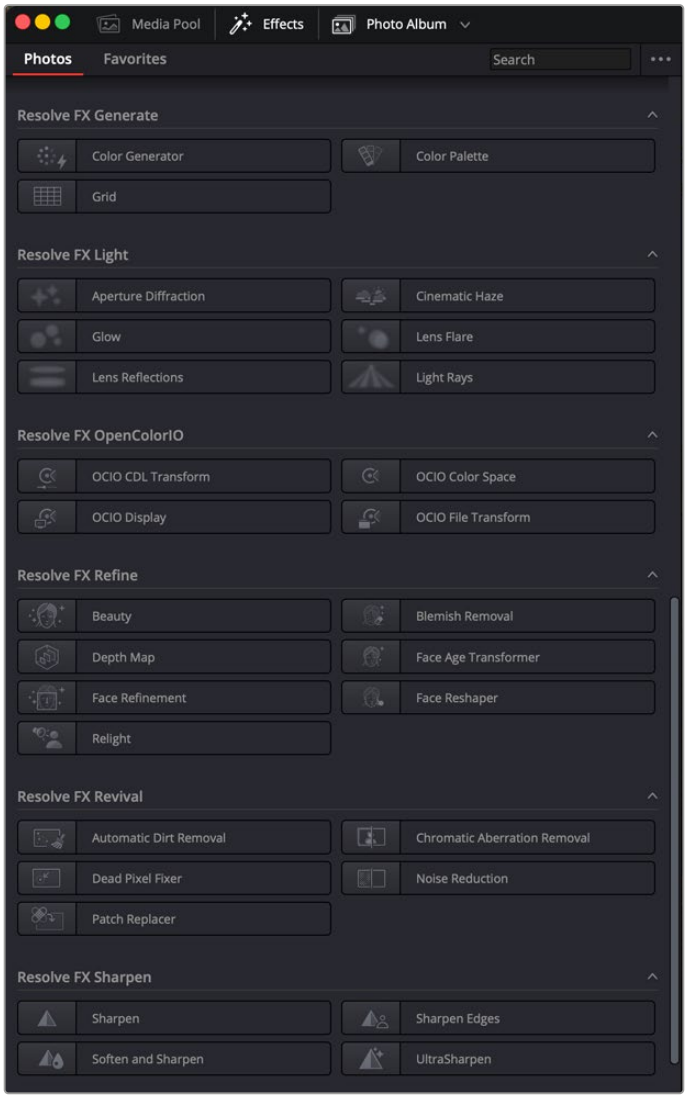


Capture: Shows or hides the capture interface that lets you capture still photos to your computer when it's tethered to your camera.

Inspector: Shows or hides the Inspector which lets you edit both RAW and debayered photo parameters, and edit any effects properties.

The Media Pool

In the Photo page, the Media Pool contains only the still-image media that you've imported for editing into the project at hand, as well as all of the albums that you're going to be using to organize your photos. Unlike the media pools found on other pages, it will not show any video, audio, timelines, or effects clips. These are hidden from view, as the Photo Page is dedicated to just still-images.

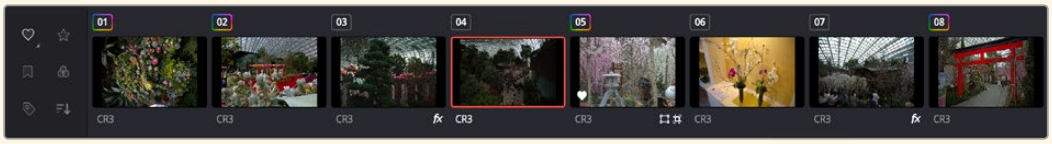


The Media Pool in the Photo Page.

Effects Library

The Effects panel shows a hierarchical list of all of the effects and filters that are available for your photos, sorted by category.

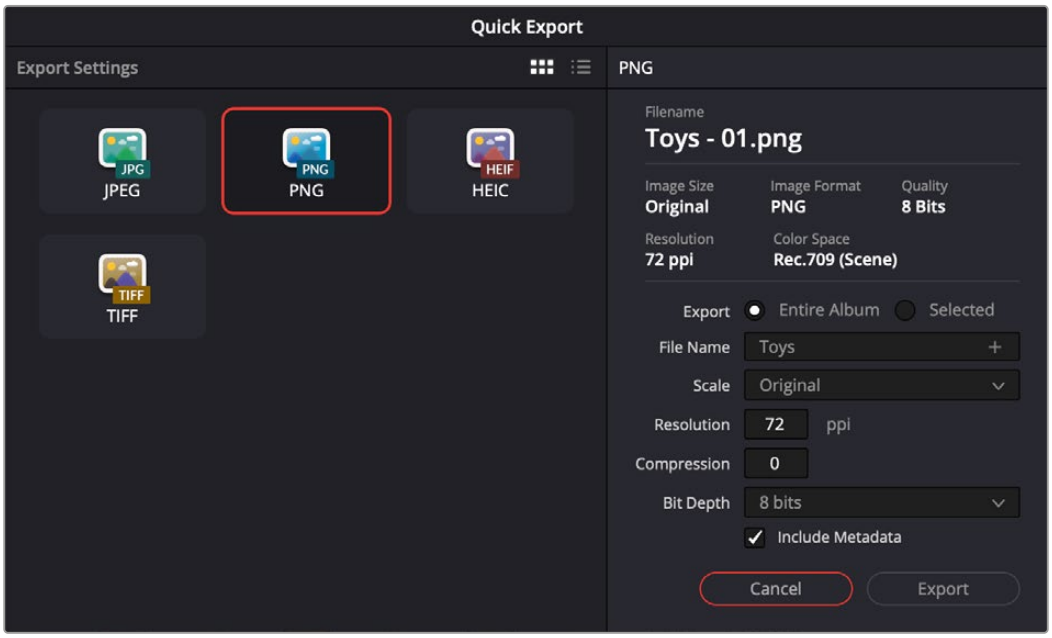
- To preview an effect, ensure that Hover Scrub Preview is checked in the Effects option menu, then simply hover your pointer over any thumbnail in the Effects tab and move it across the thumbnail. The effect will preview in the Viewer using its default parameters.
- To activate a specific effect on a photo, simply drag the thumbnail of the selected effect to a photo in the Album. To adjust the effect's parameters, open the Effects tab in the Inspector.



The Photo Effects library.

Photo Albums

This tab opens up the Photo Album at the bottom of the interface. Like their physical analog, Photo Albums in the Photo page are where you store and organize collections of still images. In DaVinci Resolve, you can equate them to a special type of timeline, built from user-curated stills.



To maximize the still photo capabilities in DaVinci Resolve 21, it's crucial that you organize your media pool images into photo albums. Photos are resolution- and frame rate-independent, while timelines are not. The Photo page uses the Photo Album as its central organizational container, and allows your photos to interact with the rest of the pages in DaVinci Resolve.

The Photo Album Interface.

Quick Export

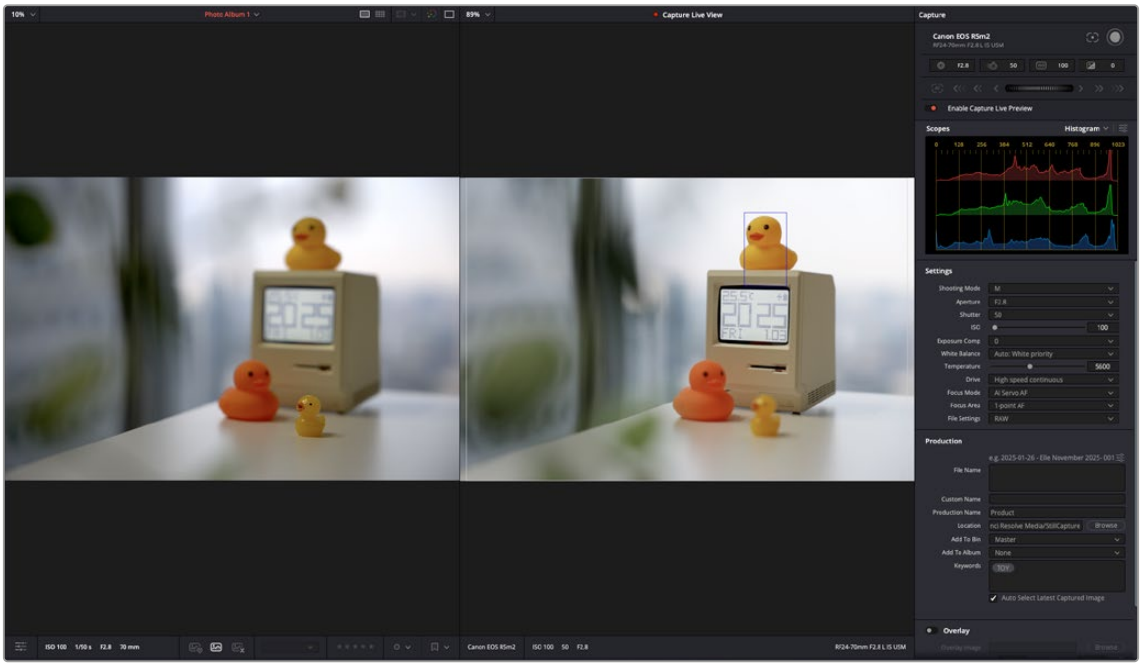
Quick Export opens a delivery window that's designed specifically for still images. Simply select your preferred image format on the left side, enter the file's parameters on the right, and click Export.

The Quick Export tab in the Photo Page.

Metadata

In the Photo page, the Metadata Editor opens in the same place as the Inspector. When you select a photo in the media pool or album, its metadata is displayed within the Metadata Editor. If you select multiple clips, only the first clip's information appears. The Metadata Editor's header contains uneditable information about the selected clip, including the file name, directory, duration, frame rate, resolution, and codec.

There are two dropdown menus at the top to choose which set of metadata is displayed in the Metadata Editor:



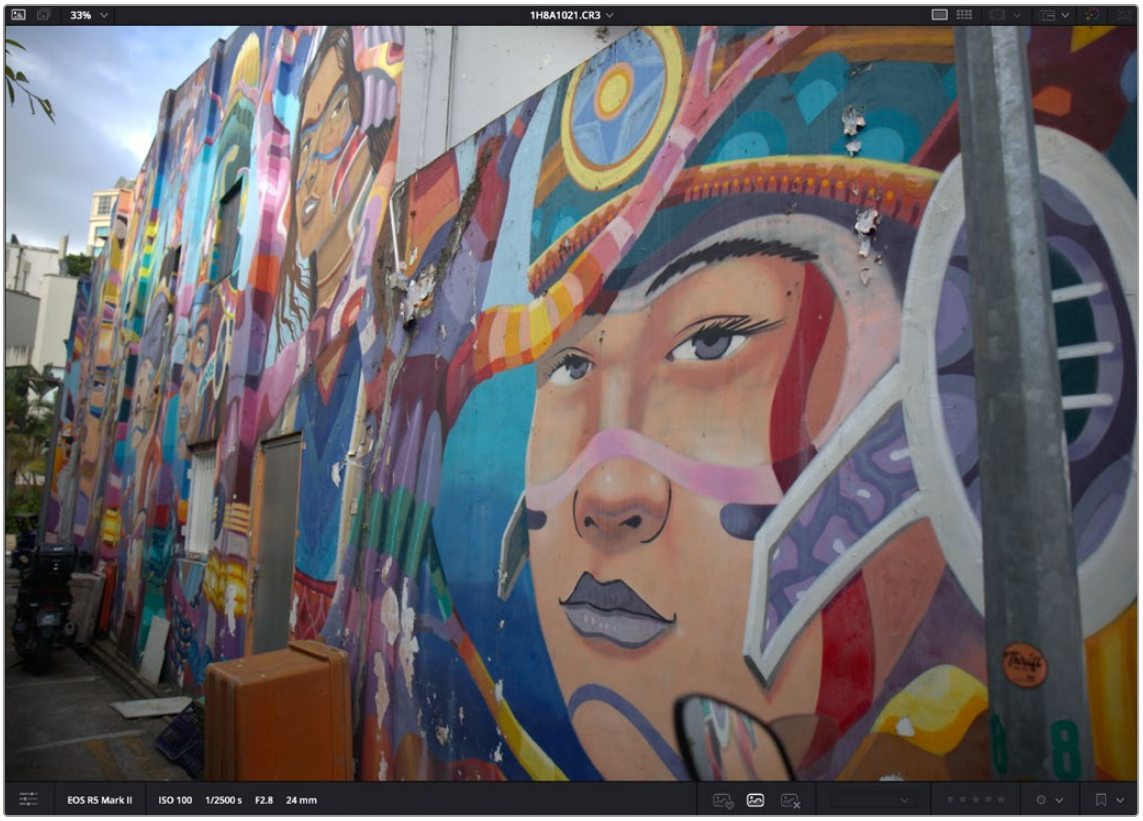
Metadata Presets (to the left): This is your default option. If you've used the Metadata panel of the User Preferences to create your own custom sets of metadata, you can use this dropdown to choose which one to expose.

Metadata Groups (to the right): This dropdown menu lets you switch among the various groups of metadata that are available, grouped for specific tasks or workflows.

The heart of the Metadata Editor is a series of editable fields underneath the header that let you review and edit the different metadata criteria that are available.

Capture

This tab opens up the Capture Live View interface for tethered shooting directly from your camera into DaVinci Resolve. This lets you instantly transfer your shots to the media pool or a photo album for editing or client review—or to simply view your image in higher resolution on a larger screen.



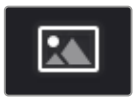
Capture Live View.

Inspector

Use the Inspector to edit RAW and Photo parameters for photos, as well as modify any applied effects and add file metadata.

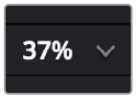
The Viewer

The Photo Viewer lets you take a detailed look at the photo you're editing. It also contains its own toolset to work with your photos.

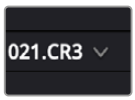


The Photo Viewer.

Top Toolbar



The Photo Viewer top toolbar.



Source: Shows the selected image in the Media Pool.

Photo Album: Shows the selected image in the Photo Album.

Zoom %: Lets you choose the zoom level of the viewer.

Album List: Shows the current album. Click on the dropdown menu to directly open a recent album.

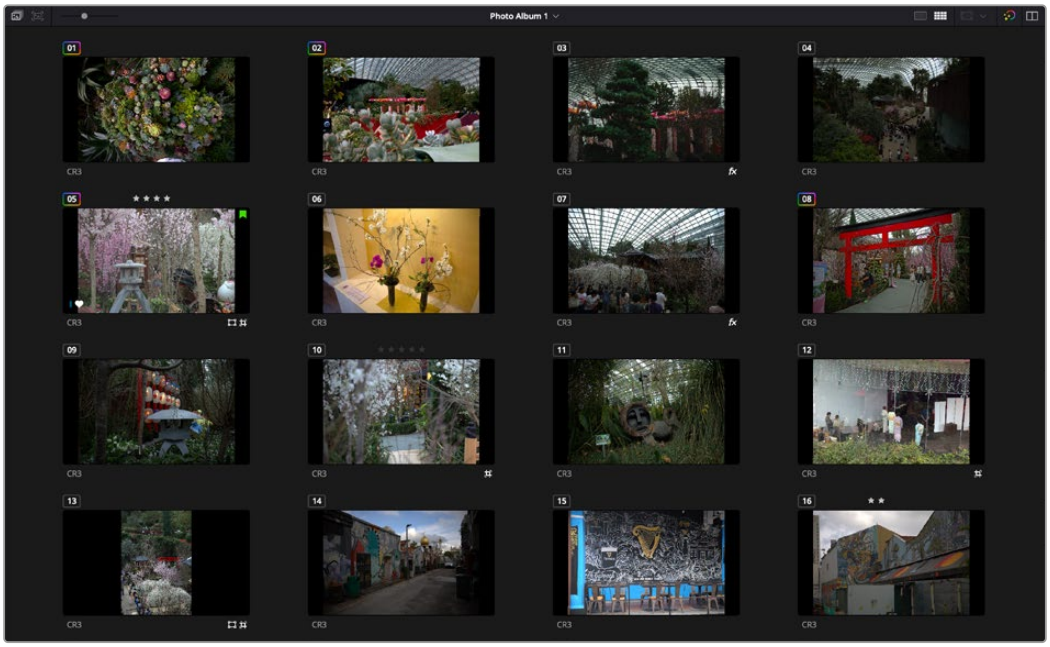
Single View: Opens a large single viewer.

Lightbox: Enters Lightbox mode, which shows resizable thumbnails of all the images in your album.

Viewer Guides: Opens guides for different aspect ratios, safe areas, and user customizable rulers and guidelines.

Photo Preview Resolution: Opens a dropdown to select reduced resolution modes for better responsiveness using very high megapixel images. The default is Auto. Regardless of this setting, DaVinci Resolve always exports using the image's native resolution.

Bypass Color and Fusion: Bypasses any Color or Fusion effects that may have been applied. You can right-click to select to bypass only Color, or only Fusion in the dropdown menu.

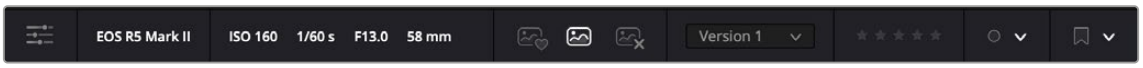


Capture Live View: Opens the live view when shooting tethered in the Capture tab.

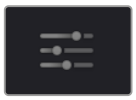
Lightbox

Clicking the Lightbox icon replaces the single photo view, with a series of resizable thumbnails for each photo in your album. This lets you see larger views of multiple photos, and gives you a general overview of what's in your album.

You can also select any image and grade it live while seeing the results update across the whole collection in real time.



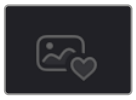
The Photo Viewer Lightbox.



Hand Mode

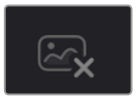
To enter Hand Mode, hold down the H key in the viewer. Once Hand Mode is active, you can drag the hand around the viewer to move the picture. Double click on an area to set the view of the image to 100%. Double-click again to zoom to fit the image to the viewer.

Bottom Toolbar

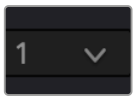


The Photo Viewer Bottom toolbar.

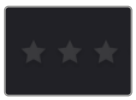
Tools: Opens the Transform, Crop, Looks, and Effects Overlay interfaces.



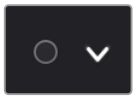
EXIF Data: Shows the camera model, ISO, shutter speed, aperture, and lens metadata.



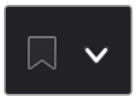
Favorite: Tags the image as a favorite, indicated by a small heart icon.



Untag: Removes the favorite or reject tag from an image.



Reject: Tags the image as rejected, with a small x icon.



Version Selector: Lets you choose another version of the image you've saved.

Star Rating: Lets you assign a one to five star rating for the image.

Color: Lets you assign a color tag to the image. Color tags can be used for organizational operations in the other pages of DaVinci Resolve.

Flag: Lets you assign a color flag to the image. Flags can be used for organizational operations in the other pages of DaVinci Resolve.

Keyboard Shortcuts

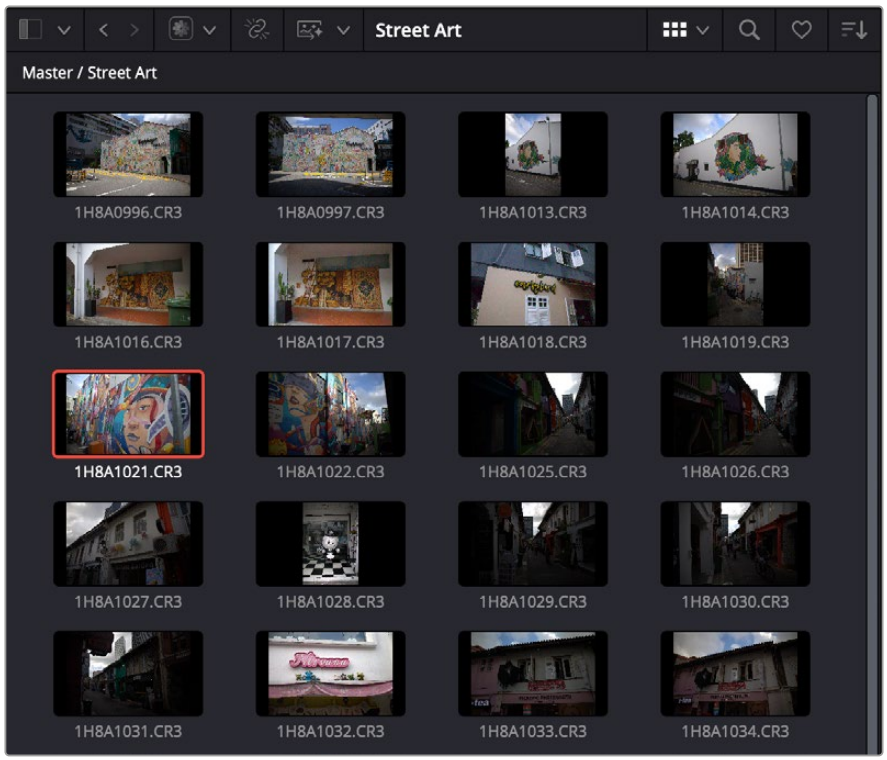
Like all other pages in DaVinci Resolve, the Photo Page has its set of keyboard shortcuts to ease the editing process:

Function	Keyboard Shortcut
Image Capture Capture Panel or Capture Live View must be active	C
Star Rating Works in both Photo Album and Media Pool	Numbers 1-5 assign star rating. 0 removes all stars.
Tag Clip	S = Good Take X = Rejected Take Pressing S or X again will clear the tag.
Rotate and Flip	**Rotate Left:** Command - [**Rotate Right:** Command -] **Flip Horizontal:** Shift - [**Flip Vertical:** Shift -]
Reset and Clea The Inspector must be in focus	**Reset Photo:** Command-R **Remove All Photo Effects:** Shift-R **Remove and Reset All:** Command-Shift-R
Navigate the photo album	**Select Next Photo:** Up Arrow or Left Arrow **Select Previous Photo:** Down Arrow or Right Arrow

Chapter 27

Importing Images to the Photo Page

This chapter describes how to import images into the Photo Page, organize them in the Media Pool, and adjust their metadata.



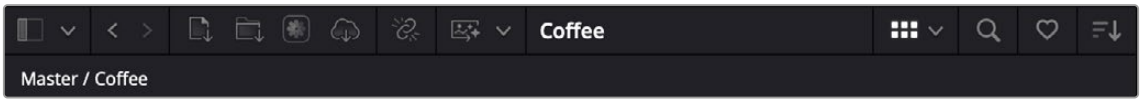
Contents

The Media Pool 601
The Media Pool Toolbar 601
Bin List 602
Importing Photos Into the Photo Page 604
Importing Adobe Lightroom Catalogs 604
Searching the Media Pool 605
Metadata 605

The Media Pool

In the Photo page, your Media Pool contains all the still image media that you've imported for editing into the current project—as well as all the albums that you'll use to organize your photos.

Unlike the media pools found on other pages, your view is limited to still images only. This means it won't show any video, audio, timelines, or effects clips.



The Media Pool in the Photo Page.

PHOTO

The Media Pool Toolbar

The top toolbar in the Media Pool includes a toolset for importing and organizing your photos.

The Media Pool toolbar in the Photo page.

Bin List: Clicking this icon opens the bin hierarchy (all bins and sub-bins) for the selected project. Clicking on a bin name opens that bin in the Media Pool.

Back/Forward: Clicking on these arrows takes you backwards or forwards in the bin history.

Import Media: Imports images using your file browser.

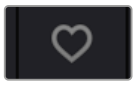
Import Media Folder: Imports an entire folder of images using your file browser..

Import From Photos (macOS only): Imports images using the Apple Photos application.

Import Blackmagic Cloud Folder: Imports images from a shared Blackmagic Cloud folder.

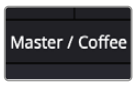
Relink Media: If DaVinci Resolve can not find a previously imported image on your file system, this icon will turn orange, and clicking it will let you find the offline images.

AI Clip Analysis: Opens the AI Clip Analysis window, which lets you queue multiple AI analysis functions sequentially. For more information on the AI Clip Analysis window, jump to this chapter: Using Clip Metadata.



Bin Name: Displays the name of the currently open bin.

Medial Pool View: Toggles the Media Pool view between Thumbnail and List views.

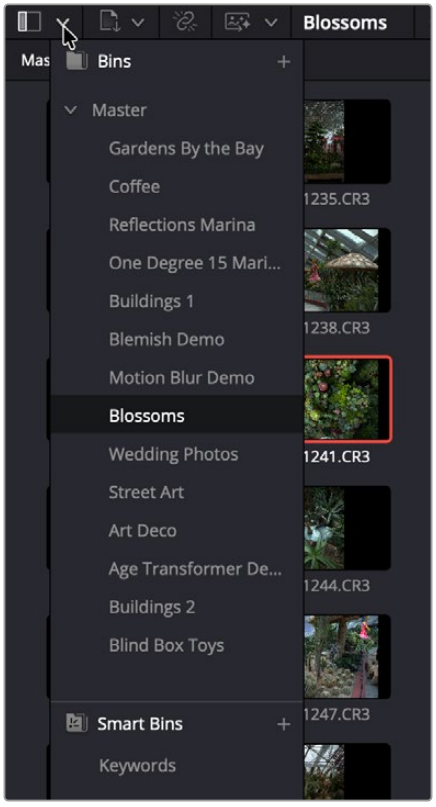


Search: Opens the search field, where you can type in search terms for file name and metadata. If the photos have been analyzed for IntelliSearch, you can use the IntelliSearch features to find images based on their content. For more information on IntelliSearch, jump to this chapter: Adding and Organizing Media with the Media Pool.

Favorites: Displays all images that have been marked as favorited in an album.

Sort: This dropdown menu lets you define the criteria that determines the arrangement of clips in the media pool. Options include: Custom, Camera, Date Time, Clip Name, Bin, Clip Color, Date Modified, Date Imported, and Online Status. You can choose to sort in ascending (bottom to top) or descending (top to bottom) order.

Bin Path: Directly underneath the toolbar is the bin path. Clicking on any bin name in that path takes you to that bin.



Bin List

When you click on the Bin List in the upper left, you can view a hierarchical list of bins used for organizing your photos—which is also used to organize your albums. By default, the Media Pool has a single bin named “Master,” but you can add more bins to organize timelines and clips by clicking on the Bin List and choosing + Add Bin. You can rename any custom bin by double-clicking on its name and typing a new one, or by right-clicking a bin’s name and choosing Rename Bin.

The browser area shows the contents of your currently selected folder. Every still photo, bin, and album appears here. You can create an unlimited number of albums within a single project.

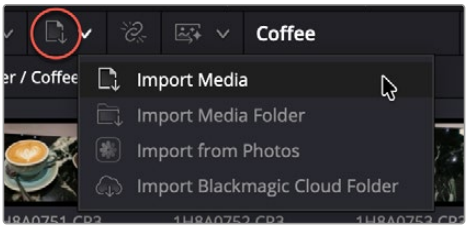
The Media Pool can be displayed in either Thumbnail view, or List view.

In List view, you can sort the contents by any subset of all the metadata available in the Metadata Editor of the Media page.

Click on the Bins icon to open the bin list dropdown.

Bins and Smart Bins

There are two kinds of bins in the Media Pool, and each appears in its own section of the Bin List. These are the differences between both bins:



Bins: Simple, manually populated folders. Drag and drop anything you like into a bin—you can also relocate your media to another bin at any time. Bins may be hierarchically organized, so you can create a matryoshka nesting doll of bins, if you'd like. To create a new bin, right-click within the bin list and choose Add Bin from the contextual menu.

Smart Bins: These are procedurally populated bins, meaning that the custom rules employing metadata are used to dynamically filter the contents of the Media Pool whenever you select a Smart Bin. In effect, Smart Bins help to organize the contents of your project—including the metadata attached to each photo, from exif data and description text to keywords and comments. This allows for the quicker retrieval of specific photos when you need them. To create a new Smart Bin, click the bin list and choose + Add Smart Bin. In the dialog box that appears, you can edit the name of that bin and the rules it uses to filter clips.

Then click Create Smart Bin.

Importing Photos Into the Photo Page

While adding photos to the Media Pool in the Media page provides the most organizational flexibility and features, if you find yourself in the Photo page and wish to import photos for immediate use, you can do so in a couple of different ways.

Clicking on the Import icon (red circle) presents a dropdown menu for your import options.

To use the Import Media icon in the Photo page Media Pool:

1. With the Photo page open, click on the Import Media list icon at the top of the Media Pool.
2. Choose from the following options:

   Import Media: Opens a file requestor to import selected photos.

   Import Media Folder: Opens a file requestor to import all photos inside the selected folder.

   Import from Photos (macOS only): Opens the Photos app in macOS and lets you choose photos for import.

   Import Blackmagic Cloud Folder: Lets you link a Blackmagic Cloud folder and imports the photos stored within.

To use the Import Media command in the Photo page Media Pool:

1. With the Photo page open, right-click anywhere in the Media Pool, and choose Import Media.
2. Use the Import dialog to select one or more photos to import, and click Open.

   Those photos are then added to the Media Pool of your project.

Importing Adobe Lightroom Catalogs

You can also import existing Adobe Lightroom Catalogs into the Photo page—but these images will be imported in their original state, without any presets or edits that you applied in Lightroom.

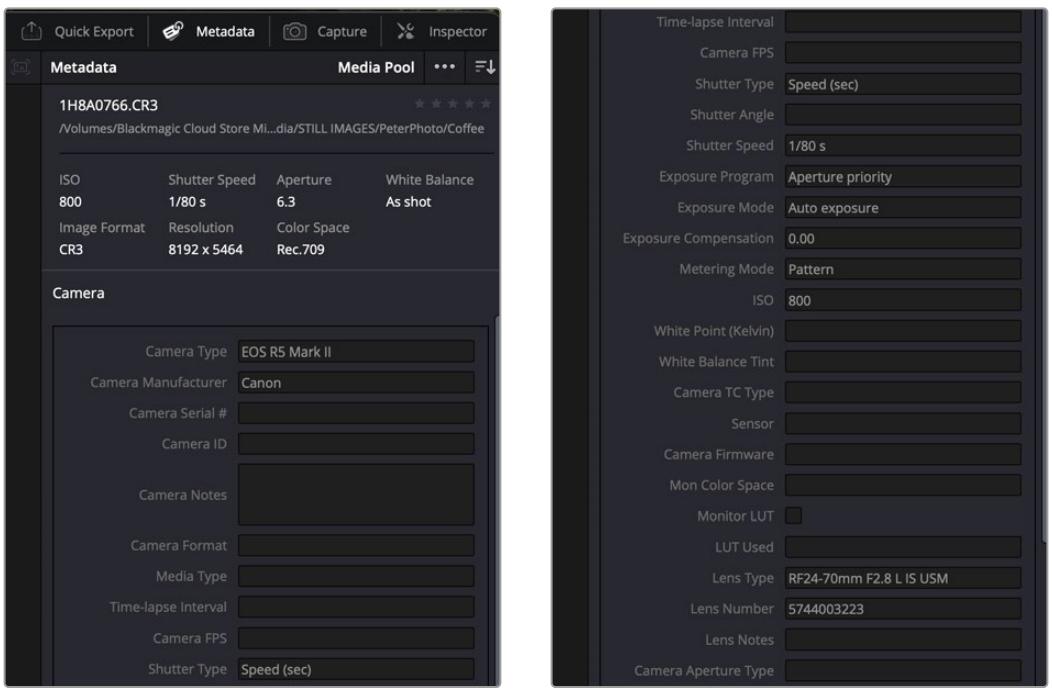
To Import a Lightroom Catalog:

1. Select File > Import > Lightroom Catalog
2. Navigate your file browser to the Lightroom Catalog you wish to import.
3. Click Open.

Searching the Media Pool

Click on the magnifying glass icon in the toolbar to open a search field, where you can look for specific image names. You can also use the IntelliSearch tool for a comprehensive, near-instant search of people and objects that you type into this field. For more information on using IntelliSearch, jump to this chapter: Adding and Organizing Media with the Media Pool.

Metadata



When you go to the Photo page and click on the Metadata tab, the Metadata Editor opens in the same place as the Inspector. Selecting a photo in the Media Pool or Album displays its metadata within the editor. If you select multiple clips, only the first clip's information appears. The Metadata Editor's header contains uneditable information about the selected clip—including the file name, directory, duration, frame rate, resolution, and codec.

To choose which set of metadata is displayed in the Metadata Editor, navigate to the two dropdown menus located at the top.

Metadata Presets (to the left): By default, this is set to "Default". If you've used the Metadata panel of the User Preferences to create your own custom sets of metadata, you can use this dropdown to choose which one to expose.

Metadata Groups (to the right): This dropdown menu lets you switch between the various groups of metadata that are available, grouped for specific tasks or workflows.

At the heart of the Metadata Editor is a series of editable fields beneath the header that let you review and edit the various metadata parameters that are available. For example, in the Camera metadata group, you can manually adjust EXIF data such as shutter speed, ISO, lens type, and so on.

The Metadata tab, opened to the Camera Metadata group. Here you can edit fields including ISO, shutter speed, aperture, and more.

Chapter 28

Using Photo Albums

Photo Albums let you organize and modify photos while maintaining their source resolution. In addition, they determine how still images in the Photo page interact with the other pages in DaVinci Resolve.

PHOTO

Contents

Understanding Photo Albums 607
Photo Album 607
Using the Same Photo in Multiple Albums 608

Photo Album Thumbnails 610
Adding Versions in a Photo Album 611
Integrating Photo Albums with Other Pages in DaVinci Resolve 612
Using Photo Albums with the Color Page 612
Using Photo Albums with the Fusion Page 613
Using Photo Albums with Cut, Edit, and Fairlight Pages 613

Understanding Photo Albums

To get the most out of DaVinci Resolve's still-photo capabilities, organizing your media pool images into Photo Albums is a must. Photo Albums are generally analogous to timelines in the other pages of DaVinci Resolve, but with two major differences:

- Photo Albums are independent of both resolution and frame rate.
- Timelines have a set resolution and frame rate.

The Photo page uses the Photo Album as its central organizational container, and determines how your photos will interact with the other pages in DaVinci Resolve.

The Photo Album translates the single-frame nature of still images into a format that can be used within DaVinci Resolve's timeline-based workflow.

Photo Album

This tab opens up the Photo Album at the bottom of the interface. Like their physical analog, Photo Albums in the Photo page are where you store and organize collections of still images, and any adjustments or changes that you've made to the image. In DaVinci Resolve, you can equate them to a special type of timeline, built from user-curated stills.

You can create an unlimited number of photo albums to organize your stills.

The Photo Album interface.

A Photo Album in the Media Pool.

To create a Photo Album:

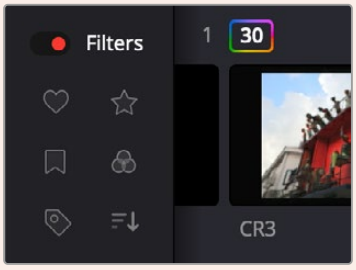
- Right-click in the Media Pool and select New Photo Album from the context menu.
- In the main menu, select File > New Photo Album.

To add an image or images to a Photo Album:

1. Select an image or group of images in the Media Pool.
2. Right-click on an image and select Add Photo(s) to Album
3. The selected photos will be added to the current Photo Album

To delete an image or images from a Photo Album:

1. Select an image or group of images in the Media Pool.
2. Right-click on an image and choose Delete Selected.
3. The selected photos will be removed from the current Photo Album.



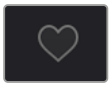
Using the Same Photo in Multiple Albums

You can add the same photo to multiple albums, but any adjustments you make to that photo will be applied across all the albums it's located in. This means the same photo cannot be adjusted independently, as long as you're in the same project.

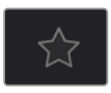
Filtering a Photo Album

Once an album has been created and populated, you can use the Photo Album toolset to organize, sort and label still images for further use in DaVinci Resolve. You can add flags, colors, and tags to images in the Viewer, then use the filter tools in the Photo Album to organize and sort them.

NOTE: You cannot rearrange the order of your photos in an photo album manually by dragging them like you would in a timeline. Unlike a video timeline, there is no "before" or "after" in a photo album. You can modify their sequence by filtering the album, as described below.



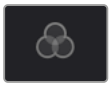
The Photo Album filtering icons.



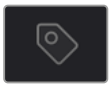
Filtering a photo album:

The filter icons generally have a click, and right-click function that work in tandem. The icons will highlight white if they're active.

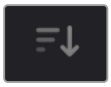
- **Filters:** Toggle this switch to turn on or off all of the filters below.



Tags: Click on this icon to filter the photos in the album based on tags. Right-click on the icon to choose the criteria by Good Take, Untagged, or Rejected flags, or a combination of those tags.

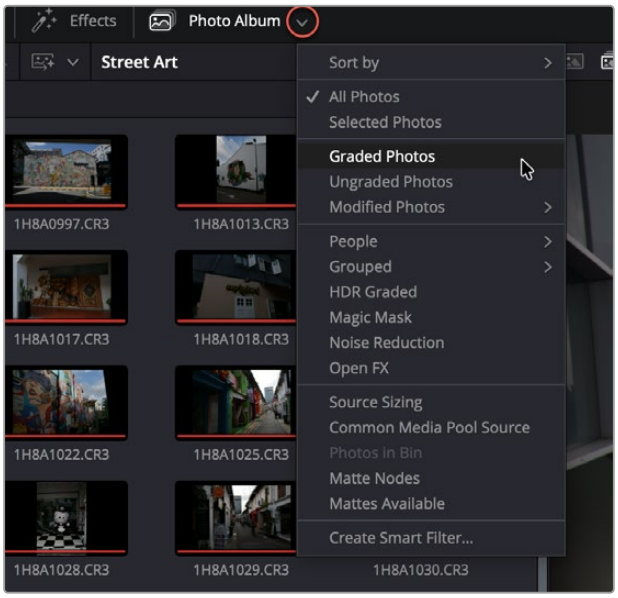


Rating: Click on this icon to filter the photos in the album based on rating. Right-click on the icon to choose the criteria—this includes equal to, is less than or equal to, and is more than or equal to. Then add the star rating you want to use as the base criteria.



Flags: Click on this icon to filter the photos in the album based on flags. Right-click on the icon to choose which color flag or flags you want to use as the criteria.

Color: Click on this icon to filter the photos in the album based on clip color. Right-click on the icon to choose which color or colors you want to use as the criteria.



Keywords: Click on this icon to filter the photos in the album based on keywords. Right-click on the icon to choose which keywords you want to use as the criteria.

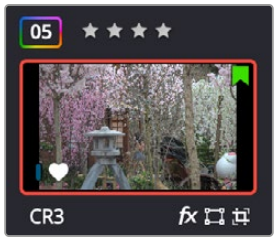
Sort Photos: Click on this icon to toggles the sort order of the photos in the album either in ascending or descending value. Right-click on the icon to choose which metadata value you want to use as the sort criteria.

Advanced Filtering

For more advanced filtering options, you can sort and filter photos using the dropdown menu beside the Photo Album tag.

Clicking on the Photo Album dropdown menu (circled red) opens up the advanced filtering options.

You can filter a photo album by the following attributes:



- **Sort By:** Opens the standard sorting criteria that is also found in the filter header of the Photo Album.
- **All Photos:** No photos are filtered, and every image in the current album is shown.
- **Selected Photos:** Filters all currently selected photos.
- **Graded Photos:** Filters all photos that have been adjusted or graded.
- **Ungraded Photos:** Filters all photos that have not been adjusted or graded.
- **Modified Photos:** Filters all photos by the most recent time they were modified. A submenu selects a time boundary for the filter (last hour, last 3 hours etc.).

- **People:** Filters photos by the individual humans in them, as analyzed by IntelliSearch.
- **Grouped:** Filters all photos belonging to a particular group, a submenu shows all available groups.
- **HDR Graded:** Filters photos based on they've been adjusted with the Color page's HDR toolset.
- **Magic Mask:** Filters photos based on if they've used the Color page's Magic Mask tool.
- **Noise Reduction:** Filters photos based on if they've used the Color page's Noise Reduction toolset.
- **Open FX:** Filters photos based on if they have an effect applied.
- **Source Sizing:** Filters photos based on if they have been resized.
- **Common Media Pool Source:** Filters all photos sharing the same source in the Media Pool as the current clip.
- **Matte Nodes:** Filters all photos with an exposed matte node in the Color page.
- **Mattes Available:** Filters all clips with a matte assigned to them in the Color page, whether they're used or not.
- **Create Smart Filter:** You can also create your own Smart Filter to sort clips based on any of the intrinsic or user-entered metadata available. Smart Filters work much the same way as Smart Bins, and they're created and edited using the same procedures.

For more information on creating a Smart Filters, jump to this chapter:
Color Page Timeline and Lightbox.

Photo Album Thumbnails

The icons on each Photo Album thumbnail indicate which operations have been applied to a photo.

The icons on a Photo Album thumbnail.

Here's the full list of Photo Album thumbnail icons and what each represents:

Rainbow Rectangle around image number: A RAW or Photo operation has been applied.

Star Rating: The user rating assigned to the clip. You can click this rating to change it.

Flag: In the upper right of the thumbnail, the colored flag icon shows you the flags that have been assigned to the photo.

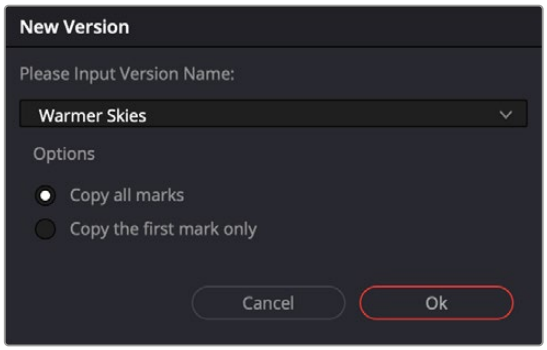
Color: In the lower left, the small colored dot shows you the colors that have been assigned to the photo.

Heart or X: This shows whether a Favorite or Rejected tag has been assigned to the photo.

Image Format: In the lower left under the thumbnail, this shows the image format of the photo.

FX: In the lower right under the thumbnail, this shows that an effect has been applied to the photo.

Transform: The rectangle icon in the lower right under the thumbnail shows that a transform operation has been applied to the photo.



Crop: The overlapping angles icon in the lower right under the thumbnail shows that a crop operation has been applied to the photo.

Adding Versions in a Photo Album

One useful feature of a Photo Album is its versioning feature. You can make adjustments to your photo, save it as a version, then try something radically different on the same image, knowing that the original version is safely stored. You can save an unlimited number of versions of an image.

It's easy to create a version, make your edits, then right-click on a photo in the Photo Album and select New Version from the context menu. This will open up the New Version dialog box, where you can add a descriptive name for your version and then click on the OK button.

The New Version dialog box.

The Version Dropdown at the bottom of the Photo Viewer.

It's equally easy to switch versions too. Any saved versions are in the exact same right-click context menu you created it with. In addition, there's a simple dropdown selector at the bottom of the Photo Viewer you can use.

IMPORTANT: Only the currently selected version will be exported in Quick Export and the Deliver page. All other versions will be ignored.

Integrating Photo Albums with Other Pages in DaVinci Resolve

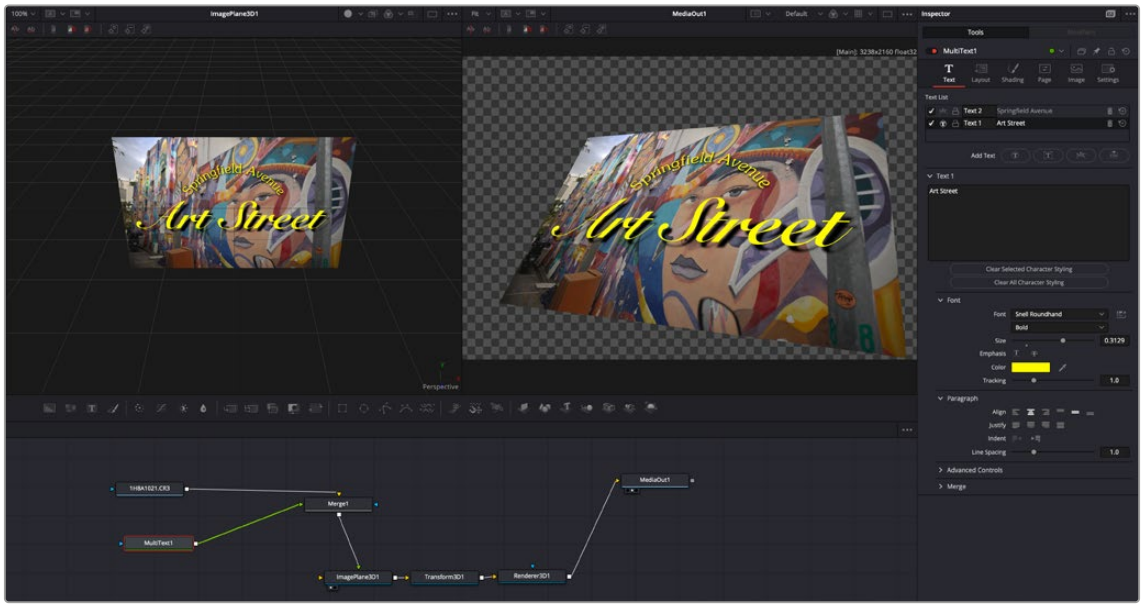
Photo Albums are also used to move still photos at their native resolution between the different pages in DaVinci Resolve. Effectively, Photo Albums translate the single-frame nature of photos into a format that can be understood by the other pages. This means that in addition to the Photo page, you can use the tools in the Color page and Fusion page on your still photos too.

NOTE: When moving into a different page, each still photo will have a default time duration assigned to it. When returning to the Photo page, this duration will collapse again. If you wish to change the default time duration of a still photo, go to DaVinci Resolve > Preferences > User > Editing > General Settings, and set a new value in the Standard still duration field.

Using Photo Albums with the Color Page

To take advantage of DaVinci Resolve's extensive motion picture color grading toolset, consider bringing your Photo Album into the Color page for photo editing. You can now apply the same color grading tools used in major films to edit your photos. The Photo Album transforms into a standard timeline while you're using the Color page's grading tools. When you're finished, the results are reflected in your album on in the Photo page. If you have a DaVinci Resolve control surface, such as a Micro or Mini Color panel, you can use all the controls to edit your photos with tactile precision.

NOTE: The edits you make in the Photo page automatically become the image's first Node when you bring it into the Color page.



A Photo Album in the Color page.

In this case, we brought a Photo Album into Color, and used the Color Warper tool to alter the woman's hair color to a darker shade of green, while leaving the rest of the image unchanged.

Using Photo Albums with the Fusion Page

Bringing a Photo Album into the Fusion page turns the application from a photo editor into a photo compositor. Fusion's deep compositing toolset lets you creatively use masks, keying, text, and a real 3D space to modify and enhance your still images.

A Photo Album in the Fusion page.

In this instance, we brought a Photo Album into Fusion, and set up a node tree that first created the titles using the Multitext tool—then took that composited image into a 3D space to scale and rotate it.

We then brought the image back into the Photo page for export in its original resolution, and as a high dpi image suitable for printing.

Using Photo Albums with Cut, Edit, and Fairlight Pages

Due to the non-temporal nature of the Photo Album, there's not much that you can do with it in the Cut, Edit, or Fairlight pages, other than view the album as a timeline. These pages are designed to work with moving video and audio clips. However, you can export an album's final image from the Photo page, and then re-import it as a normal still for use in video projects.

Image Editing in the Photo Page

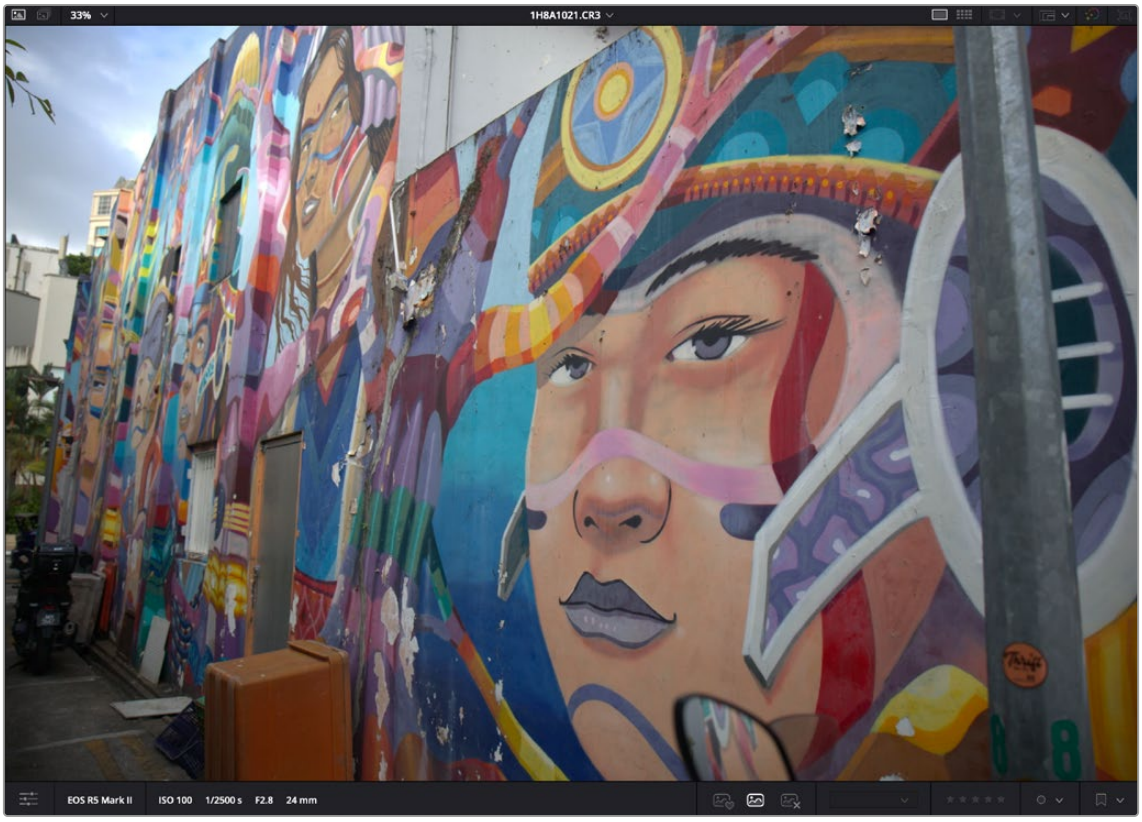

Image editing in the Photo page is non-destructive, since your edits are stored in your Photo Album. This means your original photos are never altered, and your changes are saved in your DaVinci Resolve Project.

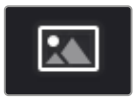
Most image editing tools are in the Inspector, but you can also find some visual-oriented adjustments in the Tools interface (bottom left of the Viewer).

NOTE: All grades and effects for still images within albums are applied at the source level. If you add the same image to multiple Photo Albums in the same project, changing that image in one album will also change it in the other one. You can get around this issue by using image Versions.

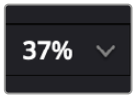
The Viewer

The Photo Viewer is the largest viewer in DaVinci Resolve, and gives you a detailed look at high-resolution images while you're editing them. It also has its own toolset to work with your photos.

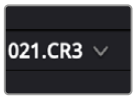


The Photo Viewer.

Top Toolbar



The Photo Viewer top toolbar.



Source: Shows the selected image in the Media Pool.

Photo Album: Shows the selected image in the Photo Album.

Zoom %: Lets you choose the zoom level of the viewer. The keyboard command-Z will fit the whole image to the viewer's size, while Option-Shift-Z will make the image 100% actual size.

Album List: Shows the current album. Click on the dropdown menu to directly open a recent album.

Single View: Opens a large single viewer.

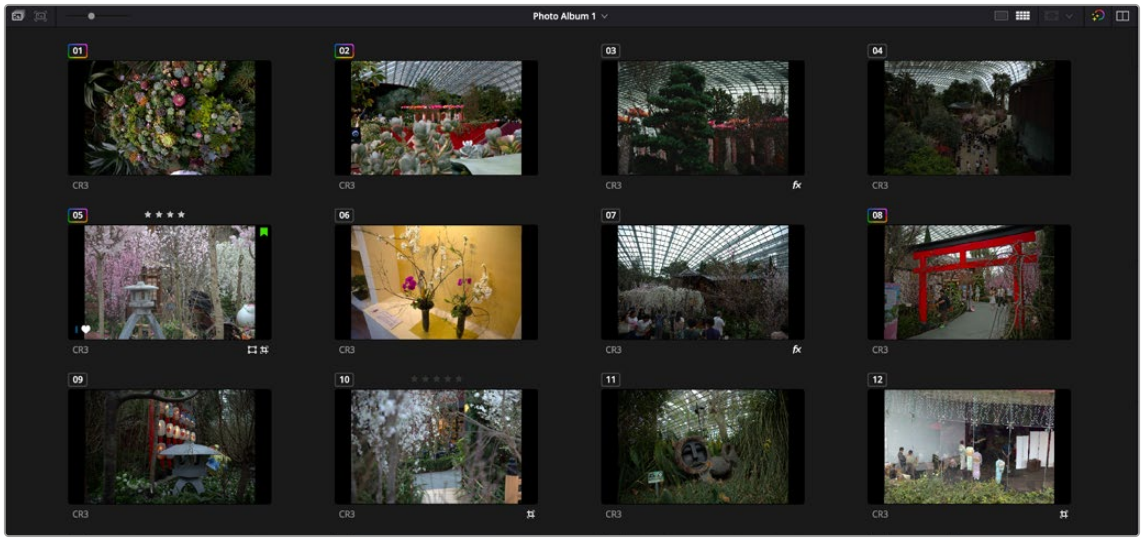
Lightbox: Enters Lightbox mode, which shows resizable thumbnails of all the images in your album.

Viewer Guides: Opens guides for different aspect ratios, safe areas, and user-customizable rulers and guidelines.

Photo Preview Resolution: Opens a dropdown to select reduced resolution modes for better responsiveness using very high megapixel images. The default is Auto. Regardless of this setting, DaVinci Resolve always exports using the image's native resolution.

Bypass Color and Fusion: To bypass any Color or Fusion effects that have been applied, right-click and select bypass only Color, or only Fusion in the dropdown menu.

Capture Live View: Opens the live view when shooting tethered in the Capture tab.



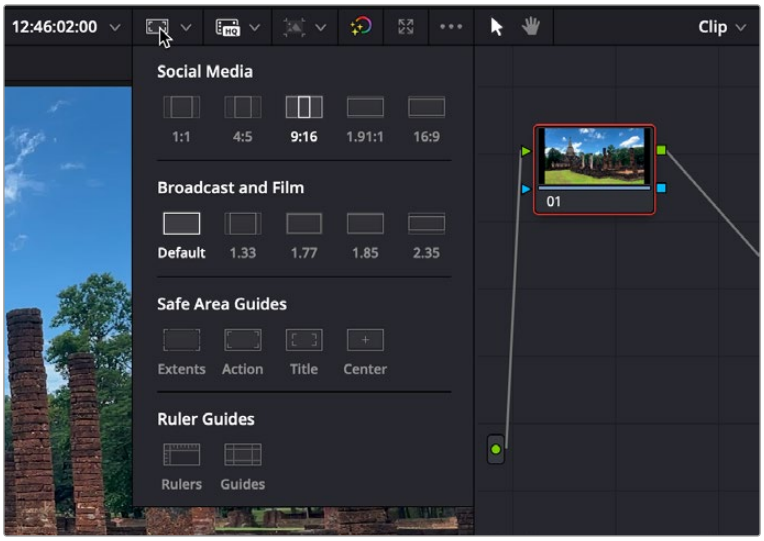
Hand Mode

Holding down the H key in the viewer enters hand mode. When hand mode is active, hdragging the hand around the viewer moves the picture. Double click on an area to set the view the image at 100% real size. Double-click again to zoom to fit image to viewer.

Lightbox

Clicking the Lightbox icon replaces the single photo view with a series of resizable thumbnails for each photo in your album. This gives you a larger view of multiple photos, and a general overview of what's in your album.

To change the thumbnail size, adjust the slider at the top left of the Lightbox. You can also select any image and grade it live while seeing the results update across the whole collection in real time.



The Photo Viewer Lightbox.

Guides and Rulers

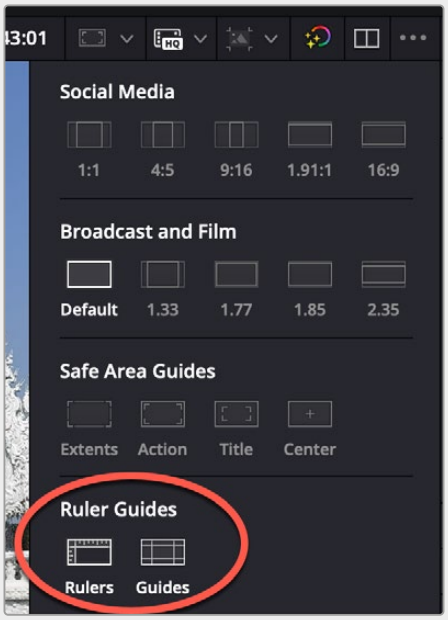
The Viewer Guides icon at the top of the Viewer gives you access to safe area overlays, and customizable rulers and guides for precise image editing needs.

Safe Area

This dropdown menu overlays many useful framing guides over the Viewer, so you can see which parts of the image will be included or cropped out, if you change the image's aspect ratio. The framing guides can be turned on and off by toggling the Safe Area Framing Guide icon in the Viewer, and the exact guides can be selected in the dropdown menu.

\The Safe Area Framing Guide icon and the possible framing options.

Custom Guides and Snapping in the Viewer

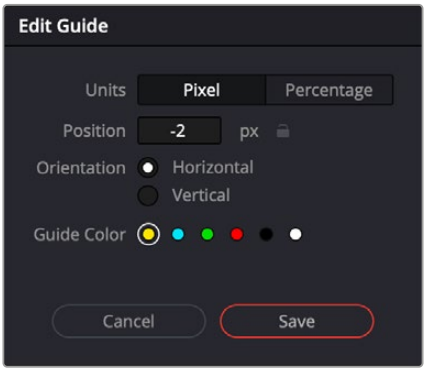


When you create custom guides in the viewer, you can fully customize and create specific geographic locations in the frame—then have the image snap to those locations in other operations. You can create Guides, which are colored lines that cross the frame horizontally or vertically, and Rulers, which provide measurement metrics along the edges of the frame. Both Guides and Rulers are overlay tools for adjusting your video position, and only show in the Viewer, not your final project output.

The Viewer with Guides and Rulers enabled.

To show Guides and Rulers independently, go to the Viewer Guides dropdown menu on the Viewer, then click on their corresponding icons in the Ruler Guides section.

Alternatively, you can independently activate them in the View > Rulers, and View > Guides menus.



The Ruler Guides section of the Viewer Guides dropdown.

To Show and Modify a Ruler:

1. Activate the Ruler by choosing View > Rulers > On. Alternatively, go to the Viewer Guides dropdown in the Timeline Viewer and click on the Ruler icon.
2. Choose which metric you want the Ruler to use in View > Rulers, or by right-clicking on the Ruler in the Viewer.

   Pixel: Shows the ruler in number of pixels from the origin point (0,0) in the middle of the frame using a standard x/y cartesian coordinate graph, that reflects the Position field in the Video Inspector.

   Percentage: Shows the ruler in percentage distance from the origin point (0%, 0%) in the top-left of the frame. The top ruler runs from 0% at the left to 100% at the right, while the side ruler measures 0% from the top to 100% at the bottom. For example, a point at the exact center of the frame would be at (50%, 50%).

The Add/Edit Guide dialog.

To Show and Create a Guide Line:

1. Activate the Guides by choosing View > Guides > On. Alternatively, go to the Viewer Guides dropdown in the Timeline Viewer and click on the Guides Icon.
2. Create a new Guide by choosing View > Guides > Add Guide. Alternatively, right-click on the Ruler in the Viewer and select Add Guides.
3. In the Add Guides dialog, choose the position and orientation of your new guide, and click Add.

   Units: Choose which metric you want the guideline to use. Pixel shows the number of pixels from the guide's origin point, while Percentage shows the percentage distance from the top left of the frame at 0%,0%.

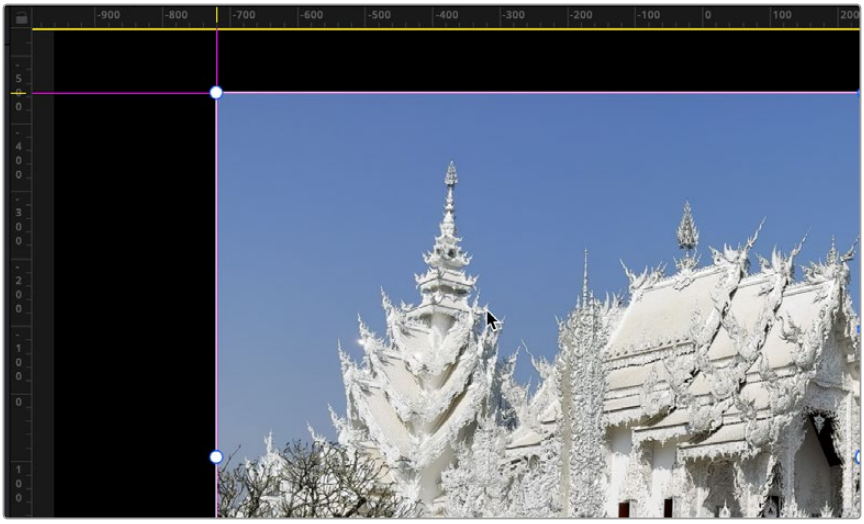
   Position: Enter a value for where in the frame you want the guideline to intersect. You can also click and drag this line in the viewer to position it by eye (a small pop-up will reveal the exact position value as you move it). To prevent this guide from being moved accidentally, click the lock icon.

   Orientation: Choose either a horizontal or vertical orientation for the line.

   Color: Choose the color of the guideline from the available options.

To Modify a Guideline:

- Click and drag the line to any position in the viewer. A small pop-up window will indicate the exact position value.
- To change the color of the Guidelines for legibility, right-click in the Ruler and select a new color from the Guide Color context menu.
- To delete a line, right-click that line in the viewer and choose Remove Guide.
- To change an existing line's position and orientation, right-click on it in the Viewer and choose Edit Guide.



- To delete all lines, only horizontal lines, or only vertical lines, choose View > Guides and choose which lines you want removed. Alternatively, simply right-click on the Ruler.
- To avoid accidental movement, you can lock a Guide by clicking on the small lock icon in the upper-left of the ruler. Alternatively, choose View > Guides > Lock Guides.

Right-click on the Ruler to open a context menu and adjust all parameters of the Rulers and Guidelines.

Snapping to Guidelines

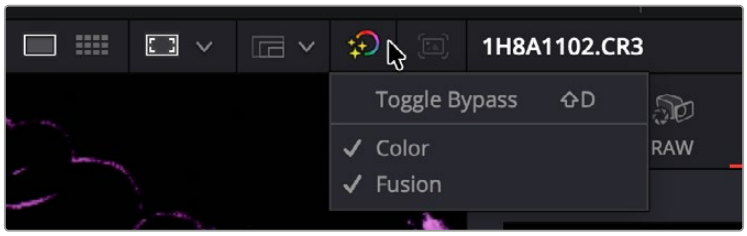
When moving the clip inside the frame using the Transform Viewer controls, the guide will automatically snap the image edge to it. The guideline then turns purple, indicating the image is accurately placed. To disable this behavior and bypass the snapping function, hold down the Option key while moving the image in the viewer.

The Guidelines turn purple when the edge of the image snaps to that location

Photo Preview Resolution

Because Photo uses the native resolution of your media, processing times depend on your camera's photo formats. Larger formats could slow down your workstation significantly.

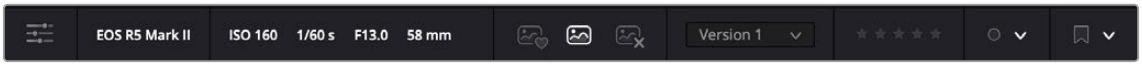
To keep performance snappy, the Photo page uses a reduced preview resolution in the Viewer. You can adjust the parameters of this setting via Playback > Photo Album Preview Resolution.



The options are:

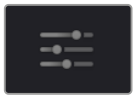
- **Auto (default):** Downscales any photo over 4K in resolution to 4K size for preview.
- **Full:** Photo will use the full-sized resolution of the image preview, regardless of performance issues.
- **Half:** Reduces the photo resolution by half the size for image preview.
- **Quarter:** Reduces the photo resolution to one quarter the size for image preview.

NOTE: This setting is used for previewing the working image only. On export, DaVinci Resolve will always use the original full-sized image for final output.



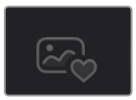
Bypass Color Grades and Fusion

To improve playback performance on low power computers, use the Bypass Color Grades and Fusion Effects button/dropdown to disable all applied grading and effects. Click the button (Shift-D) to disable or re-enable grading and effects, or right-click the same button to access a menu that lets you choose which page you want this button to bypass.



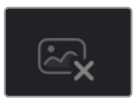
Right-click the Bypass Grades and Fusion button to view the available options.

Bottom Toolbar

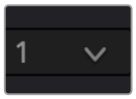


The Photo Viewer Bottom toolbar.

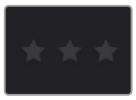
Tools: Opens the Transform, Crop, Looks, and Effects Overlay interfaces.



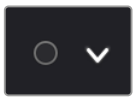
EXIF Data: Shows the camera model, ISO, shutter speed, aperture, and lens metadata.



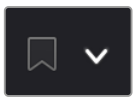
Favorite: Tags the image as a favorite, indicated by a small heart icon.



Untag: Removes the favorite or reject tag from an image.



Reject: Tags the image as rejected, with a small x icon.



Version Selector: Lets you choose another version of the image you've saved.

Rating: Lets you assign a one to five star rating for the image.

Color: Lets you assign a color tag to the image. Color tags can be used for organizational operations in the other pages of DaVinci Resolve.

Flag: Lets you assign a color flag to the image. Flags can be used for organizational operations in the other pages of DaVinci Resolve.

Viewer Tools

Click on the Tools icon in the bottom left of the viewer to access a series of toolbars, whose functions require visual user input directly in the Viewer.

NOTE: When using the onscreen controls, the tool will always show the photo with its original dimensions underneath the transform grid. This helps to guide your adjustments. To activate the transform operation and apply it to your image, close the tool bar again.

Transform Toolbar

Select Transform to manipulate the image in the Viewer with the onscreen controls. You can drag anywhere within the clip's bounding box to adjust pan and tilt, drag any diagonal corner to proportionally resize, drag any top/bottom/left/right side to squeeze or stretch the width or height, or drag the center handle to rotate.

The Transform Toolbar.

The onscreen controls also correspond to the following editable parameters, which are also editable in the Video Inspector.

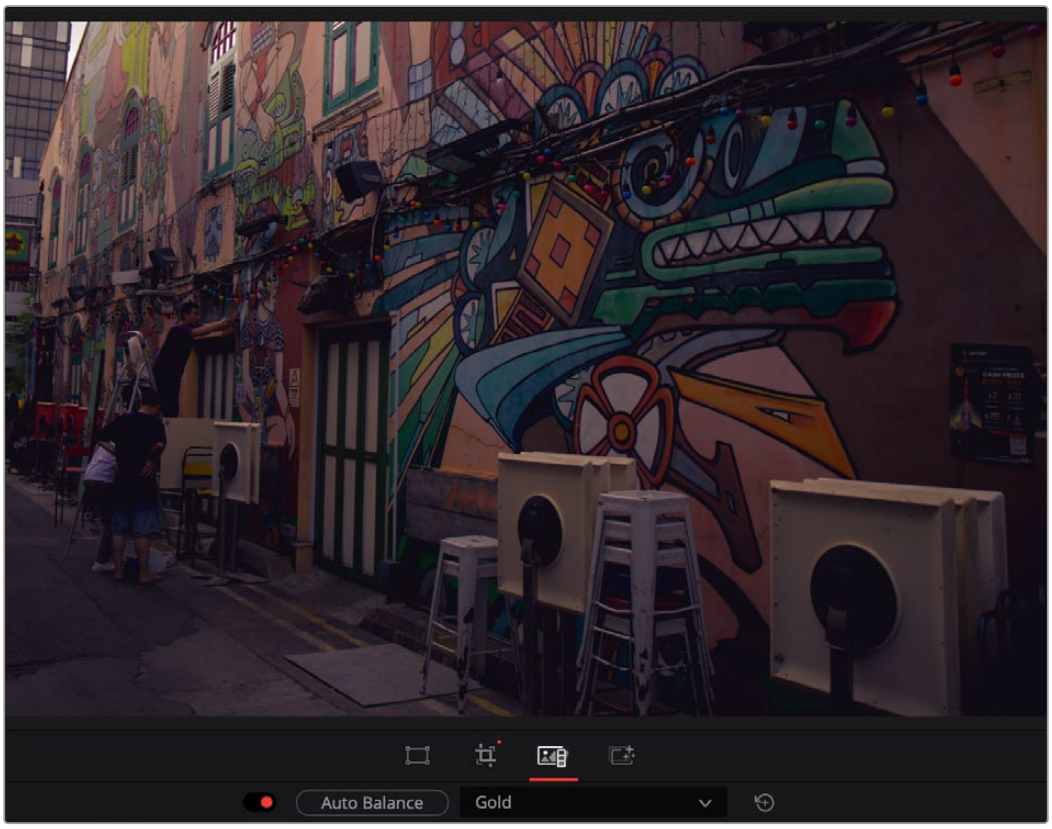
- **Toggle Button:** Lets you enable or disable an effect without losing your custom adjustments.
- **Zoom Width and Height:** Enlarges or shrinks an image. The X and Y parameters can be linked to lock the aspect ratio of the image, or released to stretch or squeeze the image in one direction only.
- **Zoom Link:** Activate this lock to link the width and height zoom together. This retains your photo's proportions in a zoom operation. Deactivate this lock to zoom width and height separately.
- **Position X and Y:** Moves the image within the frame, allowing pan and scan adjustments to be made. X moves the image left or right, and Y moves the image up or down.
- **Rotation Angle:** Rotates the image around the anchor point.
- **Pitch:** Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values will stretch the image to larger extremes.
- **Yaw:** Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and bring the right of the image forward. Higher values will stretch the image to larger extremes.
- **Flip Image:** Flips the image in different dimensions using the two buttons.

  Flip Horizontal control: Reverses the image along the X axis, left to right.

  Flip Vertical control: Reverses the clip along the Y axis, turning it upside down.
- **Reset:** Resets every parameter within a particular category of controls to the default settings.

Crop Toolbar

The Photo page has a set of onscreen controls to directly crop the image in the Viewer. Select Crop to directly manipulate the image in the Viewer. You can drag anywhere within the clip's bounding box to adjust pan and tilt, drag any diagonal corner to proportionally resize, drag any top/bottom/left/right side to squeeze or stretch width or height, or drag the center handle to rotate. Each side of the image has an individual handle for cropping. These parameters are also editable in the Video Inspector.

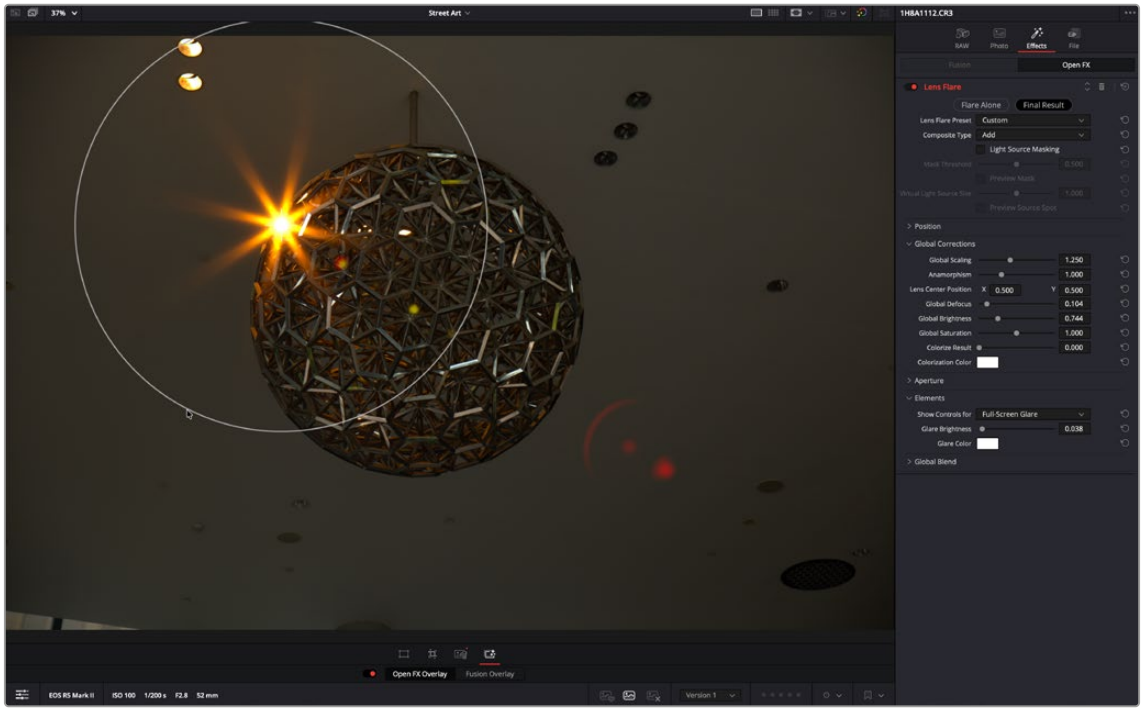


The Crop Toolbar.

- **Toggle Button:** Enables or disables an effect without losing your custom adjustments.
- **Aspect Ratio:** Lets you choose common aspect ratios for still photo and video formats, or chose your own custom ratio. Defaults to As Shot, which is your camera's native aspect ratio.
- Lock Aspect Ratio Activate this lock to lock the currently selected aspect ratio for any crop operations. Unlock to crop to a freeform aspect ratio.
- **Crop Left, Right, Top, and Bottom:** Lets you cut off, in pixels, the four sides of the image.
- **Reset:** Resets every parameter within a particular category of controls to the default settings.

Looks Toolbar

This toolbar applies a DaVinci Resolve preset to an image. You can apply a look as is, or refine it with the editing controls in the Inspector. To use your own looks, add a LUT to the image instead (described later in this chapter).



The Looks Toolbar.

- **Toggle Button:** Lets you enable or disable an effect without losing your custom adjustments.
- **Auto Balance:** Performs a function that automatically sets the dynamic range and color balance of the photo.
- **Look Selector:** This dropdown menu lets you choose which look to apply.
- **Reset:** Resets every parameter within a particular category of controls to the default settings.

Open FX and Fusion Overlays

If you've applied an Open FX or Fusion Effect that has onscreen viewer controls, you can access those controls here, by pressing the appropriate icon.

The Overlay Toolbar showing the Tilt Shift Blur effect's on screen controls.

Inspector

The Inspector is the main interface for editing RAW and Photo parameters for photos, modifying applied Effects, and adding File metadata.

The Inspector in the Photo page showing the RAW, Photo, Effects and File tabs.

Methods of showing parameters in the Inspector:

If the Inspector is already open: Simply select a clip or effect to view its controls in the Inspector.

If the Inspector is closed: Click on the Inspector tab.

NOTE: The Inspector activates various tabs at the top so you can switch between different pages of parameters. For example, selecting a RAW photo will activate its corresponding tab. If you select a normal post-debayered photo such as a .jpg, the RAW section will be deactivated. By default, the Effects tab is also deactivated until you apply an effect to a photo.

Scopes

The Photo page defaults to the Histogram Scope, as this will be the most familiar to photographers, but you can use any of the other scopes in DaVinci Resolve. For more information on the available scopes and how they work, jump to this chapter: Viewers, Monitoring, and Video Scopes.

TIP: You can detach and expand the size of the scope viewer by clicking on the expand icon in the upper right of the histogram.

RAW

These tools let you edit the image using its pre-debayered RAW data settings. RAW editing uses pure sensor data and is generally tuned to your specific camera, so it is the preferred way to adjust exposure and color. If your file is not in a RAW format, this tab will be grayed out.

Your file's RAW settings may vary based on the camera manufacturer, so it's best to refer to your camera's documentation manual. Below are the common controls for RAW de-bayering:

- **Decode Quality:** Lets you de-bayer RAW files at Full, Half, or Quarter resolution to improve performance on slower systems. Lower resolution media has a quicker processing time. If you're working on a low-power system, choose a lower resolution setting for better real-time playback—then switch to a higher quality when rendering the final output. To adjust the decode quality for all photos based on the project settings, select Project Settings.
- **White Balance:** The first option uses the white balance that was as shot in camera. The other options offer White Balance presets, which automatically adjust the Temperature and Tint parameters. These options include Daylight, Cloudy, Shade, Tungsten, Fluorescent, and Flash.
- **Color Space:** Choose your preferred color space for editing and delivering the photo. In RAW settings, it's generally advised to use a color space from your camera's manufacturer, or choose a color space for common video standards.
- **Gamma:** Choose the gamma curve to apply to the image. Either one from your camera's manufacturer, or specific gammas for common video standards.
- **Color Temp:** Adjusts the white balance color temperature to alter the "warmth" of the image. Adjustable in degrees Kelvin. Lower values correct for "warmer" lighting, while higher values correct for "cool" lighting.
- **Tint:** Alters the green to magenta balance of the image (for images with fluorescent tinting). Lower values add green to balance out magenta lighting, while higher values add magenta to balance out green lighting.
- **Exposure:** Increases or lowers image lightness in units relative to *f*-stops. If your intended exposure adjustment lifts image data above the maximum white level, don't worry; all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –5 to +5.

- **Sharpness:** A debayer-specific sharpness filter applied to provide the appearance of enhanced image detail. 10 is unity. The range is 0 to 100.
- **Noise Reduction:** This slider adjusts noise reduction on the image. Typically, high ISO images or darker photos will require some noise reduction.
- **Highlights:** Lets you selectively retrieve blown-out highlight detail in high-dynamic-range media by lowering this parameter, and achieves a smooth blend between the retrieved highlights and the unadjusted midtones for a natural result. 0 is unity. The range is –100 to +100.
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones as is. 0 is unity. The range is -100 to +100.
- **Color Boost:** Lets you increase or lower the saturation of regions of low saturation, sometimes referred to as a vibrance operation. 0 is unity. The range is -100 to +100.
- **Saturation:** Adjusts the color intensity of the image. 0 is unity. The range is -100 to +100.
- **Lift:** Adjusts the black point of the media, raising or lowering it while scaling all midtone values between it and the white point. Regardless of your adjustments, all image data is preserved and can be retrieved in subsequent adjustments. The range is –100 to +100.
- **Midtone Detail:** When this parameter is raised, the contrast of regions of the image with high edge detail is raised to increase the perception of image sharpness, sometimes referred to as definition. When this parameter is lowered to a negative value, regions of the image with low amounts of detail are softened, while areas of high detail are left alone. 0 is unity. The range is -100 to +100.
- **Gain:** Adjusts the white point of the media, raising or lowering it while scaling all midtone values between it and the black point. Regardless of your adjustments, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.
- **Contrast:** Raising contrast reduces shadows and raises highlights, while leaving midtones at 50 percent unaffected. Regardless of your adjustments, all image data is preserved and can be retrieved in subsequent adjustments. 0 is unity. The range is –100 to +100.

RAW Format Support

DaVinci Resolve supports the following RAW camera formats:

- Canon CR3
- Fujifilm RAF
- Apple ProRAW
- Nikon NEF
- Sony ARW
- Panasonic Lumix RW2

Photo

These tools let you transform, crop, color, and adjust the exposure of your image.

Source Transform

- **Zoom X/Y:** Enlarges or shrinks an image. The X and Y parameters can be linked to lock the aspect ratio of the image, or released to stretch or squeeze the image in one direction only.
- **Position X/Y:** Moves the image within the frame, allowing pan and scan adjustments to be made. X moves the image left or right, and Y moves the image up or down.
- **Rotation Angle:** Rotates the image around the center point.

- **Pitch:** Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values will stretch the image to larger extremes.
- **Yaw:** Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and pull the right of the image forward. Higher values will stretch the image to larger extremes.
- **Flip Image:** Two buttons let you flip the image in different dimensions.

  Flip Horizontal control: Reverses the image along the X axis, left to right.

  Flip Vertical control: Reverses the clip along the Y axis, turning it upside down.

Source Cropping

- **Ratio:** Choose a width-to-height ratio for the image. You can choose from common still photo ratios, or leave it As Shot to use your camera's native ratio.
- **Lock Aspect Ratio:** Check this box to lock the aspect ratio when using cropping functions. Once locked, the photo's original aspect ratios remain even while cropping. When unlocked, the photo's aspect ratio changes during cropping.
- **Crop Left/Right/Top/Bottom:** Lets you cut off, in pixels, the four sides of the image.

Looks

- **Type:** Apply a preset Look filter from the dropdown menu, or leave it as Default (Original) to bypass the Look filters.

Adjustments

- **Auto Balance:** A one-button solution that automatically adjusts the dynamic range and white balance based on machine learning.
- **Temp:** Lets you adjust the image along a warm/orange to cool/blue axis that corresponds to the naturalistic spectrum of color temperatures used for lighting. Raise this parameter to adjust the color balance towards warm/orange tones, or lower the parameter to a negative value to adjust the color balance towards blue/cyan tones.
- **Tint:** Lets you adjust the image along a magenta to green axis that corresponds to the color temperatures found in artificial lighting sources, such as fluorescent and sodium vapor lighting fixtures. Raise this parameter to adjust the color balance towards magenta tones (sometimes referred to as "minus green" to correct for fluorescent lighting), or lower the parameter to a negative value to adjust the color balance towards green tones ("plus green" to correct for other kinds of lighting).
- **Lift:** Lets you adjust the perceived shadow density of the image by altering the black point of the image. Drag the Lift slider to the left to darken the darkest values in the image, which increases the distance between the black and white points of the image and stretches the midtone values in-between. Drag the Lift slider to the right to lighten the darkest values in the image, which reduces contrast and squeezes all the midtone values between the black and white points.
- **Gamma:** Lets you adjust the overall perceived lightness of the image. It works by altering the distribution of midtones that fall between the Lift and Gain master wheel settings. Dragging the Gamma master wheel to the left darkens the overall image, while dragging it to the right brightens it.
- **Gain:** Lets you adjust the lightness of the highlights by altering the white point of the image. Dragging the Gain slider to the left makes the lightest values of the image darker, squeezing the midtones between the white and black points of the image. Dragging Gain to the right makes the lightest values even lighter, eventually clipping at maximum white.

- **Contrast:** The Contrast parameters let you quickly narrow or widen image contrast about a user-definable pivot point. This one parameter lets you increase or reduce the distance between the darkest and lightest values of an image, raising or lowering image contrast.
- **Pivot:** Changes the center of tonality, so that dark and bright parts of the image are stretched or narrowed during a contrast adjustment. Darker images may require a lower Pivot value to avoid "crushing" the shadows when stretching image contrast. Lighter images may benefit from a higher Pivot value to increase shadow density adequately.
- **Midtone Details:** Raising this parameter increases the contrast of high-detail edges, enhancing the perceived image sharpness of the image (this is also known as definition). Lowering this parameter to a negative value softens areas with less detail while leaving high-detail regions as is.
- **Shadows:** Lets you selectively lighten or darken shadow detail. Raising this value retrieves shadow detail recorded below 0 percent, while leaving the midtones alone.
- **Highlights:** Lower this parameter to selectively retrieve blown-out highlight detail in high-dynamic-range media—this results in a smooth blend between the retrieved highlights and the unadjusted midtones.
- **Saturation:** A uniform saturation operation that raises (above 50) or lowers (below 50) the color intensity of every color value within the image. 50 is unity, showing unaltered saturation. The range is 0 (completely desaturated) through +100 (saturation is doubled).
- **Hue:** Rotates all hues of the image around the full perimeter of the color wheel. The default setting of 50 shows the original distribution of hues. Raising or lowering this value rotates all hues forward or backward along the hue distribution as seen on a color wheel.

Effects

If you've applied an effect from the Effects tab to your photo, you can adjust its parameters here. If no effect is applied, this tab will be grayed out.

> **NOTE:** All Effects are described in detail in the Resolve FX section of the DaVinci Resolve Reference Manual.

File

These settings contain data about your file format, and edit commonly used metadata fields.

File Data

- **File Name:** The file name of the photo.
- **Star Rating:** Lets you assign a one to five star rating for the image.
- **ISO:** Shows the ISO setting that the photo was shot with.
- **Shutter Speed:** Shows the shutter speed that the photo was shot with.
- **Aperture:** Shows the lens aperture that the photo was shot with.
- **White Balance:** Shows the current white balance setting from the RAW controls.
- **Image Format:** Shows the image file format.
- **Resolution:** Shows the source resolution of the image.
- **Color Space:** Shows the current Color Space setting from the RAW controls.

Metadata

- **Date Created:** Adjust the date that the photo was taken.
- **Camera:** Lets you add a camera name, letter, or number for organizational purposes.
- **Tag:** Lets you tag a photo as Good, Untagged, or Rejected for organizational purposes.
- **Keywords:** Lets you assign keywords to the photo for organizational purposes.
- **Color:** Lets you assign a color code to the photo for organizational purposes.
- **Name:** Lets you adjust the name of the photo used in the media pool. Changing this name does not change the original file name.
- **Comments:** Lets you add comments that are attached to the photo.
- **Flags:** Lets you assign a color flag to the photo for organizational purposes.
- **Auto Select Next Photo:** When this box is checked, the next photo in the Media Pool is selected when you hit the return button after entering a metadata field, and the cursor is automatically placed in the same field. This allows rapid sequential metadata entry without having to manually click to load each individual photo in the Media Pool.
- **Next Photo:** This button will select the next photo in the Media Pool, regardless of the Auto Select Next Photo checkbox status.

Inspector Option Menu

The three dot option menu in the upper right of the inspector gives you the following options.

- **Reset Photo:** (Command-R) Resets any adjustments made in the Photo tab.
- **Remove All Photo Effects:** (Shift-R) Removes any effects that have been applied to the image.
- **Reset Camera Raw:** Resets adjustments made in the RAW tab back to their default state.
- **Remove and Reset All:** (Shift-Command-R) Removes all applied effects and resets the image back to its original state.

Adding and Exporting LUTs

If you've installed a custom or pre-made Look Up Table (LUT) into DaVinci Resolve, any photo in the Media Pool or the Photo Album can have a LUT applied to it. To do so simply right-click the photo's thumbnail and choose the LUT from the LUT context menu.

To save a look for use in other projects and photos, create your own LUT by right-clicking on the image in the Photo Album, and selecting Generate LUT from the context menu. Generally the 33 Point Cube option is the most compatible. You will then need to re-import that LUT back into DaVinci Resolve.

NOTE: Generally only settings in the Photo tab carry over into the LUT. RAW adjustments and Effects will not be saved into the LUT.

For more information on using LUTs, jump to this chapter: Using LUTs.

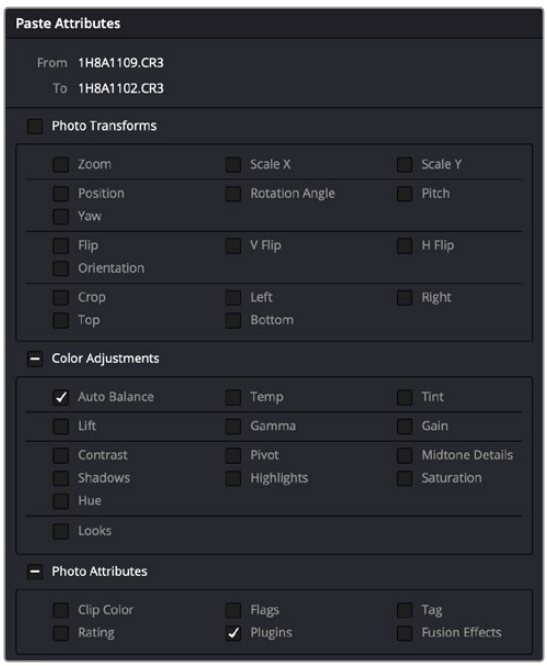
Copy and Paste Edits Between Images

To apply the same edit from one image to another photo (or photos) in your album, either: directly apply the effect in the Photo Album, or use the copy and paste attributes function.

Applying Edits From One Photo to Another in an Album

To copy-paste an edit from one image to another in the same Photo Album:

1. Select the photo(s) you want to apply the edits on. These photos will be highlighted.
2. Middle-mouse click on the photo whose edits you want to copy.
3. The effect will be copied to the your selected photos.



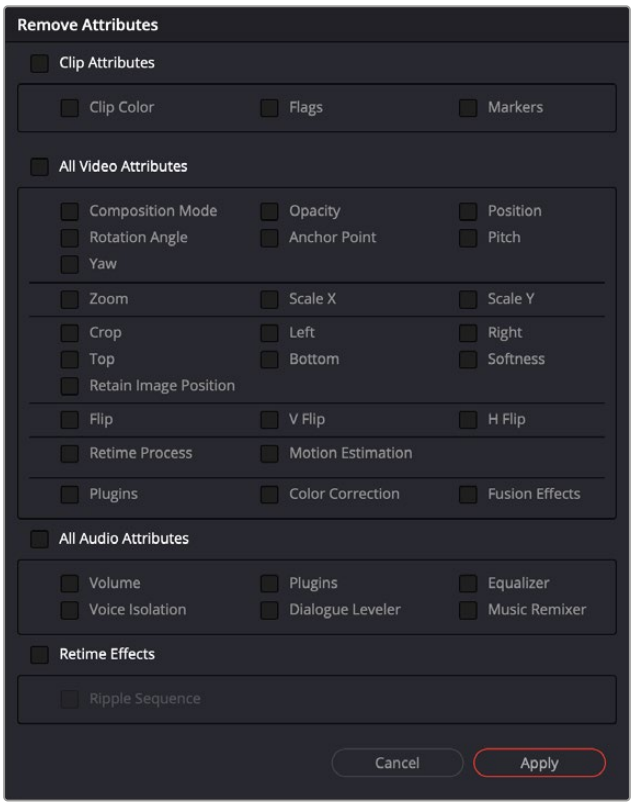
NOTE: This operation will not copy any applied effects. It will copy RAW settings, as long as the images involved all are the same RAW format file type.

Copy and Paste Photo Attributes

You can copy-paste photo attributes and effects from one clip to multiple clips with the Paste Attributes command.

To copy attributes:

1. Select a photo whose attributes you want to apply to other clips, and press Command-C.
2. Select one or more other photos to paste to.
3. Choose Edit > Paste Attributes (Option-V), or right-click one of the selected clips and choose Paste Attributes from the contextual menu.
4. When the Paste Attributes window appears, enable the checkboxes of your chosen attributes, then click Apply.



The Paste Attributes window.

The top of the Paste Attributes window indicates the name of the photo you're copying from, and the name of the photo(s) you're pasting. The checkboxes let you choose the attributes you'd like to paste.

TIP: To paste an effect to other photos, go to the Photo Attributes section and enable the Plugins checkbox.

Remove Attributes

You can also eliminate specific attributes from one or more photos by opening the Remove Attributes window.

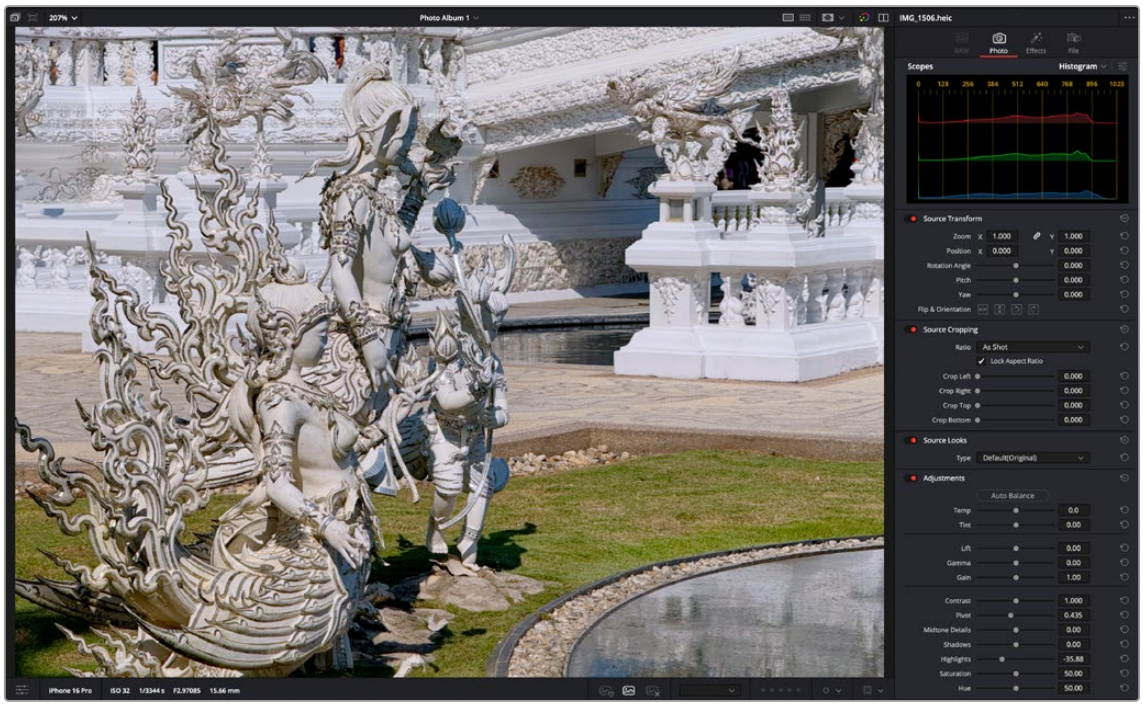
The Remove Attributes window.

To remove attributes:

1. Select one or more photos that have effects you want to remove.
2. Choose Edit > Remove Attributes, or right-click one of the selected photos and choose Remove Attributes from the contextual menu.
3. When the Remove Attributes window appears, the checkboxes of effects that can be removed are enabled, so check the boxes of the attributes you want to remove.
4. Click Apply when you're done.

Photo Multiuser Collaboration and Blackmagic Cloud Syncing

The Photo page lets you take advantage of DaVinci Resolve's extensive Multiuser collaboration and Blackmagic Cloud tools. For example, using Capture Live View in a collaboration project, lets another user view the video feed online from another location. You can also sync and store photos in a Blackmagic Cloud Folder, allowing multiple users around the world access to your photo edits, as week as make changes collaboratively.



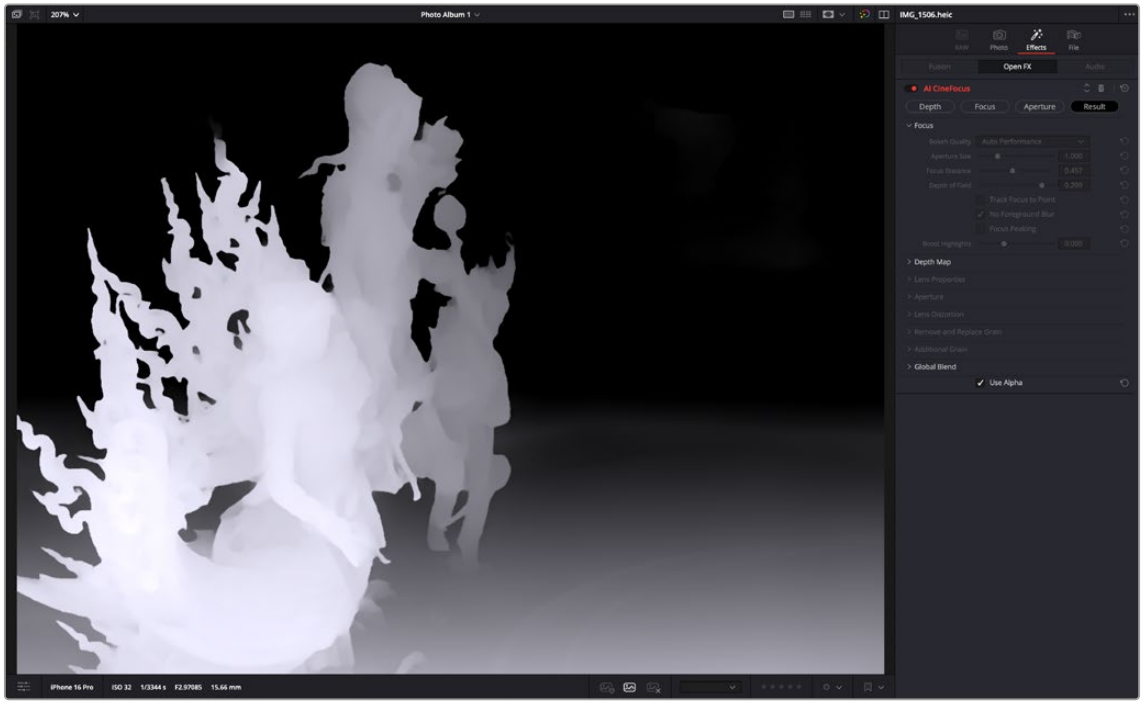
For more information on using these tools, see the Blackmagic Cloud section of this manual.

Photo Editing Example

Having a still image editor embedded in DaVinci Resolve's film and video editing tools opens you up to a spectrum of creative and practical photo effects.

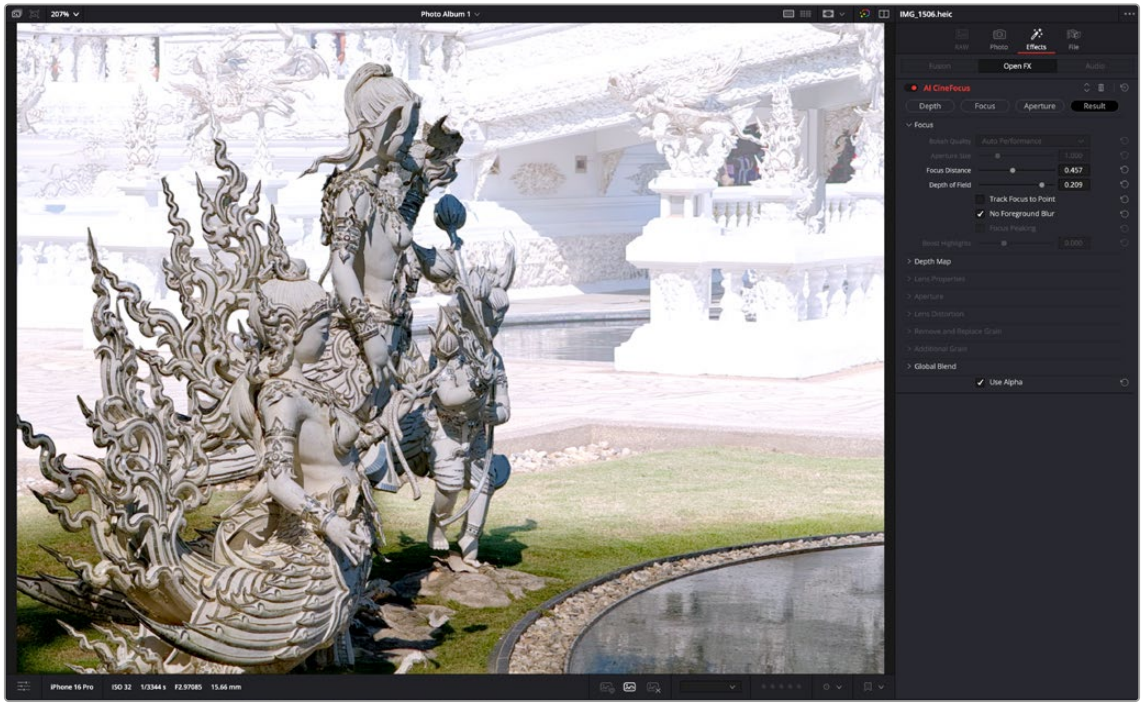
As an example, let's edit this image (taken on a standard phone camera) to look like it was shot on 35mm motion picture film.

First, use the Photo Inspector to adjust the image's exposure and color balance.



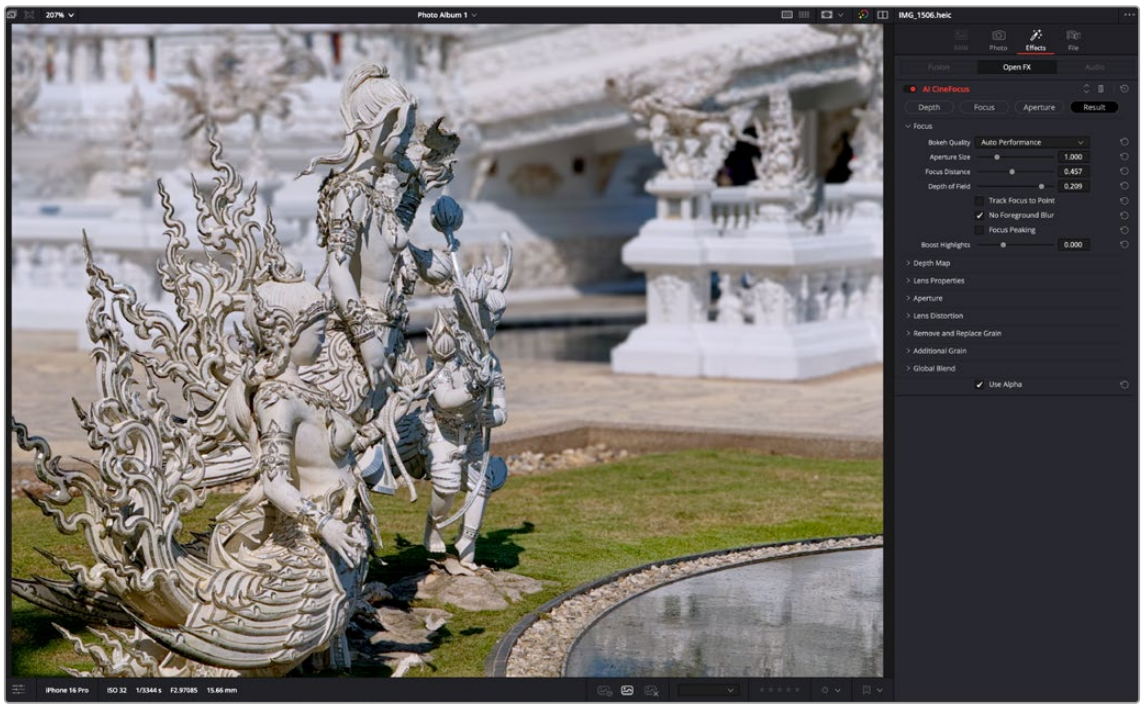
The original image, taken on a standard camera phone.

In this image, the details on the statues (in the foreground) seem to blend into the background. This is because the entire image is in sharp focus.



To fix this, drag DaVinci Resolve's new CineFocus effect on top of the image in the album to create a virtual lens with a larger aperture, shallower depth of field characteristics, and improved bokeh.

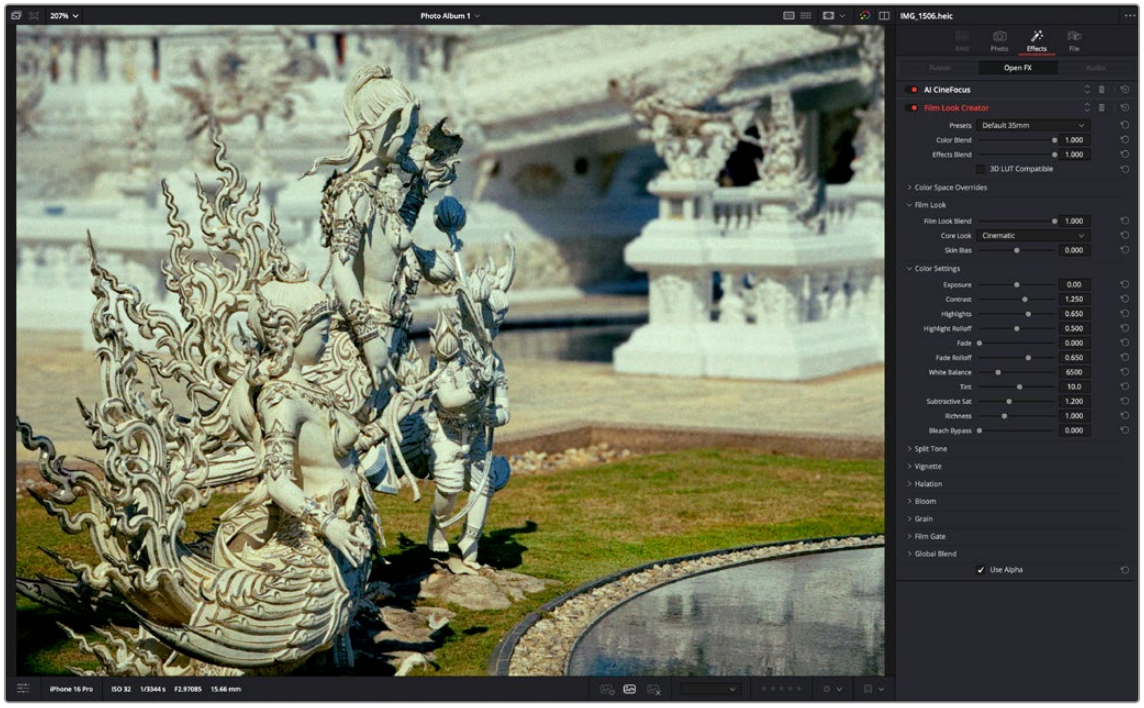
CineFocus first analyzes the photo to create a Depth Map of perceived distances inside the 2D image.



The CineFocus Depth Map analyzes which parts of the image are in the foreground (brighter) and which are in the background (darker).

Then using Focus mode, adjust the aperture and depth of field to isolate the foreground statues, while pushing everything in the background out of focus.

The CineFocus Focus mode lets you set a new focus distance and depth of field (color images) vs out of focus areas (white).



Now tweak the exact lens parameters to your liking. In this example, we've gone from a basic virtual lens to an 11-bladed anamorphic lens with some chromatic aberration, and a slightly off-center lens curvature.

In this CineFocus image, the background is now blurred. The blur also increases gradually with distance, which is more realistic than simply masking an area and blurring it.

The image now looks like it was shot on a cinematic lens. To complete the effect so that it appears to have been shot on 35mm motion picture film, drag the Film Look Creator effect on top of the image in the Photo Album. We now have two effects working on the same image simultaneously.

The Film Look Creator lets you adjust film parameters like halation, grain, bloom, vignetting etc. In this case, we've gone with the Default 35mm film preset, which adds a filmic color profile with the a convincing grain pattern.

The finished image, with the Film Look Creator applied.

The statues now appear more striking against the background, and the entire frame has been treated with a filmic look.

Keyboard Shortcuts

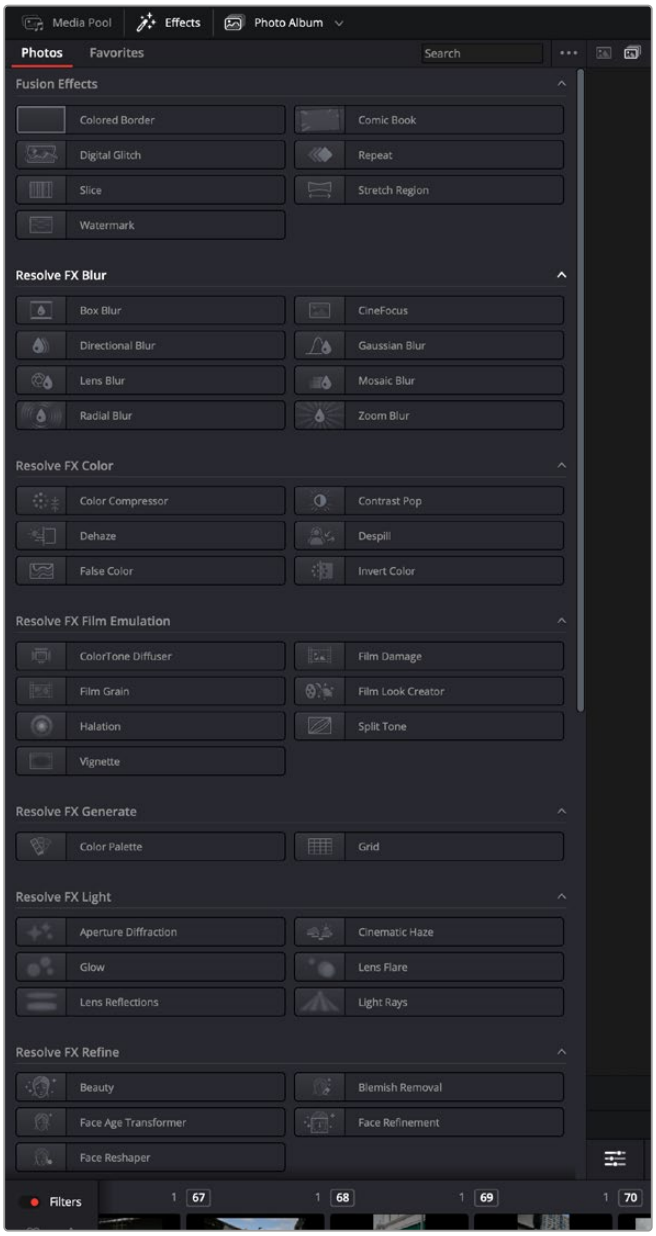
Like all other pages in DaVinci Resolve, the Photo Page has its own set of keyboard shortcuts to make working more efficient.

Function	Keyboard Shortcut
Image Capture Capture Panel or Capture Live View must be active	C
Star Rating Works in both Photo Album and Media Pool	Numbers 1-5 assign star rating. 0 removes all stars.
Tag Clip	S = Good Take X = Rejected Take Pressing S or X again will clear the tag.
Rotate and Flip	**Rotate Left:** Command - [**Rotate Right:** Command -] **Flip Horizontal:** Shift - [**Flip Vertical:** Shift -]
Reset and Clea The Inspector must be in focus	**Reset Photo:** Command-R **Remove All Photo Effects:** Shift-R **Remove and Reset All:** Command-Shift-R
Navigate the photo album	**Select Next Photo:** Up Arrow or Left Arrow **Select Previous Photo:** Down Arrow or Right Arrow

Chapter 30

Photo Effects

The Photo Page gives you direct access to DaVinci Resolve's extensive library of image effects. While there is a curated group of effects for still images on the Photo Page, you'll be able to access many more effects by moving a photo album to another page in DaVinci Resolve.

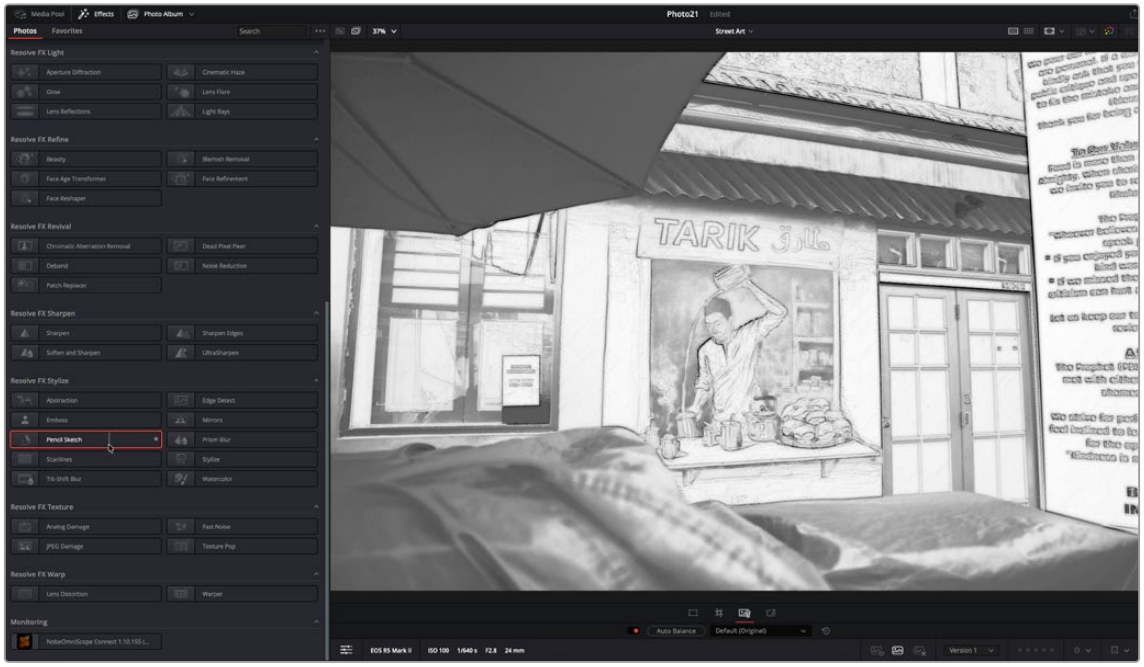


PHOTO

Contents

The Effects Library 639
Previewing an Effect 639
Searching the Effects Library 640
Applying an Effect 640
Favoriting Effects 641
Editing an Effect 641
Resolve FX Onscreen Controls 642
Removing or Disabling an Effect 643
Copy and Pasting an Effect 643

The Effects Library



The Effects panel contains a hierarchical, categorized list of all of the effects and filters you can add to your photos:

The Photo Effects library.

Previewing an Effect

To preview an effect before placing it on a photo, ensure that Hover Scrub Preview is checked in the Effects option menu—it should be, by default. Then hover your pointer over any thumbnail in the Effects tab and move it across the thumbnail. The effect will preview on the image in the Viewer using its default parameters.

Hover the pointer over an effect (orange rectangle) to preview that effect on the image in the viewer.

PHOTO

Searching the Effects Library

Use the search bar at the top of the Effects Library to search for a particular effect. Pressing shift-space will bring up the Effects Search dialog in the Photo page. If you have a photo selected, double-click on the effect in the search list to apply that effect to the selected photo.

You can search for effects and transitions using Category Names as a search term. For example, searching for Stylize will bring up all the Resolve FX under the Stylize section. You can also search for effects using the language set in DaVinci Resolve > Preferences > User > UI Settings, in addition to English.

Applying an Effect

You can apply an effect on a single image, or bulk-apply that effect on multiple images in an album. You can do so in the following ways:

To apply an effect to a photo in an album:

1. Drag the thumbnail of the selected effect to any photo in the Album
2. OR double-click on an effect in the Effects Library to apply it to the selected photo in the album.

To apply an effect to multiple photos in an album:

1. Select the photos you want to apply the effect to in the album, either by command-clicking (multiple selection), or shift-clicking (range). To select all the photos in an album, use command-A.
2. Double-click on the effect in the Effects Library you want to apply.

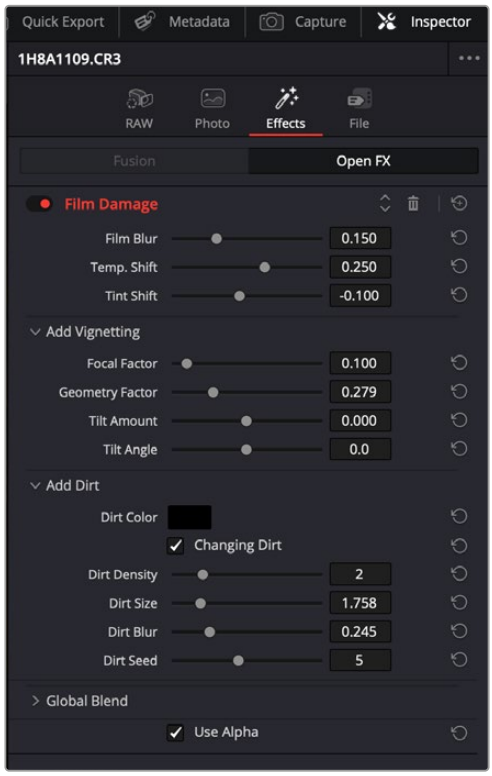
NOTE: You can apply as many effects to a photo as you want. They will stack up in the Inspector under the Effects tab.

Favoriting Effects

If you have an effect that you use often, you can right-click on the effect's thumbnail and select Add to Favorites from the context menu. Alternatively, you can click on the small star icon in its thumbnail to favorite it.

Favorited effects show up in the Favorites tab in the Effects Library. This gives you quick access to your most-used effects.

To remove an effect from Favorites, right-click on its thumbnail and select Remove from Favorites in the context menu. Alternatively, you can simply click the star icon again.



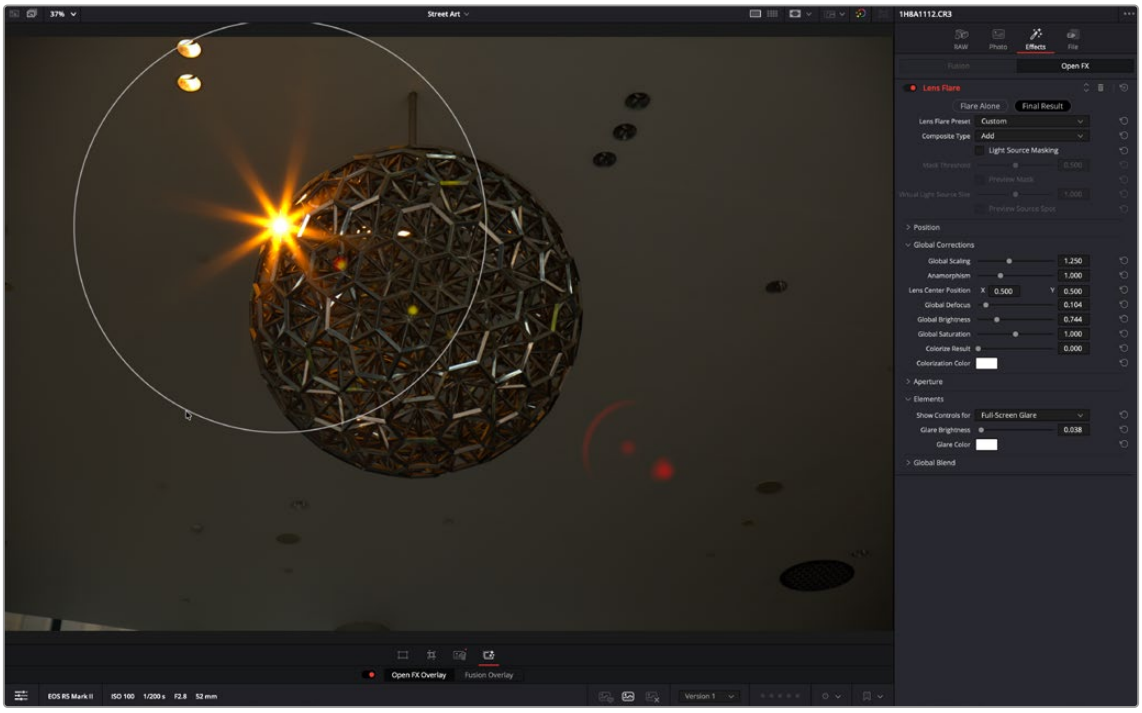
NOTE: Favoriting an effect does not save any custom attributes you may have previously set. The effect will subsequently apply with its default values.

Editing an Effect

When you select a photo with an effect on it, you can edit and adjust the effect's parameters by opening Inspector and choosing the Effects tab. This will show you every parameter associated with that effect, ready for customization.

If more than one effect is applied to a photo, they will all be stacked in the Effects tab, and will work on the image sequentially from top to bottom. You can rearrange the order of an effect by clicking on the up and down arrows next to the effect's name in the Effects tab.

Adjust any of the standard controls to manipulate that plugin's effect on the image, which will be reflected in the viewer.



The parameters of the Film Damage effect, located in the Inspector > Effects tab.

NOTE: All Effects parameters are detailed in the Resolve FX section. For more information, jump to this chapter: Resolve FX.

Resolve FX Onscreen Controls

In addition to the parameters in Inspector, some effects also use onscreen controls that can be manipulated in the viewer. Different effects expose different custom controls, letting you control the effect or manipulate the image, depending on that effect's function.

The Lens Flare effect has an onscreen control which lets you adjust the size of the flare in the viewer by dragging the mouse.

When an effect has an onscreen control, you will need to enable Effects Overlay mode in the viewer to see it. Generally, the effect will open and set this mode by default. However, you can also set it yourself by clicking on the Tools icon at the bottom of the viewer, then clicking on the Effects Overlay icon, and selecting either Open FX Overlay (if using a Resolve FX), or Fusion Overlay (if using a Fusion Effect).

To display onscreen controls for an effect, click on the Tools icon (circled red) then select the Effects Overlay icon (red underline), and choose an overlay type.

TIP: You can temporarily hide or show the onscreen controls in the Viewer, which gives you a cleaner interface when adjusting your image. These onscreen controls can be toggled off and on by pressing shift-` (tilde).

Removing or Disabling an Effect

If you've changed your mind about an effect, you can either remove it entirely, or disable its output (while still retaining the custom parameters you set up) in Inspector.

To remove an existing effect on a photo:

1. Open Inspector.
2. Click on the Effects tab.
3. Find the effect you wish to remove.
4. Click on the small trash-can icon to the right of its name.

To disable an existing effect on a photo:

1. Open Inspector.
2. Click on the Effects tab.
3. Find the effect you wish to remove.
4. Click on the orange toggle switch next to its name. To enable the effect again, toggle the switch once more.

Copy and Pasting an Effect

To copy and paste an effect (with its custom parameters) from one photo to another, use the Paste Attributes window. Here's how:

To copy an effect from one photo to another:

1. In your chosen album, select the photo that you want to copy the effect from.
2. Right-click on the photo and choose Copy Attributes (command-C) from the context menu.
3. Go to the photo you want to paste the effect to, then right-click and choose Paste Attributes (Option-V) from the context menu.
4. In the Paste Attributes window that appears, check the box next to Plugins in the Photo Attributes settings.
5. Uncheck any checkboxes from other attributes that you do not want to copy from the original photo.
6. Click Apply.

   The effect will then be pasted into the Effects tab of the new photo, which you can use as-is or continue to manipulate.

For more information on using the Paste Attributes window, jump to this chapter:
Editing Images in the Photo Page.

Chapter 31

Capture and Tethering

The Studio Version of DaVinci Resolve lets you tether a still camera directly to the Photo page for live image capture during a photo session.

Contents

Capture (Studio Version Only) 645
Setting up Camera Tethering 645
Capture 646
Scopes 646
Settings 646
Production 647
Overlay 647

Capture (Studio Version Only)

This tab opens up the Capture Live View interface for tethered shooting directly from your camera into DaVinci Resolve. This lets you instantly transfer your shots to the Media Pool or a Photo Album for editing, client review, or just to see your image in higher resolution on a larger screen.

Setting up Camera Tethering

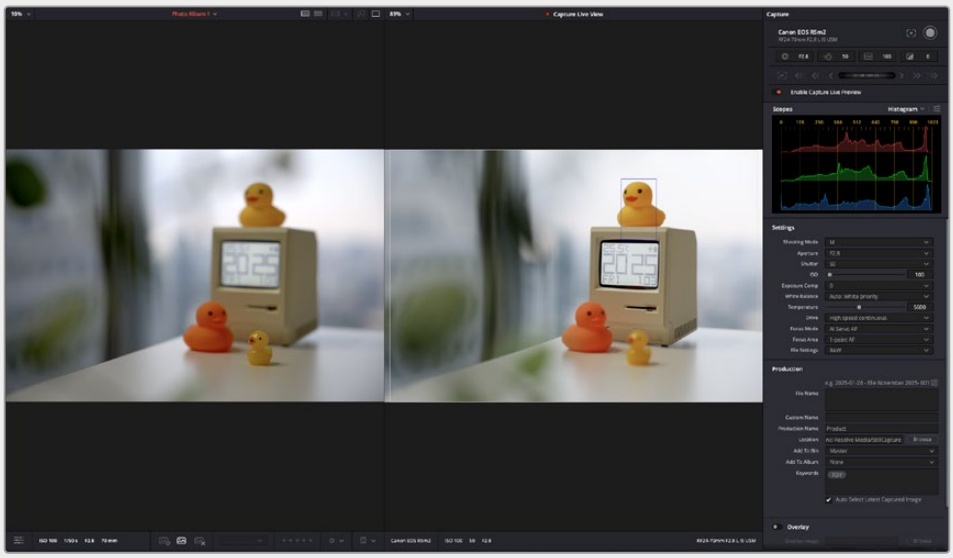
To start, set up Camera Tethering on your camera. This is dependent on your camera model and its make, so it's best to refer to your camera manual for specifics.

Next, connect your camera to your DaVinci Resolve Workstation with a USB cable.

PHOTO

Your local computer may require some additional setup:

Hardware and Software Compatibility Notes



At the time of writing, only Canon and Sony cameras are supported for tethered live capture.

- **macOS:** Both Canon and Sony cameras are supported natively.
- **Windows:** Canon cameras are supported natively. Sony cameras are supported, but require additional software to be installed: https://creatorscloud.sony.net/catalog/en-us/ie-desktop/index.html
- **Linux:** Tethering is not supported.
- **iPad:** Tethering is not supported.

If you're having trouble connecting your camera to DaVinci Resolve, try these troubleshooting tips:

- Ensure you have no other open programs that automatically connect to the camera, such as photo editing applications.
- Sometimes, you may need to restart DaVinci Resolve to connect to your camera.

Once your camera and computer system are set up, press the Capture tab to automatically connect to your camera. You can also press the Capture Live View icon at the top of the viewer to go to the Capture Live View interface.

The Capture Live View interface.

In the right-hand column, you'll see capture controls based on your camera model. You'll also be able to change your camera settings from the capture interface.

In addition, the top toolbar lets you adjust settings for aperture, shutter speed, ISO and exposure compensation. Directly underneath it, you can adjust focus by rotating the wheel or pressing the direction buttons. For extra granularity, go further down in Settings to access more advanced camera settings. Unsupported camera settings will be grayed out.

To the immediate left is Capture Live View, which updates in real-time based on what your camera sees—including on-screen displays such as focus boxes and focus peaking.

The display to the far left is the most recent photo that you captured, so you can see the difference between it and your current shot setup. You can pause Live View at any time by toggling the Capture Live View slider.

Once you're happy with the live view in your camera, go ahead and capture the image by pressing the shutter release button in the upper right of the capture controls.

Capture

This toolset lets you control your camera and capture images.

- **Camera Name:** The model of camera that is connected to capture.
- **Half Press:** Click this icon to send a half-press signal to the camera, often used to lock autofocus before firing the shutter.
- **Shutter Release:** Click this icon to activate the camera's shutter release and take a photo.
- **Aperture:** Shows the currently selected aperture of the camera lens.
- **Shutter Speed:** Shows the currently selected Shutter Speed of the camera.
- **ISO:** Shows the currently selected ISO of the camera.
- **Exposure Compensation:** Shows the currently selected exposure compensation of the camera.
- **AutoFocus:** Click this icon to set the autofocus.
- **Control Wheel:** Depending on which parameter is active and controllable, you can use the control wheel and the arrow controls to adjust that parameter.
- **Enable Capture Live Preview:** Activate this toggle switch to turn on Live Camera Preview in the viewer.

Scopes

The scopes here are identical to those found in Inspector. The selected scope will update in real-time from the camera data.

Settings

These settings let you directly control the tethered camera from the Capture interface. Depending on your camera model and its make, some or all of these modes may be disabled.

- **Shooting Mode:** Sets a shooting mode for the camera. Common modes are A (aperture priority), S (shutter priority), P (program), and M (manual). The options available to you are dependent on your camera model and its make.
- **Aperture:** Sets the lens' aperture.
- **Shutter:** Sets the camera's shutter speed.

- **ISO:** Sets the camera's ISO.
- **Exposure Comp:** Sets the number of stops of for the camera's exposure compensation.
- **White Balance:** Sets the camera's white balance setting preset.
- **Temperature:** Sets an exact white balance temperature in degrees Kelvin (K).
- **Drive:** Sets the camera's drive mode. Common modes are Timer, High Frame Rate, and so on. The choices available to you are dependent on your camera model and its make.
- **Focus Mode:** Sets the camera's focus mode. Common modes are AF-S, AF-C, Manual, and so on—but these depend on your camera model and its make.
- **Focus Area:** Sets the camera's focus area for automatic focus settings. Common modes are Wide, Center, Zone, and so on—but these depend on your camera model and its make.
- **File Settings:** Sets the format you want the image captured in. Common formats are RAW, .jpg, RAW+.jpg, and so on. The choices available to you are dependent on your camera model and its make.
- **File Size:** Sets the file size of the photo format.

Production

This toolset is designed to help with file and photo management operations.

- **File Name:** Lets you set up automatic file name conventions using combinations of text and metadata variables (activated by first typing in the % symbol) for your subsequently captured photos.
- **Custom Name:** Type in a more human-readable photo name that will reflect in the Media Pool without interfering with the original file name.
- **Production Name:** Lets you type in a production (shoot) name to add this field for organizational purposes.
- **Location:** Click the browse button to open a file requester to choose where to store the captured photos.
- **Add To Bin:** Lets you select a Media Pool bin for the captured photos to be automatically added to.
- **Add to Album:** Select an album for the captured photos to be automatically added to.
- **Keywords:** Add specific keywords to describe the photo for organizational purposes.
- **Auto Select Latest Captured Image:** Check this box to always select the last-captured image in the interface for further modification.

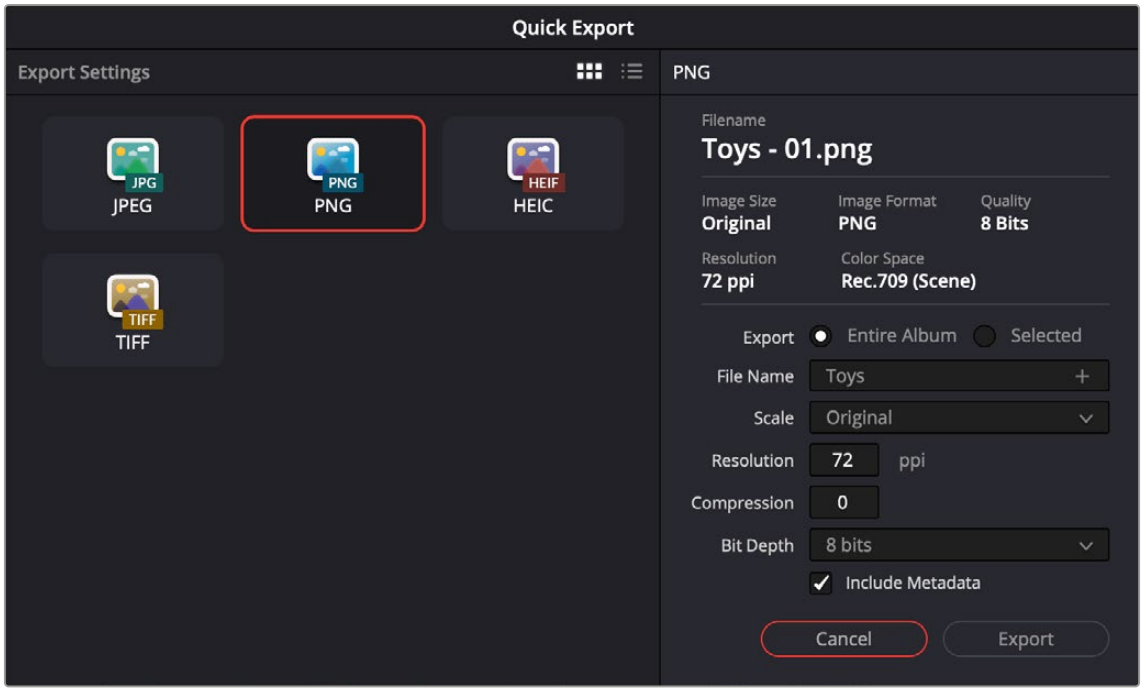
Overlay

This toolset lets you overlay an existing image on top of the Capture Live View, which helps in the composition for model placement, aspect ratio, or to match a previous shot.

- **Overlay Image:** Click the Browse button to choose an image that you wish to overlay on the Capture Live View window.
- **Zoom X/Y:** Zoom the overlay image in or out as needed to match the shot in the Capture Live View window.
- **Center Position X/Y:** Move the overlay image up and down as needed to match the shot in the Capture Live View window.
- **Opacity:** Adjust this slider to change the transparency of the overlay image.
- **Flip:** Click these icons to flip the overlay image horizontally or vertically.

Chapter 32

Exporting Images



Once your photos have been edited, there are two ways of exporting the final images: Quick Export, and the Deliver page. Both of these options are described in this chapter.

Contents

Quick Export 649
Export Formats 649
Export Parameters 649
Exporting Images from the Deliver Page 650

Quick Export

Quick Export opens a simple delivery window that's designed specifically for still images. You simply select the image format you want to use on the left side, enter the file's parameters on the right, then click Export.

Quick Export tab in the Photo Page.

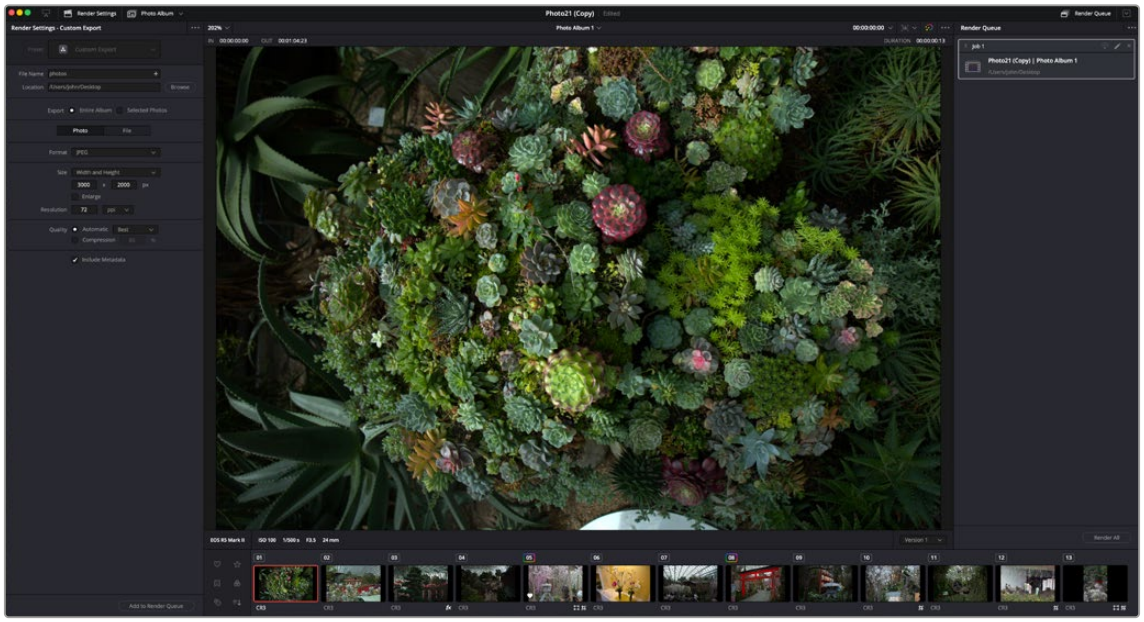
The Quick Export window lets you list the formats either by thumbnail or list, and to the right will show the selected photo's file information.

Export Formats

The export image formats supported by the Photo page are:

- JPEG
- PNG
- HEIC
- TIFF

Export Parameters



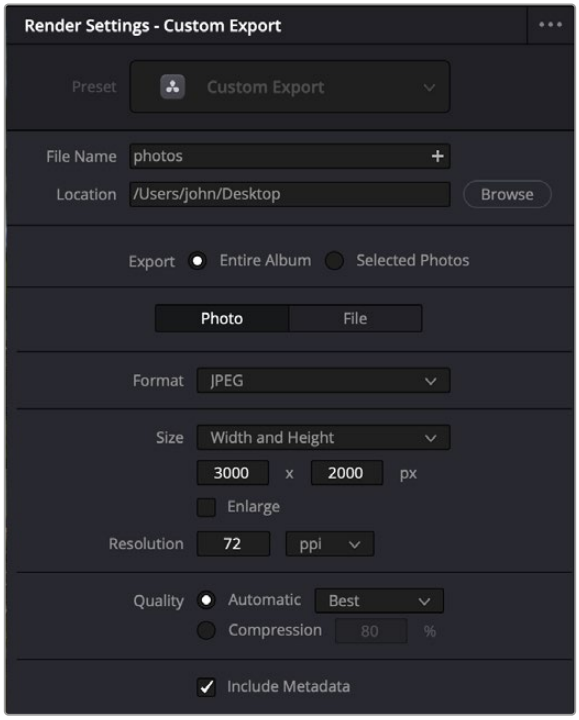
The exact file parameters shown will depend on the image format that you choose, but the common ones are:

- **Export:** Choose between exporting the entire Album of photos, or just the ones that have been selected.
- **File Name:** Adds text to be used as a file name prefix.
- **Scale:** Choose from either the original resolution, or a percentage reduced resolution for smaller file sizes.
- **Resolution:** Sets the resolution of the photo in ppi (pixels per inch). 72 is the standard for video and internet delivery, resolution for print media can be significantly higher.

- **Quality:** Sets the quality level of the selected image format. Lower quality settings reduce file sizes.
- **Compression:** Sets the compression amount or type of the selected image format.
- **Bit Depth:** Lets you choose a bit depth supported by the image format.
- **Include Metadata:** Check this box to include the photo's metadata in the final image.

Exporting Images from the Deliver Page

Still photos can be exported with greater control from the Deliver page. Clicking on Deliver while having an Album active will open a special export view, designed specifically for stills.



The Deliver page in Photo Album mode.

To export photos from the Deliver page:

- Go to Render Settings and select your File Naming, Location and Image Format.
- Choose to either export the entire album or selected photos from the album.
- Press the Add to Render Queue button. You can change any of the export settings and then press Add to Render Queue again to export multiple output formats.
- In the Render Queue, press Render All to start processing your images.

Render Settings

- **File Name:** Type in the base name of the rendered photo or photos. Pressing the + icon lets you choose common metadata types to add to the file name that automatically populate based on each photo. By default, the exported file will use this name, and then a numbered suffix to ensure each shot has a unique file name.
- **Location:** The file location where your photos will be saved. To change the file location, click on the Browse button.
- **Export:** Choose Entire Album to export all photos in the album, or Selected Photos to export only the photos you've selected in the album at the bottom of the Deliver page.

The Deliver page in Photo Render Settings.

Photo

These settings let you choose the parameters for your exported photo format. Not all formats will have all of these parameters.

- **Format:** Choose a photo format to export to: HEIF, JPEG, PNG and TIFF.
- **Bit Depth:** Choose the bit depth for the exported photo.
- **Include Alpha Channel:** If your format supports an alpha channel, check this box to enable it to provide transparency information.
- **Size:** Choose any of the below methods to size your photo:

  Original: Exports your photo exactly to it's original dimensions.

  Width and Height: Lets you set the exact width and height in pixels for your photo export.

  Short Side: Lets you set the exact pixel value for the short side of the image (generally height), and will automatically adjust the long side based on aspect ratio.

  Long Side: Lets you set the exact pixel value for the long side of the image (generally length), and will automatically adjust the short side based on aspect ratio.

  Percentage: Lets you define a percentage value to reduce the size of your image. Values run from 25% to 100%.

  Megapixels: Lets you resize your image based on megapixels values.

- **Resolution:** Choose the desired resolution of the image here, in either Pixels per Inch (ppi), or Pixels per Centimeter (ppcm).
- **Quality:** Sets the quality level of the selected image format. Lower quality settings reduce file sizes.
- **Compression:** If your format supports image compression, enter your desired values here.
- **Include Metadata:** Check this box to include metadata like location data, lens values, etc. in the exported photo.

File

These settings let you choose how the file naming of the exported photos is handled:

- **File Name Uses:** Lets you enter either a custom name with your preferred naming structure, or a photo album name. The latter uses the album's name and a numerical suffix.
- **Custom Name:** Enter text here to define the custom name. You can also include metadata variables that update with each photo, by first typing in % then choosing the metadata field from the dropdown list.
- **File Suffix:** Enter text here that appears as a suffix to the custom name chosen above.
- **Use X Digits in the File Name:** This refers to the number of decimal places the file numbering system will use in the file name. For example, 3 digits will use numbers from 1-999, while 8 digits will use numbers from 1-99,999,999.

Chapter 33

Using the Cut Page

The Cut page is a focused environment for fast editing. It's useful in situations where you need to quickly cut a news segment, build an episode of web content, edit a straightforward program, experiment with multiple arrangements of a scene, or put together a first assembly edit.

The Cut page is also a good introductory editing interface for people who are new to editing, as it presents a streamlined set of tools that are fast to learn and simple to use. Whatever your background, you'll find the Cut page to be a valuable addition to your editing experience in DaVinci Resolve.

Overview of the Cut Page

With the addition of the Cut page, DaVinci Resolve now has two editing environments, intended for two different audiences. While the Cut and Edit pages share many of the same panels such as the Media Pool, the Timeline, and the Viewer, the controls that are exposed on the Cut page have been designed for speed, so you can cut professional programs faster than you've ever been able to before.

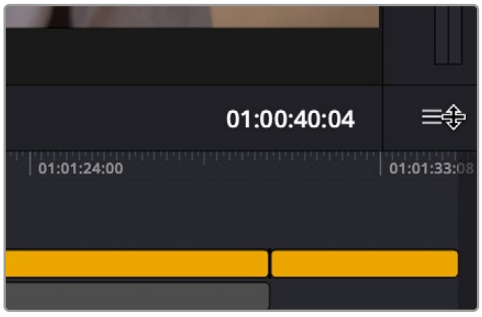
Overview of the Cut Page User Interface

The default workspace of the Cut page consists of the Media Pool, a single Viewer, and the Timeline area. These three regions let you quickly import and organize clips, edit clips, and even export the result, all from within the Cut page.

The Cut page interface

Customizing the UI

A User Interface toolbar at the top of the Cut page lets you hide and show different panels as necessary. For example, you can hide the Media Pool if you wanted more room for the Viewer. You can also replace the Media Pool with other browsers in the Media Pool's default area, showing the Sync Bin, Transitions, Titles, or Effects Browser in order to add those effects to your program in the Timeline. On the right side of the User Interface toolbar you can perform a Quick Export, expand the Viewer to Full Screen, or open the Inspector.



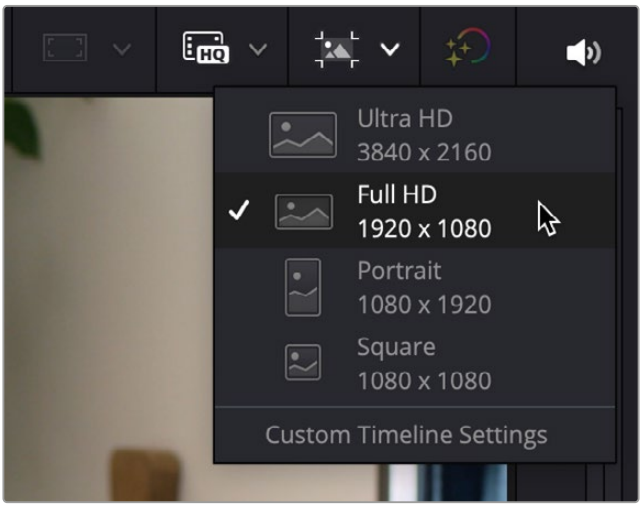
Separate tabs on the left let you open the Media Pool,
Sync Bin, Keyframe Editor, Transitions, Titles, and Effects browser.

You can resize the Media Pool and Viewer by dragging the vertical seam that connects them to the left or right, in the process making one panel bigger and the neighboring panel smaller.

The Viewer resize handle

The Timeline resize handle

You can also resize the Timeline area by dragging the timeline handle (at the upper right corner of the Timeline) up or down, making more or less room for the Timeline while simultaneously resizing the Media Pool and Viewer areas.



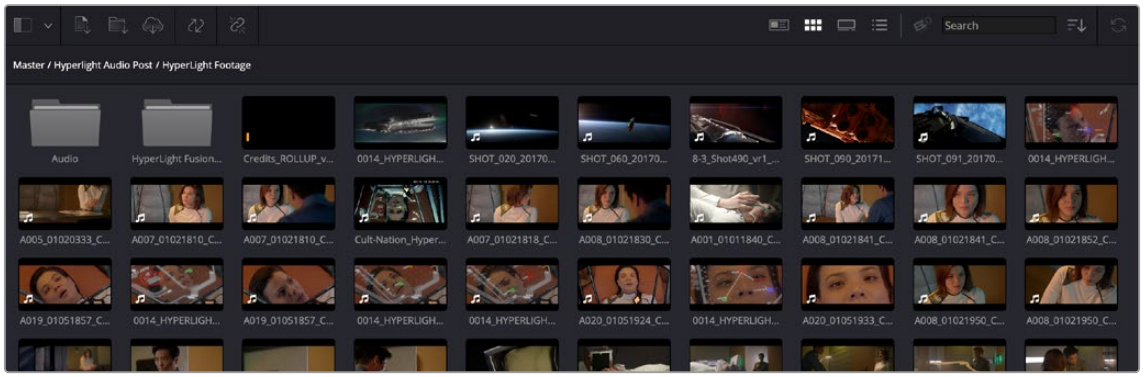
Choose Settings Before You Start

When you first create a new project, you need to define its Timeline settings; you can optionally choose from common presets or a fully custom setup.

Timeline Resolution Quick Menu

This drop-down menu, to the top-right of the Viewer, lets you quickly choose which resolution you want to work at. A Custom option lets you open up the Timeline Settings panel in order to choose your own options.

For more information on the Timeline Settings, jump to chapter: Project Settings.



The Project Settings quick menu

The Media Pool

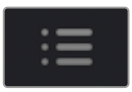
The Media Pool contains all video clips, audio clips, graphics, and other media that you import into your project. You can create bins with which to organize all of this media, to make it easier to find what you need quickly. These bins are opened via the bin drop-down at the upper left-hand corner.

Each piece of media you import, whether it's video, audio, or graphics, appears as an individual clip and can be selected, scrubbed for fast viewing, reorganized into bins, opened into the Viewer for playback, or edited into a timeline using the edit buttons or via drag and drop.

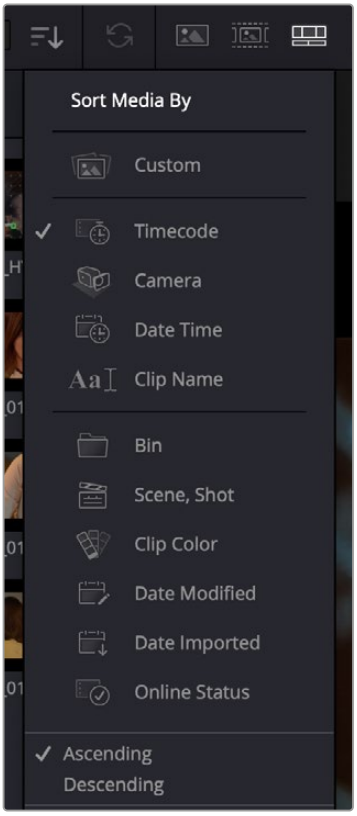
The Media Pool in Thumbnail view

View icons at the upper right of the Media Pool let you see your clips in different ways, depending on what you need to accomplish.

The Viewing ModeFs buttons



Metadata view: Each clip is represented by its own card with a scrubbable thumbnail and basic clip metadata information visible. This view is designed to have more metadata information than a thumbnail view but more targeted information than the List view.



Thumbnail view: Each clip is represented by a scrubbable thumbnail. Hover the playhead over each thumbnail and move it left and right to see the clip's image play, and use the I and O keys to mark sections of a clip that you want to use. Clicking on the lower right corner of a thumbnail reveals the clip's metadata.

Filmstrip view: Each clip is represented by a filmstrip of consecutive frames the length of the Media Pool. Hover the playhead over the clip and move it left and right to see the clip's image play, and use the I and O keys to mark sections of a clip that you want to use.

List view: Each clip appears as an item in a multi-column list showing a variety of metadata about each clip. In List view, you can click the header of any column to sort the contents by that column's information (clicking again toggles the sort order between Ascending and Descending). Scrolling right reveals additional columns of information.

The Sort Media By dropdown menu

A Sort Media By drop-down menu lets you choose which criteria defines the order in which clips in the Media Pool are arranged. Options include: Custom, Timecode, Camera, Date Time, Clip Name, Bin, Scene Shot, Clip Color, Date Modified, Date Imported, and Online Status. You can choose to sort in Ascending (bottom to top) or Descending (top to bottom) order.

Lastly, a search field lets you type a term you want to use to find one or more clips that match that criteria. When you type anything, the contents of the Media Pool shrink to show only clips that match your criteria.

The Viewer

The Viewer lets you see clips from the Media Pool, or clips in the Timeline, and has numerous controls to control what you see and how things play.

The single Viewer in the Cut page

The Viewer has four mode options. Which option is currently in use can be seen, and switched, by four buttons in the upper lefthand corner of the Viewer.

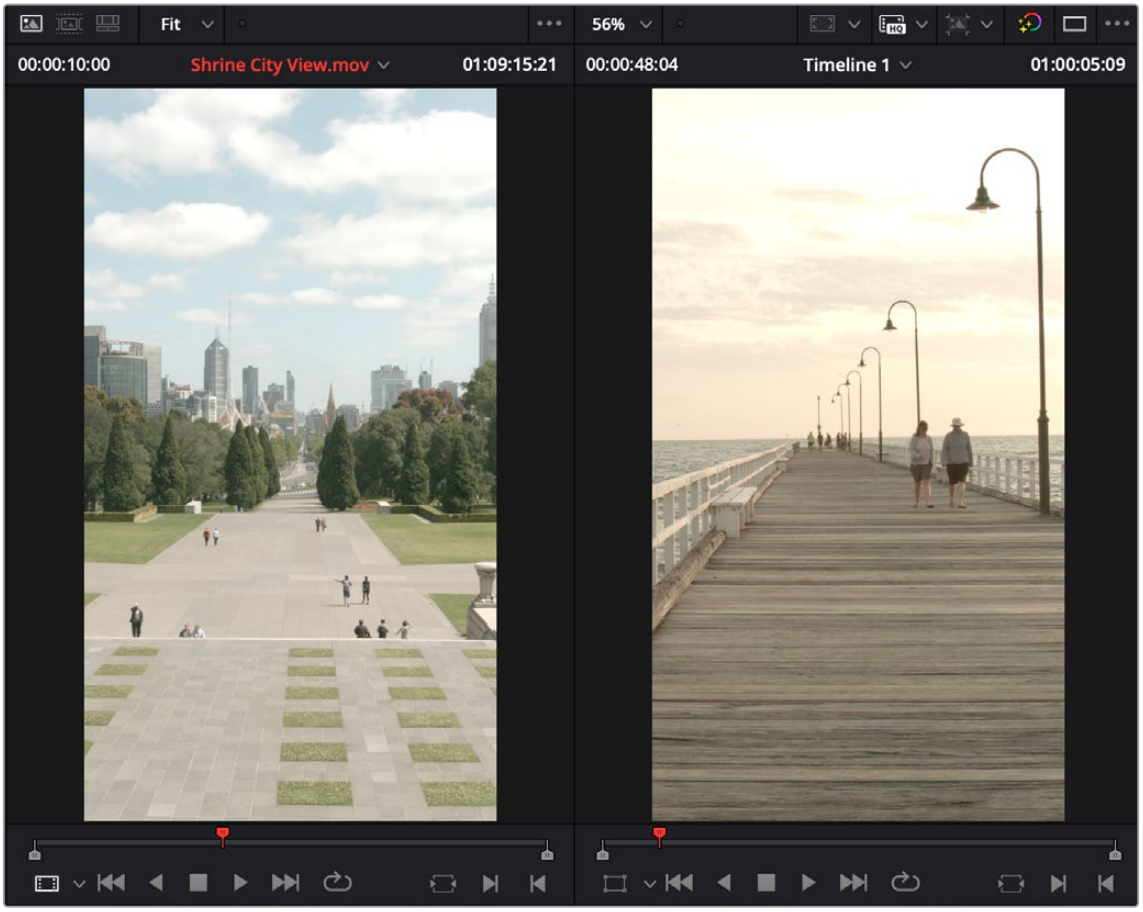
The Viewer modes buttons

The Different options are entered automatically by various actions (from left to right):

- You can double-click any clip to open it into the Viewer as a Source Clip.
- You can view an entire bin full of clips in the Source Tape.
- You can play your edited program in the Timeline.
- You can see all of your synced material at the same time in the Multi Source viewer.

Playing Clips and Navigating the Timeline

Several controls sit at the bottom of the Viewer. These let you play through and otherwise navigate clips and the Timeline in different ways. These controls are described from left to right.



The toolbar at the bottom of the Viewer

- **Tools button:** The Tools button reveals a variety of controls for transform, crop, audio, speed effects, camera stabilization and lens correction, dynamic zoom, and compositing, covered in more detail later in this chapter.
- **Voiceover:** Reveals controls for recording voice over directly into the timeline.
- **POI and Add POI:** These tools are used for selecting and modifying Points of Interest in Replay, which is described in its own manual. For more information on these tools, see the “DaVinci Resolve Replay Editor Instruction Manual.”
- **Fast Review button:** Intended to help you watch through a large collection of media quickly, clicking this button begins accelerated playback through the Source Tape or through the Timeline, where the speed of playback is relative to the length of each clip you’re playing through. Long clips play faster, whereas shorter clips play closer to real time. In this way, you can watch a lot of material really quickly.
- **Jog control:** Clicking and dragging within the jog control lets you scrub very precisely through the content of the Viewer.
- **Transport controls:** A set of Previous Edit (Up Arrow), Stop (Spacebar), Play (Spacebar), Next Edit (Down Arrow), and Loop Playback (Command-/) buttons constitute clickable controls for controlling playback of clips and the Timeline. Each button has a matching keyboard shortcut.
- **Mark In/Out:** Clickable controls to set In and Out points respectively.
- **Playhead timecode:** A number field shows you the timecode value at the playhead of a clip or of the Timeline to give you a numeric reference for where you are.
- **Skim Playhead:** You can skim footage in any viewer in the Media, Cut, Edit, Color, and Deliver pages by holding down the C key, and scrubbing the pointer back and forth in the viewer.

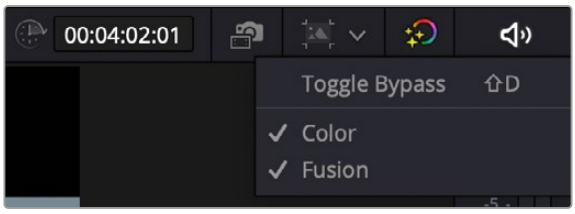
Optimized UI Layouts for Vertical Editing

Optimized layouts for vertical timelines and projects are supported in DaVinci Resolve. When a vertical timeline or project is loaded, the UI automatically switches to a layout optimized for vertical viewers on the Cut, Edit, and Color pages. Loading a normal landscape timeline or project then automatically switches back to the original layout. No additional user intervention is needed.

You can change this behavior in Preferences > User > UI Settings > Use optimized UI layouts for vertical video. Unchecking this box retains the normal horizontal layout, even for vertical video timelines.

The UI now changes format to accommodate vertical video timelines automatically.

Tools



Clicking the Tools button reveals a toolbar that you can use to add and edit clip effects, right within the Viewer with no Inspector needed. The Tools button reveals a variety of controls for transform, crop, audio, speed effects, camera stabilization and lens correction, dynamic zoom, and compositing, covered in more detail later in this chapter.

The Tools bar shown opened to the transform controls.

Bypass Color Grades and Fusion

The Bypass Color Grades and Fusion Effects button/drop-down lets you turn off all grades and effects that you may have applied in the Color page and/or Fusion page in order to improve playback performance on low power computers. Click the button (Shift-D) to disable or reenable grading and effects, or right-click this button to access a menu that lets you choose which things you want this button to control.

The Bypass Grades and Fusion button, shown being right-clicked to view its options

Export The Current Frame from The Viewer

You can now export a still frame from the Viewer in the Media, Cut, and Edit pages.

To Export a Still Frame from the Viewer:

1. Use the Viewer's playback controls to navigate to the frame you want to export.
2. Select File > Export > Current Frame as Still.
3. Enter the name of the still frame in the File System viewer.
4. Enter the desired format of the still frame in the File System viewer.
5. Click on the Export button.

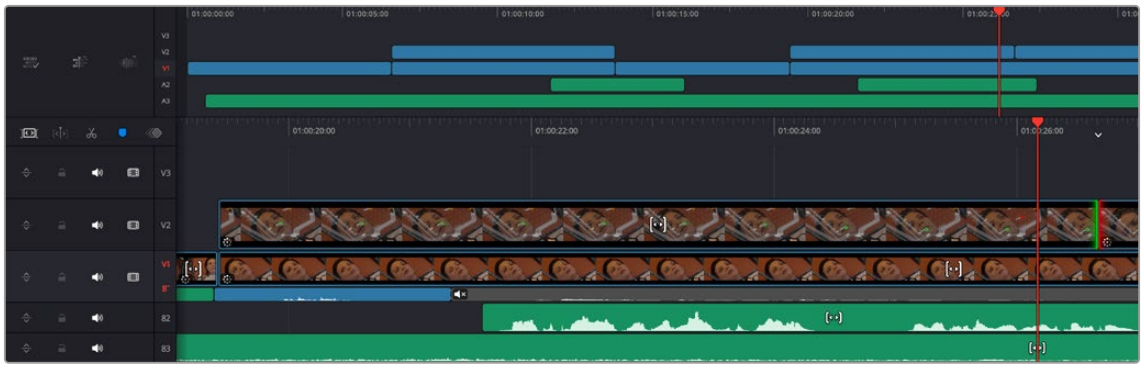
Audio Meter

An audio meter to the right of the Viewer shows you a graphical representation of the audio levels playing in the current clip or in the Timeline as you play through the Viewer, via animated vertical bars that are tinted to indicate how loud the levels are:

- Green indicates safe levels
- Yellow indicates levels that are peaking at approximately safe levels
- Red indicates levels that may be peaking at levels that are too high, risking clipping the signal and causing distortion

These animated bars serve as a visual reference you can use to help you adjust the volume of different clips to create a pleasing balance, and to make sure you don't exceed the maximum desired level and introduce clipping. A speaker button at the top of the meters lets you mute or unmute audio playback.

The Audio Meter showing an audio signal



The Timeline

The word “timeline” refers both to an edited sequence of clips, which constitutes a program that is stored in the Media Pool, and to the area of the Cut page interface where you can open this sequence of clips to see its contents, and for playback and editing.

Timelines are created and stored in the Media Pool, along with all of your other clips. However, each timeline is assembled and edited in what is sometimes referred to as the Timeline Editor. Different pages of DaVinci Resolve show your timeline differently according to the special requirements of each page focusing variously on different methods of editing, grading, compositing, and audio.

However, while the interface of the Timeline Editor changes from page to page, the actual contents of the Timeline are identical, because each page’s Timeline Editor is in fact showing the exact same Timeline that is currently open. This means that the advanced user can use every page of DaVinci to do different things to the same Timeline, with only the interface changing to make different functions possible in different pages.

For the Cut page user, the Timeline is divided into an Upper Timeline at the top, and a larger and more detailed Timeline Editor showing a zoomed in portion of the Timeline around the playhead at the bottom. Working together, these two views of your edited sequence make it possible to navigate your entire project and cut in great detail.

The Timeline of the Cut page, comprising the Upper Timeline and the zoomed in Lower Timeline

Upper Timeline

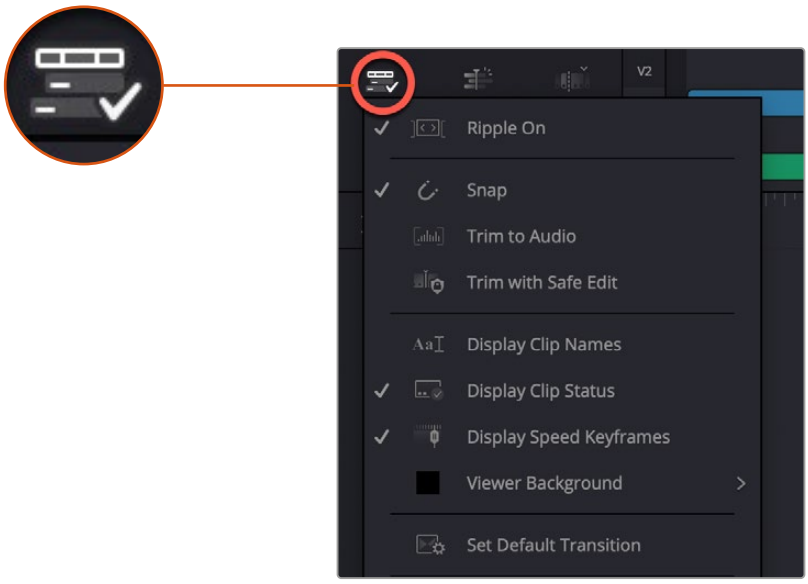
The Upper Timeline always shows the entire program within the full width of your computer’s display. The Upper Timeline’s playhead is always free, which makes it easy to use your pointer to scroll around the entire program by dragging within the Timeline Ruler at top. This also serves as a visual reference for keeping track of where you are in your program while you’re editing within the zoomed-in Lower Timeline below.

Despite the Upper Timeline’s relatively small size, you can still edit in it, with most editing and trimming functions that are available in the Lower Timeline also available in the Upper Timeline. Most interestingly, it’s also possible to drag clips from one part of your program in the Lower Timeline, to another area of your program in the Upper Timeline, and vice versa. Right-clicking on a clip in the Upper Timeline will open the same context menu as right-clicking on a clip in the Cut page’s main timeline, allowing you to perform the same operations.

A set of small numbers to the left of the Upper Timeline lets you click a number to choose the currently selected track; this selection is mirrored on the zoomed in timeline below. The currently selected track affects where incoming clips will be placed when editing, among other things.

Lower Timeline

The zoomed in Lower Timeline (often referred to simply as “the Timeline”) shows you a close-up view of the portion of the currently open timeline that immediately surrounds the playhead. The zoom level is fixed; you cannot change it. The zoomed-in lower timeline is intended for detailed editing, but clips can be dragged between the Timeline and Upper Timeline for fast reordering of clips across the entire duration of your program.

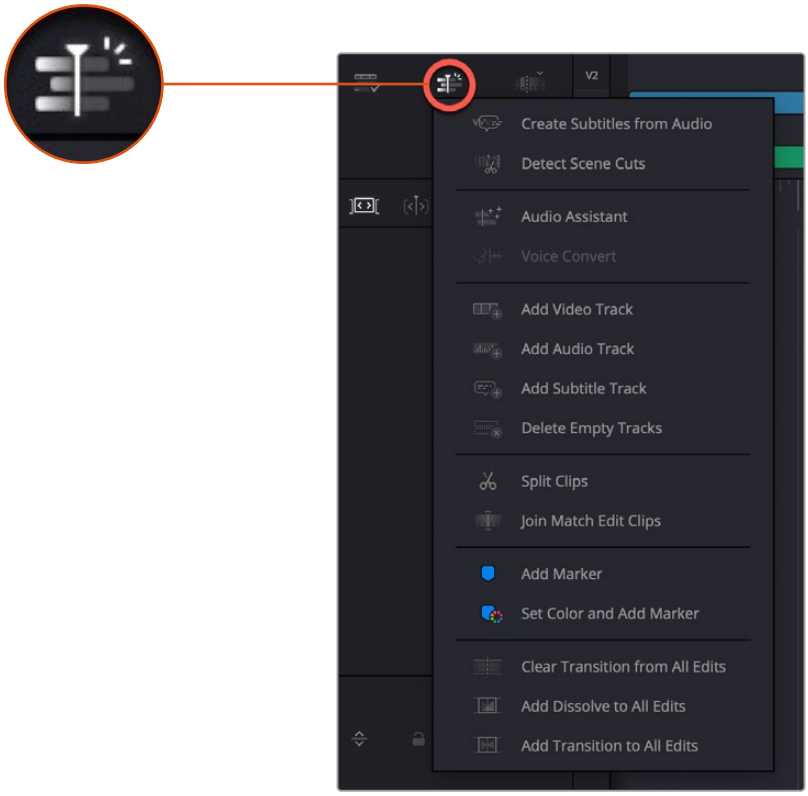


The Toolbar contains several editing functions grouped together in Action and Option menus. These functions are accessed by clicking on the appropriate icon and selecting a function from the drop-down menu. These tools are discussed in detail throughout the Cut section of the manual.

The Toolbar icons (from left to right):
Timeline Options, Timeline Actions, Edit Actions

Timeline Options

The tools under this icon deal with how the clips and timeline are displayed, and certain modes and tools that apply to the whole timeline.



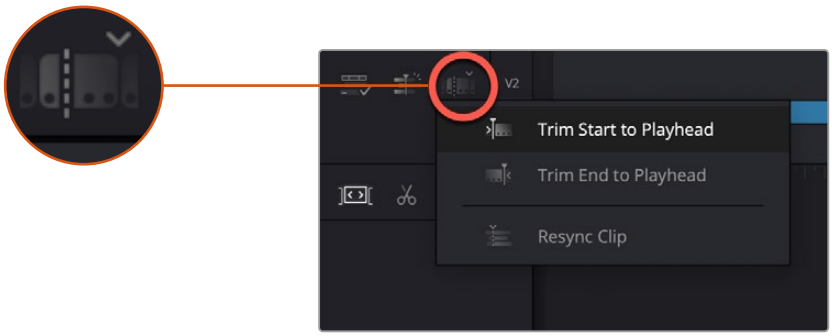
All of the Timeline Options functions

- **Ripple On:** Toggles ripple editing behavior on track V1.
- **Snap:** Toggles the playhead snapping behavior on or off.
- **Trim to Audio:** Opens an expanded audio view on the timeline when trimming a clip.
- **Trim with Safe Edit:** Toggles the Safe Edit function to prevent you from accidentally overwriting adjacent clips while trimming.
- **Display Clip Names:** Toggles displaying the clip name on the timeline clip.
- **Display Clip Status:** Toggles displaying the status icons of various operations on the timeline clip.
- **Display Speed Keyframes:** Toggles displaying the Speed Keyframes on a clip with speed changes applied.

- **Viewer Background:** Lets you choose how the blank areas of the Viewer background are displayed, either Checkerboard, Black, Gray, or Alert Red.
- **Set Default Transition:** Opens the Set Default Transition window, letting you choose the transition type, duration, and alignment for the default transition.
- **Edit Using (Audio Track):** Lets you choose either All audio tracks or select specific audio pairs to edit with on the Cut page.
- **Minimize Subtitle Track:** Shrinks the vertical size of the subtitle tracks to give you more room in the timeline.
- **Fixed Playhead:** Toggles the fixed playhead on or off. On leaves the playhead in place while the timeline passes underneath it, while off makes the playhead move along the timeline.
- **Boring Detector:** Activates the Boring Detector.

Timeline Actions

The tools under this icon are generally used to add new items or make modifications to the Timeline.



All of the Timeline Actions functions

- **Create Subtitles from Audio:** Automatically creates subtitles for all dialog in the timeline.
- **Detect Scene Cuts:** Performs a Detect Scene Cuts operation, splitting one long clip of a finished program into individual clips again.
- **Audio Assistant:** Uses AI to automatically perform an audio mix of your timeline based on common deliverable requirements.
- **Voice Convert:** Uses AI to let you change the speaking voice from one person to another.
- **Add Video Track:** Adds a video track to the timeline.
- **Add Audio Track:** Adds an audio track to the timeline.
- **Add Subtitle Track:** Adds a Subtitle Track to the timeline.

- **Split Clips:** Splits the current clip in two at the playhead position.
- **Join Match Edit Clips:** Rejoins two continuous clips that have been split.
- **Add Marker:** Adds a marker at the playhead position.
- **Set Color and Add Marker:** Adds a marker and opens the Markers editor, so you can change the color and add comments, etc.
- **Clear Transition from All Edits:** Removes all existing transitions from the timeline.
- **Add Dissolve to All Edits:** Adds a Cross Dissolve to every edit point on the timeline.
- **Add Transition to All Edits:** Adds the last used transition to every edit point on the timeline.

Edit Actions

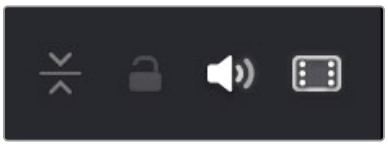
The tools under this icon are used to adjust clips on the Timeline.

All of the Edit Actions functions

- **Trim Start to Playhead:** Deletes everything of the clip to the left of the playhead.
- **Trim End to Playhead:** Deletes everything of the clip to the right of the playhead.
- **Resync Clip:** If a clip has slipped sync from the rest of the program, this operation will resync it.

Tracks

The Timeline is divided into multiple tracks, with each track capable of holding a sequence of clips in order to create a program. The main tracks, which are labeled numerically, combine a clip's video and audio into a single item in the Timeline, for simplicity. Editing the In or Out point of a clip edits the video and audio together.



Cut Page Timeline tracks. Track ST1 shows a subtitle track. Track V1 shows both Video only and combined Video+Audio clips in an enlarged view. Track A4 shows a separate audio track.

TIP: In the Edit page, Video+Audio clips are presented as separated Video and Audio items on different tracks. When you open the Fairlight page, audio is presented on tracks with lanes, where each audio channel can be seen. In this way, each page gives you different sets of controls over the contents of the Timeline that are appropriate for each page.

Track Header Controls

The track controls, in order, allow you to enlarge a track, lock the track for edits, mute audio, and enable or disable video for the track.

Controls to enlarge, lock, mute audio, and disable video for the track

The Importance of Track 1

Each track in the Timeline of the Cut page is designed to carry specific parts of your program. Track 1 is intended for the primary video+audio of your program, often called the “A-roll,” since these are the primary shots comprising the timing and pacing of the story you’re telling. Adding, deleting, inserting, trimming, or otherwise rearranging clips on Track 1 results in the rest of the edited timeline being automatically rippled to accommodate the change you’ve made, with clips to the right of the changed area moving left to fill the gap of a deleted or shortened clips, or moving right to make room for an inserted or lengthened clip.

Tracks 2 and Above

Tracks 2 and above are intended for “B-roll,” which is additional footage you stack on top of other clips in Track 1 to illustrate what someone is saying in the audio of Track 1, or for superimpositions used for compositing effects that combine two images together in creative ways. Moving or resizing clips on Track 2 and above only moves or resizes that one clip; other clips in the Timeline are not rearranged and the Timeline is not rippled when you do this.

For instances where multiple video clips overlap one another on multiple tracks, the video clip on the highest track obscures those on lower tracks, meaning that only the top clips appear during playback. This is useful when you’re experimenting with rearranging multiple clips in a complex scene. For example, you could be editing a scene where an interview clip is on the bottom track, and various b-roll clips are edited on tracks above the interview so you can freely rearrange them in different ways, while it’s always easy to reveal the speaker on the bottom track by leaving a gap in the superimposed b-roll clips.

Editing a scene with multiple superimposed clips

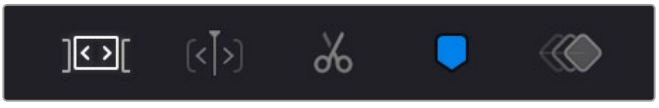
However, if you superimpose video-only or video+audio clips for compositing, you can use the composite modes and the opacity slider found in the Composite section of the Viewer Tools controls to mix multiple images together in different ways for artistic effects.

(Left) Superimposing clips you want to composite,
(Right) Creating compositing effects with multiple superimposed clips

You can add additional Video+Audio tracks, when necessary, by either dragging a clip to the undefined gray area of the Timeline above the other existing tracks to make a new track automatically, by clicking the New Track button at the upper lefthand corner of the Timeline, or by right-clicking in the timeline header area and choosing “Add Video Track” from the contextual menu.

Audio-Only Tracks

You can also edit audio-only clips such as music, narration, or sound effects, onto separate audio-only tracks underneath, which are then labeled A1, A2, A3, etcetera. If you drag an audio clip to the undefined gray area of the Timeline below the other existing tracks, an audio-only track will automatically be created.

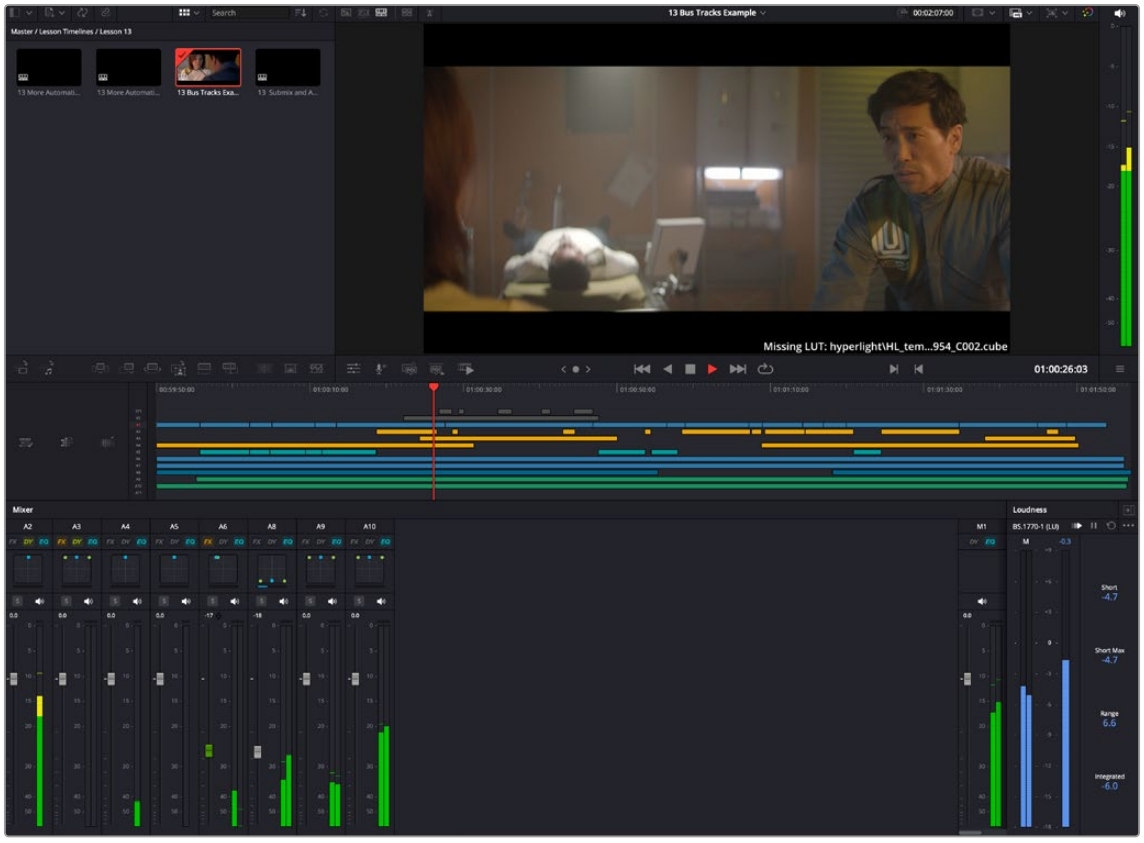


Audio-only tracks in the Cut page Timeline

Gaps

Because Track 1 is meant to hold the principal clips for your program, the Timeline automatically ripples itself to close gaps that would otherwise result when you move or rearrange clips in Track 1, and superimposed clips in Tracks 2 and above move to keep in sync with the clips they’re superimposed over. However, you can move superimposed clips on Tracks 2 and above to place them wherever you want, and gaps will be left between multiple clips on the same superimposed track so they can be edited at specific places.

Timeline Controls



The Timeline controls in the upper left-hand corner of the Timeline let you enable/disable Rippling on Track 1, enter Dynamic Trim mode, Split a clip at the playhead position, create Markers, and open the Keyframe Editor.

The Cut page Timeline controls

Audio Mixer

The Cut page can show a full Audio Mixer, with access to all the tracks and busses of your mix, in addition to shortcuts to any audio Track FX, Dynamics, and Equalizer tools. To enable the Audio Mixer, select the Mixer tab at the top of the Cut page.

The Audio Mixer expanded, allowing you to see all audio tracks while still editing in the Upper Timeline of the Cut page.

Audio Mixer Controls

Each track's channel strip has the following controls:

- **Track Number:** The number of the timeline audio track corresponding to each channel strip appears here.
- **Track Effects:** Double-click on one of the track effects at the top of the fader controls to open.

  FX: Opens the Track Effects controls in the Inspector.

  EQ: Opens the Track Equalizer.

  DY: Opens the Track Dynamics.

- **Pan control:** Lets you pan a Mono track's audio from left to right, or invert a Stereo track's left and right audio channels, or do surround mixing.
- **Name:** The name of the audio track that channel strip corresponds to. If you've edited the audio track names in the Timeline, those names will appear here.
- **Solo:** Mutes all tracks other than ones that are soloed.
- **Mute:** Disables that audio track.

- **dB:** Shows you the volume, in decibels, that track is currently set to.
- **Fader:** Each track's vertical fader can be dragged with your mouse or other pointing device to adjust the volume of that track and perform automation recording. Dragging up increases volume, dragging down decreases volume.
- **Audio meters:** Audio meters to the right of each fader display the audio volume of all channels on that track during playback. Each channel strip has individual meters corresponding to the number of channels that track has been set to accommodate.

Mute and Solo Tracks For Output

When you use the Mute or Solo controls of the Audio Mixer, track audio is disabled, both during playback and delivery for output. Make sure you have re-enabled any tracks you need before heading to the Deliver page. You can only modify mute and solo tracks on the Edit, Cut, and Fairlight pages.

Replay

The Cut page allows live multi-camera broadcast editing, playout, and replay with speed control.

Some of the Replay features are only available with Blackmagic Design hardware, such as a desktop video interface, cloud store and ATEM switcher.

> For more information, please see the dedicated DaVinci Resolve Replay Editor Instruction Manual.

The Cut page Timeline controls

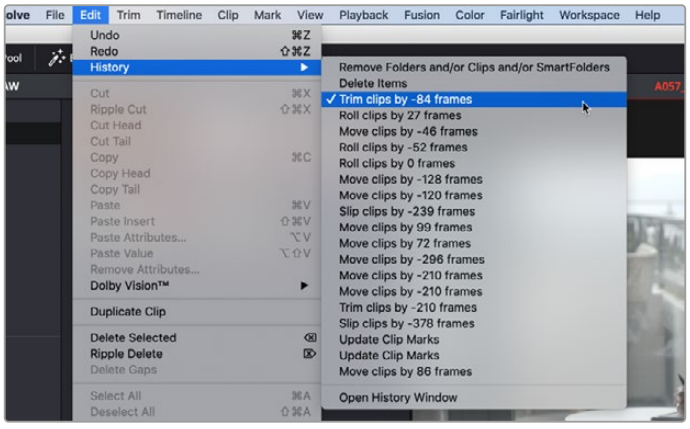
Undo and Redo in DaVinci Resolve

No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you've taken or commands you've executed, and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you've done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo "stacks" to help you manage your work.

- The Media, Edit and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
- Each clip in the Fusion page has its own undo stack, so you can undo changes you make to the composition of each clip, independently.
- Each clip in the Color page has its own undo stack, so you can undo changes you make to grades in each clip, independently.

In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you're in.



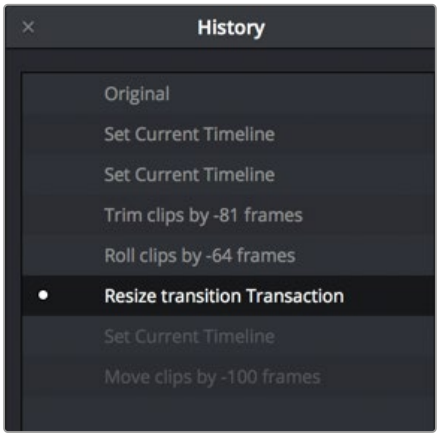
To simply undo or redo changes you've made one at a time:

- Choose Edit > Undo (Command-Z) to undo the previous change.
- Choose Edit > Redo (Shift-Command-Z) to redo to the next change.

> You can also undo several steps at a time using the History submenu and window. At the time of this writing, this only works for multiple undo steps in the Media, Cut, Edit, and Fairlight pages.

To undo and redo using the History submenu:

1. Open the Edit > History submenu, which shows (up to) the last twenty things you've done.
2. Choose an item on the list to undo back to that point. The most recent thing you've done appears at the top of this list, and the change you've just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what's possible. However, if you've undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.



The History submenu, which lets you undo several steps at once

Once you've selected a step to undo to, the menu closes and the project updates to show you its current state.

To undo and redo using the History window:

1. Choose Edit > History > Open History Window.
2. When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you've done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.
3. When you're done, close the History window.

The Undo history window that lets you browse the entire available undo stack of the current page

Chapter 34

Importing and Organizing Media in the Cut Page

Before you can start editing, you need to import the clips you want to use for your program into the Media Pool, which is the central repository of clips in your project.

This can include video, audio, and graphics files in any format that's supported by DaVinci Resolve. Once imported, the Media Pool on the Cut page has many organizational tools you can use to make your project's media faster for you to access and sort through as you find the clips you need to create your program.

Importing Media

Two Import buttons at the top of the Media Pool let you use import dialogs to select media you want to bring into the Media Pool for use in your project.

The Import Media and Import Folder buttons

To import individual clips:

1. Do one of the following:
   a) Click the Import Media button.
   b) Press Command-I.
   c) Right-click the Media Pool and choose Import Media.
2. Use the Import dialog to select one or more clips to import, and click Open.
3. If you're prompted to change the frame rate of a currently empty project to match that of the incoming media, click Change.

   Each piece of media you import, whether it's video, audio, or graphics, appears as an individual clip in the Media Pool. You can also import an entire folder full of media as a bin in the Media Pool.

To import a folder full of media into a bin:

1. Click the Import Media Folder button.
2. Use the Import dialog to select a folder containing media you want to import, and click Open.
3. If you're prompted to change the frame rate of a currently empty project to match that of the incoming media, click Change.

   Each folder you import appears as a bin in the Media Pool. Double-clicking a bin opens its contents into the Media Pool, enabling you to view each individual clip.

TIP: For additional media import features, you can use the Media page, with its Media Storage browser and more feature-rich version of the Media Pool.

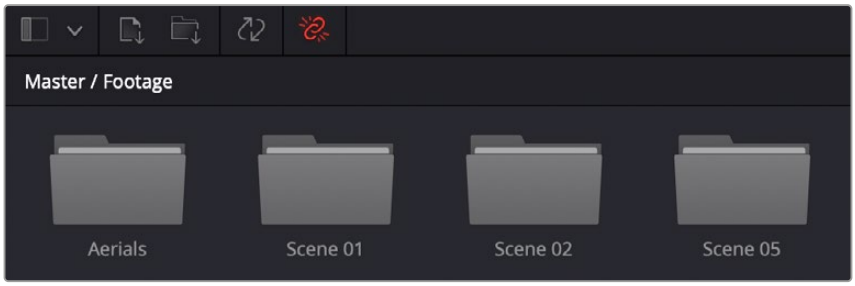
Removing Media

If there are clips you no longer want in your project, you can simply select them and press the Delete or Backspace keys. A Dialog asks if you want to remove the selected clip or clips; clicking Remove will remove them from the Media Pool, while leaving them intact on your media storage device.

If you want to remove every clip in the currently open bin (even the Master bin), you can also right-click anywhere within the Media Pool and choose Remove All Clips in Bin from the contextual menu.

Organizing Media into Bins

For short projects, having all your clips together in a single bin (the Master bin is the top level of the Media Pool) can be fast. However, for longer projects, organizing your media into subsets of clips within individual bins can make browsing each bin's contents using the Source Tape of the Viewer more manageable.



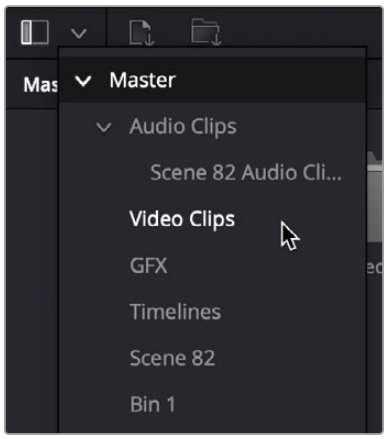
TIP: You can move clips you know you don't want, such as instances where the camera rolled on unusable scenery or moments, or completely unusable takes, into another bin so those clips don't present themselves in the Source Tape for bins containing clips you want to use.

Master Bin

At the top level of your project hierarchy is the Master bin. The Master bin contains all of the media content (clips, timelines, graphics, other bins, etc.) for your project. In the Cut page, the Master bin also shows all of your project's timelines for easy access, regardless of where they've been created in your project.

Creating and Using Bins

You can create bins with which to organize your media by choosing File > New Bin (Shift-Command-N), or by right-clicking in the Media Pool and choosing New Bin from the contextual menu. You can create bins inside of other bins, and in so doing hierarchically organize the clips you need in a variety of ways.



Bins seen in the Media Pool

Once you've created a bin, you can move one or more selected clips into it via drag and drop, just as you would on the desktop of your operating system's file manager.

Opening Bins

Any visible bin in the Media Pool can be opened by double-clicking it, or by clicking the Bin drop-down at the upper left-hand corner of the Media Pool and choosing a bin to open from the menu (they're shown as a hierarchical list). When opened, a bin's contents fill the Media Pool, and a path indicator at the top of the Media Pool lets you see how many levels deep you are in cases where you have bins inside of bins. You can click any level of this path to jump back up the hierarchy, or you can choose another bin from the Bin drop-down.

The hierarchical Bin drop-down menu

Create Bin With Selected Clips

You can also create a bin and put clips into it in one step. Select one or more clips in the Media Pool, right-click one of the selected clips, and choose Create Bin With Selected Clips from the contextual menu. A new bin appears called “Bin X” (where X is the next number that’s available) displaying the selected clips it now contains.

Renaming Bins

To rename a bin, click its name once, then slowly click a second time (clicking too fast is a “double-click” which opens the bin), and the name becomes highlighted, ready for editing. You can also right-click a bin and choose Rename Bin from the contextual menu, which also highlights the bin’s name, ready for editing. When you’re done typing a new name, press Return (or Enter).

Import and Export Specific DaVinci Resolve Project Bins

You can import/export specific bins from one DaVinci Resolve project to another, allowing you to pass bins quickly between projects and workstations that have access to the same media. All Metadata, In/Out points, Timelines, etc. are transferred along with the clips in the bin, but none of the actual media files are included.

To export bins from the Media Pool:

1. Select one or more bins in the Media Pool.
2. Right-click the selection and choose “Export Bin,” or choose File > Export > Export Bin.
3. Choose where to save the DaVinci Resolve Bin file (.drb) in the file system dialog, and click Save.

To import bins into the Media Pool:

1. Right-click in the Media Pool and choose “Import Bin,” or choose File > Import > Import Bin.
2. Do one of the following:
   - Choose a DaVinci Resolve Bin file (.drb) from the file system dialog.
   - Double click the .drb file in your file system.

The bin or bins will appear in the Media Pool. Any bins imported this way will have the word “import” appended to their name, to avoid duplicate names. If you import a bin that contains clips that were already in the Media Pool, the potentially duplicate clips are excluded from the import and instead relinked to the media referenced by your project. This keeps your Media Pool tidy. However, if the bin or bins have been moved to another computer, you may have to relink offline media.

Import and Export Individual DaVinci Resolve Timelines

You can export and import individual timelines from one DaVinci Resolve project into another previously existing DaVinci Resolve project, allowing you to pass timelines quickly between projects and workstations, without creating additional imported project files. Just the timeline and its associated clip information is exported, none of the actual media files are included.

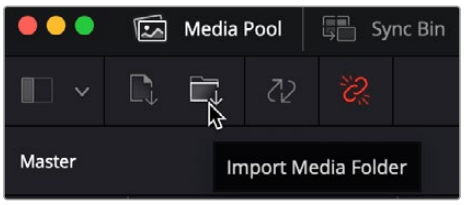
To export a timeline from the Media Pool:

1. Select a timeline from the Media Pool.
2. Choose File > Export > Export AAF, XML, DRT (Shift-Command-O).
3. Choose “DaVinci Resolve Timeline Files (*.drt)” from the format options drop-down in the file system dialog.
4. Choose where to save the DaVinci Resolve Timeline file (.drt) in the file system dialog, and click Save.

To import a timeline into the Media Pool:

1. Choose a bin in the Media Pool in which you want the imported timeline to be saved.
2. Do one of the following:
   - Choose File > Import Timeline > Import AAF, XML, DRT (Shift-Command-I), then Select a DaVinci Resolve Timeline file (.drt) from the file system dialog, and click Open.
   - Double click the .drt file in your file system.

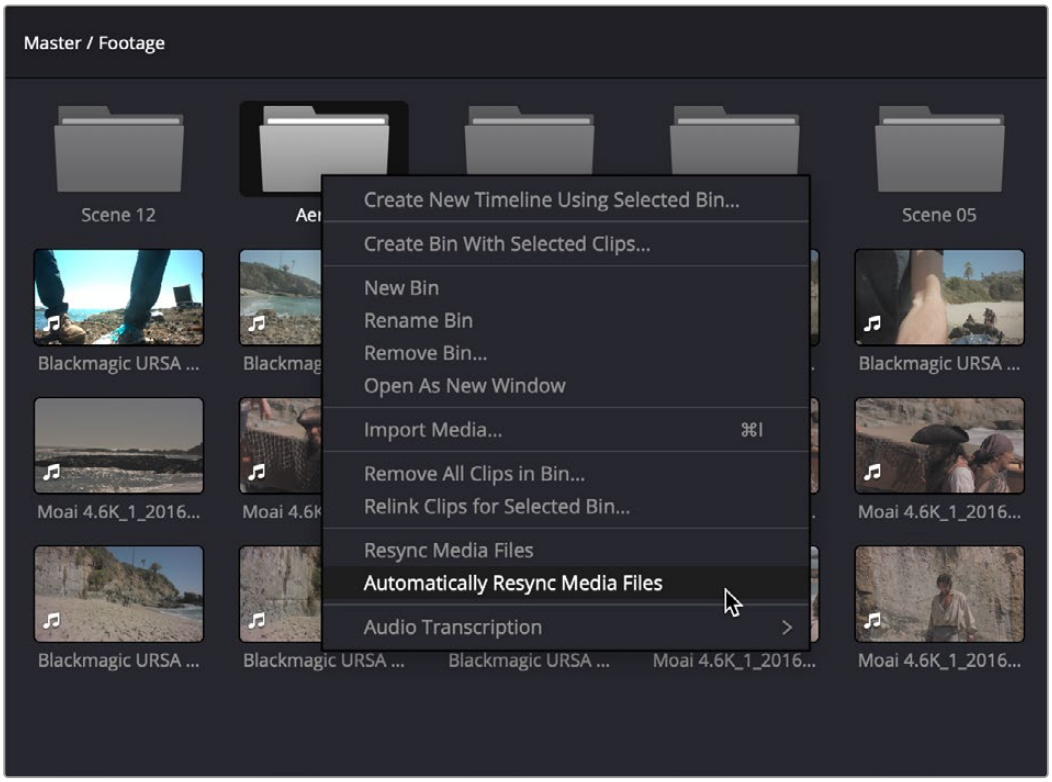
The timeline will appear in the Media Pool, along with all of the clips associated with it. Any timelines imported this way will have the word “import” appended to their name, to avoid duplicate names. The imported timeline will be automatically conformed to corresponding media that’s already in the Media Pool. However, if the timeline has been moved to another computer, you may have to reimport or relink missing or offline media in to bring the imported timeline fully online.



NOTE: Only a single timeline can be imported and exported at a time using this method. To import or export multiple timelines, use the Import/Export Bin function described above.

Sync Media Pool Bins with File System Folders

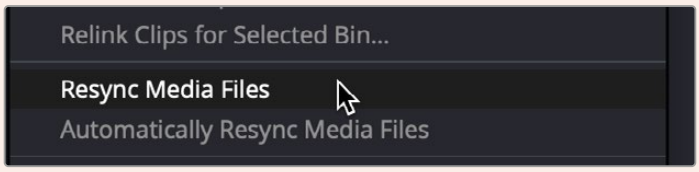
You can now sync a Media Pool bin with a folder on your computer's file system (MacOS, Windows, Linux etc.). This allows you to add additional media into a folder on your computer and have it automatically import to its respective bin in DaVinci Resolve.



To set up a folder with Automatic Syncing:

1 On the Cut page, use the Import Folder icon on the top menu bar to set up matching folder and sub folder names.

Use the Import Media Folder icon in the Cut page



2 Right-click on the imported folder and choose "Automatically Resync Media Files."

Right-click on the bin and select Automatically Resync Media Files

Newly added clips in this folder will be added automatically to the media bin. This can be useful when working with cloud-synced media files (as when using DaVinci Resolve's Replay capabilities), or any files that may be added to the folder later.

To manually resync the contents of a Media Pool bin once, right-click a bin and choose ”Resync Media Files.”

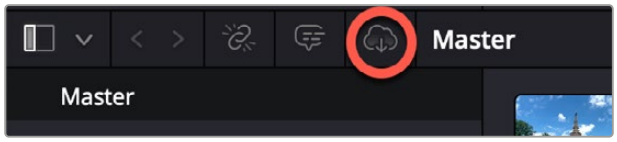
Right-click on the bin and select Resync Media Files to perform the sync operation manually.

For both Resync actions, ensure that:

- At least one clip is present in the media bin.
- All existing clips in the media bin share the same file path.
- The media bin name matches the parent folder of the clip paths. You can ensure this is set up correctly by using “Import Media Folder” in the Cut page, or “Add Folder and SubFolders into Media Pool (Create Bins)” in the Media page.

Sync actions will add new clips from sub-folders if the corresponding sub-bins exist. However, newly created sub-folders without corresponding media bins are not tracked, and new media bins without the corresponding sub-folders are skipped.

For example, say you were editing a sporting event, and you had a graphics operator creating animated lower-thirds for each of the players. By creating a common network folder called “CG” and automatically syncing it in DaVinci Resolve, each time a new lower-third was finished and saved, it would automatically appear in your bin in the Media Pool, ready for use.



Here’s how you would set this up:

- Create a folder on your network storage called “CG.” Both the editor and the graphics operator need to have access to this folder.
- Note that because this folder is currently empty, it can not be used in a Resync action yet. Only after there is at least one media file in the folder can you perform a Resync.
- The graphics operator finishes his first animated lower third and saves it to the “CG” folder as a .mov file (though any DaVinci Resolve readable media format would work).
- The editor then imports the “CG” folder into the Media Pool in DaVinci Resolve and selects Automatically Resync Media Files from the context menu.
- As the graphics operator finishes and saves additional lower thirds into that folder, they automatically appear in the Editor’s “CG” bin in the Media Pool, without having to specifically import them.
- For organizational purposes, the graphics operator then creates a new folder in “CG” for the other team, called “Team B.” Unfortunately, because this folder structure was not in the original imported bin, it does not show up in the editor’s media pool. However if they had created this Team B folder before the editor imported it, and it had media in it, it would been there.
- Now in this case, the editor simply imports the same bin again, selects Automatically Resync Media Files, and the new folder and all its media appear as expected. Any further files in dropped in “Team B” will show up in the editor’s media pool.

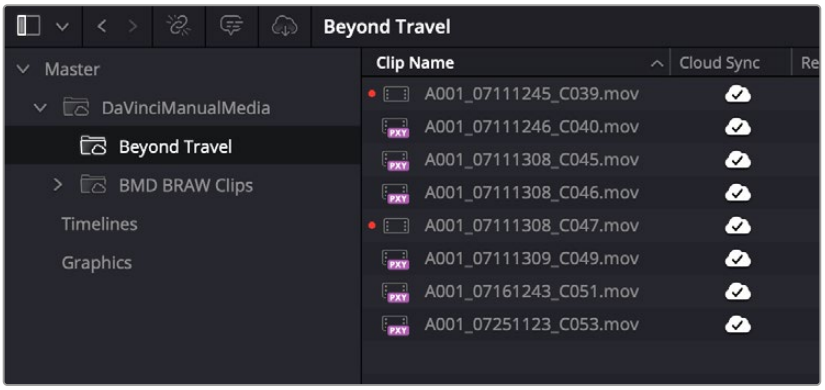
IMPORTANT: Media entries for clips that are removed or not found on the file system are set as offline media. This allows for retention of metadata and is useful when the clip path is temporarily offline, on cloud storage where file status may be in flux, or moved away by apps or workflows seeking to write a new version in its place.

Import Blackmagic Cloud Shared Folders to Media Pool

You can now import and sync Blackmagic Cloud Folders into the Media Pool. This allows you to connect to one or more cloud media folders and selectively download media from them to your local machine. Blackmagic Cloud Folders are online common storage folders that are not tied to a specific project. This lets you create a pool of commonly used media assets, such as title sequences, credits, bumpers etc, and share them online without having to import them separately into each individual project.

The Import Cloud Folder icon at the top of the Media Pool

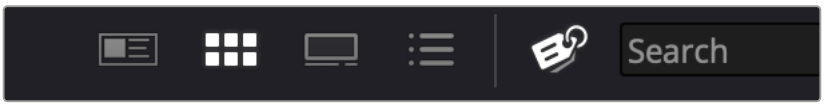
To link a Blackmagic Cloud Folder to your project:



1. Sign into your Blackmagic Cloud account in DaVinci Resolve.
2. Click on the Import Blackmagic Cloud Folder icon at the top of the Media Pool in any page.
3. In the Blackmagic Cloud Folder dialog, click select to choose a Blackmagic Cloud Folder. The choices here will show any Blackmagic Cloud Folder that you have created or someone else has shared with you. Click the Add button.
4. In the Download Folder Location, select a file location on your local system that you want the media from the Blackmagic Cloud Folder to be stored in.
5. Choose whether you want to sync proxies only, or proxies and used originals.
6. Press Download to add the Cloud Folder to your Media Pool.

The Blackmagic Cloud Folder link dialog

When you open the Blackmagic Cloud Folder in the Media Pool, it will be empty and populate one clip at a time as their clip names (not their media) are downloaded from the cloud. Also the Blackmagic Cloud Folder is not actually linked to your project yet; it is only linked when the first media clip is "used."

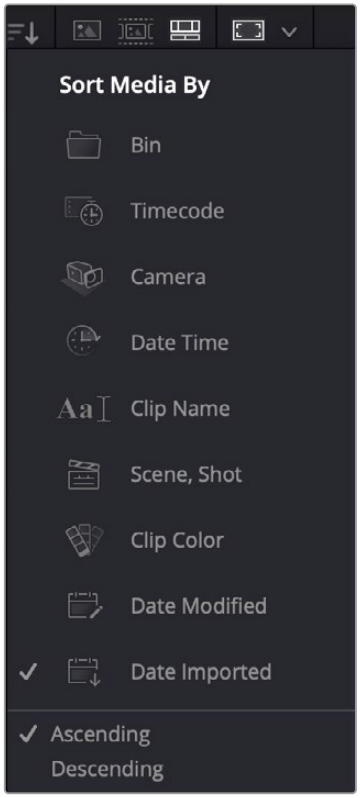


A "used" clip is new terminology in DaVinci Resolve and simply means a clip that has been altered in any way inside the project. A clip can be used be by putting it on a timeline certainly, but also includes other actions like applying a flag, altering its metadata, transcribing it, etc. Once a clip is used, its media will start to download to your local machine. Clips that are used are denoted by a red dot next to them in the Media Pool. Any unused clips will remain as virtual clips in the Cloud Folder until used. Once downloaded, clips in Cloud Folders can be used just like any other clip in the Media Pool.

The Cloud Folder linked in List view. Clips with red dots are "used" and the original media has been downloaded. Unused clips have just their proxies available to view. The Cloud Sync column shows that the media is registered and synced with the Blackmagic Cloud.

Media Pool Views

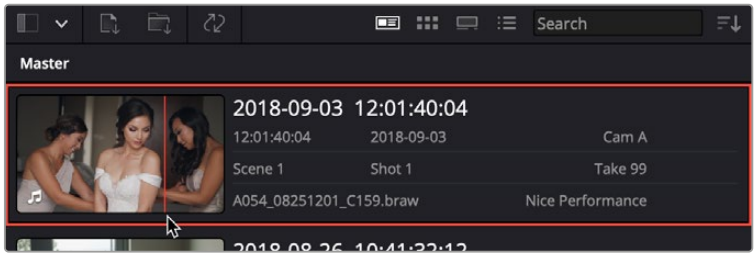
Once you've imported some clips into the Media Pool, three controls at the upper right-hand side let you control how they look, depending on what you need to accomplish.



The View Mode buttons

Metadata View

In the Metadata view mode, each clip is represented by its own card with a thumbnail and basic clip metadata information visible. This view is designed to have more metadata information than a thumbnail but more targeted information than the List view. This feature, combined with its sort modes, is a powerful way to organize and reorganize your clips in the Media Pool.

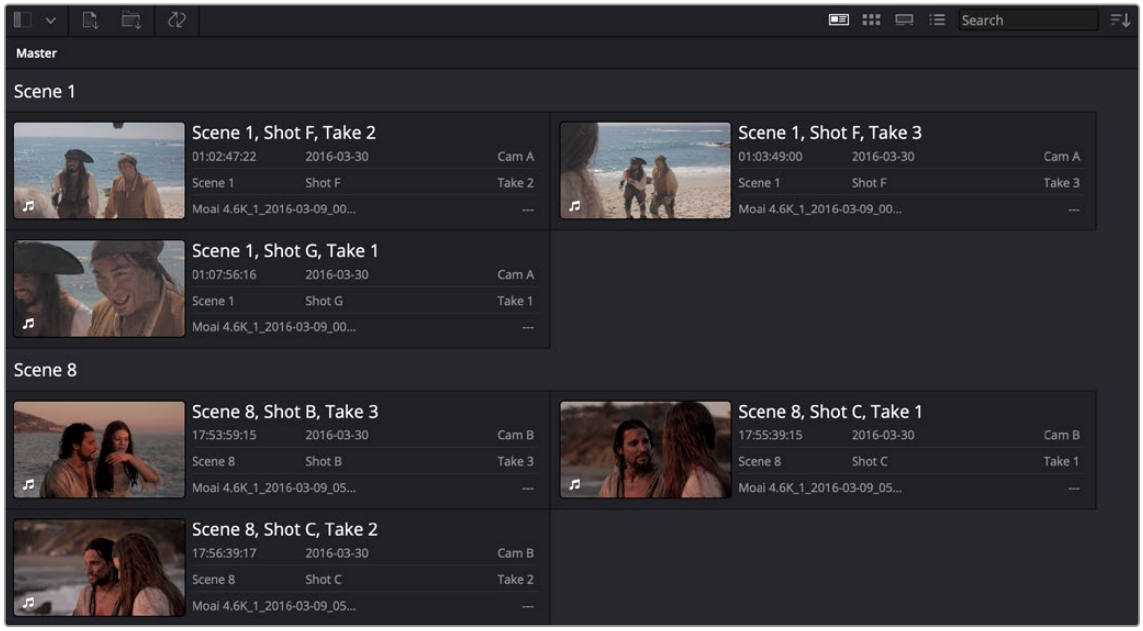


The metadata fields of the Metadata view (from the top down):

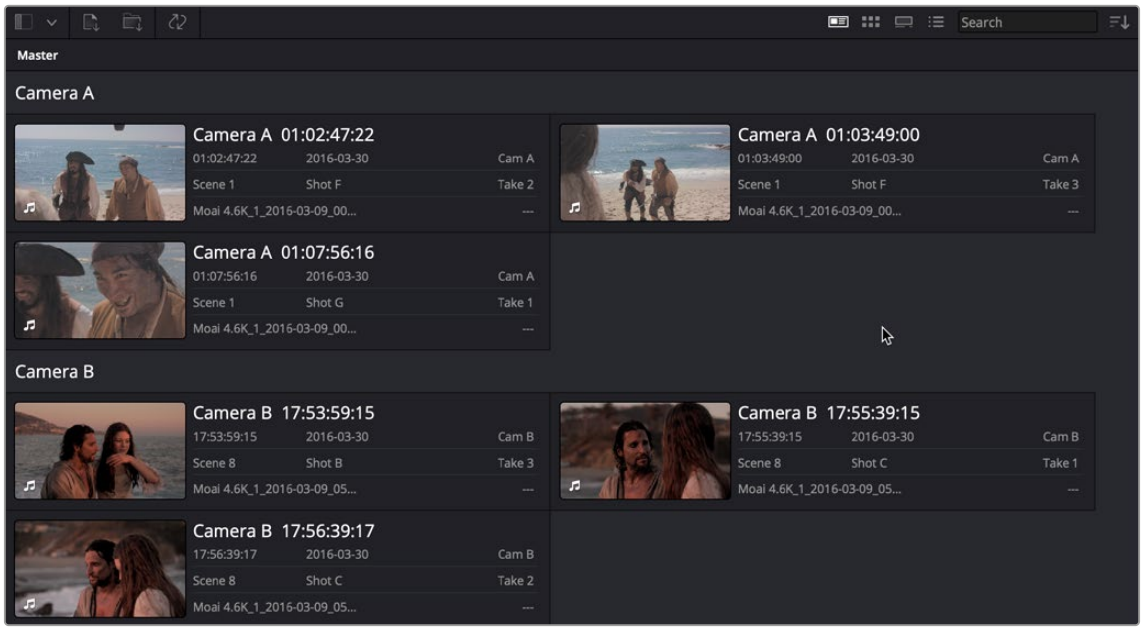
- **Thumbnail:** A scrubbable thumbnail image of your clip.
- **Row 1:** A main description field that is variable and determined by the sort order selection.
- **Row 2:** Start Timecode, Date Created, Camera #.
- **Row 3:** Scene, Shot, Take.
- **Row 4:** Clip Name, Comment.

The Media Sort options

The strength of the Metadata view is the automatic clustering of your clips in the Source Tape, based on the sort order you choose in the Media Pool Sort By menu at the very upper-right corner of the Media Pool. It is also possible to use these sort options in the Thumbnail, List, and Filmstrip views as well.



The Metadata View icon view (highlighted icon in the top bar), showing the thumbnail being scrubbed next to the clip's metadata



Each different sort mode changes the main description field on the card and re-arranges the Source Tape to reflect the selected organization method.

The sort modes available in the Metadata view are:

- **Timecode:** This mode clusters the clips by creation date, changes the main description field to creation date and start timecode, and orders the list by timecode.
- **Camera:** This mode clusters the clips by Camera #, changes the main description field to camera # and start timecode, and orders the list by timecode.
- **Date Time:** This mode clusters the clips by day, changes the main description field to creation date and file name, and orders the list by timecode.
- **Clip Name:** This mode clusters the clips by the first letter of the clip name in alphabetical order, changes the main description field to clip name, and orders the list by timecode.
- **Bin:** This mode clusters the clips by bin, changes the main description field to clip name, and orders the list by timecode.
- **Scene, Shot:** This mode clusters the clips by scene, changes the main description field to scene-shot-take, and orders the list by scene-shot-take.
- **Clip Color:** This mode clusters the clips by clip color name, changes the main description field to creation date and start timecode, and orders the list by timecode.
- **Date Modified:** This mode clusters the clips by day, changes the main description field to creation date and file name, and orders the list by the last time the clip was modified by the OS filesystem.
- **Date Imported:** This mode clusters the clips by day, changes the main description field to creation date and file name, and orders the list by the date the clip was added to the Media Pool.
- **Online Status:** This mode clusters the clips by proxy or original status.
- **Ascending:** Orders the Media Pool from lowest numerical value to highest, and alphabetically from A to Z.
- **Descending:** Orders the Media Pool from highest numerical value to lowest, and alphabetically from Z to A.

The Metadata view with clips sorted by Scene-Shot-Take

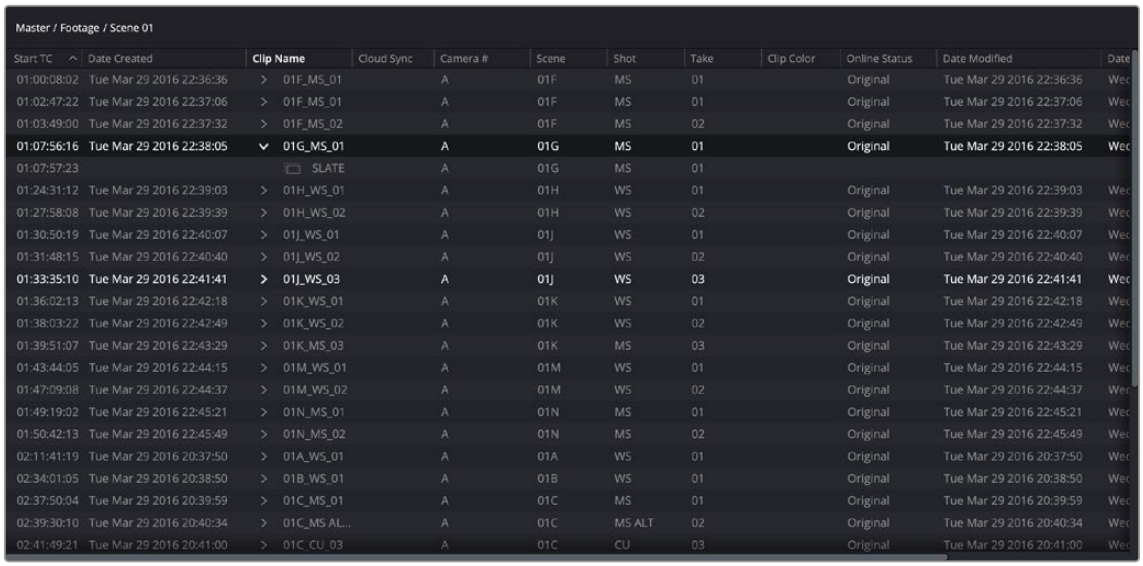
The Metadata view with the same clips sorted by Camera

Thumbnail View

Each clip is represented by a scrubbable thumbnail. Hover the playhead over each thumbnail and move it left and right to see the clip's image play, and use the I and O keys to mark sections of a clip that you want to use. Hover scrub can be enabled and disabled using the Media Pool option menu on the Edit page.

The Icon View mode

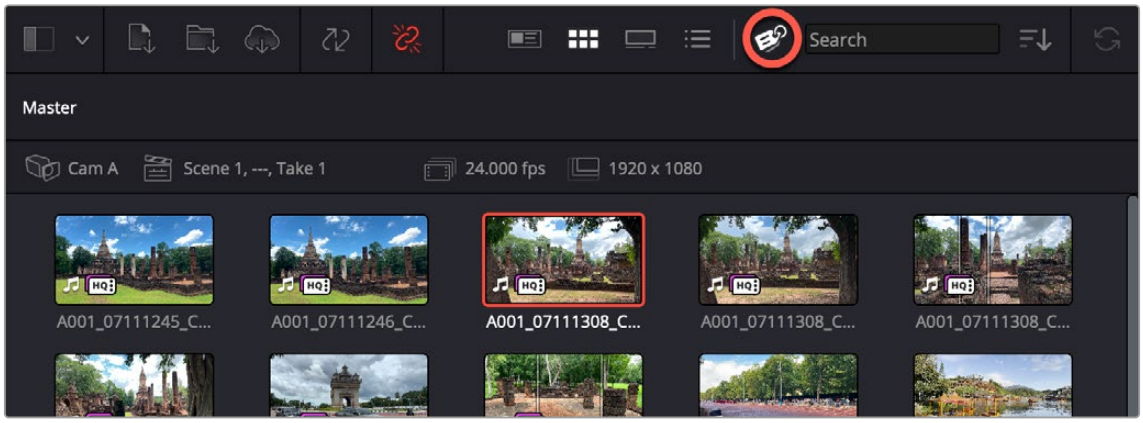
Filmstrip View



Each clip is represented by a filmstrip of consecutive frames the length of the Media Pool. Hover the playhead over the clip and move it left and right to see the clip's image play, and use the I and O keys to mark sections of a clip that you want to use.

The Filmstrip View mode

List View



Each clip appears as an item in a multi-column list showing a variety of metadata about each clip. In list view, you can click the header of any column to sort the contents by that column's information (clicking again toggles the sort order between Ascending and Descending). Scrolling right reveals additional columns of information. Clicking on an item on the list may let you change its value, depending on the column.

The List View mode

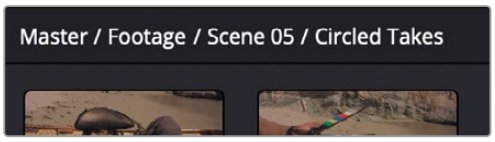
Metadata Display Palette

When in the Source Tape or Source mode in the Viewer, a small tag icon becomes available directly to the left of the search bar in the Media Pool. Clicking on this icon activates the Metadata Display palette at the top of the Media Pool. The display shows basic information about whatever clip is selected in order for you to quickly review the details about selected clips.

Next to the search bar in the Cut page Media Pool, is a small tag icon (circled red) that opens the Metadata display panel at the top of the Media Pool.

The information on the display includes: Camera Name, Scene/Shot/Take, Frame Rate, and Resolution.

Sorting and Searching



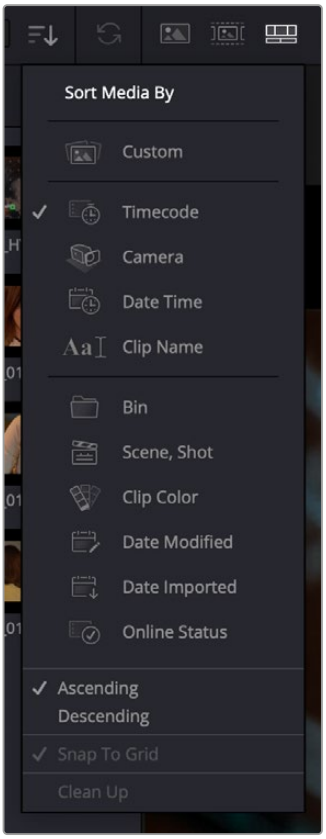
Once you've imported media into your project, searching and sorting controls help you find what you need.

Searching

A search field lets you type a term you want to use to find one or more clips that match that criteria. When you type anything, the contents of the Media Pool shrink to show only clips that match your criteria.

Navigable Clip Paths

The Media Pool in the Cut page has a navigable title bar that shows a clip's Media Pool hierarchy. As you navigate in the Media Pool, the current clip is highlighted, and its hierarchy will now appear in top of the Media Pool title bar. By clicking directly on bins in this bin path, you can quickly broaden or narrow the scope of the Media Pool, say from Shoot Day to Camera to Card to Clip and vice versa.



The Media Pool title bar showing a clip's Media Pool hierarchy. Clicking directly on these bins will narrow or broaden the scope of the clips in the Source tape.

Sort Media By

A Sort Media By drop-down menu lets you choose which criteria defines the order in which clips in the Media Pool are arranged. Options include: Custom, Timecode, Camera, Date Time, Clip Name, Bin, Scene Shot, Clip Color, Date Modified, Date Imported, and Online Status, and you can choose to sort in Ascending (bottom to top) or Descending (top to bottom) order.

Lastly, a search field lets you type a term you want to use to find one or more clips that match that criteria. When you type anything, the contents of the Media Pool shrink to show only clips that match your criteria.

The Media Pool Sort options

TIP: If you want to sort by a criteria that's not in the drop-down menu, you can switch the Media Pool to List view, then sort by any column you might want (such as "Date Created"), and then switch back to Icon or Filmstrip view.

Finding Timeline Clips in the Media Pool

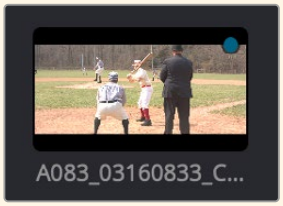
From time to time, you'll find yourself wanting to find the source clip in the Media Pool that corresponds to a clip in the Timeline. For example, you might want to go back to a part of an interview clip you've already used to find another phrase on the same topic.

To find a timeline clip in the Media Pool:

- Right-click a clip in the Timeline, and choose Find in Media Pool from the contextual menu. The corresponding clip is selected in the Media Pool, which scrolls to show that clip, if necessary.
- If you have several clips that are synced, right-click a clip in the Timeline, and choose Find in Multi Source from the contextual menu. The corresponding clip is selected in the Media Pool and opened in the Multi Source Viewer, which allows you to choose another camera angle of the same shot.

Clip Color

Clip colors are an organizational tool that make it easier to keep track of different kinds of clips visually. For example, you can assign colors based on good takes, based on characters or subjects in the program, based on type of media (b-roll versus a-roll for example), or using any one of a number of organizational strategies. Whatever helps you keep track of things you need to keep track of.

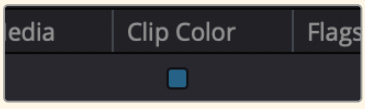


Changing clip colors:

You can assign colors to clips by right-clicking one or more selected clips in the Media Pool or Timeline, and choosing one of 16 available colors from the Clip Color submenu of the contextual menu.

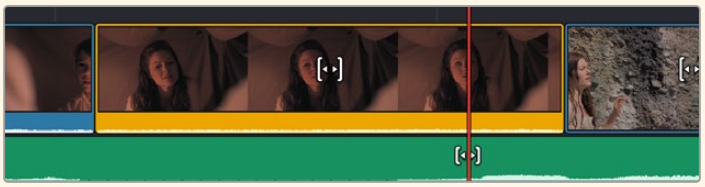
Removing clip colors:

Clip colors can be removed by right-clicking one or more selected clips in the Media Pool or Timeline, and choosing Clear Color from the Clip Color submenu of the contextual menu.



Clip colors appear as a colored dot on a clip thumbnail when in Thumbnail view, as a clip color in Filmstrip view, and as a patch in the Clip Color column when in Column view.

Clip color in – Thumbnail



Clip color in – Filmstrip

Clip color in – Column views

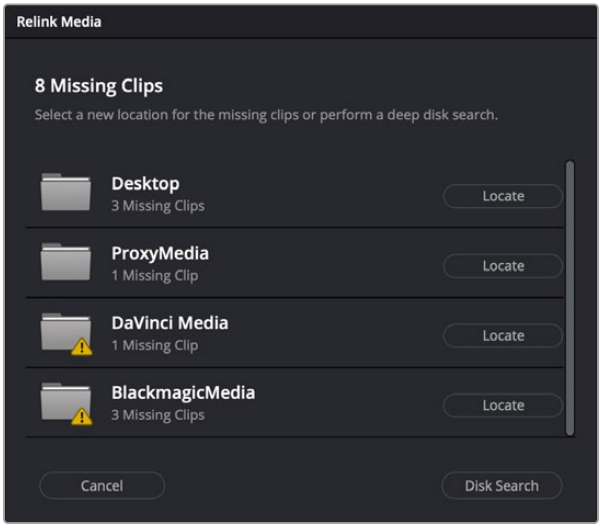
Clips with assigned colors also appear tinted in the Timeline, similarly to the Filmstrip tint in the Media Pool.

A timeline with a video clip that has been colored to identify what they are to the editor

Relinking Media

DaVinci Resolve attempts to automatically keep track of the relationship between clips in your project and their corresponding source media on disk. If, for whatever reason, source media that links to clips in your project becomes unavailable because it's been moved, DaVinci Resolve has several different methods of relinking those clips in the Media Pool. This section summarizes two methods of relinking, "Relink Media" and the "Relink Selected Clips" command.

For more information on other methods of conforming projects and relinking media, jump to section: Conforming and Relinking Media.



Relink Media

If DaVinci Resolve fails to find your media, a Relink Media icon in the Cut page's and Edit page's Media Pools will highlight orange.

The Relink Media icon that appears for unlinked media

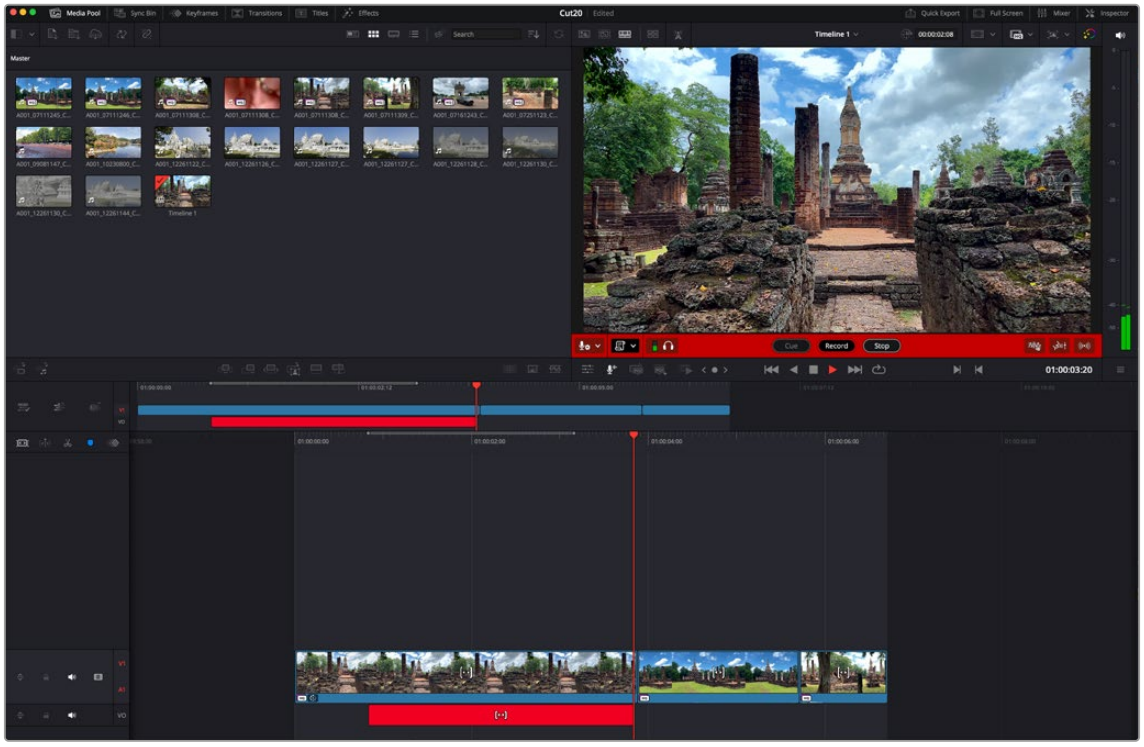
Clicking this icon opens a dialog box showing the volumes that the missing files initially belonged to. You can then use this information to track down the media on your file system, find that specific hard drive, or ask a client if they provided you the media from this volume. Clicking the Locate button lets you re-connect the missing clips to a new file location of your choosing. If the quick search initiated by the Locate buttons doesn't find media that you know is there, you can initialize an exhaustive deep disk search for the media by clicking on the Disk Search button.

The Relink Media dialog showing the volume names where the missing clips originated

Relink Selected Clips

The appropriately named “Relink selected clips” command is the most flexible method of relinking clips in your project with clips in a directory of your choice, using file name and timecode as the primary criteria for reconnecting the relationship between each clip and its corresponding media file on disk.

To relink selected clips or clips in a selected bin:



1. Do one of the following:
   - Select one or more clips in the Media Pool browser that you want to relink, then right-click one of the selected clips or the selected bin, and choose “Relink Selected Clips” from the contextual menu.
   - Select a bin in the Media Pool bin drop-down menu that contains clips you want to relink, then right-click the selected bin and choose “Relink Clips for Selected Bin” from the contextual menu.
2. When the Relink File dialog opens, choose a volume and directory in which to look for the files you want to relink to, and click OK. DaVinci Resolve attempts to find every clip with a matching file name in the subdirectories of the directory you chose, using the original file paths of the clips being relinked to do this as quickly as possible. By first looking for the clips in the directories they were originally in, relinking can be quite fast.
3. If there are any clips that couldn’t be found using the method in step 2, you’re prompted with the option to do a “deep search” by a second dialog. If you click Yes, then DaVinci Resolve will look for each clip inside every subdirectory of the directory you selected in step 2. This may take significantly longer, but it should be completely successful so long as the media that’s required is within the selected directory structure.
4. If there are still other clips that couldn’t be found, you’re prompted to either choose another directory altogether to continue searching, or quit.

Voiceover Tool

The Cut page in DaVinci Resolve has a dedicated voiceover and teleprompter interface, easily accessible in the Viewer by clicking on the Voiceover icon. The Voiceover tool makes it simple to record perfectly timed scripts directly into the Cut page timeline. You can even apply Voice Isolation and the Dialog Leveler on the fly to get great results, even with substandard microphones and recording environments.

The Voiceover icon (red) opens the Voiceover toolset

Recording a VO audio track directly into the Cut Page timeline using the Voiceover tool

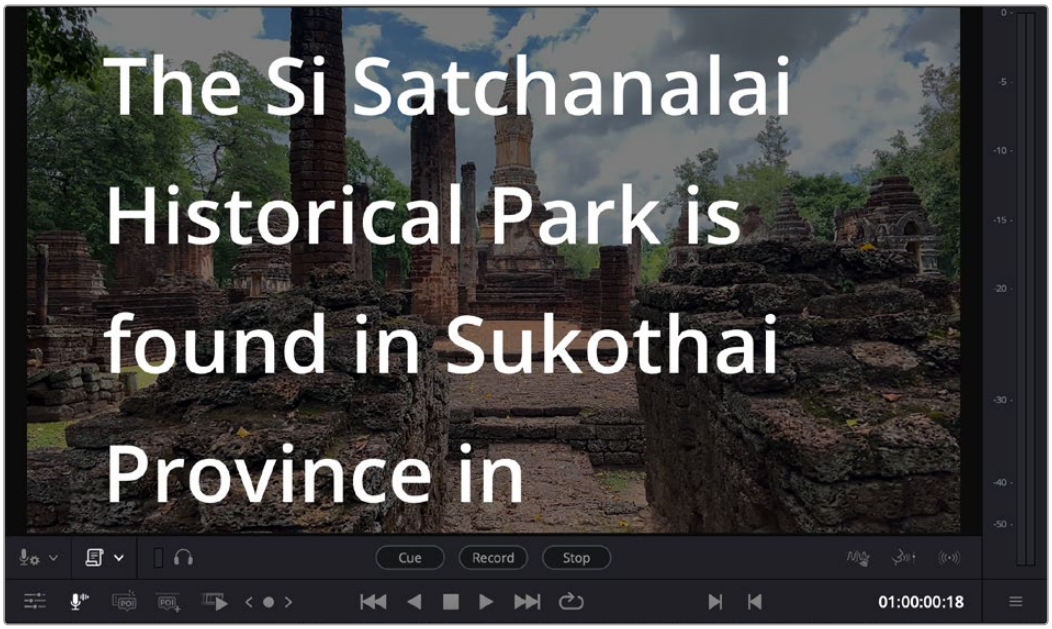
Using Voiceover on the Cut Page

At its most basic, you can quickly “punch in” a recording using only a microphone and an In point, but the Voiceover tool has a variety of features to make the process more precise and repeatable, including teleprompter support and AI-based audio tools. Below is a sample setup that makes the most out of the Voiceover features on the Cut page.

1. Connect an external microphone and headphones to your computer, then format a plain text (.txt) script for your VO.
2. Press the Voiceover tool icon in the Viewer.
3. In the Voiceover settings, select your microphone interface.
4. Select the Audio Track you want the voiceover clip to be recorded to. By default, the Cut page creates a new track called VO.
5. You have additional options for countdowns and to select the file folder that your voice recordings are saved into.

6 Determine where in the timeline this voiceover is needed. In a simple setup, just place the playhead at the location you want the VO to start. You can also set an In point in the timeline to serve as a cue point that the Voiceover tool returns to for subsequent takes.

7 You can optionally turn on the Voice Isolation and Dialog Leveler, if you're recording in a substandard audio environment (for example, directly into your laptop microphone in an office environment) to clean up your audio as you record it.



8 Click the Record button to start the teleprompter and recording to the selected track. The interface will change to red to let you know you're "on the air."

9 Click Stop to end the recording. The playhead will automatically snap back to your start position, so you can then play your new voiceover in place.

10 If you need to try again, press the Cue button to automatically return to the In point, and press Record again to give it another take. The new voiceover will automatically overwrite the old take on the timeline. However, all of your previous VO takes will still be saved in the Media Pool, if you want to go back to them.

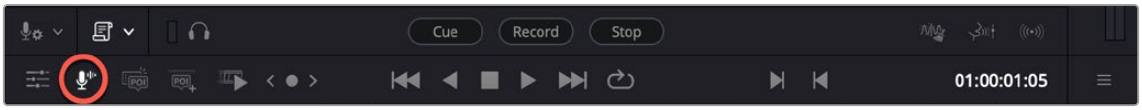
Using the Prompter

The Voiceover tool has a build-in Prompter toolset that lets you import a text (.txt) script, and during recording the text scrolls over the picture for accurate voiceover performance and placement.

The built-in Prompter in the Voiceover tool

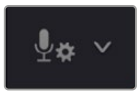
To use the Prompter while recording voice over:

1 Open and set up the Voice Over tool as described above.



2 In the Script Settings, enable the Prompter Overlay, and load the Script File. You have additional settings for how the script is formatted in the Viewer.

3 You can set In and Out points on the timeline to mark the VO range for the teleprompter. The teleprompter will then adjust its speed automatically to start scrolling at the In point, and end at the Out point. By default, the script scroll length will cover the entire timeline if no In or Out points are set.



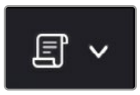
4 When you press record, the text will scroll over the image while your voice over is being recorded.

Voiceover Settings

The Voiceover tool has several optional settings to fine tune your VO session.

Clicking on the Voiceover icon (red) opens the Voiceover toolset at the bottom of the Viewer

Voiceover Settings



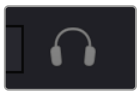
- **Audio Input:** Select which computer interface your microphone is connected to.
- **Record Track:** Select which audio track in the timeline you want the VO to be recorded to. By default the Cut page creates a new track labeled VO, but you can manually override it to another track in this setting.
- **Monitoring**

  Timeline & Microphone: Lets you hear both the timeline audio and your voice input while you're recording.

  Timeline Audio Only: Lets you hear the timeline audio only while you're recording.

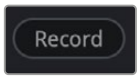
  Microphone Audio Only: Lets you hear your voice input only, and mutes the timeline while you're recording.

  Mute Monitoring When Recording: Mutes all audio playback while you're recording. Useful to avoid audio feedback in certain recording setups without headphones.
- **No Countdown:** No visual countdown appears, when you press Record, start talking.
- **3 Secs Countdown:** Puts a three second visual countdown on the viewer before the recording begins, to allow a little time to get ready first.
- **5 Secs Countdown:** Puts a five second visual countdown on the viewer before the recording begins, to allow a little time to get ready first.
- **Voiceover Recording File Location:** Select where your new audio files are saved to.

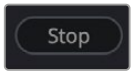


Script Settings

- **Enable Prompter Overlay:** Turns on or off the text overlay for the loaded script.
- **Load Script File:** Opens a file selector to choose a text file to load into the prompter.
- **Clear Script File:** Removes the text file from the prompter.
- **Font Size:** Lets you choose the font size of the on screen text.
- **Line Spacing:** Lets you choose the line spacing of the on screen text.
- **Side Margin:** Lets you choose how big of a margin to use for the on screen text.
- **Background Opacity:** Lets you choose the transparency level of the on screen text.



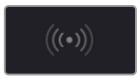
Audio Meters: A miniature set of audio meters shows your microphone's audio levels.



Input Monitoring: Click the headphone icon to toggle between hearing your microphone input while you're recording, or muting it.

Cue: Snaps the playhead back to the initial record In point.

Record: Starts the audio recording into the timeline.



Stop: Stops the audio recording.

Voice Isolation: Activates the Voice Isolation effect as you are recording to minimize any background noise.

Dialog Leveler: Activates the Dialog Leveler effect as you are recording to keep a constant volume for your track.

Stereo Fixer: Activates the Stereo Fixer effect as you are recording to eliminate common channel errors involved in translating between mono and stereo sources.

ATEM Switcher Integration

If you've recorded a multi-camera event with the ATEM Mini Pro ISO or ATEM Mini Extreme ISO, it is possible to move that entire project into DaVinci Resolve. ATEM projects include the master program clip, as well as each individual camera's "ISO" (isolated) clips, and each camera angle's audio recordings. All transitions, timecode, and camera number metadata are imported, as well as whatever graphics were stored in the ATEM's Media Pool. Once the project is loaded, you can seamlessly continue your multi-camera edit in the Cut page.

This initial live recording coupled with later post-production editing workflow is often referred to as "Live to Tape." Live to Tape gives you the all the benefits of the spontaneity, verisimilitude, and fast turnaround inherent to live production but with the added benefit of being able to later add and remove sections and adjust the editorial flow of the program. Live to Tape also allows you to fix simple mistakes, such as choosing a better camera angle, or replacing a title or graphic with an updated version. Because of this flexibility, Live to Tape is the preferred method of recording almost all broadcast network game shows, current events shows, and sitcoms. Essentially, any type of multi-camera production that does not primarily depend on being live in real time for its main purpose (like news or sports) is shot Live to Tape instead.

The Live to Tape workflow requires the following elements, all of which are provided by the ATEM Mini Pro ISO and ATEM Mini Extreme ISO.

- A program master clip that was shot live, including all the mixed camera angles, audio, transitions, etc. from the beginning of the show until the end, for reference.
- Separate ISO recordings from each camera used to shoot the program master clip. An ISO is an isolated (ISO) camera recording of the entire show from that camera's perspective only, from the beginning to end and without interruption.
- A timeline of the live recorded show that indicates where all the camera angles were switched, what transitions were used, and what graphics were involved.

NOTE: The live webcam view from the ATEM is available only on MacOS.

Importing ATEM Mini Pro ISO Projects

Importing an ATEM project essentially rebuilds the master program clip as a timeline inside DaVinci Resolve from the camera ISOs, transitions, and graphics. This new timeline will match the master program clip in every way, just created from the original source materials rather than as a single compressed video file.

Refer to your ATEM's specific documentation for how to set up ISO recording, but one important setting is to make sure that you've checked the "ISO Record All Inputs" setting in the ATEM software control before you start shooting.

To import an ATEM Mini Pro ISO Project:

1. (Before you shoot) Check the "ISO Record All Inputs" setting in the ATEM software control.
2. At this point, record your show using the ATEM device, and note the project's folder location.
3. Select File > Import Project.
4. Select the DaVinci Resolve Project file (.drp) in the ATEM project folder, in the file browser.
5. Click on the Open button.

An ATEM Mini Pro project opened in the Cut page Sync bin

Relinking Blackmagic Camera Masters to ATEM ISOs

The ATEM records each camera's ISO as an H.264 HD video stream, which may not be of high enough resolution or quality for some purposes. It's possible to instantly switch your ATEM camera ISOs to the original camera recordings made in a Blackmagic Camera instead. This workflow enables the highest visual quality of Blackmagic RAW and the ability to output in higher resolutions (such as 4K or UHD) than are supported by the ATEM internally. Essentially, the ATEM can reference an additional set of higher quality ISOs recorded in the cameras, rather than those from the ATEM itself. This feature is only available using Blackmagic Cameras.

This workflow requires one more step in the process, namely making sure that you have sufficient recording space attached to each camera to record the show in its entirety. Refer to your ATEM's specific documentation for how to set up ISO recording and camera control, but one important setting is to make sure that you've checked the "ISO Record All Inputs" and the "Record in All Cameras" settings in the ATEM software control before you start shooting.

To relink to Blackmagic Camera masters from ATEM ISO recordings:

1. (Before you shoot) Check the “Record in All Cameras” setting in the ATEM software control.
2. (Before you shoot) Check the “ISO Record All Inputs” setting in the ATEM software control.
3. At this point, record your show using the ATEM device and note the project’s folder location.
4. Copy all the resulting camera masters from each camera’s memory card to the ATEM project’s “Video ISO Files” folder, and then import the project into DaVinci Resolve.
5. DaVinci Resolve automatically creates a separate Blackmagic RAW folder in your project and moves all the camera masters to that folder.
6. Use the menu Timeline > Switch to Camera Originals to instantly switch between referencing the ATEM H.264 ISOs and the Blackmagic Camera masters.

Once your project is imported successfully into DaVinci Resolve, it can be edited using the variety of specialized Multicam editing tools found in the Cut page, including the Sync Bin, Live Overwrite, and the DaVinci Resolve Speed Editor.

For more information on using these tools, jump to chapter: Fast Editing in the Cut Page.

Chapter 35

Fast Editing in the Cut Page

The editing methods in the Cut page have been streamlined for fast editing, and the interface of this page and the methods of assembling clips together using different types of edits are designed to be easy to learn and quick to use.

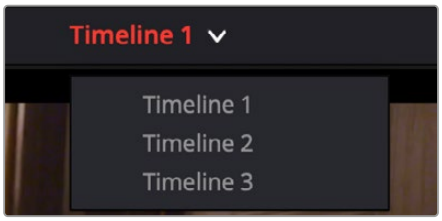
Creating and Modifying Timelines

After you've imported and organized the media you need to use in a program, the next thing you must do is create a timeline. Timelines are the organizational entities that contain the edited sequences of clips that make up your program. You can have as many timelines as you like in your project, with each timeline being an independent arrangement of clips. Timelines are stored in the Media Pool and can be organized using bins, just like clips.

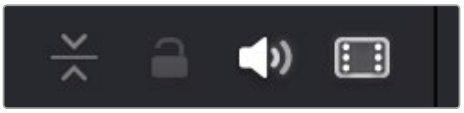
Creating New Timelines

A timeline is automatically created when you edit your first clip into the Timeline. You'll see an icon for the new timeline in the Media Pool, where you can rename it.



You can also create a new timeline by either choosing File > New Timeline (Command-N), or right-clicking in the background of the Media Pool and choosing Create New Timeline. A dialog appears that lets you choose a start timecode (the default is 01:00:00:00), a name, how many video and audio tracks you want it to have, what kind of audio (the default is stereo), and whether or not you want to create an empty timeline, or a timeline that automatically includes all clips in the Media Pool with or without selected In/Out points (a quick and easy way of creating a stringout of all clips you've imported).

By default, all timelines share the same frame rate, resolution, and monitoring settings as the overall project. If you like, you can also click the Use Custom Settings button to choose individual frame rate, resolution, and monitoring settings for that timeline.



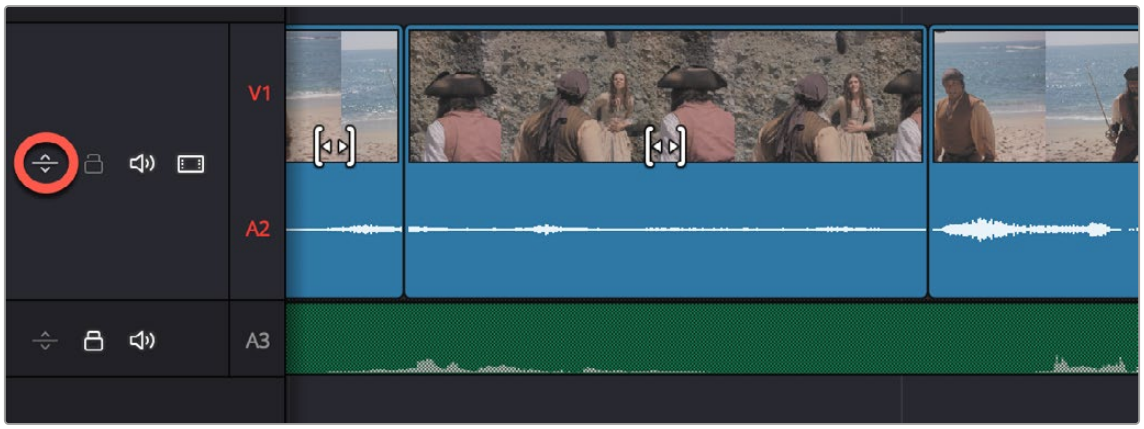
Once you've created a new timeline, double-clicking it will open it into the Timeline Editor.

Opening Timelines

If you only have one timeline in your project, that timeline is always seen in the Timeline Editor. If you have multiple timelines, you can double-click any timeline in the Media Pool to open it into the Timeline Editor, ready for editing. You can also switch from working on one timeline to another by using the drop-down list at the top of the Cut page Viewer. This unifies Viewer Timeline Selection behavior across the Cut, Edit, Color, and Deliver pages.

The Timeline Selection drop-down at the top of the Cut page Viewer

The Enlarge, Lock, Audio Enable, and Video Enable buttons in the header of a timeline track



About Tracks in the Cut Page Timeline

Tracks in the Cut page timeline combine a clip's audio and video into a single track for convenience, as this makes it easy to keep audio and video organized and in sync when superimposing many clips together. This means that tracks have both video and audio enable controls in the track header controls, so that you can selectively disable video and mute audio when necessary.

Each track also has a lock control, which lets you prevent clips on that track from being altered in any way.

Enlarging Tracks

Track size can be enlarged and minimized by clicking on the Track Sizing icon on the left side of the track header. An expanded video track shows a full size video and audio track, if attached. This makes it easier to see just the track you want to focus on. Only one track can be expanded at a time.

Clicking on the Track Sizing icon expands the track to show the full audio track of the clip

Adding Tracks

If your timeline doesn't have enough tracks, you can click on the Timeline Actions menu and select Add Video/Audio/Subtitle track, or right-click anywhere in the Timeline and choose "Add Track," and a new track will be added on top of the previously existing tracks.

TIP: Dragging a new clip to the undefined gray area at the top of the Timeline also adds a new track.

Deleting Tracks

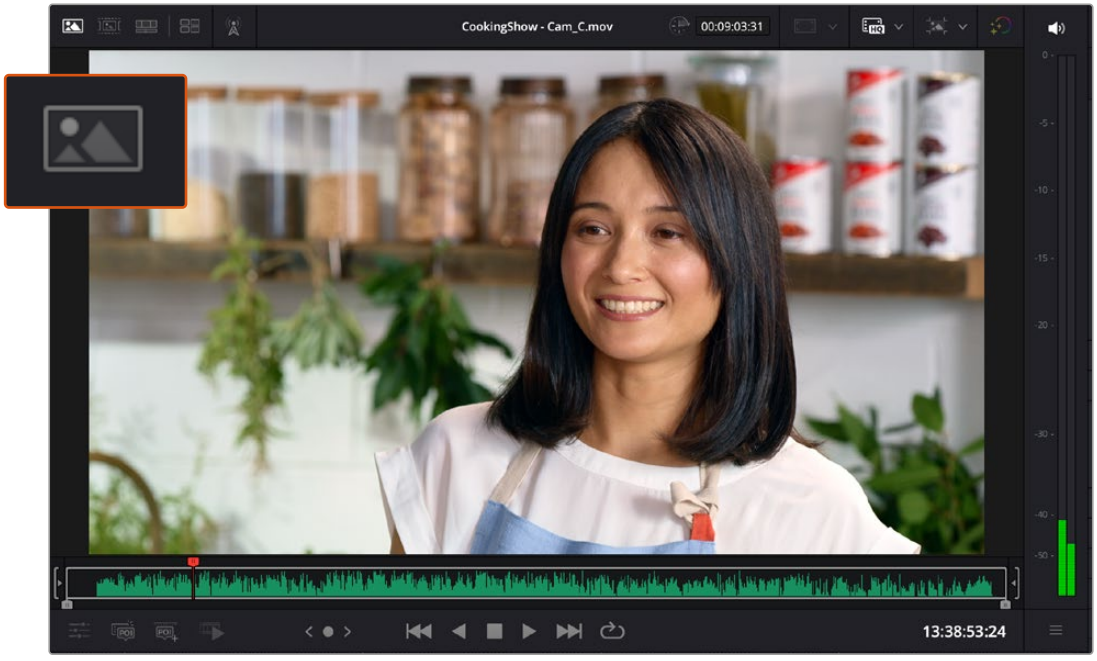
If you want to delete a specific track along with all clips on that track, you can right-click anywhere in that track's header and choose "Delete Track."

If your timeline has too many empty tracks, you can right-click anywhere in the track header and choose "Delete Empty Tracks" and all empty tracks will be removed.

Navigating Clips in the Viewer and Timeline

Before you can start editing, you need to find which parts of which clips you want to use and define where in the currently open timeline you want to make an edit. The Single Viewer in the Cut page has different options that let you choose what media you want to play through using the transport controls found at the bottom.

Viewer Options

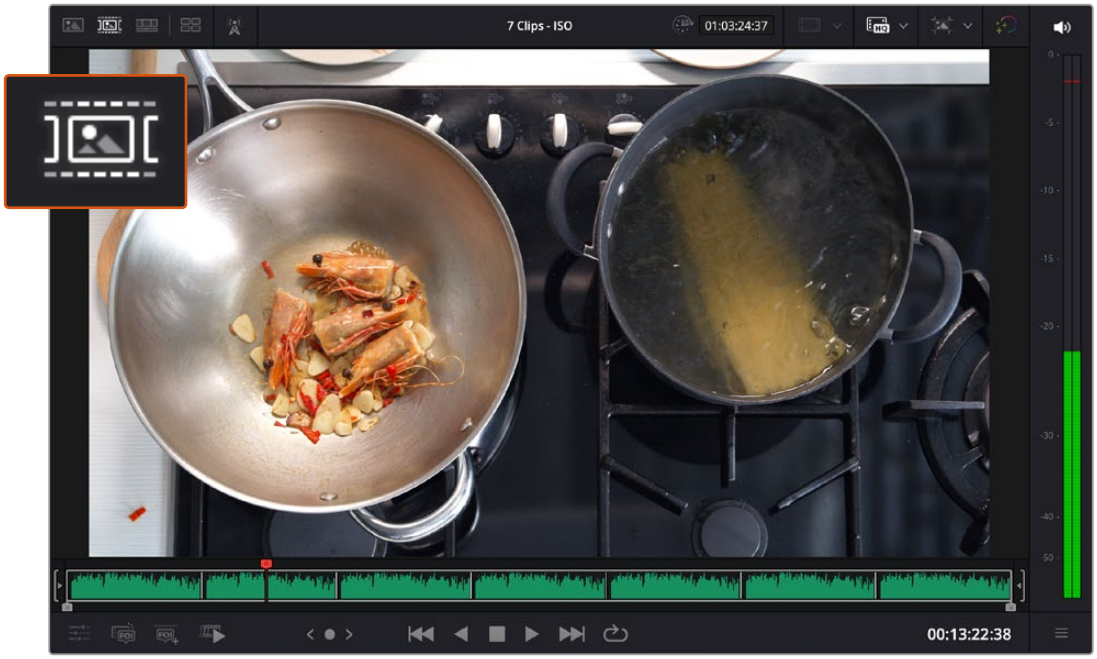


Three options, selectable via buttons at the upper left of the Viewer, let you control what the Viewer shows.

The Viewer option buttons (left to right): Source Clip, Source Tape, Timeline, and Multi Source

Source Clip

This option shows the currently selected clip in the Media Pool. This is the mode the Viewer automatically switches to whenever you double-click a clip in the Media Pool. In Source Clip, a scroll area appears at the bottom of the Viewer, the width of which represents the duration of the currently open clip. A playhead within the scroll area lets you scrub through the clip as a zoomed-in waveform and shows whatever audio is playing within the clip. Handles to the left and right of the scroll area let you reposition In and Out points within the clip to choose a section you want to edit into the Timeline. These In and Out points can also be set using the I and O keys. Once set, you can drag In and Out points to change them.

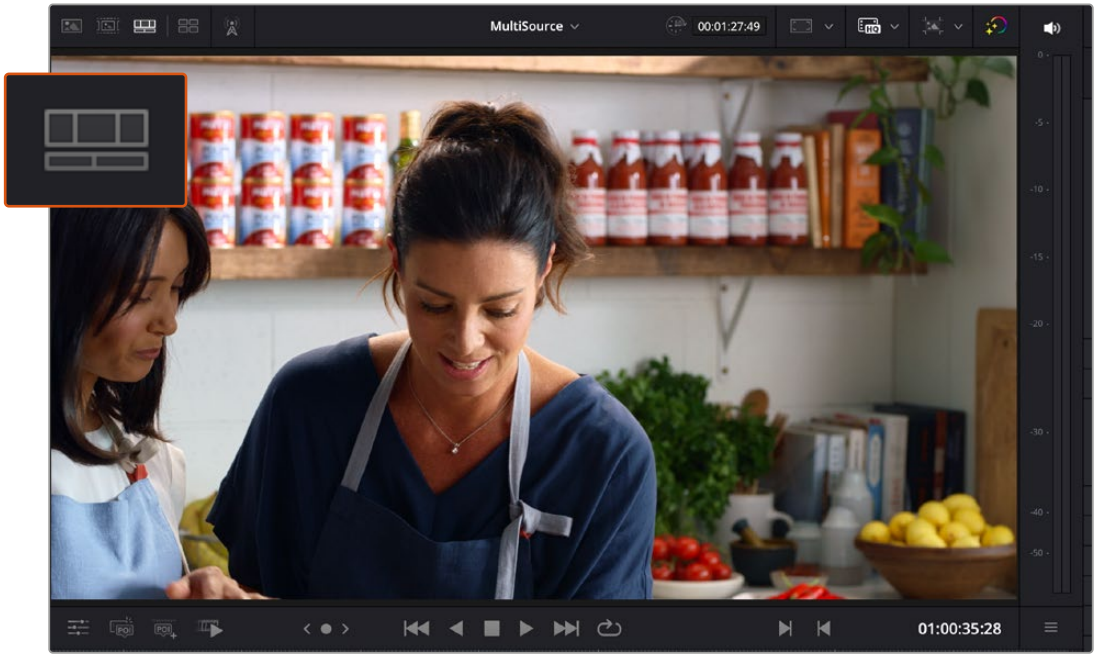


The Viewer showing Source Clip

The scroll area in Source Clip option, with In and Out points positioned to either side of the playhead

Source Tape

Using this option, every single clip in the currently open bin, and any subfolders in that bin, of the Media Pool is shown in the Viewer as a “stringout” in the scroll area at the bottom of the Viewer. In the scroll area, each clip appears one after the other in a long strip, with the order determined by the Sort order. This makes it easy to scrub through a whole collection of clips while you’re figuring out what you want to use. As you play through, whichever clip the playhead intersects is selected in the Media Pool, so you know which clip you’re looking at.



The Viewer showing Source Tape

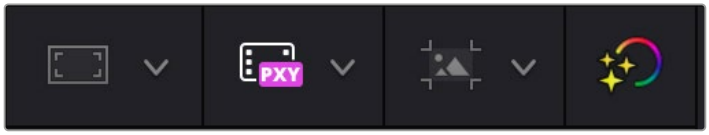
The scroll area in the Source Tape, with each clip separated by a thin line

Timeline

This option shows the current frame at the position of the playhead in the Timeline. Whenever you click, drag, or adjust a clip in the timeline area, the Viewer switches to the Timeline. In this option there is no scroll area; you must use the timeline area to scrub through your program. However, in the space where the scroll area would otherwise be, icons appear to indicate when the playhead is positioned at the first or last frame of a clip in the Timeline.

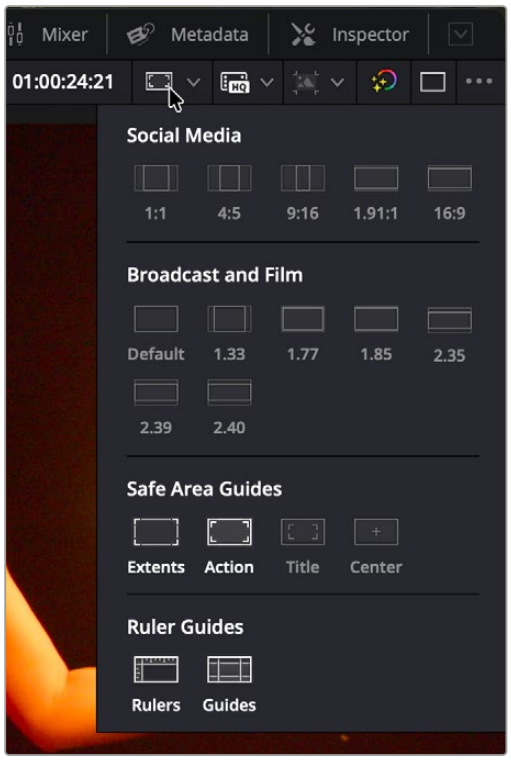
The Viewer showing the Timeline

Multi Source



If you have multiple clips that are synced either by timecode or waveform, you can view them all at once, even across multiple bins in your project. Choosing this option opens up the Multi Source viewer in the Source Tape. It will lay out all synced media in a grid, and all media is ganged together as you scrub through. Setting In and Out points in this mode are constant across the different angles, so you can switch cameras and the same In and Out points you set remain valid on each clip. These features let you quickly choose the best angle for a multi-camera shoot.

The Viewer showing the Multi Source



In and Out points set in the Multi Source. These points remain set when you switch camera angles.

The right side Viewer controls (left to right): Safe Area, Proxy Handling, Timeline Resolution, and Bypass Color Grades and Fusion

Safe Area

This drop-down menu overlays many useful framing guides over the Viewer to let you see what part of the image will be included and what will part will be cropped out if you change the Timeline's aspect ratio. The framing guides can be turned on and off by toggling the Safe Area Framing Guide icon in the Viewer, and the exact guides can be selected in the drop-down menu.

The Safe Area Framing Guide icon and the possible framing options

Social Media: 1:1, 4:5, 9:16, 1.91:1, 16:9.

Broadcast and Film: Default (your current timeline aspect ratio), 1.33, 1.66, 1.77, 1.85, 2.35.

Safe Area Guides: These options add additional guide lines on the Viewer to protect your composition from possibly being cut off at the extreme edges of a physical cathode ray tube. While somewhat anachronistic in this age of flat screen digital televisions, many legacy programs still adhere to these guidelines. Safe Areas still can be useful guides in ensuring your image is not inadvertently cropped by the variety of mobile devices and social media sites in use today.

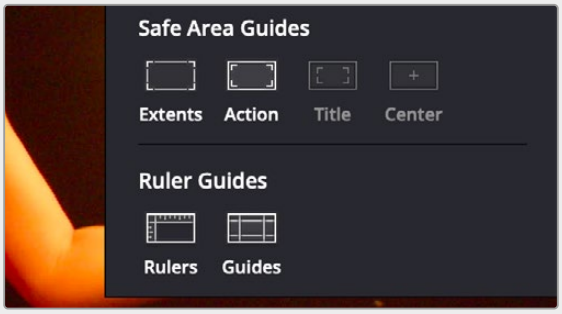
Extents: Show the full boundary of the frame.

Action: Keep all movement and important action within this box.

Title: Keep all on screen text within this box.

Center: Designates the exact middle of the image.

You can toggle the extents Safe Area overlay on or off, in addition to the Action, Title, and Center overlays. You can access this features at View > Safe Area > Extents.

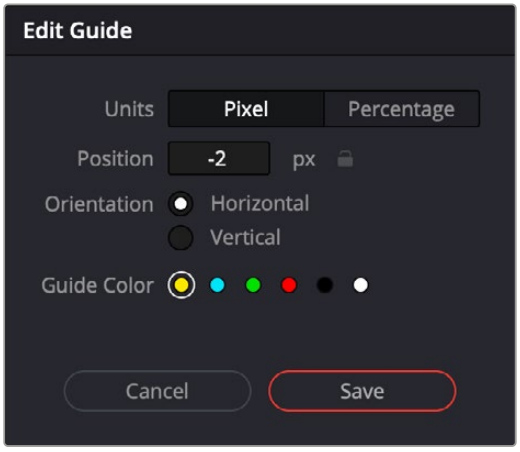


Custom Guides and Snapping in the Timeline Viewer

You can create your own custom guides in the Timeline Viewer. This lets you fully customize and create specific geographic locations in the frame, and then have the image snap to those locations in other operations. You can create Guides, which are colored lines that cross the frame horizontally or vertically, and Rulers, which provide measurement metrics along the edges of the frame. Both Guides and Rulers are overlay tools for adjusting your video position, and only show in the viewer, not your final project output.

The Timeline Viewer with Guides and Rulers enabled

Both Guides and Rulers can be shown independently by clicking on their icon in the Ruler Guides section of the Viewer Guides drop-down menu on the Timeline Viewer. They can also be independently activated in the View > Rulers, and View > Guides menus.



The Ruler Guides section of the Viewer Guides dropdown

To Show and Modify a Ruler:

1. Activate the Ruler by choosing View > Rulers > On, or clicking on the Ruler Icon in the Viewer Guides dropdown in the Timeline Viewer.
2. Choose which metric you want the Ruler to use in View > Rulers, or by right-clicking on the Ruler in the Viewer.

   Pixel: Shows the ruler in number of pixels from the origin point (0,0) in the middle of the frame using a standard x/y cartesian coordinate graph, that reflects the Position field in the Video Inspector.

   Percentage: Shows the ruler in percentage distance from the origin point (0%, 0%) in the top-left of the frame. The top ruler runs from 0% at the left to 100% at the right, while the side ruler measures 0% from the top to 100% at the bottom. For example a point at the exact center of the frame would be at (50%, 50%).

The Add/Edit Guide dialog

To Show and Create a Guide Line:

1. Activate the Guides by choosing View > Guides > On, or clicking on the Guides Icon in the Viewer Guides dropdown in the Timeline Viewer.
2. Create a new Guide by choosing View > Guides > Add Guide, or by right-clicking on the Ruler in the Viewer and selecting Add Guides.
3. In the Add Guide dialog, choose the position and orientation you want the new guide to be, and click Add.

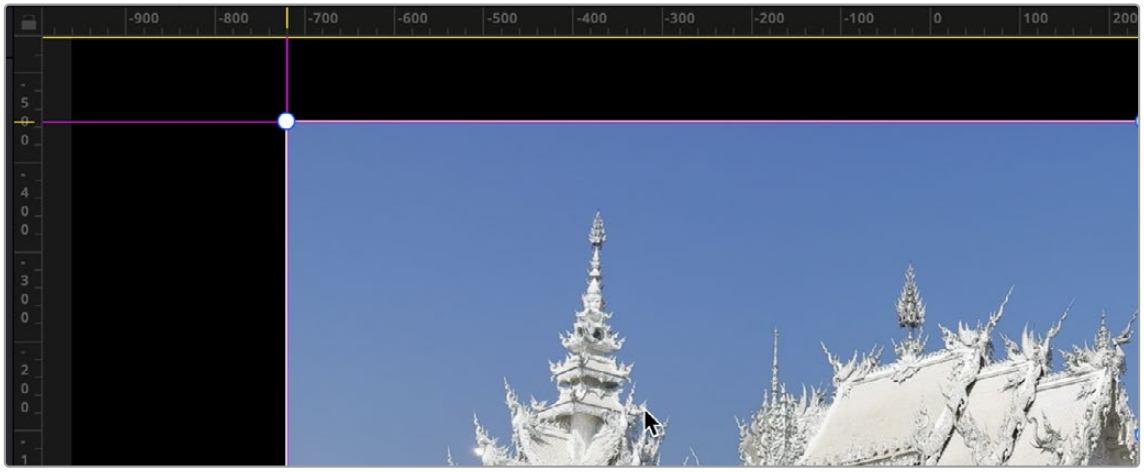
   Units: Choose which metric you want the guide line to use. Pixel shows the number of pixels from the guide's origin point, while Percentage shows the percentage distance from the top left of the frame at 0%,0%.

   Position: Enter a value for where in the frame you want the guide line to intersect. You can also click and drag this line in the viewer to position it by eye (a small popup will reveal the exact position value as you move it). Optionally you can click the lock icon to prevent this guide from being moved accidentally.

   Orientation: Choose either a horizontal or vertical orientation for the line.

   Color: Choose the color of the guide line from the available options.

To Modify a Guide Line:

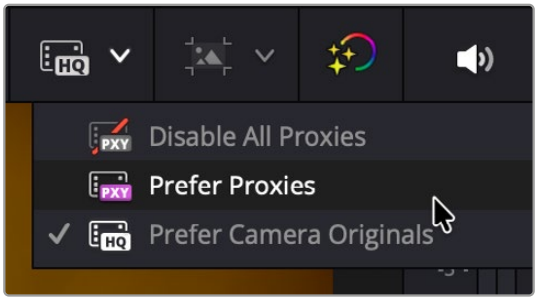


- Click and drag the line to any position in the viewer, a small pop-up window will appear to show you the exact position value.
- You can change the color of the Guide Lines for legibility by right-clicking in the Ruler and selecting a new color from the Guide Color context menu.
- You can delete a line by right-clicking on the line in the viewer and choosing Remove Guide.
- You can change an existing line's position and orientation by right-clicking on it in the viewer and choosing Edit Guide.
- You can delete all, only horizontal, or only vertical lines, by choosing View > Guides > and selecting the appropriate lines to remove. You can also do this by right-clicking on the ruler.
- Guides can be locked in place to avoid accidental movement by clicking on the small lock icon in the upper-left of the Ruler, or by choosing View > Guides > Lock Guides.

Right-clicking on the Ruler opens a context menu letting you adjust all parameters of the Rulers and Guide lines

Snapping to Guide Lines

By default, when moving the clip inside the frame using the Transform Viewer controls, whenever the edge of the image gets near a Guide line it will automatically snap the image edge to it, turning the Guide line purple so you know that it is exactly placed. If you want to disable this behavior, simply hold down the option key while moving the image in the viewer to bypass the snapping.

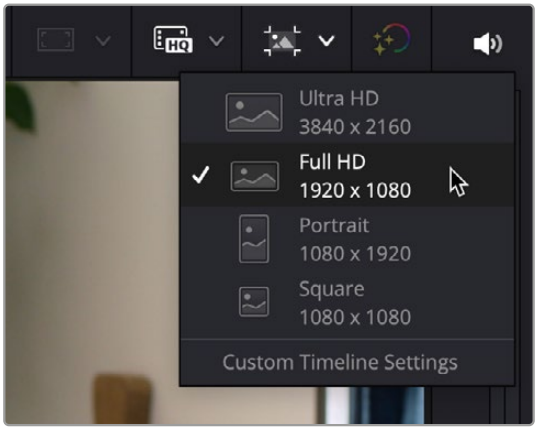


The Guide lines turn purple when the edge of the image snaps to that location

Proxy Handling

You can switch between using your original source media and the proxy media for playback in the Cut page by using the Proxy Handling icon in the Viewer, and selecting one of the following options:

- **Disable All Proxies:** This option disables the proxies altogether and forces the original media playback only. If the original media is not available, the clip is replaced with a Media Offline graphic.
- **Prefer Proxies:** This option will use proxies files for playback, and if there is no proxy file for a clip, the original media will automatically be used instead.
- **Prefer Camera Originals:** This option will use the original media files for playback, and if there is no original media file for a clip, the proxy media will automatically be used instead.

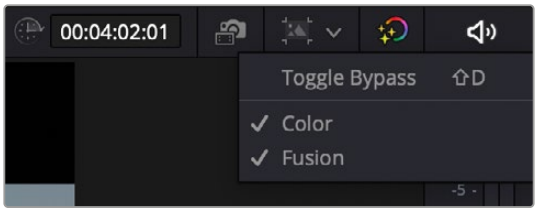


The Proxy Handling icon in the Cut page Viewer lets you select how you want to use proxy files.

Timeline Resolution

This drop-down menu, to the top-right of the Viewer, lets you quickly choose which resolution you want to work at. A Custom option lets you open up the Timeline Settings panel in order to choose your own options.

For more information on the Timeline Settings, jump to chapter: Project Settings.



The Project Settings quick menu

Bypass Color Grades and Fusion

The Bypass Color Grades and Fusion Effects button/drop-down lets you turn off all grades and effects that you may have applied in the Color page and/or Fusion page in order to improve playback

performance on low power computers. Click the button (Shift-D) to disable or reenable grading and effects, or right-click this button to access a menu that lets you choose which things you want this button to control.

The Bypass Grades and Fusion button, shown being right-clicked to view its options

Playing Clips and Navigating the Timeline in the Viewer

Several controls sit at the bottom of the Viewer. These let you play through and otherwise navigate clips and the Timeline in different ways. These controls are described from left to right.

The toolbar at the bottom of the Viewer

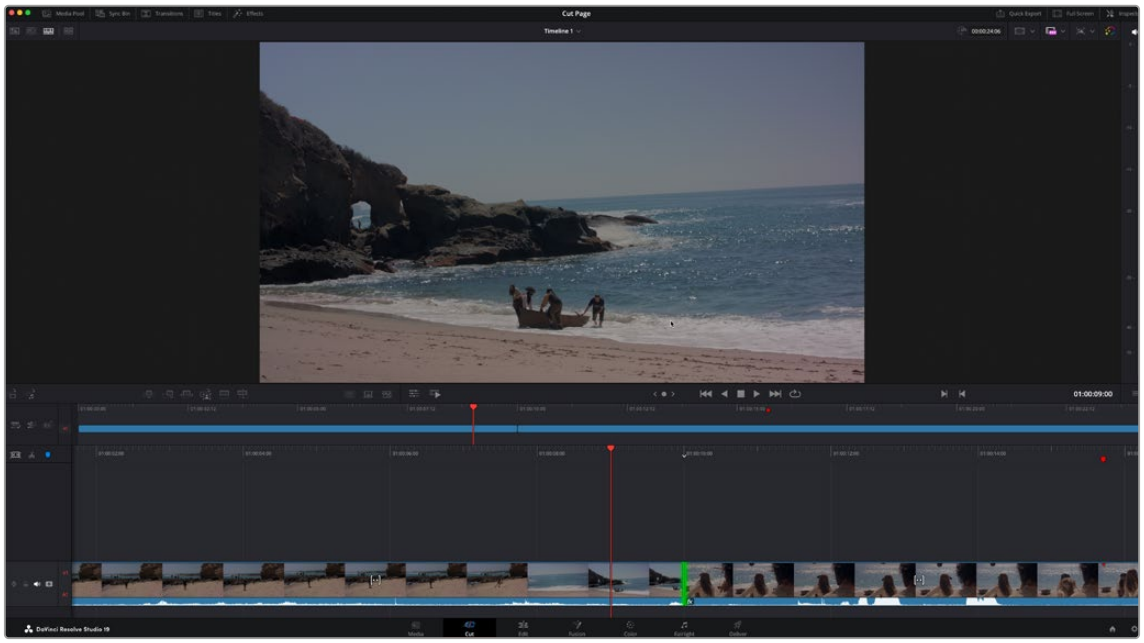
- **Tools button:** The Tools button reveals a variety of controls for transform, crop, audio, speed effects, camera stabilization and lens correction, dynamic zoom, and compositing, covered in more detail later in this chapter.
- **POI and Add POI:** These tools are used for selecting and modifying Points of Interest in Replay, which is described in its own manual. For more information on these tools, see the "DaVinci Resolve Replay Editor Instruction Manual."
- **Fast Review button:** Intended to help you watch through a large collection of media quickly, clicking this button begins accelerated playback through the Source Tape or through the Timeline, where the speed of playback is relative to the length of each clip you're playing through. Long clips play faster, whereas shorter clips play closer to real time. In this way, you can watch a lot of material really quickly.
- **Jog control:** Clicking and dragging within the jog control lets you scrub very precisely through the content of the Viewer.
- **Transport controls:** A set of buttons provide clickable controls to control playback of source clips and the Timeline, whichever the Viewer is set to display; each button has a matching keyboard shortcut. These include Previous Edit (Up Arrow), Stop (Spacebar), Play (Spacebar), Next Edit (Down Arrow), and Loop Playback (Command /).
- **Mark In/Out:** Clickable controls to set In and Out points respectively.
- **Playhead timecode:** A number field shows you the timecode value at the playhead of a clip or of the Timeline, to give you a numeric reference for where you are. There is also a dedicated timecode entry mode for the Cut page.

  There are three ways of telling DaVinci Resolve that you want to perform a timecode action, regardless of what the numeric keypad keys are assigned to in the Keyboard Customization preferences.

  - Select Playback > Goto > Timecode (=) and enter your timecode value.
  - Press "+" or "-" keys, and enter your timecode value to move the current position forward or backward by that amount.
  - Click on the Timeline Timecode display on the Viewer, and enter your timecode value.

- **Skim Playhead:** You can skim footage in any viewer in the Media, Cut, Edit, Color, and Deliver pages by holding down the C key, and scrubbing the pointer back and forth in the viewer.

Full Screen Viewer



The Cut page has a Full Screen Viewer icon in the upper right that can be clicked to enable Full Screen view. Press Escape to return to your normal view mode.

The Full Screen Viewer icon

Enhanced Viewer

The Enhanced Viewer is an alternative for use in the Cut page. The larger viewer will take up the top half of the screen, while leaving the timeline area in place. You can toggle the Enhanced Viewer by pressing Option-F.

The Enhanced Viewer in the Cut page

Scrolling Through the Timeline

The playhead in the Cut page is fixed. When you play, shuttle, or jog through your program, the clips in the Timeline flow past the playhead from right to left if you're playing forward, or from left to right if you're playing backward. This means that for playback, editing, or trimming, you bring the frame you want to see to the playhead, rather than bringing the playhead to the frame (as you do on the Edit page).

To scroll or scrub through the Timeline, do one of the following:

- Set the Viewer to show the Timeline, then use any transport or playback controls or keyboard shortcuts to move the clips in the Timeline back and forth, with the playhead indicating the current frame.
- Position the pointer within the Timeline Ruler of the Upper Timeline, and drag to the left or right to scrub through your entire program.

- Position the pointer within the Timeline Ruler of the larger Timeline Editor below, and drag to the left or right to scrub through the immediate vicinity of the current frame.
- You can use the navigation tools Playback > Previous / Next > Clip (Up Arrow/Down Arrow) or Marker (Shift - Up Arrow/Shift - Down Arrow) to navigate the Cut page Timelines.

TIP: If at any time you need to analyze the video in the Viewer, DaVinci Resolve's full set of scopes is available in the Cut page by selecting Workspace > Video Scopes > On (Shift-Command-W).

Display Clip Names and Status in the Timeline

If you wish, you can see clip names and clip status icons directly on your clips in the Timeline, for easier identification.

To Display Clip Names for Clips in the Cut Timeline:

- Click on the Timeline Options icon.
- Select Display Clip Names from the drop-down menu.

To Display Clip Status Icons for Clips in the Cut Timeline:

- Click on the Timeline Options icon.
- Select Display Clip Status from the drop-down menu.

Scene Cut Detection in the Cut Timeline (Studio Version Only)

You can use the Scene Cut functionality directly in a Cut timeline. This is useful if you've imported video files of an already edited program, and you wish to automatically cut it back up into individual clips.

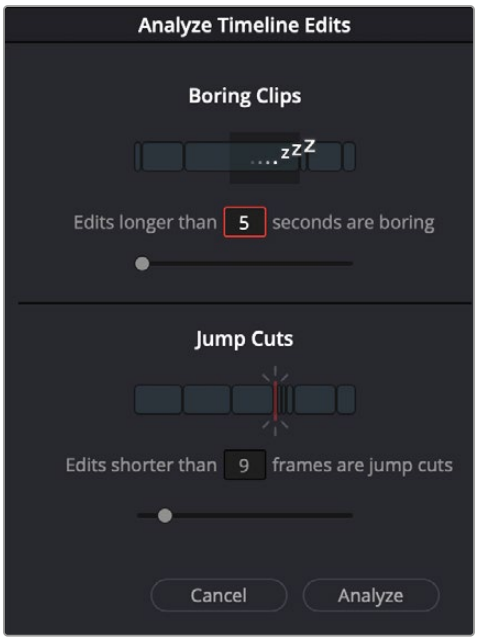
For more information on using Scene Cut Detection, Using Scene Detection.

To use Scene Cut Detection on a Cut Page Timeline:

1. Select the video clips you want to split back into multiple cuts on the Timeline.
2. Select the Timeline Actions icon and choose Detect Scene Cuts from the drop-down menu.

The Boring Detector

The Boring Detector performs a live analysis of the lengths of each of your clips on the Timeline and then highlights areas that are too long or too short and may demand your attention. It's accessed by clicking the Timeline Options icon and selecting Boring Detector. It can be toggled off by clicking the icon again.



The Boring Detector icon and the Timeline showing its results

Analyze Timeline Edits

The Boring Detector's parameters are modifiable in its Analyze Timeline Edits window.

- **Boring Clips:** By adjusting this slider, you can set the minimum number of seconds that a clip's duration has to be before being flagged as too long. Clips that exceed this length are highlighted in light gray on the Upper Timeline.
- **Jump Cuts:** Adjusting this slider sets the maximum number of frames that a clip's duration has to be before being flagged as too short. Clips that are shorter than this length are highlighted in red on the Upper Timeline. Setting this to 2 frames can help you automatically find accidental "flash frames."
- **Cancel:** Closes the window without making any changes to the Boring Detector's analysis.
- **Analyze:** Starts the live analysis of your timeline using the criteria you've selected above. The Boring Detecter is persistent and continues to function as you make further edits in the Cut page. It can be turned off by clicking the Boring Detector icon again.

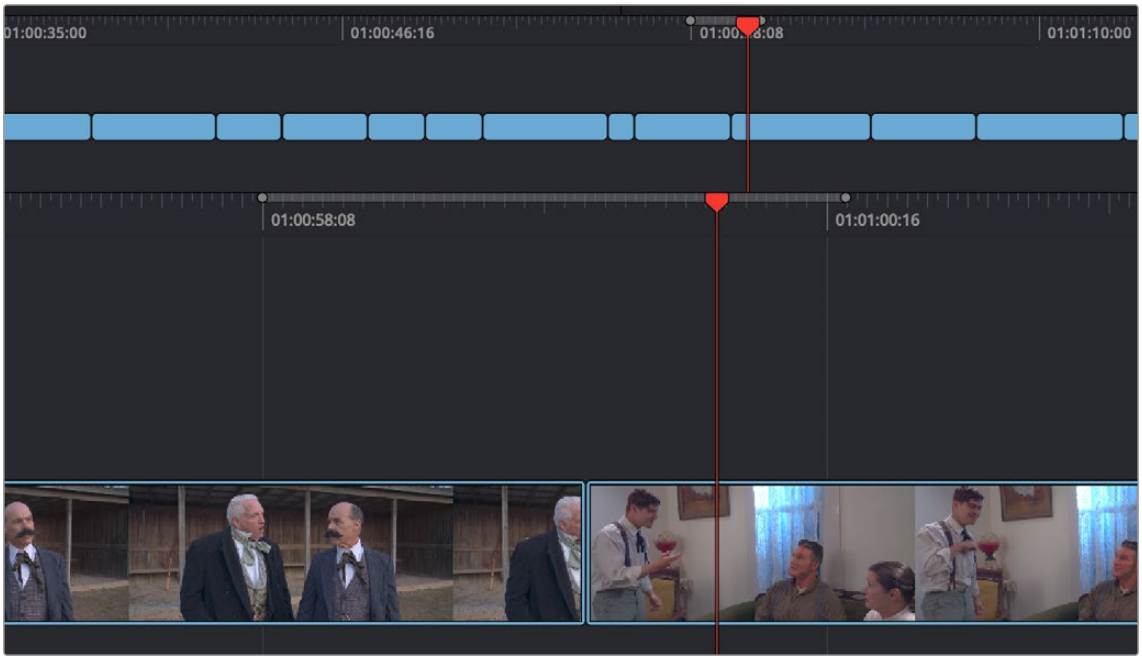
The Boring Detector's Analyze Timeline Edits window

Setting In and Out Points

Ordinarily, source media is much longer than the actual clips you'll be using in a program, so it's important to be able to define a range of media you want to edit into the Timeline. This is done by setting In and Out points, either in the Media Pool in Thumbnail or Filmstrip mode, or in the Viewer in Source Clip or the Source Tape.

Setting In and Out Points Using the Keyboard

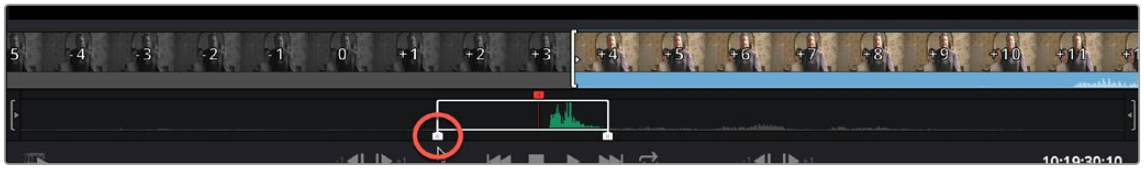
When scrubbing through a thumbnail or filmstrip in the Media Pool, you can press the I (In) or O (Out) keys to define a range of media. The edit points appear superimposed over the thumbnail area of the clip, as well as the scroll area of the Viewer if the clip is being mirrored there.



Defining a range of media in the Media Pool using In and Out points (in white)

When scrubbing or shuttling through media in the Viewer in Source Clip or the Source Tape, or through your program with the Viewer in Timeline mode, you can press the I (In) or O (Out) keys to define a range of media.

Defining a range of media in the Viewer using In and Out points

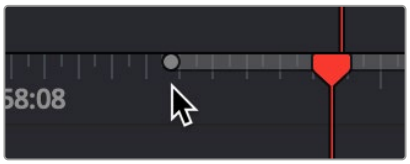


When scrubbing or shuttling through the Timeline as you drag the ruler to the left and right, you can press the I (In) or O (Out) keys to define a range for incoming edit operations. The range is marked in both the upper and lower areas of the Timeline.

Defining a range of the Timeline for editing operations using In and Out points

Setting In and Out Points Using the Pointer

If you're using a pointing device such as a mouse, trackpad or tablet, you can drag the In and Out handles found underneath the scroll area at the bottom of the Viewer to define a range of media.

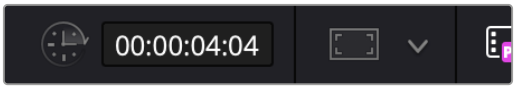


The draggable In and Out controls at the bottom of the Viewer

Once you've set In and Out points, the jog In and Out controls, located at the far left and right of the scroll area in the Viewer, let you fine-tune the location of the In and Out points. Click and drag on the Jog In or Jog Out controls to move either edit point in precise increments. While you drag, a filmstrip above shows you how many frames you're trimming.

The draggable Jog In control being used to trim the In point

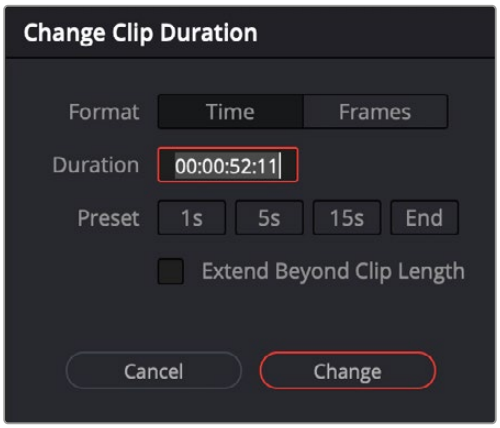
In and Out points set in the Timeline Ruler (either of the Upper Timeline or the Timeline Editor) can be dragged to the left or right to fine-tune them.



The draggable In and Out points
in the Timeline Ruler

Editing the Duration Field in the Cut Page Viewer

When editing in the Cut page, you set In and Out points to insert a specified range of video. The duration of that video range appears in the Duration field, which is in the upper-right corner of the Viewer.



This field is now editable, and updates the Out point to match the value you enter. You can directly enter a certain number of frames, use the + or - modifiers to change the value by that exact amount, or make adjustments to the hh:mm:ss:ff field directly.

The editable duration field in the top right of the Viewer

Change Clip Duration Dialog

The Change Clip Duration dialog allows you to directly change the duration of a clip by typing in frames, a timecode value, or using time and frame-based presets. You can activate the Change Clip Duration dialog by selecting one or more clips on the Timeline and choosing Clip > Change Clip Duration (Command-D), or by right-clicking on a clip and choosing Change Clip Duration from the contextual menu. The Change Clip Duration dialog works both on the Cut and Edit pages.

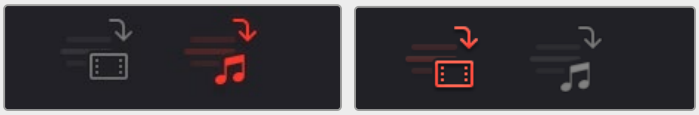
The new Change Clip Duration box in Timecode mode.

Options for the Change Clip Duration Dialog box:

- **Format:** You can chose between working with Time (Timecode) or Frame values.
- **Duration:** Type in the timecode value or number of frames you wish to make the new duration of the selected clip.
- **Preset:** Select a duration by clicking on 1, 5, or 15 seconds (or their equivalent value in frames). End will extend the duration to the last frame of the selected clip, regardless of any Out points set.
- **Extend Beyond Clip Length (Cut page only):** This will append black filler to any clip whose duration is set longer than the clip itself.
- **Cancel/Change:** Click Cancel to to exit without changing the duration of the clip, or Change to apply the duration change to the selected clip.

TIP: You can change the duration for more than one clip at a time by selecting multiple clips before opening Change Clip Duration. All clips selected will be the changed to the same duration set in the Change Clip Duration dialog box.

Video Only and Audio Only Edits



Normally, any edit function in the Cut page uses both the Audio and Video sections of a clip to insert into the Timeline. However, there are several scenarios where you would only want either the Audio or the Video portions to be used instead.

To perform an Audio Only edit:

Select the Audio Only icon to the left of the Upper Timeline, deselect to return to the normal audio and video edit.

To perform a Video Only edit:

Select the Video Only icon to the left of the Upper Timeline, deselect to return to the normal audio and video edit.

(Left) The Audio Only icon, (Right) The Video Only icon

Drag and Drop Editing

Drag and drop editing can be an easy way of assembling clips into a loose edit. Once you've defined a range of media using the Source Clip or the Source Tape, you can click and drag either from the Viewer or the Media Pool to the Upper Timeline or the Timeline below to edit a clip into your program. How and where you drag determines how that clip will be edited.

Append

If you drag a clip onto an empty timeline, or to the dark gray area to the left of clips in the Timeline, that clip will become the first clip of your edit. If you drag a clip to the far left or right edge of all other clips in the upper or lower areas of the Timeline, you will append that clip to the ending or beginning of the Timeline.

(Top) Dragging a clip to the far right of the Timeline to append it,

(Bottom) The appended clip

Ripple Overwrite

If you drag a clip onto a pre-existing clip in either the Timeline or Upper Timeline so that the entire clip highlights and you drop it immediately, you'll perform a Ripple Overwrite edit, substituting the previous clip in the Timeline with the new clip. If you've ripple overwritten a clip on Track 1, all clips to the right of it will be rippled to make room if the incoming clip is longer, or close the gap if the incoming clip is shorter.

(Top) Dragging clip DD onto clip BB on the Timeline to Ripple Overwrite clip BB,

(Bottom) Clip DD is shorter than clip BB, so the Timeline becomes shorter once the edit is done

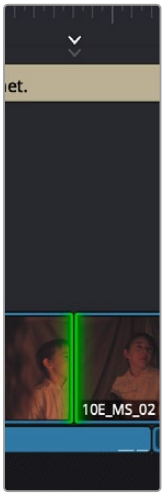
Overwrite

If you drag a clip onto a pre-existing clip in either the Timeline or Upper Timeline and wait a moment, the Timeline overlay changes from a highlight over the whole clip to a highlight showing just the portion of the incoming clip overlaid on the existing clip. When you drop the clip, you'll perform an Overwrite edit, which writes over the media that's already in the Timeline with the media of the incoming clip. Overwrite edits don't ripple the Timeline.

(Top) Dragging clip DD onto clip BB on the Timeline and pausing to perform an Overwrite,

(Bottom) Clip DD overwrites the middle of clip BB, breaking it into two pieces while the Timeline remains the same duration

Using Cut Page Edit Commands



At the bottom of the Media Pool is a set of five buttons that let you make other kinds of edits. Some of these edits have keyboard shortcuts assigned to them and are also available via dedicated keys on the DaVinci Resolve Editor Keyboard.

The edit buttons underneath the Media Pool, (Left to Right) Smart Insert, Append, Ripple Overwrite, Close Up, Place On Top, Source Overwrite

Smart Indicators

Some of the intelligent tools in the Cut page do not require you to select specific In and Out points in the Timeline; they rely on the playhead's relative position over a clip to guess where you likely will want to make your edit. The point where DaVinci Resolve intends to make that edit is marked using a Smart Indicator icon on the Timeline Ruler. To make the edit points easier to identify on the Timeline, after a few seconds, the Smart Indicator will move up and down on the Timeline ruler, while the actual edit point will strobe green (red if the clip has reached its start or end frame).

Smart Indicator showing where an edit will occur

Setting Up and Performing Edits

No matter what kind of edit you intend to make, the process of setting them up and performing them is the same. This section describes the general process of setting up an edit, and the following sections will describe how each particular edit works.

To set up and perform an edit:

1. First, locate a clip you want to edit into the Timeline. There are two general ways of doing this:
   a) Open a bin with clips you want to use, then click the Source Tape in the Viewer to show a stringout of all clips in the current bin, and its subfolders, in the currently selected sort order. Now, you can scrub around all these clips using JKL or the DaVinci Speed Editor's shuttle/jog/scroll wheel to find the media you're looking for.
   b) Open a bin with clips you want to use, and navigate the thumbnails, filmstrips, or columns to select the clip you want, using the Search field if necessary to help find the clip you're looking for.
2. Scrub a thumbnail or filmstrip, or use the controls in the Viewer, or use the controls of your DaVinci Speed Editor to locate frames at which you want to set In and Out points to define an edit range, and use the I (In) and O (Out) keys to set those points.

3 If necessary, choose which video track you want to edit to by clicking in its track header to select it. Selected tracks are highlighted.

4 Perform an edit to put the selected range of the source clip into the selected video track at the desired frame, using either the buttons at the bottom of the Media Pool, or keyboard shortcuts. Different edit commands will put the source clip into different locations.

5 After you've committed your edit, you can press Q (or click the Timeline Viewer button) to switch the Viewer to the Timeline to play and review the edit you've just made, and then press Q again to switch back to the Source Clip or Source Tape (whichever was last used) to locate the next clip you want to edit, starting all over again at Step 1.

Smart Insert

Automatically inserts an incoming clip at the closest edit point to the playhead (as shown by the Smart Indicator) on the selected track, pushing all clips to the right of the edit point forward to make room for the incoming clip if you've inserted to Track 1. Because this is a smart operation, you are prevented from inserting a clip at any arbitrary frame; incoming clips are only inserted at the closest previously existing edit point.

(Top) Before doing a Smart Insert,

(Bottom) After inserting clip DD between clips AA and BB

Append

The position of the playhead is ignored; incoming clips are always placed after the last clip in the Timeline.

Performing an Append edit of clip DD to the Timeline

Ripple Overwrite

At its simplest, Ripple Overwrite substitutes a clip in the Timeline with an incoming clip. If you use Ripple Overwrite on a clip on Track 1, this will automatically move all clips that are to the right of the affected clip in the Timeline either forward to make room if the incoming clip is longer, or back to eliminate gaps if the incoming clip is shorter.

Performing a Ripple Overwrite to substitute an entire clip at the playhead (BB) with the incoming clip (DD)

However, Ripple Overwrite works differently if you've set In and Out points in the Timeline to define a range. In this case, the incoming clip substitutes whatever portion of the Timeline falls within this range, moving all other clips that are to the right of the affected range either forward to make room if the incoming clip is longer, or back to eliminate gaps if the incoming clip is shorter.

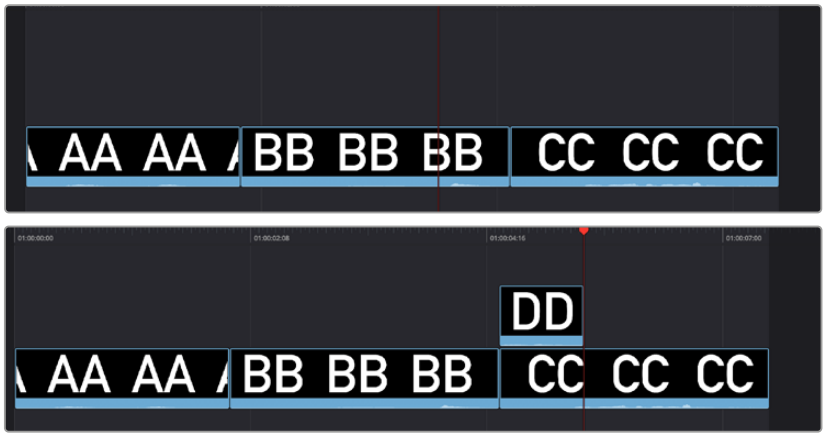
Performing a Ripple Overwrite to substitute a In/Out range of the Timeline (part of clips BB and CC) with the incoming clip DD

Close Up

Lets you edit a clip into the Timeline as a zoomed-in close up, to make up for a lack of actual close ups that would have been shot with either longer lenses or by moving the camera closer to the subject. This function is particularly useful when you're working with 4K media in a 1080 timeline, or 8K media in a 4K timeline, which enables you zoom into existing wide shots to create medium shots, or medium shots to create close up shots, with no loss of quality.

Performing this edit adds the incoming clip as an approximate 150% scaled close up, also performs a face detection, and if a face or faces are found, automatically re-positions the face in the frame. Which frame of the Timeline the incoming clip aligns with depends on the following:

- If no In or Out points are set on the Timeline, the incoming clip aligns with the Timeline playhead as the In point.
- The incoming clip aligns with a timeline In point if one has been set.
- The incoming clip's Out point will align with a timeline Out point if one has been set without an In point. This "backtimes" the clip.

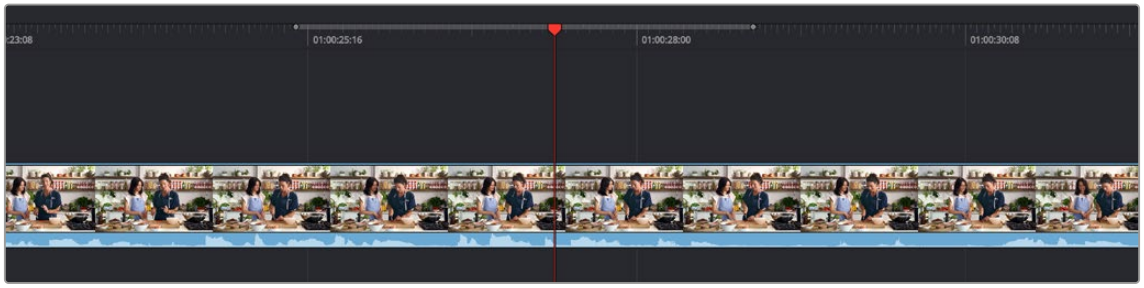


(Top) Before a Close Up edit, (Bottom) After editing clip DD into the Timeline with a Close Up edit

Place On Top

Lets you edit the incoming clip as a superimposition above whatever other clips are in the Timeline; the incoming clip is always placed on top, so if there are clips in tracks 1, 2, and 3, the incoming clip is automatically placed on track 4, regardless of which track is selected. The frame the incoming clip aligns with depends on the following:

- When the playhead is near an edit point (within five frames), the incoming clip aligns with the closest timeline edit point in proximity to the playhead (as shown by the Smart Indicator) if no timeline In or Out points have been defined.
- When the playhead is not near an edit point, the incoming clip aligns with the playhead if no timeline In or Out points have been defined.
- The incoming clip aligns with a timeline In point if one has been set.
- The incoming clip's Out point will align with a timeline Out point if one has been set without an In point. This "backtimes" the clip.

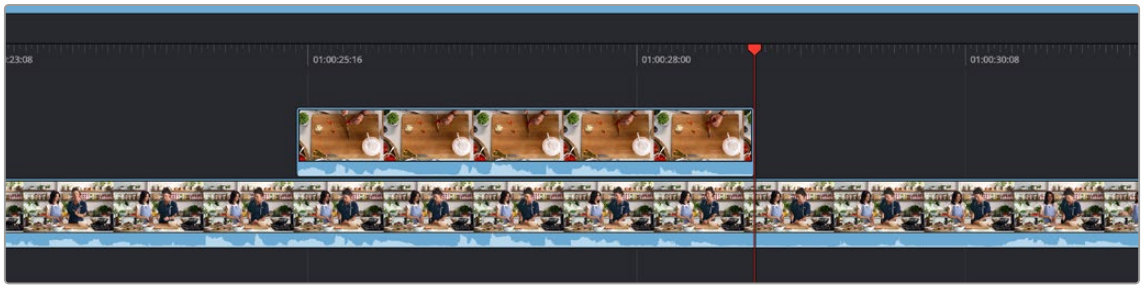


(Top) Before placing a clip on top, (Bottom) After editing clip DD into the timeline with a Place On Top edit

Source Overwrite

This edit requires overlapping timecode in multiple clips to work properly, such as when recording synced timecode to multiple cameras during a multi-cam shoot. If there is no overlapping timecode, this edit does nothing.

If you are working with footage from multiple cameras that have synced timecode, then the easiest way to use this edit type is to set In and Out points over a clip in the Timeline where you want to cut away to another angle. In the following example, a wide shot of a cooking show covers the moment when the chef starts slicing a chili.



Setting Timeline In and Out points to identify a cutaway

You can then select a clip in the Media Pool that corresponds to the desired angle you want to add as a cutaway, that has synced timecode that overlaps with the clip in the Timeline. Don't set In and Out points; if necessary you can clear previously set In and Out points by pressing Option-X.

Choosing a Media Pool clip from another camera that has overlapping timecode

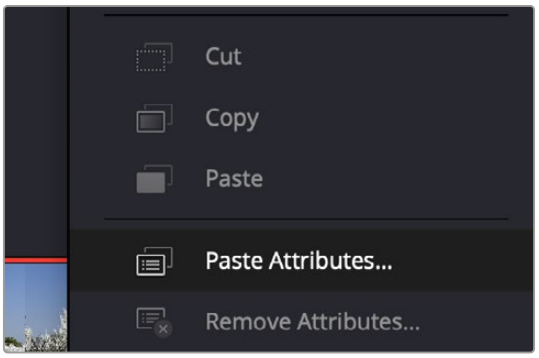
When you click the Source Overwrite button, a synced section of the selected Media Pool clip will be edited into the Timeline between the In and Out points you placed, superimposed on top. The result is a perfectly timed cutaway.

Using Source Overwrite to edit a superimposed and synced section of the source clip into the Timeline between the In/Out points

Alternatively, you can also use Source Overwrite to automatically place a source clip with a marked In/Out region on top of a clip in the Timeline so that its timecode syncs with the timecode of the timeline clip, when you don't know exactly how much of the incoming source clip you want to edit into the Timeline, and you just want it synced appropriately.

Overwrite

While there's no button available for performing an overwrite edit, you can use the F10 key to perform an overwrite edit, which overwrites a section of the Timeline with the incoming clip, without moving other clips in any way. The frame the incoming clip aligns with depends on the following:



- The incoming clip aligns with the playhead if no timeline In or Out points have been defined.
- The incoming clip aligns with a timeline In point if one has been set.
- The incoming clip's Out point will align with a timeline Out point if one has been set without an In point. This "backtimes" the clip.

(Top) Before, positioning the playhead at the frame you want to use as the In point for the incoming clip, (Bottom) After overwriting the end of clip CC with incoming clip DD

Copy, Paste and Remove Attributes from Timeline Clips

You can copy, paste, and remove attributes from clips in the Cut page timeline, similar to how the Edit page operates. To do so, right-click on the clip in the timeline you want to get the attributes from, and select copy. Then select the clip you want to modify on the timeline, right-click and select Paste Attributes. A check box menu will appear, allowing you to select the specific attributes that you want to paste.

You can cut, copy, and paste clip attributes from the Cut page timeline, using the controls in the context menu.

Subtitles

Subtitles in the Cut Timeline

The Cut page now has the same subtitle support as the Edit page, including the automatic Create Subtitles from Audio feature.

For more information on how to use subtitles, jump to chapter: Subtitles and Closed Captioning.

To Add a Subtitle Track in the Cut Timeline:

- Click on the Timeline Actions icon.
- Select Add Subtitle Track from the drop-down menu.

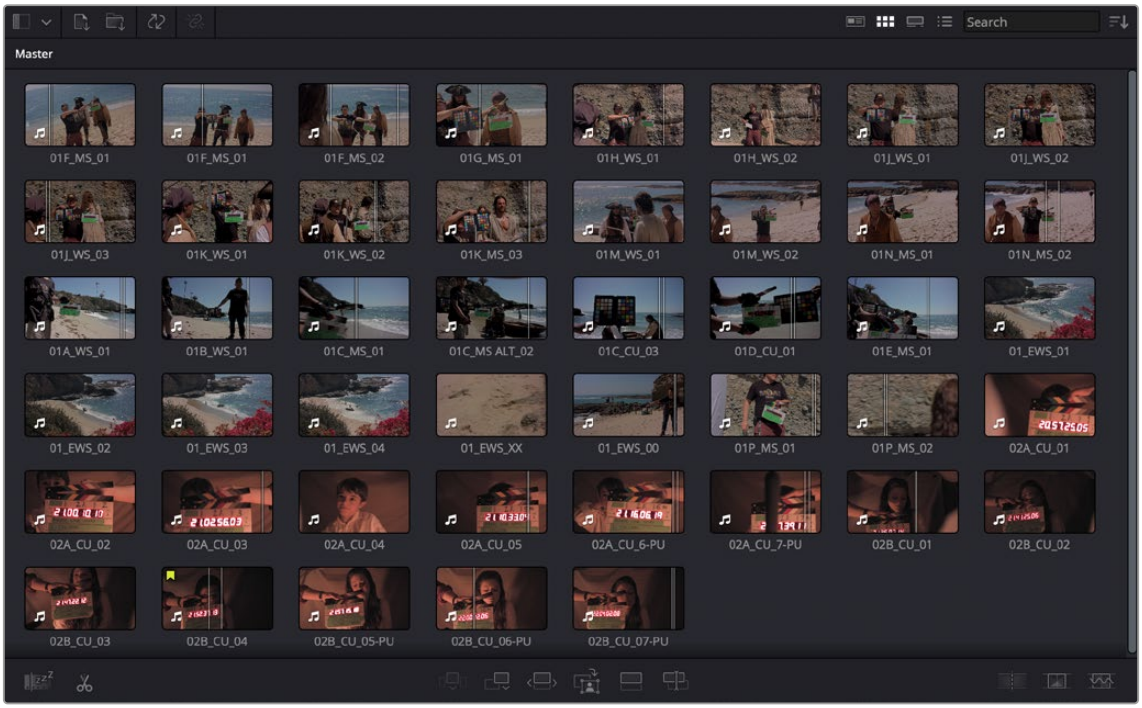
Subtitle Tracks can be minimized in the Cut page to give more room for Audio and Video tracks by clicking on the Timeline Options icon, and selecting Minimize Subtitle Track.

Create Subtitles from Audio (Studio Version Only)

You can automatically create subtitles from your timeline's audio tracks by using the DaVinci Resolve Neural engine to analyze the speech, and automatically turn it into text subtitles.

For more information on automatic subtitling, jump to chapter:
Subtitles and Closed Captioning.

To Automatically Detect and Create Captions from Timeline Audio:

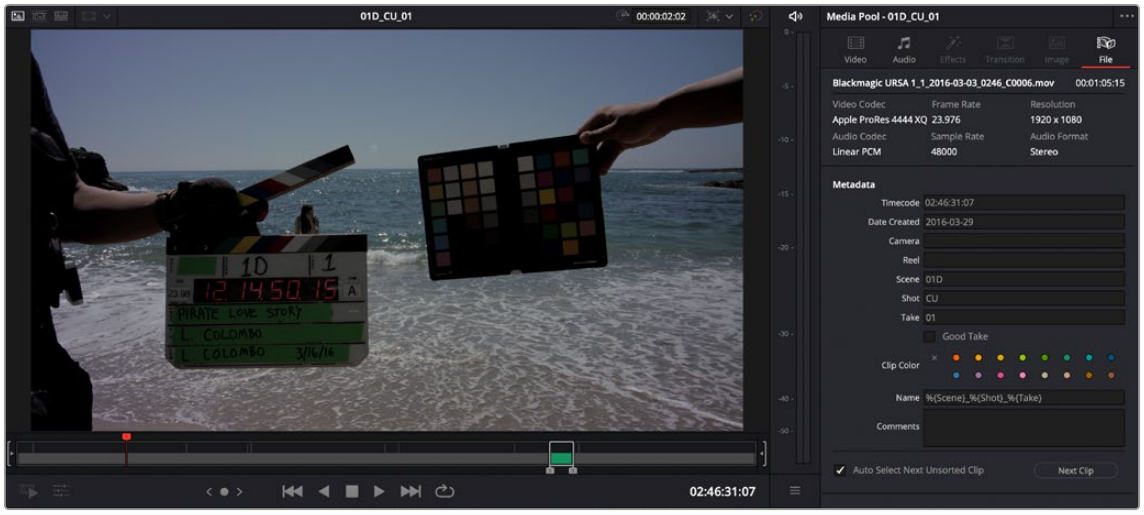


- Open the timeline with the video and audio clips you want to caption.
- Select the Timeline Actions icon and choose Create Subtitles from Audio from the drop-down menu.

Source Tape Editing

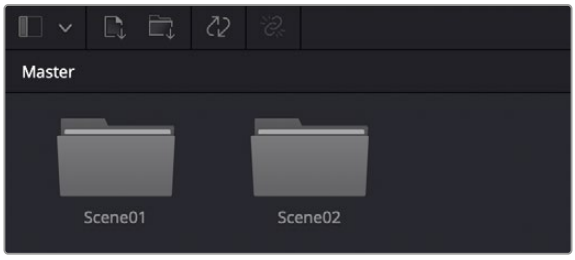
While all the features of the Cut page can be used individually, certain features are designed to be used in conjunction with each other to make your editing experience more streamlined. For example, combining the File Inspector, Source Tape, Metadata View, and the Navigable Folder Structure can create a well structured and organized project out of a single folder of unorganized clips.

Metadata Entry Using the File Inspector



The first step in organizing any project is metadata entry. In our initial project we have a large amount of clips all residing in a single Master Bin. We need to add appropriate metadata to these clips, and to do this we will be using the File Inspector.

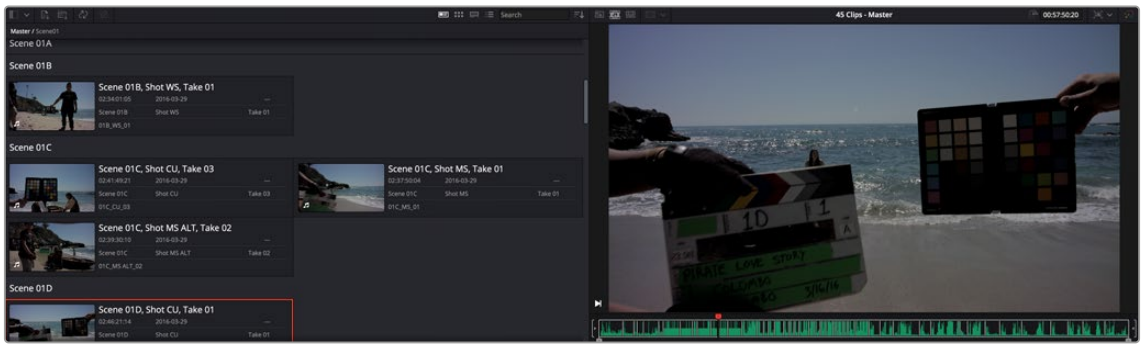
An unorganized Media Pool in the Cut page



After the File Inspector is open, check the box Auto Select Next Unsorted Clip, and this will automatically select the same metadata field in the next clip in the Media Pool, after you hit the return key. Enter in the Scene, Shot, and Take metadata for each clip, based on the information on the slate in each clip.

Once each clip has its scene, shot, and take metadata, select all the clips in the Media Pool, then enter the text string “%{Scene}_%{Shot}_%{Take}” in the Name field of the File Inspector. These variables will replace the clip names for all clips with their scene shot and take numbers separated by underscores, for example: “02A_CU_03”.

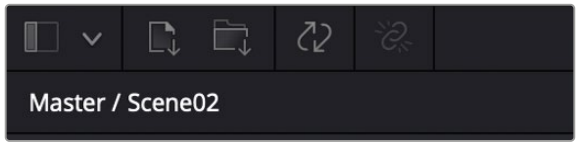
Entering Scene, Shot, and Take metadata in the File Inspector, and renaming all clips via variables



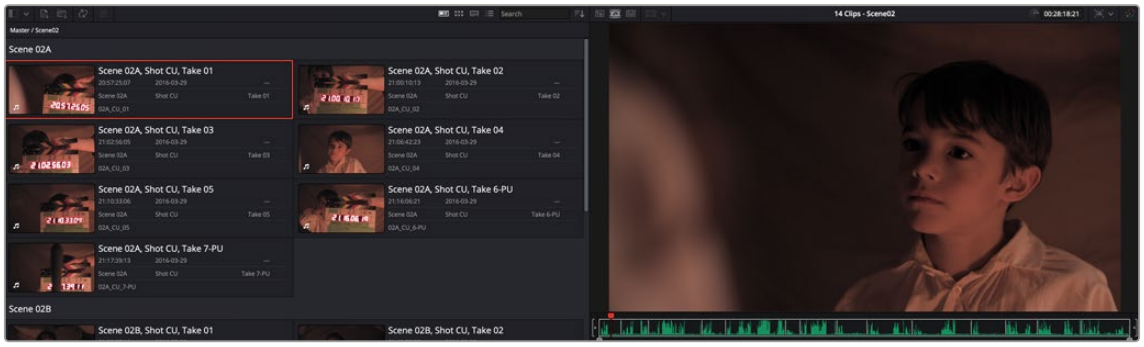
Now make two new bins in the Media Pool, Scene01 and Scene02, and drag all the clips that start with the name 01 into the Scene01 folder, and all the clips that start with the name 02 into the Scene02 folder. Our metadata entry for this project is now done.

The Media Pool with all scene 1 clips in the Scene01 folder, and scene 2 clips in the Scene02 folder

Using the Source Tape

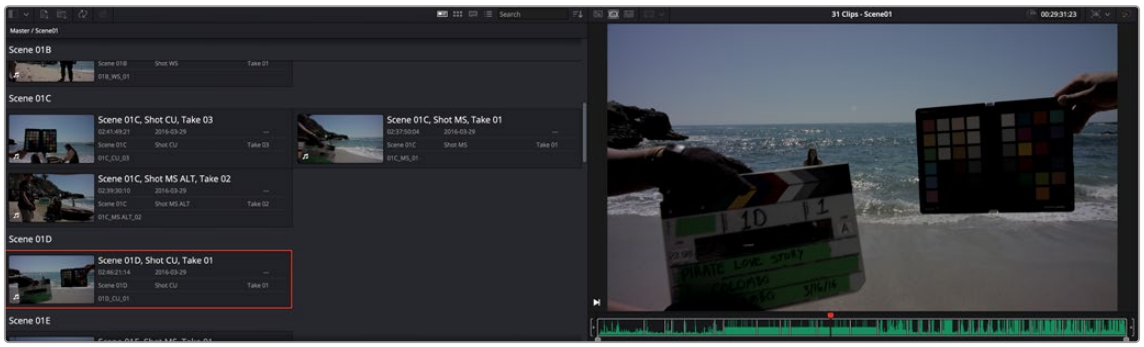


Now turn on the Source Tape, by clicking on its icon in the Viewer. Select Metadata View from the Media Pool view options, and then Sort By Scene, Shot in the Sort menu. You will now see the clips clustered by scene in the Media Pool, and all clips from both scenes are laid out in scene order in the Source Tape viewer. Selecting a specific clip in the Media Pool will snap the playhead to the first frame of that clip in the Source Tape. From here you can easily see the progression of the shots (take two follows take one, etc.), and continue your editing from here without having to hunt and click in the Media Pool.

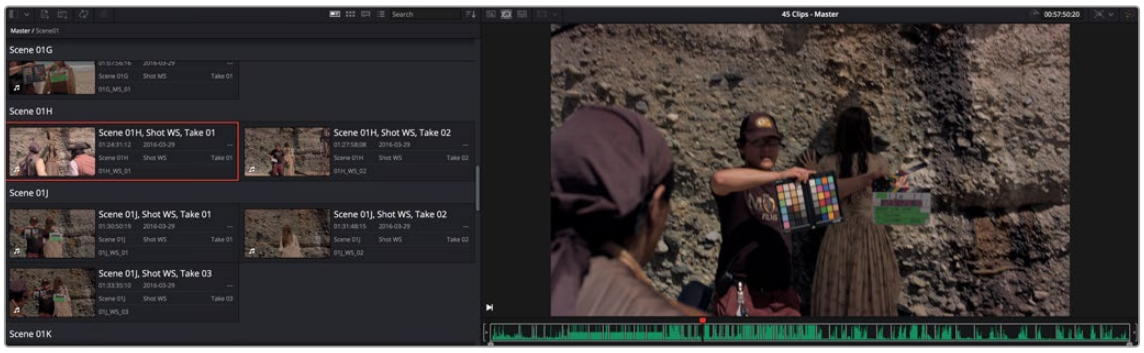


The Source Tape reflecting all clips in the Media Pool,
and the Metadata View showing the clips clustered by Scene

Limiting the Source Tape Scope by Folder Structure



As your project grows, it can become unwieldy to constantly have an entire film's worth of media in the Source Tape. It is possible to limit the scope of the Source Tape at the bin level. As you navigate in the Source Tape, the current clip is highlighted, and its hierarchy will now appear in top of the Media Pool title bar. By clicking directly on bins in this bin path, you can quickly broaden or narrow the scope of the Source Tape. If you click on Scene02, the Source Tape will then zoom in to only show you clips in that folder. Clicking back on Master will zoom out the Source Tape to show the clips in all folders again.



The navigable folder structure; clicµking on these levels
will narrow or broaden the scope of the Source Tape.

The Source Tape limited to showing only clips from Scene02

The Source Tape limited to showing only clips from Scene01

The Source Tape broadened to showing all clips in the Master folder

This is also useful when navigating bin structures that reflect the original camera file system. For example, you may have a camera that records to each memory card as a separate folder, and then each individual clip is saved as a separate folder inside that folder. When you bring this file system into the Media Pool using the Create Bins option, these nested levels are mirrored in the Media Pool bin structure. Now when you click on a card bin in the Source tape, it will directly show you all the clips on that card, rather than show many individual sub-bins. This view is also viewable in Thumbnail, List, and Filmstrip views.

Sync Bin Multicam Editing

DaVinci Resolve has a number of tools to make editing multi-camera productions more intuitive and efficient. If simultaneously recorded clips from different cameras share common timecode, DaVinci Resolve can automatically sync all of these different camera angles together as you edit. The tools described in this section act as a sort of digital assistant editor that is constantly searching through all your media, and presenting all of the relevant shots to you at the exactly the right time. This functionality, combined with the DaVinci Resolve Speed Editor, makes the Cut page an extremely powerful multi-camera editor.

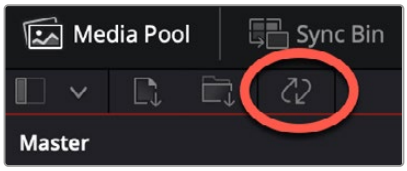
Preparing Footage for Sync Bin Editing

In order to properly work with the Sync Bin, every clip in that bin must have the following characteristics.

All Clips Must Have a Common Timecode

Professional video cameras and audio recorders generally have the ability to “jam-sync” their timecodes together so that each separate video and audio source records the exact same timecode at the exact same time. Jam-syncing timecode is the quickest, easiest, and most reliable method to ensure your footage syncs perfectly.

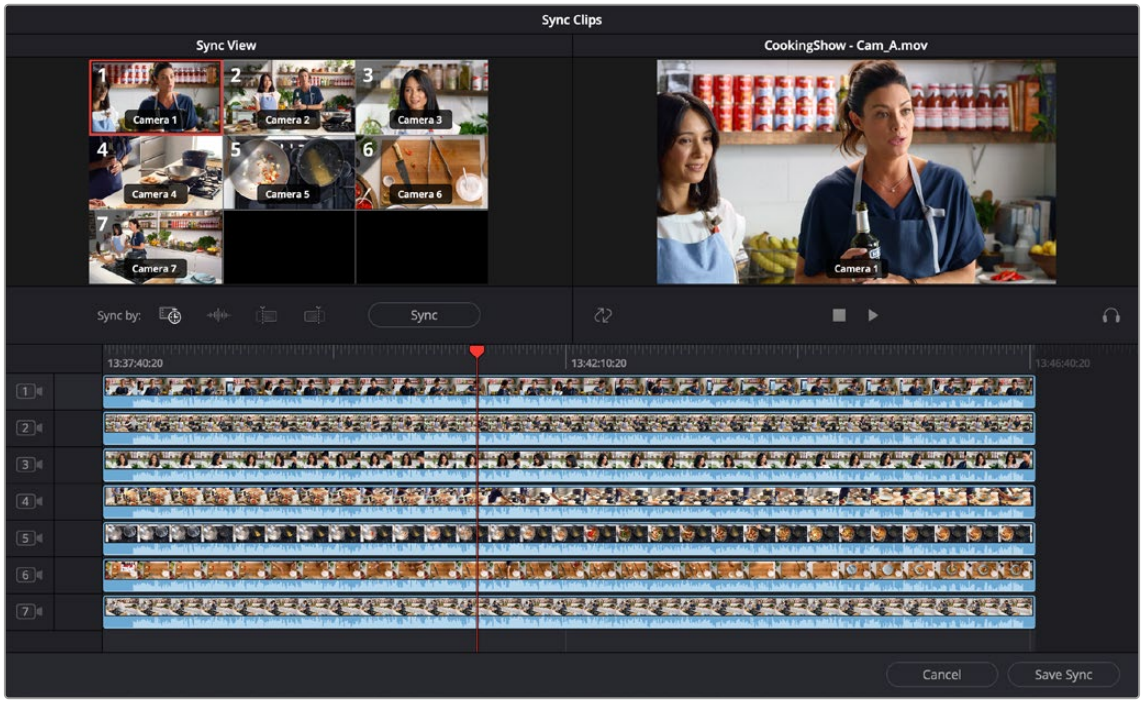
If your footage does not have a common timecode, you will need to go through some extra steps to ensure that all your material matches up at the correct time. For more information, see the Sync Clips Window section below.



All Clips Must Have a Unique Camera Name

Most professional video cameras will have some sort of mechanism for naming the camera in its internal menu system. This camera name is then recorded as metadata in each captured clip, which can be read automatically by DaVinci Resolve. Cameras should be named either alphabetically (A, B, C, etc.), or numerically (1, 2, 3, etc.), and in a sequential order totaling the number of cameras that you are recording with.

If your camera does not automatically record this information (or it's set incorrectly), you can manually set the camera's name by modifying the Camera # field in the Metadata Editor in the Media Pool.



Sync Clips Window

If your footage does not share common timecode, or if the existing timecode needs to be modified for any reason, the Media Pool in the Cut page offers a Sync Clips window that allows you to modify the sync of all clips in a bin. It is accessed by clicking on the Sync Clips Window icon on top of the Media Pool.

The Media Pool Sync Clips window icon

The Sync Clips window opens and shows a live multi-camera sync Viewer on the left, and a standard clip Viewer on the right. There is also a timeline below that shows the temporal relationship of all the clips in the bin.

The Media Pool Sync Clips window

Sync By Tools

DaVinci Resolve offers several tools to automatically align your shots into perfect sync.

- **Timecode:** This button will try to align all the clips in the Sync Clips window by timecode; this is the default option.
- **Audio:** This button will try to align all the clips in the Sync Clips window by analyzing the audio tracks of each clip. In order for this to work, each clip must have at least a portion of the same audio track recorded clearly enough to analyze. An error message will notify you of which tracks could not be synced by this method.
- **In Point:** This button will try to align all the clips in the Sync Clips window by their user set In point. This is useful if you have a common mark that was shot across all cameras, for example a slate that claps closed, or a camera flash.
- **Out Point:** This button will try to align all the clips in the Sync Clips window by their user set Out point. This is useful if there was a common tail slate.
- **Sync:** This button will execute the Sync By method selected above.

  Once all of the clips in the window are synced appropriately, hit the Save Sync button in the lower right-hand side of the window.

The Media Pool Sync By icons (L-R: Timecode, Audio, In point, Out point)

Manually Syncing Clips in the Sync Clips Window

If none of the Sync By tools is appropriate for the clips in your bin, you can manually sync the clips together by dragging each clip to the appropriate position on the Sync Clips Window timeline. For finer control, select the clip you want to sync and press the Comma (,) or Period (.) keys to nudge the clip backward or forward by one frame. Shift-Comma (,) or Shift-Period (.) nudges the clip by 5 frames (default), or by the amount of frames set in the “Default fast nudge length” setting in the General Settings section of the Editing panel in the User settings of the Resolve Preferences. Each clip has its own track, and you can enable sync lock in the right-hand Viewer to prevent accidental slipping.

Once all of the clips in the window are synced appropriately, click the Save Sync button in the lower right-hand corner of the window.

Using Your Newly Synced Clips

After saving the sync on your clips, a new Multicam clip will appear in the Media Pool. If you select the Thumbnail View, a Sync icon appears on all the clips you modified. If you want to modify your sync, right-click on a thumbnail and select Open Sync Group to reopen your clips in the Sync Clips window. Once you place your first clip on the Timeline as a reference, you are now ready to use the Sync Bin to edit.

Sync icons (upper left arrows) identifying synced media clips

Sync Bin Editing

The core idea behind the Sync Bin layout is that instead of traditionally scrubbing through your timeline and clips independently, you now only have to scrub through your timeline. In the Media Pool, all of the clips that exist with that same timecode value will automatically scrub in sync with the playhead. This allows you to always have the exact clips that will fit perfectly in your timeline available at your fingertips.

Selecting this mode automatically changes the layout of the Media Pool and the Viewer to better accommodate multi camera editing in the Cut page.

Edit in Your First Clip from the Media Pool

Choose a clip that will be your base layer and place it on Track 1. This clip is used as the reference for all of the other clips in the Sync Bin. Then press the Sync Bin icon.

The Sync Bin icon

Media Pool in the Sync Bin

All of the clips in the bin, and its subfolders, are presented in filmstrip mode. The clips are ganged together automatically by timecode and sorted by camera number. An additional playhead appears at the current timeline position, and moving any of the three playheads in the Cut page will scrub through all of the clips in the Sync Bin at the same time.

Viewer in the Sync Bin

The Viewer switches to a live Multi Viewer for up to nine cameras. Each camera is labeled, numbered, and the active camera in the Timeline is highlighted in red. Cameras that were not active at the current playhead time are blacked out.

The Sync Bin camera selection can be viewed full screen in the Cinema Viewer by pressing “P” on your keyboard, allowing you to see a larger, more detailed view of each specific camera. In this full-screen mode, the Sync Bin view controls operate identically to those in the normal Viewer.

The Media Pool and Viewer in Sync Bin view

Select Your Timeline In Point

Select the In point on your timeline by scrubbing the timeline playhead to the position you wish your media to start. As you do this, all of the clips in the Sync Bin will scrub along with the playhead position. Finding and selecting your edit points in the Sync Bin is greatly simplified, as all of your possible synced media choices are available instantly.

When the “Video Only” mode is activated in the Cut page, audio from the sources in the Sync Bin are now muted, and the audio playback is from the clips in the Timeline only.

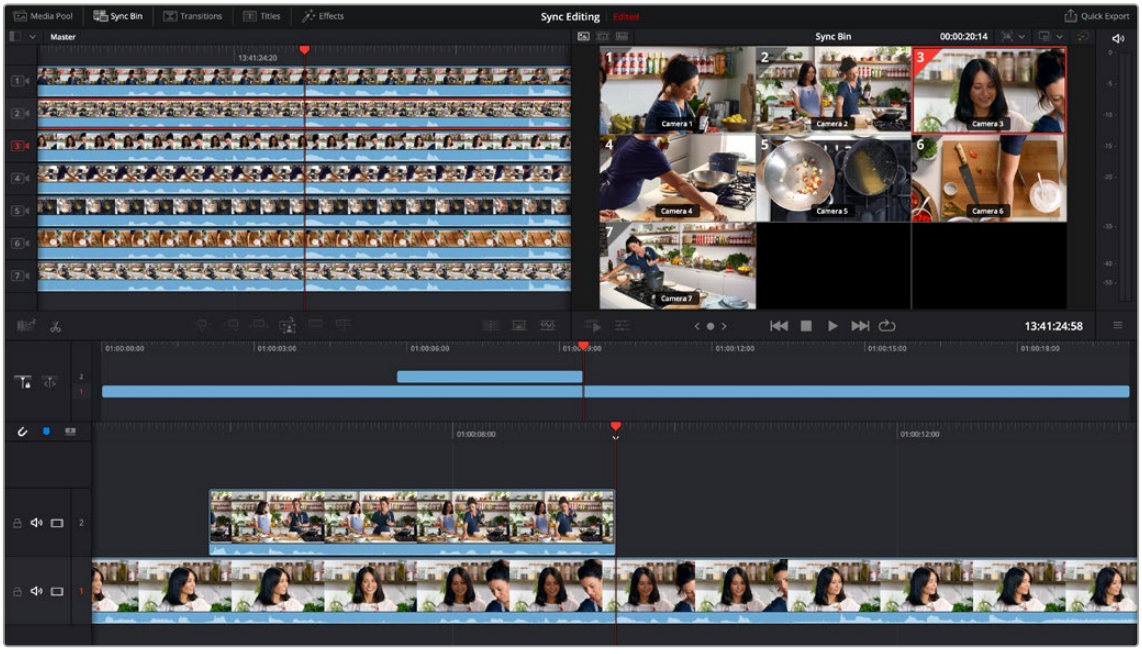
Select Your Camera

In the Multicam Viewer, select the camera angle you wish to use as your source material by doing one of the following:

- Clicking on the appropriate camera in the Multicam Viewer
- Clicking on the appropriate camera number icon in the Filmstrip Viewer
- Pressing the number key of the camera on the keyboard

The Viewer will then go into Single Clip mode, showing the camera you selected. To return to the Multi Viewer, click on the circled X close icon, or simply press the Escape key.

The clip will automatically set an In point at your current timeline position, with a default duration of five seconds. You can then manually set the Out point of the clip wherever you want.



The Multicam Viewer selection

Make the Source Overwrite Edit

Once your clip's edit points are chosen, click on the Source Overwrite button and your selected camera clip will be perfectly positioned in sync on your timeline. The playhead will then automatically advance to the clip's Out point, the Multi Viewer will return, and so be instantly ready for the next edit.

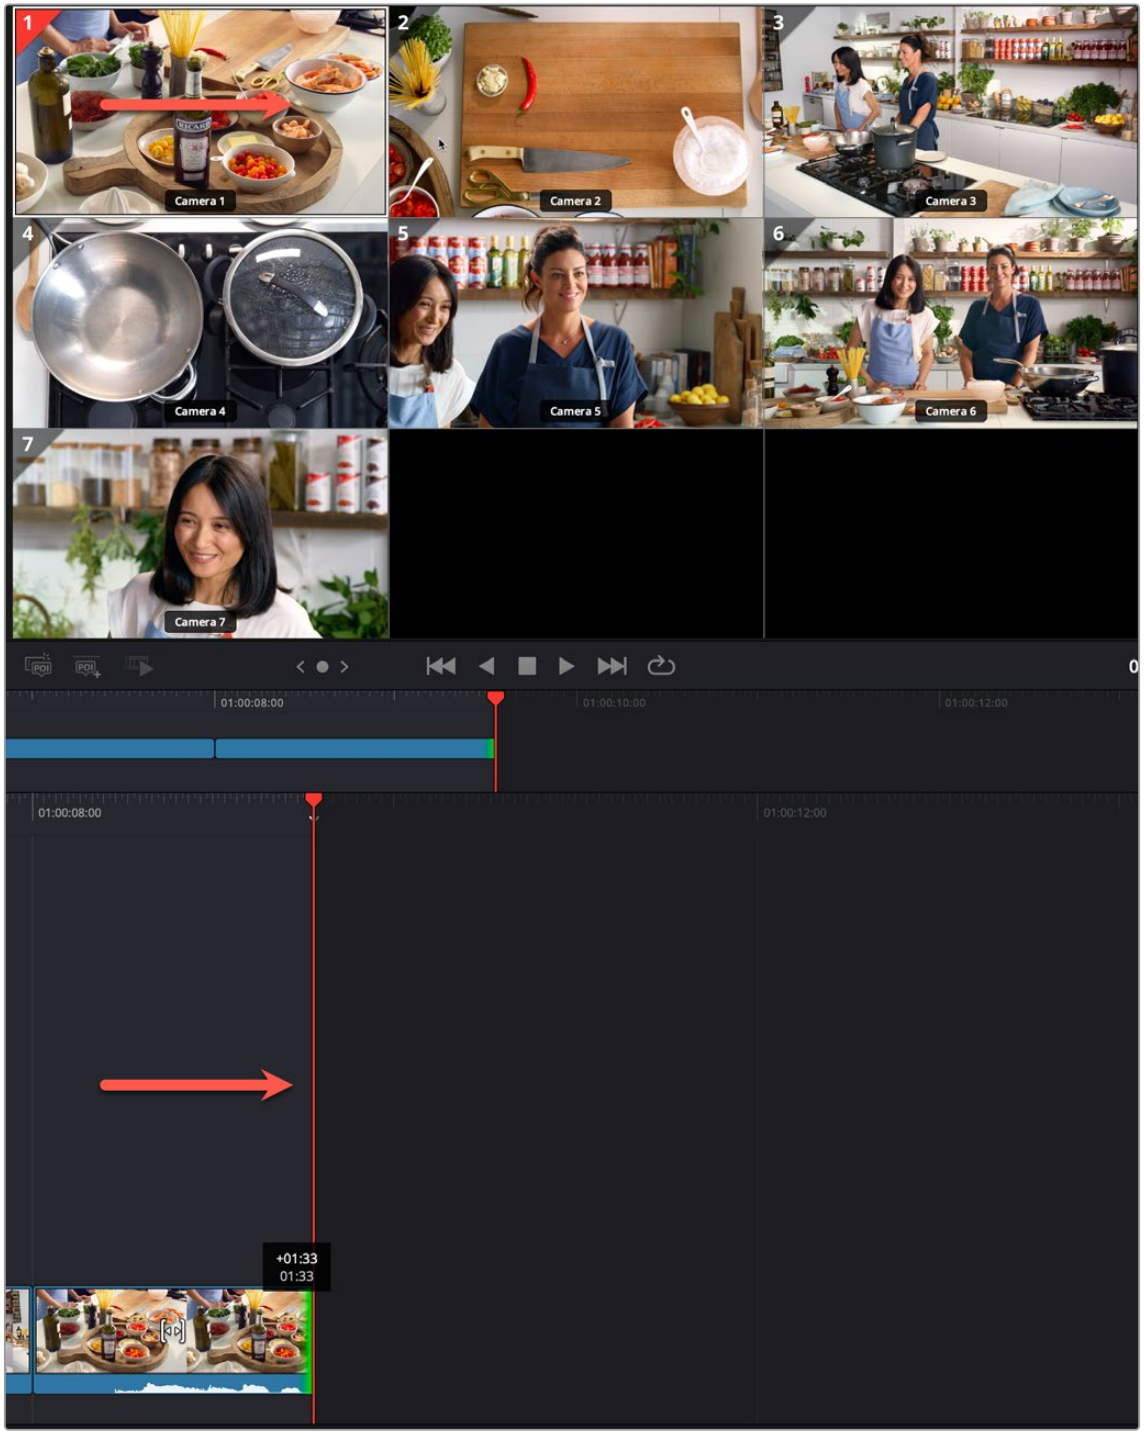
Selected Camera 2 and Playhead In point on the Timeline, ready for Source Overwrite edit.

The completed Source Overwrite edit showing Camera 2 edited in, and the Timeline ready for the next edit

TIP: Because the actual media in the Sync Bin determines the overall limit of the clips, and not the Timeline, it is possible to scroll past the end of the Timeline to make an edit. When you are past the end of the Timeline, the playhead now represents the Out point instead, which allows the clip to backfill itself to fit the exact duration required to fill in the Timeline.

Resync Misaligned Synced Clips

While editing with synced Multicam clips, if your shot accidentally goes out of sync with the timeline, it will be indicated by a warning icon in the lower left of the clip. You can easily bring this clip back into sync again with the timeline by clicking on the Edit Actions icon, and selecting Resync Clip from the contextual menu.



If a clip accidentally slips sync in Multicam footage, a red sync warning indicator will now appear in the lower left of the clip.

Live Overwrite with a Mouse Drag

If you don't have a Speed Editor, you can still use the paint on functionality of Live Overwrite on multicam material using your mouse.

To do so, open all your multi camera angles either in the Sync Bin, or the Multi Source viewers. Then simply click on the angle you wish to use, then drag horizontally in the image to live paint the angle on the timeline at the playhead position. Then click on another angle and drag it to paint on the next camera.

Because of the unique syncing nature of the Sync Bin that keeps all your footage locked together, you can very quickly create an entire multicam production just using simple mouse drags.

By clicking and dragging on camera angle 1 in the Viewer, the angle is “painted on” to the timeline for the same duration as the drag. You can continue to click and drag multiple angles for a quick multicam production.

Audio Transcription and Text Based Editing (Studio Version Only)

The most critical metadata about any clip is knowing what people have said in it. A full transcription of a shot is useful in narrative film letting you find specific clips based on the dialog in the script, but a transcript is especially important in unscripted documentary and news production, both to understand what pieces of the story you actually captured and for a variety of organizational, creative, and legal requirements.

Until recently, transcribing audio was a labor-intensive process, requiring a human being to listen to a clip in real time and then type out what was being said in a log sheet. With recent advances in the DaVinci Resolve Neural Engine, your computer can now perform the tedious work of transcribing each clip for you automatically, and most importantly, accurately. In addition, having text transcripts attached to the clips in your project gives you powerful new text-based editing tools to select, search, and insert clips into your timeline.

For more information on Text Based Editing in detail, jump to chapter: Text Based Editing.

Chapter 36

Trimming in the Cut Page

Once you've assembled a sequence of clips together into a loosely edited timeline, the Cut page provides numerous methods for modifying them in the Timeline.

These tools are intended to improve the pace of your program by fine-tuning the timing of each clip, as well as the edits that separate them them. The idea is to make these kinds of adjustments easy, so your program's content is clear, and the timing of your program's playback is satisfying. This process of making modifications to the edits in a timeline is referred to as "trimming."

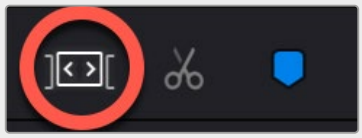
Tools That Help You Work in the Timeline



As you begin the process of trimming clips in the Timeline, a series of buttons at the top left of the Timeline help you to align clips and keep track of important frames while you work.

Ripple on Main Track Option to Disable Ripple Trims

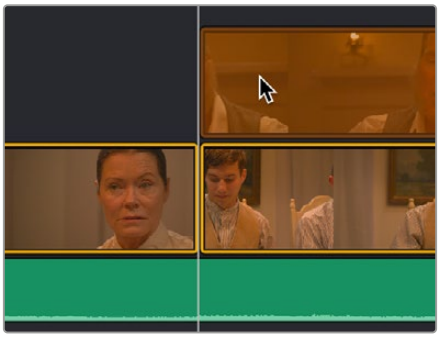
When trimming on the main track (track 1) in the Cut page, you can disable the automatic rippling of the clips on that track. This lets you have the option to make simple trim adjustments without the other clips in the Timeline moving up and down the Timeline.

To Enable or Disable Rippling on a Cut Page Timeline:

- Click on the Timeline Options icon and select Ripple On in the contextual menu, or click directly on the Ripple On icon to the left of the Timeline ruler. Click it again to toggle Rippling on or off.
- Alternatively you can hold down the Option key while trimming with the mouse on the main track to temporarily disable rippling.

The Ripple On control toggles r
ippling on the main track.

Fixed or Free Playhead



You can choose whether to keep the default fixed playhead on the Cut timeline (video flows under the playhead), or have it move freely with the video instead (playhead flows over the video). To choose the mode, click on the Timeline Options icon, and check or uncheck Fixed Playhead,

- When checked, the playhead is fixed in the center of the Timeline, and your edited clips scroll past it as you play (press the Spacebar), jog, or shuttle (use the JKL keys) in either direction. Locked mode works great when you use the DaVinci Resolve Editor Keyboard, because the Timeline flows past the playhead while you use the Jog/Shuttle/Scroll wheel. You can also scroll the Timeline using your pointer by dragging the Timeline Ruler at the top to the left or right, which also drags all of your clips to the left or right.
- When unchecked, the playhead moves across the clips as you play (press the Spacebar), jog, or shuttle (use the JKL keys) in either direction; the clips stay still. This mode can be useful when you're doing precision trimming in the Timeline using a pointing device, as the clips stay put while you drag parts of clips to make adjustments. Once the playhead gets to the right or left edge of the Timeline, the Timeline pages over to reveal the next part of your edit. You can also move the playhead by clicking in the Timeline Ruler to jump the playhead to that frame, or by positioning the pointer over the playhead's top handle, or over the playhead itself, and dragging the playhead wherever you want it to go.

Snapping

You can turn Snapping on or off by clicking the Timeline Options icon and checking or unchecking the magnet-shaped Snap icon, or press N to enable or disable snapping.

When snapping is turned on, clip in and out points, markers, and the playhead all snap to line up with one another, making it easy edit clips together at their boundaries, or to line up clips with markers or the playhead as reference for key frames you want to cut to. When a clip's boundary is snapping, a white line shows you the edges that are being aligned with one another.

The indicator that appears when clip boundaries are snapping to another edge

NOTE: When the playhead is locked, clips don't snap to it.

However, it's also important to be able to turn snapping off when this behavior impedes your ability to make small adjustments to clips in the Timeline. You can press N to temporarily turn snapping on or off while you're in the middle of dragging a clip in the Timeline, or while scrubbing the playhead using the pointer.

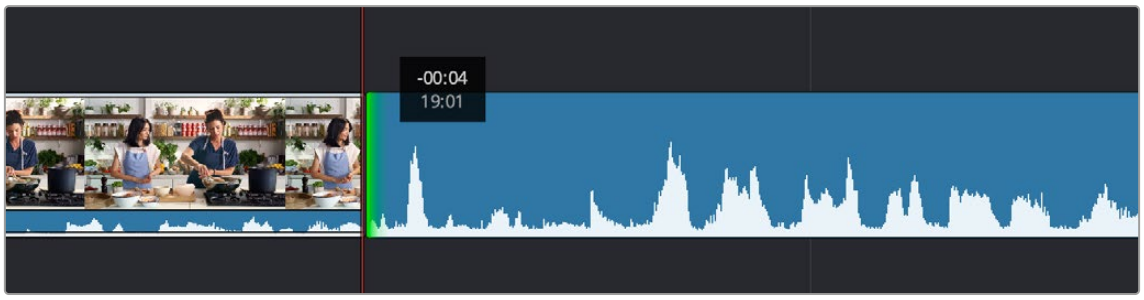
- When you change snapping while dragging a clip, an edge, or the Timeline, it's considered to be a temporary operation, and snapping reverts to its previous state when you release the mouse button.
- When you change snapping in between dragging operations, the snapping state remains set until the next time you change it.

Locking, Muting and Disabling Tracks

As you work in the Timeline, you may find it useful to lock tracks with clips you don't want to accidentally change as you work. For example, you might lock an audio track that has an edited piece of music you're now cutting other video and audio clips to, so you don't accidentally alter or trim the music that serves as the base of your program. Clips on locked tracks appear stippled to let you know they can't be altered.

A locked audio track, the Lock icon is closed and clips on that track are stippled

You may also find it useful to mute the audio or disable the video of tracks you don't want to see while playing the Timeline. For example, you might want to disable a track filled with title graphics if you want to get a closer look at the underlying video in the background. Each track has Mute and Enable controls, while audio-only tracks only have Mute controls. White controls are enabled, while gray controls are disabled.



Track 1 is disabled; the Enable button is orange and clips on the track are dimmed

Audio Trim View

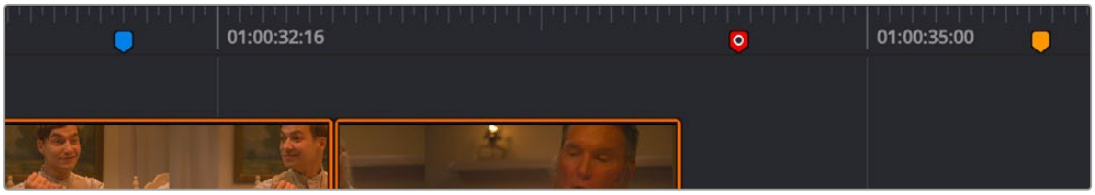
When performing a trim operation in the Cut page, you can set the option to expand the audio waveform of a Timeline clip while trimming. This mode gives a much more accurate view of the audio, making it easier to pick a specific edit point between words, beats, etc.

To toggle Audio Trim view: Click the Timeline Options icon, and check Trim to Audio.

With this option enabled, you'll see an expanded waveform for audio/video clips that are being trimmed in the Timeline, while you're trimming. This shrinks back down after you finish the trim operation.

The Audio Trim view showing an expanded audio waveform while trimming in the Timeline

Timeline Markers



You can place markers in the Timeline Ruler (of both the Upper Timeline and the Timeline Editor) to keep track of important frames of clips you want to remember, alternate edit points you're thinking of, key moments in the edit, or to make notes of things you need to do. You can edit marker text, which appears as an overlay in the Viewer, and you can change the color of markers to distinguish them from one another.

The Marker button in the Timeline track header

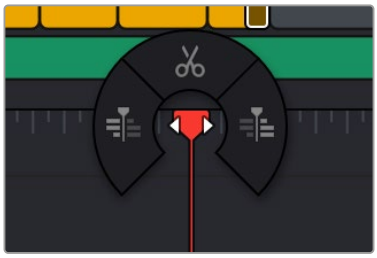
Methods of working with markers:

- **To add a marker:** Move the playhead to a frame you want to mark, then click the Marker button in the Timeline header, or press the M key. You can also add a marker from the Timeline Actions icon.
- **To add a marker with a specific color:** Move the playhead to a frame you want to mark, then click the Timeline Actions icon, and select Set Color and Add Marker. This will both add a marker and open the Markers Edit window, letting you pick a specific color and add a comment.
- **To jump the playhead among markers:** Hold the shift key and press the Up or Down Arrow keys to jump the playhead from marker to marker.
- **To edit a marker's name, text, color, or keywords:** Double-click a marker, or jump the playhead to a marker and press M again. When the marker dialog opens, edit the Name, Notes field, Keyword field, or color of the marker, then press Return or click Done to close the dialog. Markers with custom notes appear with a dot.
- **To move a marker:** Drag a marker to another frame in the Timeline Ruler.
- **To delete a marker:** Select a marker, and press Delete. Or, align the playhead with a marker, and press Option-M. Or, jump the playhead to a marker, press M to open the marker dialog, and then click Remove Marker.

Blue, red, and orange markers in the Timeline; the red marker contains text, the others do not

Making Selections

As you continue to work in the Cut page, it becomes increasingly helpful to know how to make different kinds of selections, both in the Media Pool and in the Timeline. Most of these methods of selection should be familiar to you if you have experience with other media applications or file managers.



Methods of selecting clips in the Media Pool:

- **To select a single clip:** Click a clip in the Media Pool. Once you've selected a clip, you can use the Up and Down arrow keys to move the selection to other clips.
- **To select a contiguous range of clips:** Drag a selection box over all the clips you want to select, or click to select the first clip in a series, then Shift-click the last clip to select those clips and everything in between.
- **To select a noncontiguous range of clips:** Command-click each clip you want to include in the selection. Or, you can hold the Command key down while you drag bounding boxes over unselected clips to add them to the current selection, or over selected clips to remove them from the selection.
- **To select all clips:** Select one clip, then choose Edit > Select All (Command-A).

Methods of selecting clips in the Timeline:

- **To select one clip:** Click a clip with the mouse. Command-clicking that clip de-selects it.
- **To de-select all clips in the Timeline:** Click in any empty area of the Timeline to de-select everything, or press Command-Shift-A.
- **To select a continuous range of clips by dragging:** Drag a bounding box from an empty area of the Timeline to surround a group of clips.

- **To select a continuous range of clips by Shift-clicking:** Click the first clip you want to select, and then Shift-click the last clip you want to select, and all clips in-between will automatically be selected as well.
- **To select a discontinuous range of clips:** Command-click any clips to select them no matter where they appear on the Timeline. Command-clicking a selected clip deselects it.
- **To select all clips under the playhead:** You can select all the clips under the playhead at once, regardless of how many tracks they are spread across by selecting Trim > Select All Clips Under Playhead (Option-Shift-V).
- **To select all clips in the Timeline from the playhead forward:** Right-click the top handle of the playhead, and click the right button on the radial menu that appears.
- **To select all clips in the Timeline from the playhead backward:** Right-click the top handle of the playhead, and click the left button on the radial menu that appears.

The radial menu that appears when you right-click the top handle of the playhead

Methods of selecting edits in the Timeline using the pointer:

- **To select an edit to roll:** Move the mouse to the center of an edit point, and when the ripple cursor appears, click to select the edit.
- **To select just the incoming or outgoing half of an edit point to resize:** Move the mouse to the left or right of the center of an edit, and when the resize/ripple cursor appears, click to select that portion of the edit.
- **To select multiple roll points:** Command-click the center of multiple edit points. Command-click a selected edit point to deselect it.
- **To select multiple resize points:** Command-click the left or right sides of multiple edit points.
- **To de-select all clips in the Timeline:** Click in any empty area of the timeline to de-select everything.

Keyboard shortcuts for selecting edits in the Timeline:

- **To select an edit point from the keyboard:** Press V to select the nearest edit point to the playhead.
- **To change an edit selection from the keyboard:** Once you've selected an edit point, press U to toggle among selecting the outgoing half, incoming half, or the entire edit.
- **To de-select all edits in the timeline:** Press Command-Shift-A.

Moving Clips in the Timeline

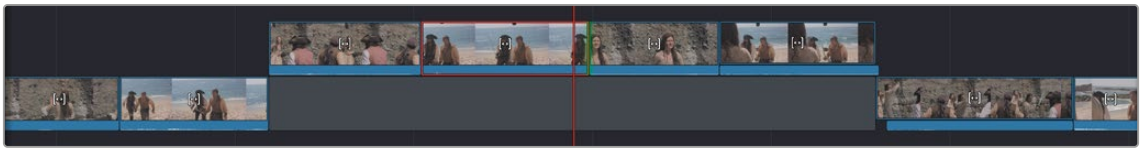
Once you've edited some clips into the Timeline, you'll probably want to start fine-tuning the edit by moving clips around. Different operations can be performed depending on how you move these clips. All of these techniques work in both the Upper Timeline and the Timeline Editor.

Ripple Overwriting An Entire Clip in Track 1

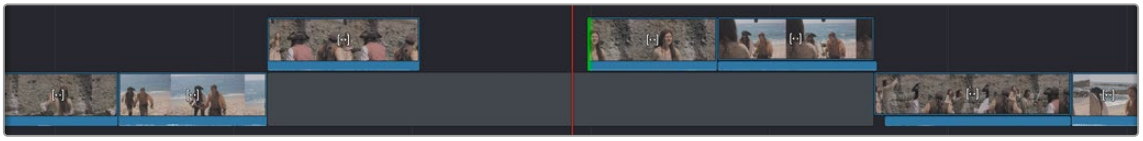
Drag a clip in the Timeline or Upper Timeline over another clip in the Timeline so that the pointer overlaps that clip, and quickly drop it onto another clip in Track 1. The clip you dragged replaces the clip you dropped it onto, and all clips to the right are moved to either make room (if the dragged clip is longer) or to close the gap (if the dragged clip is shorter).

Clicking clip BB to begin dragging it

Dragging clip BB onto clip DD to ripple overwrite it

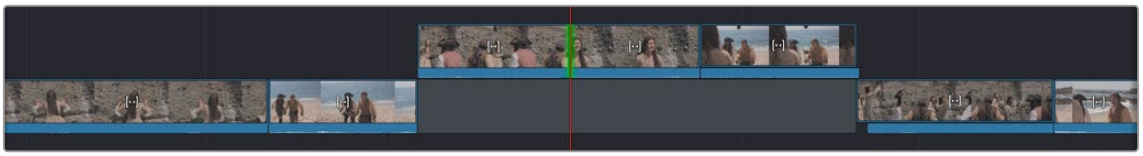


Clip BB is moved and takes the place of clip DD, while the rest of the Timeline moves left to close the gaps in Track 1



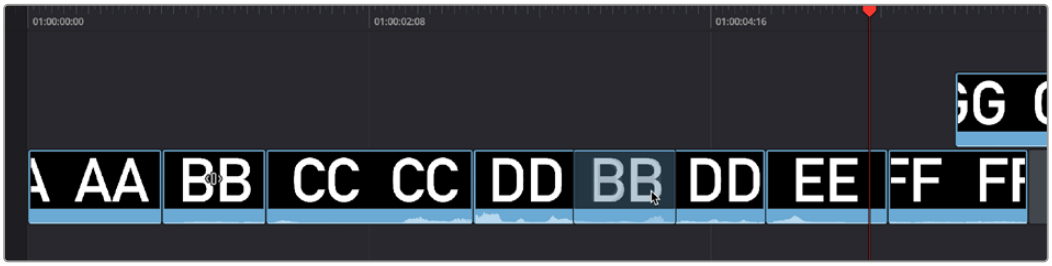
NOTE: If you wait too long, this Ripple Overwrite operation will turn into an overwrite operation. If you drag a clip in Track 1 onto a clip in any other track, you can only do an overwrite, not a ripple overwrite.

Ripple Trimming on Secondary Tracks



You can use the Cut page's ripple editing on secondary tracks as well, but only when there is no underlying video on the primary video track (Track 1). Use the Ripple On control in the Cut page timeline header to toggle this ripple behavior on or off.

We want to delete the selected clip and close the gap, even though our clips are on a secondary track. Note the primary track (Track 1) is empty.

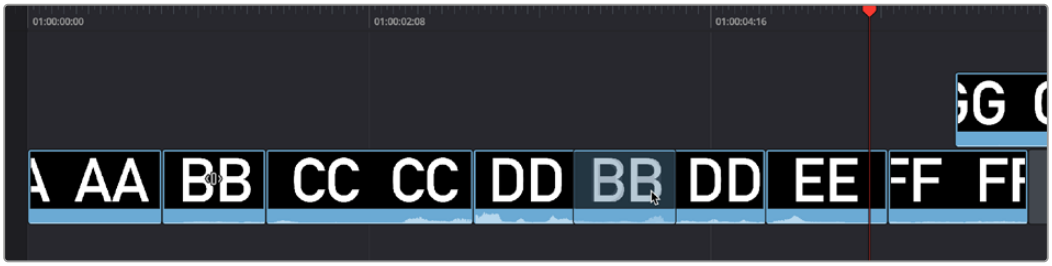


Deleting a clip leaves a gap in the secondary track when Ripple On is disabled.

Deleting a clip closes the gap in the secondary track when Ripple On is enabled.

Overwriting the Middle of Other Clips

Drag a clip in the Timeline or Upper Timeline over another clip in the Timeline so that the pointer overlaps that clip, and pause until the clip you've selected is overlaid on top of the second clip, and release the mouse button. The target clip is overwritten by the duration of the clip you dragged and split in two.



Dragging clip BB and pausing to overwrite part of clip DD

Clip BB is moved, overwriting the middle of clip DD which is now in two pieces; the rest of the Timeline moves left to fill the gap left by moving clip BB in Track 1

Overwriting The Edges of Other Clips

Drag a clip in the Timeline or Upper Timeline over the edge of a neighboring clip without letting your pointer overlap it, then drop the clip. The overlapping part of the neighboring clip will be overwritten.

Dragging clip CC to partially overlap clip DD in order to overwrite it

After dropping clip CC to partially overwrite the beginning of clip DD, clip DD is shortened and the other clips in the Timeline move left to fill the gap in Track 1

Swapping Clips

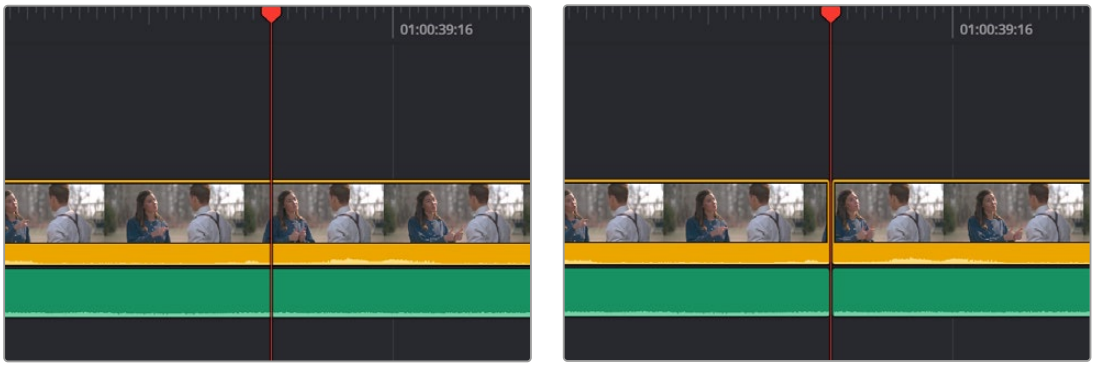
Drag one or more clips from one part of the Timeline or Upper Timeline to another so that the pointer overlaps an edit between two clips (the edit point turns purple), and drop the clip. The clip(s) you dragged are now moved so that they're inserted at the edit point you targeted.

(Top) Dragging clip CC to swap it between clip II and JJ. (Bottom) Dropping clip CC rearranges the Timeline, which automatically closes all gaps and move clips to the right where necessary; superimposed clips are kept in sync with clips in Track 1 that have moved

Copy, Cut, and Paste

Clips can be cut, copied, and pasted in the timeline or Upper Timeline to duplicate them or move them around, just like words in a word processor.

To cut/copy and paste in the Timeline:



1. Select one or more clips in the Timeline.
2. Do one of the following:
   a) Press Command-C to copy them (the selected clips remain where they are).
   b) Press Command-X to cut them (the selected clips are removed and the Timeline automatically ripples itself to close the gap).
3. Move to another part of the Timeline, then press Command-V to paste the clips. The clips are pasted to the frame at the playhead, to the same track they were copied from, and overwrite whatever other clips are at that part of the Timeline.

Splitting Clips

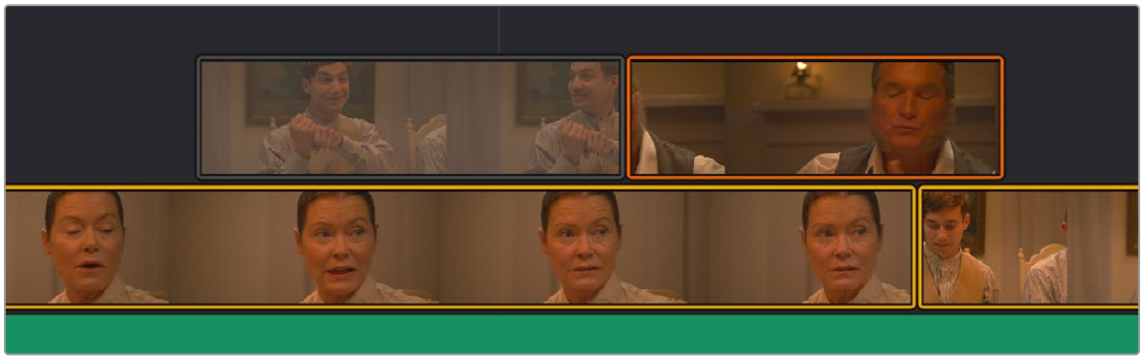
You can split any clip into two pieces, effectively adding an edit point in the middle, in preparation for moving part of a clip, deleting part of a clip, inserting another clip at that edit point, or adding an effect of some kind to one part of a clip but not another.

To split a clip:

1. Move the playhead to the frame of a clip where you want to split it.
2. Do one of the following:
   - Click on the Edit Actions icon, and select split from the drop-down menu.
   - Right-click the top handle of the playhead and click the Split button that appears on the radial menu.
   - Press Command-Backslash.
   - Press the Split Clips (scissor) icon on the far left of the Cut page Edit commands.

(Left) Before splitting a clip, (Right) After, a new edit point bisects the clip into two pieces

Disabling and Deleting Clips

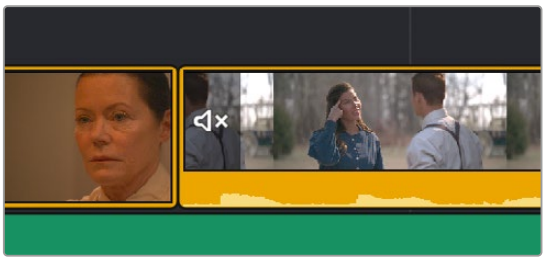


Clips that you no longer want can be disabled or deleted.

Disabling and Muting Clips

You can turn off the audio and/or video for a clip in the Timeline, without removing the clip itself. This is useful in instances where you want to use a clip's audio or video selectively, or for instances where you want to disable the audio and video for a clip that you don't want to use, without eliminating it completely from the Timeline in case you change your mind.

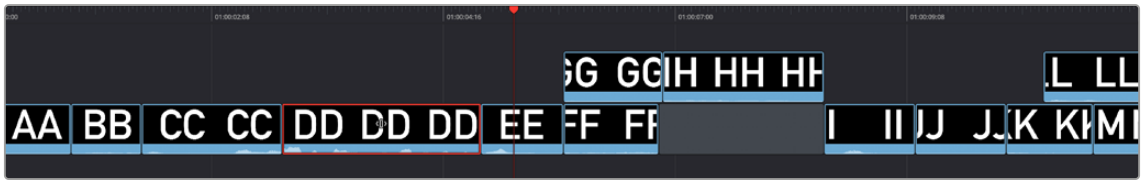
Disabling Clips



You can turn off a clip's video while leaving it in the Timeline by selecting it and pressing D, or by right-clicking it and deselecting Enable from the contextual menu. The clip turns dull to show it's disabled. Audio will continue to play for that clip unless you mute it as well.

A disabled clip in the Timeline

Muting Clips

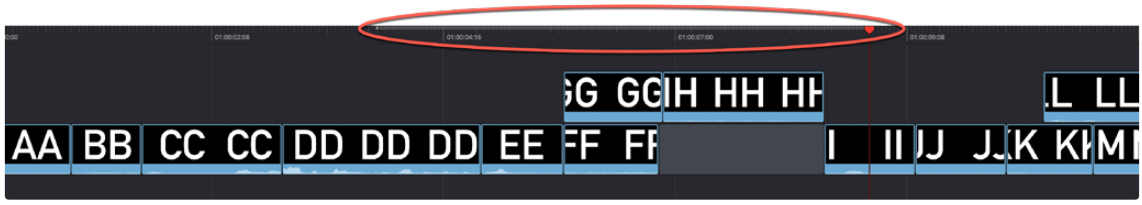


You can turn off a clip's audio while leaving it in the Timeline by right-clicking it and choosing Mute from the contextual menu. A mute icon is superimposed over the beginning of the clip to show audio is disabled. Video will continue to play for that clip unless you disable it as well.

A muted clip in the Timeline

Deleting Clips

If you want to completely eliminate one or more clips from the Timeline, select them and press the Delete key. The clip(s) will be removed. If you've deleted a clip on Track 1, the Timeline will ripple to close the gap automatically.



Selecting clip DD to delete it

Deleting clip DD results in clips EE through NN moving left to fill the gap in Track 1; superimposed clips move to keep in sync with the clips underneath them

Deleting Parts of Clips

If you want to delete only part one or more clips, set In and Out points around the section of the Timeline you want to delete, and press the Delete key. The section of the Timeline between the In and Out points will be removed. If you've deleted part of a clip on Track 1, the Timeline will ripple to close the gap automatically.

Marking In and Out points to delete that section of the Timeline

After deleting whatever's between the In and Out points, all clips to the right of the marked section move left to close the gap in Track 1

Trimming Clips

You can also quickly modify your edited timeline by resizing the In and Out points of any clip, moving the edit points between clips, and slipping the contents of a clip.

Resize Clips While Rippling the Timeline

If you move the pointer over the far left or right edge of a clip in the Timeline or Upper Timeline, it turns into a Resize icon to indicate that you can drag the In or Out point of that clip to make it shorter or longer, in the process rippling all clips to the right in the Timeline to accommodate the new length of the clip. While you drag, a tooltip shows you how many frames you've moved the clip and the clip's new duration. As you do so, the audio will scrub along with the Resize cursor.

If you resize a clip in Track 1, the rest of the edited timeline automatically ripples to accommodate the changes you've made, with clips to the right of the changed area moving left to fill the gap of a deleted or shortened clips, or moving right to make room for an inserted or lengthened clip.

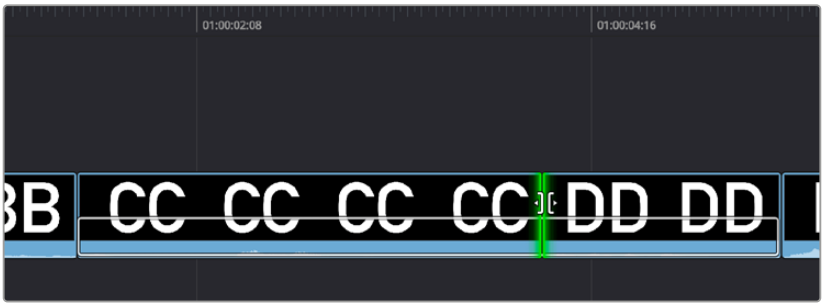
Clicking the Out point of clip DD in Track 1

Dragging to shorten clip DD ripples the Timeline; a tooltip appears to show you how many frames you've resized

Moving or resizing clips on Track 2 and above only moves or resizes that one clip; other clips in the Timeline are not rearranged and the Timeline is not rippled when you do this.

Clicking the out point of clip HH in Track 2

Dragging to lengthen the clip doesn't ripple the Timeline

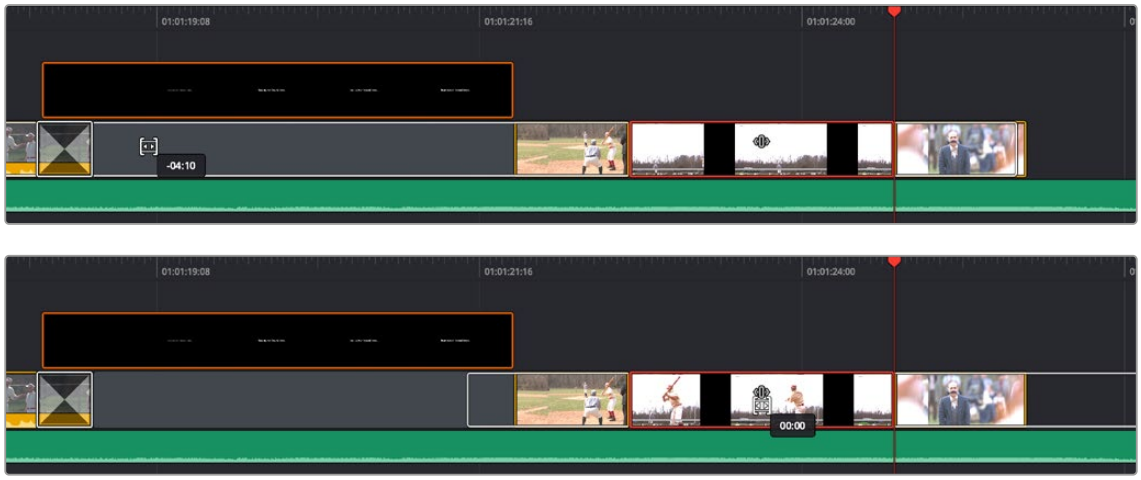


TIP: When you resize the Out point of a clip on Track 1 that's underneath a superimposed clip, and the superimposed clip has an In point that's to the right of the In point of the clip you're resizing, then dragging the Out point of the clip you're trimming past the left of the In point of the superimposed clip will delete that superimposed clip from the Timeline.

Rolling an Edit

You can click and drag any edit point between two clips in the Timeline or Upper Timeline to "roll" it, basically resizing the Out point of the outgoing clip and the In point of the incoming clip simultaneously. This lets you move an edit point without changing the duration of the overall timeline. While you drag, a white overlay in the Timeline lets you see how much media you have available for rolling (depending on the available handles in the source media). As you do so, the audio will scrub along with the right clip's In point.

Clicking an edit between clips CC and DD



Dragging to the right rolls it forward, simultaneously resizing clips CC and DD

Slipping Clip Content

For each clip in the Timeline, a Slip handle appears at the center of the clip. Dragging this handle lets you slip the contents of that clip to present a different range of media, without changing the position or duration of the clip, and without changing any other part of the Timeline.

You can even select multiple clips, such as two superimposed clips, or a number of clips in a row, and slip them all at the same time. While you drag, a white overlay in the Timeline lets you see how much media you have available for slipping (depending on the source clip's duration).

(Top) Clicking a clip's slip handle, (Bottom) Dragging a clip's slip handle to change the range of media within that clip

Roll and Trim Audio Edit Points to Add Split Edits

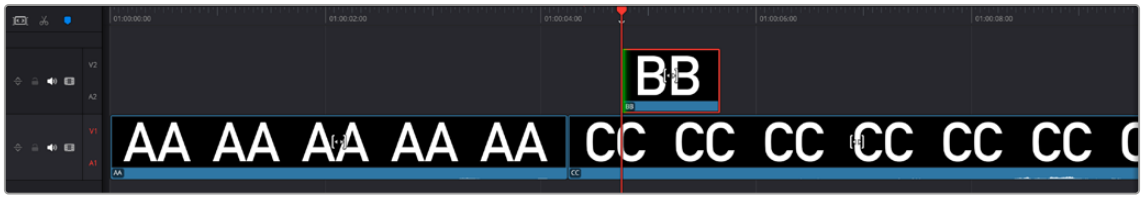
You can independently trim the audio channel of a video clip in the Cut page. This allows you to do a split edit (L-cut or J-cut), where the audio of one video clip is extended under the video of a different clip. This lets you manipulate the flow and rhythm of a scene in terms of reaction shots and more natural sounding dialogue.

To Trim Audio Only and Perform a Split Edit on a Cut Page Timeline:

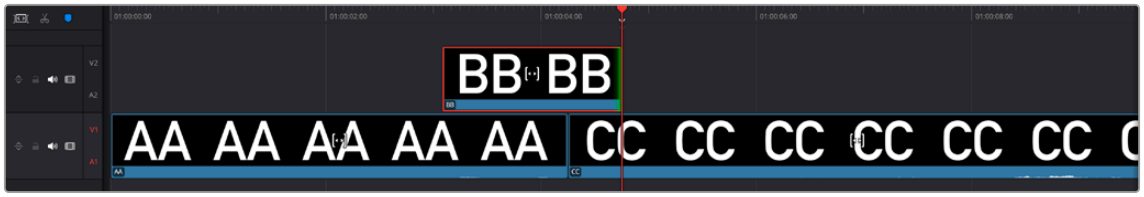
- Expand the track on the Cut page by clicking on the Enlarge Track icon on the left side of the track header. This is not strictly necessary but makes it easier to find the correct trigger point for the tool and see the audio waveform as you're trimming it.
- Hover the pointer over the edit point in the lower audio portion of the track. When the trim icon shows a musical note to the right, you can then slide that edit point back and forth and only the audio portion of the clip will be expanded forwards or backwards.
- The Trim View will also appear in the Viewer as you edit, along with expanded audio waveforms that are zoomed into the frame level for precision.

Placing the pointer in the audio part of the track triggers the trim indicator with the musical note icon. This allows you to drag just the audio edit point back and forth in the Timeline, leaving the video in place.

Trim or Extend Clip to Playhead



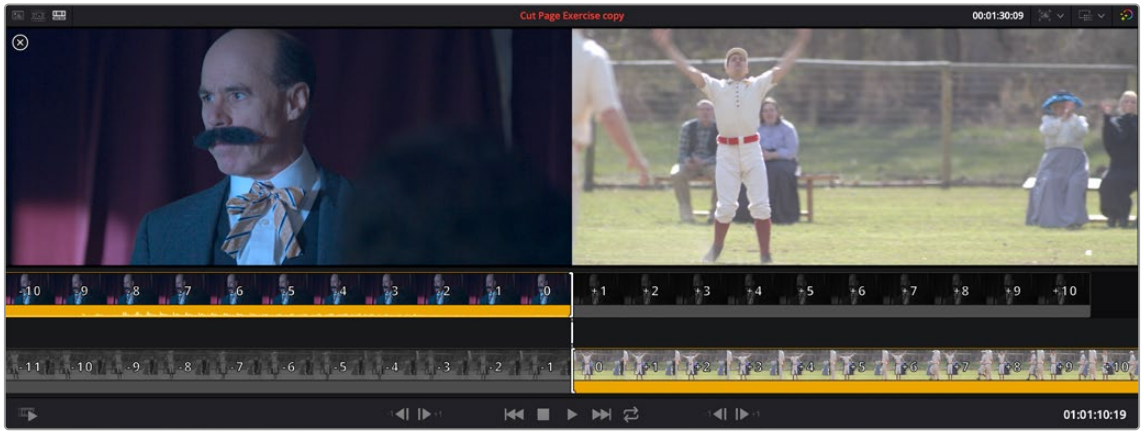
You can easily trim or extend a clip to a specific length by positioning the playhead on the Timeline exactly where you want the video to start or end and then selecting the appropriate operation by clicking on the Edit Actions icon.



To Trim or Extend Clip to Playhead:

- Place the playhead at the point that you wish to either extend the clip to, or cut the clip off at.
- Click on the Edit Actions icon.
- Select Trim Start to Playhead from the contextual menu to cut or extend the left side of the clip to the playhead position.
- Select Trim End to Playhead from the contextual menu to cut or extend the right side of the clip to the playhead position.

The original Timeline with playhead intersecting between the second and third set of “BB’s,”



(Top) The resulting clip when Trim Start to Playhead is selected,
(Bottom) The resulting clip when Trim End to Playhead is selected

Trimming Edits in the Viewer

You can double-click any edit point between two clips in the Timeline or Upper Timeline to open up the Trim Editor, which provides a detailed method of adjusting both halves of an edit point. A graphical A/B roll interface shows two filmstrips with the outgoing clip on top and the incoming clip on the bottom. These controls are draggable:

- Drag the left side of the top filmstrip’s handle to trim the Out point of the outgoing clip
- Drag the right side of the bottom filmstrip’s handle to trim the In point of the incoming clip
- Drag the white handle between the top and bottom filmstrips to roll the edit point, simultaneously adjusting the outgoing and incoming edit points

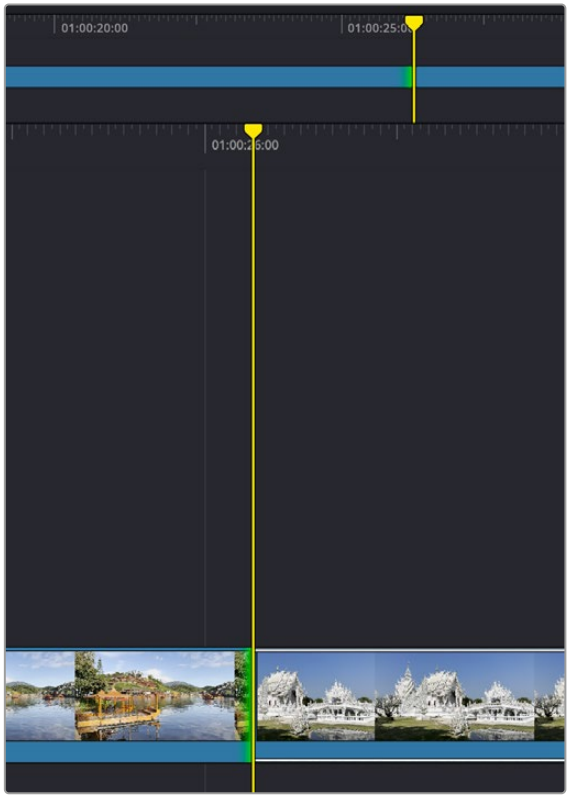
Numbers over each frame let you see exactly how many frames you’re trimming, while a pair of buttons to the left and right of the transport controls in the Viewer toolbar let you adjust the outgoing clip’s Out point and incoming clip’s In point in one frame increments.

The Viewer Trim Editor seen when you double-click an edit in the Timeline

Trimming Transitions in the Viewer

If you double-click a transition, that transition appears sandwiched between the outgoing and incoming clips, with handles you can use to trim the transition's length, as well as the outgoing and incoming halves of the edit point to which the transition is applied.

The Viewer Trim Editor seen when you double-click a transition in the Timeline



Dynamic Trimming Using JKL Controls

The Edit page's Dynamic Trim mode using the JKL controls on the keyboard has been added to the Cut page for quick keyboard trimming.

The Dynamic Trim mode lets you resize selected edit points and clips using the JKL transport control keyboard shortcuts. This means that you can make an appropriate selection in the Timeline, then trim them during playback, all while monitoring audio and watching the video.

Trimming while viewing the selected clip or edit point playing back has the advantage of letting you get emotionally involved in what you're watching, as well as experiencing the timing of a clip as it plays, in order to help you get a better feel for how exactly you need to trim a particular cut.

While you're dynamically trimming, you see the same two-up display, the same Timeline overlays, and the same dynamically updating timeline that appear when you use the Trim tool with the mouse. The only difference is that you're trimming while your program plays.

(Top) The Dynamic Trim icon in the Timeline toolbar

(Left) The playhead turns yellow to show you are in Dynamic Trim mode. The green highlight shows that only the Out point of the first clip is active. Using the JKL keys on the keyboard will then shift that edit point forward or backward.

To use Dynamic Trim mode to dynamically trim one or more selected clips or edits:

1. Select one or more edit points on the timeline that you wish to trim. Otherwise, the edit closest to the smart indictor will be selected for trimming.
2. Press W to enter Dynamic mode, or select Trim > Dynamic Trim Mode, click the Dynamic Trim tool in the toolbar. Once you've entered Dynamic Trim mode, the playhead tool turns yellow to serve as a constant reminder that in this mode all you can do is trim clips.
3. Right-click the Dynamic Trim tool in the toolbar to choose the Dynamic Trim mode.

   Slip: Keeps a clip in the same place in the Timeline, while changing the range of media that appears in that spot. Slip edits do not change the duration of the overall Timeline.

   Slide: Keeps a clip's range of media the same, but moves that clip to the left or right by either shortening the outgoing clip to its left while lengthening the incoming clip to its right, or vice versa.
4. The edit point will be highlighted in green to show which edges of the clip are selected for trimming. Press U to toggle through the available edit point types, or select Trim > Edit Point Type.
5. Use any combination of the JKL keyboard shortcuts to initiate playback and trimming, including:
   - J+K or K+L to trim in slow motion, with slow motion audio playback
   - Pressing K while tapping J or L to trim a frame at a time
   - Pressing J or L to trim with real time playback
   - Pressing J or L repeatedly to trim in fast-reverse or fast-forward, at a variety of speeds
6. As you dynamically trim, all audio clips in all audio tracks will play back as the playhead scrolls across them, so you can hear your entire mix as you're trimming.
7. After you've made a trim, pressing the Spacebar initiates Play Around Current Selection so you can see how well that trim plays. In Dynamic Trim mode, the Spacebar only executes a Play Around Current Selection operation, rather than play forward as it usually does.

8 When you're finished, you can use the Up and Down Arrow keys to move both the selection and playhead to another edit point or clip you'd like to trim, or you can press W again to toggle Dynamic Trim mode off.

You always want to be sure to turn Dynamic mode off when you're done (W), otherwise using the JKL keys will continue trimming selections whenever one or more edits or clips are selected, instead of playing the Timeline.

Trim with Safe Edit

Editing in the Cut Page timeline can be fast and furious, and if you wish to avoid accidentally overwriting an adjacent clip while trimming you can turn on "Trim with Safe Edit" in the timeline options.

In the Timeline options, select Trim with Safe Edit to prevent accidental overshoots.

With this mode enabled, you can trim and extend an edit point as normal until it intersects another clip. When the trim cursor reaches the next clip's bounds, it stops the trim and shows a small timer on the cursor rather than pushing on with the overwrite. If you actually do want to overwrite the adjacent clip, continue dragging with the mouse or rotating the Speed Editor dial to override the timer and overwrite the adjacent clip with the trim operation.

The Safe Edit cursor stopping you from overwriting the subsequent clip; continue dragging the clip to perform the overwrite anyway.

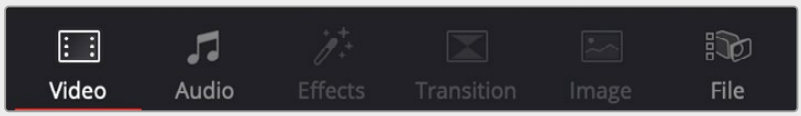
Chapter 37

Using the Inspector in the Cut Page

The Inspector holds all the controls to modify, resize, retime, and generally adjust anything related to a clip, transition, or effect on the Cut page Timeline.

Contents

Using the Inspector 755
Video 755
Audio 763
Effects 768
Transition 769
Image 770
File 771



Using the Inspector

The Inspector has been redesigned to make it easier to find specific controls and to adjust common settings for your clips. Instead of a long vertical list, different aspects of the Inspector have now been organized into panels, with each controlling specific grouped sets of parameters for your clip.

The Inspector is activated by clicking on the Inspector Panel in the upper-right section of the User Interface toolbar. The Inspector is broken up into individual Video, Audio, Effects, Transition, Image, and File panels. Inspector panels that are not applicable to your clip or selection are grayed out.

The Inspector Panel icon in
the upper right of the UI toolbar

The Inspector panels showing Video, Audio, and
File parameters available for adjustment; others are grayed out.

Methods of using controls in the Inspector:

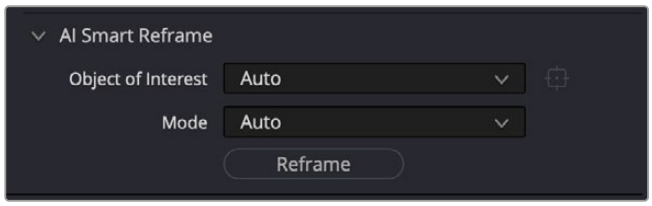
- **To activate or deactivate a control:** Click the toggle to the left of the control's name. The orange dot on the right means the control is activated. A gray dot on the left means the control is deactivated.
- **To reveal a control's parameters:** Double-click the control's name.
- **To reset controls to their defaults:** Click the reset button to the right of the control's name.

Video

The Video panel of the Inspector exposes a vast array of controls designed to manipulate the size, speed, and opacity of your clips.

Transform

The Transform section of the Video Inspector panel



The Transform group includes the following parameters for resizing and repositioning your clips:

- **Zoom X and Y:** Allows you to blow the image up or shrink it down. The X and Y parameters can be linked to lock the aspect ratio of the image, or released to stretch or squeeze the image in one direction only.
- **Position X and Y:** Moves the image within the frame, allowing pan and scan adjustments to be made. X moves the image left or right, and Y moves the image up or down.
- **Rotation Angle:** Rotates the image around the anchor point.
- **Anchor Point X and Y:** Defines the coordinate on that clip about which all transforms are centered.
- **Pitch:** Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values stretch the image more extremely.
- **Yaw:** Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and push the right of the image forward. Higher values stretch the image more extremely.
- **Flip Image:** Two buttons let you flip the image in different dimensions.

  Flip Horizontal control: Reverses the image along the X-axis, left to right.

  Flip Vertical control: Reverses the clip along the Y-axis, turning it upside down.

Smart Reframe (Studio Version Only)

The Smart Reframe section of the Video Inspector panel

The Smart Reframe feature makes it easier to quickly reframe material across extreme aspect ratio changes. It's useful for situations where you've shot a 16:9 horizontal video and find yourself needing to create a vertically-oriented 9:16 version for mobile phones and social media deliverables, or using 4:3 archival footage in a 2.39:1 widescreen movie. Smart Reframe can be used manually, or automatically executed using the DaVinci Resolve Neural Engine.

- **Object of Interest:** Tools for selecting the subject that the resize will frame around.

  Auto: DaVinci Resolve's Neural Engine will analyze the clip and choose its most representative object. This will be the only option if more than one clip is selected for Smart Reframing.

  Reference Point: Allows you to manually adjust a bounding box around the subject to reframe around.

- **Mode:** Tools for limiting the AI reframing to a specific axis.

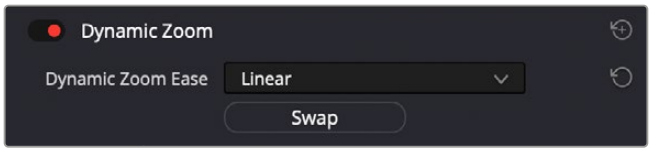
  Auto: Smart Reframe will adjust the pan and tilt of a clip as it deems necessary to properly reframe the target.

  Pan Only: Smart Reframe will adjust the pan (left and right) motion of the clip only.

  Tilt Only: Smart Reframe will adjust the tilt (up and down) motion of the clip only.

- **Reframe:** This button executes the Smart Reframe command. This can take some time depending on the length and number of clips.

Cropping

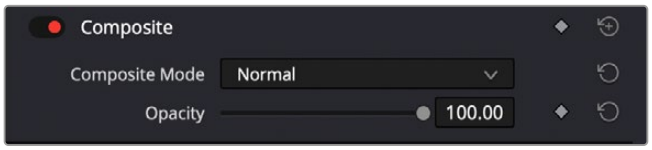


The Cropping section of the Video Inspector panel

The Video Inspector controls the image's cropping parameters.

- **Crop Left, Right, Top, and Bottom:** Lets you cut off, in pixels, the four sides of the image. Cropping a clip creates transparency so that whatever is underneath shows through.
- **Softness:** Lets you blur the edges of a crop. Setting this to a negative value softens the edges inside of the crop box, while setting this to a positive value softens the edges outside of the crop box.
- **Retain Image Position:** Clicking this checkbox will lock the crop parameters in place when you resize the image using the Transform tool above. Unchecking this box will scale and position the crop as well as the image.

Dynamic Zoom



The Dynamic Zoom section of the Video Inspector panel

The Dynamic Zoom controls, which are off by default, make it fast and easy to do pan and scan effects to zoom into or out of a clip. Turning the Dynamic Zoom group on activates two controls in the Inspector that work hand-in-hand with the Dynamic Zoom onscreen adjustment controls.

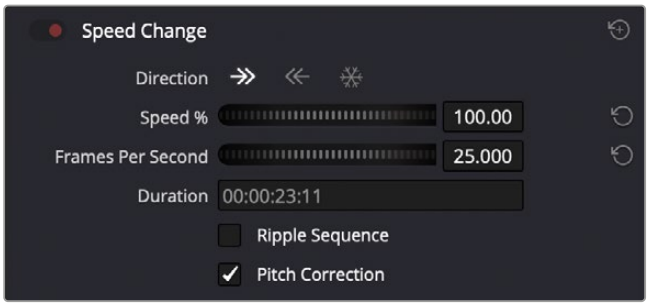
> For more information on using the Dynamic Zoom controls, jump to chapter: Compositing and Transforms in the Timeline.

- **Dynamic Zoom Ease:** Lets you choose how the motion created by these controls accelerates. You can choose from Linear, Ease In, Ease Out, and Ease In and Out.
- **Swap:** This button reverses the start and end transforms that create the dynamic zoom effect.

Composite

The Composite section of the Video Inspector panel

Composite modes can be used to combine clips that are superimposed over other clips in the Timeline.



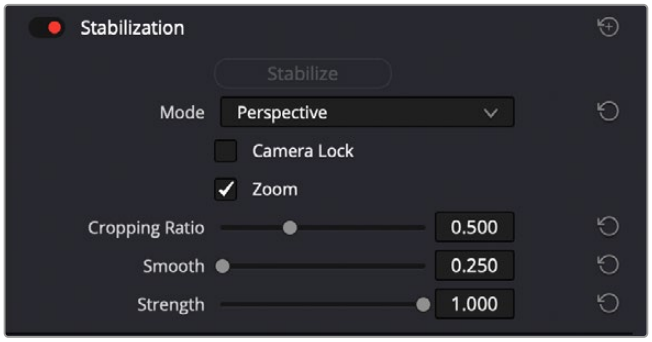
- **Composite Mode:** This selects the type of composite mode to combine the superimposed clips. The default “Normal” means no compositing mode is applied.

> For more information on Composite Modes, jump to chapter: Compositing and Transforms in the Timeline.

- **Opacity:** This slider makes a clip more or less transparent in addition to compositing already being done.

Speed Change

You can change the speed of your clip directly in the Video Inspector’s Speed Change controls. This method has the benefit of being available in both Cut and Edit pages.



The Speed Change controls in the Video Inspector

- **Direction:** Selects the desired motion of the clip, forward, backward, or freeze frame.
- **Speed %:** Adjusting this slider changes the clips motion on a percentage basis. This value can be keyframed.
- **Frames Per Second:** Adjusting this slider changes the clips motion by increasing or decreasing the number of frames per second to play the clip back at. This value can be keyframed.
- **Duration:** You can directly select how long you want the clip to be by setting a specific duration here in HH:MM:SS:FF format. This will then automatically adjust the speed of the clip to playback all frames in that exact amount of time.
- **Ripple Sequence checkbox:** If you want the speed change you’re about to make to ripple the Timeline, pushing or pulling all clips following the current one to accommodate the clip’s new size, then turn on this checkbox.
- **Pitch Correction checkbox:** Checking this box will perform pitch correction on the audio attached to the clip so that while the audio duration is changed to match the picture speed, it will still sound natural. Be aware that pitch correction on large speed adjustments may not sound as good as pitch corrections made to small speed adjustments.

Stabilization

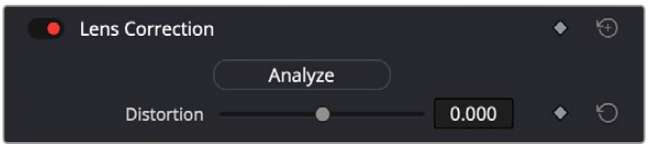
These controls let you smooth out or even steady unwanted camera motion within a clip.

The analysis is performed in such a way as to preserve the motion of individual subjects within the frame, as well as the overall direction of desirable camera motion, while correcting for unsteadiness.

The Stabilization section of the Video Inspector panel

These are the same stabilizer controls found in the Color page's Tracker palette (minus the tracker graph), and the resulting stabilization analysis is mirrored on the Color page, where you can see the data visualized on the graph, if necessary.

A pop-up menu provides three different options that determine how the selected clip is analyzed and transformed during stabilization. You must choose an option first, before clicking the Stabilize button above, because the option you choose changes how the image analysis is performed. If you choose another option, you must click the Stabilize button again to reanalyze the clip.



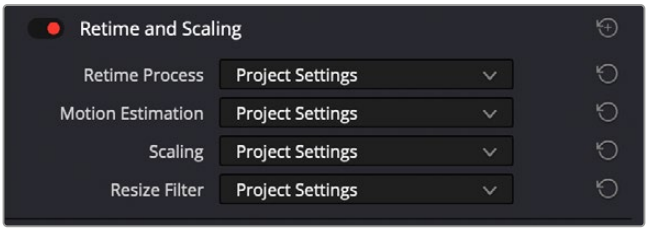
- **Perspective:** Enables perspective, pan, tilt, zoom, and rotation analysis and stabilization.
- **Similarity:** Enables pan, tilt, zoom, and rotation analysis and stabilization, for instances where perspective analysis results in unwanted motion artifacts.
- **Translation:** Enables pan and tilt analysis and stabilization only, for instances where only X and Y stabilization gives you acceptable results.

The other controls let you customize how aggressively the selected clip is stabilized.

- **Stabilization Toggle:** The toggle control for the Stabilization controls lets you turn stabilization off and on to be able to compare the stabilized and unstabilized image.
- **Camera Lock:** Turning on this checkbox disables Cropping Ratio and Smooth, and enables the stabilizer to focus on eliminating all camera motion from the shot in an effort to create a locked shot.
- **Zoom:** When this checkbox is turned on, the image is resized by a large enough percentage to eliminate the blanking (black edges) that is the result of warping and transforming the image to eliminate unwanted camera motion. The lower a value Cropping Ratio is set to, the more DaVinci Resolve will need to zoom into an image to eliminate these blanked edges. If you turn this off, the image is not zoomed at all, and whatever blanking intrudes into the image is output along with the image, on the assumption that you'll have dedicated compositing artists deal with eliminating this blanking by filling in the missing image data in a more sophisticated manner. You may also leave this checkbox turned off if you're planning on animating the Input Sizing Zoom parameter to dynamically zoom into and out of a shot being stabilized to eliminate blanking only where it occurs, using only as much zooming as is necessary for each region of the shot.
- **Cropping Ratio:** This value limits how hard the stabilizer tries to stabilize, by dictating how much blanking or zooming you're willing to accept in exchange for eliminating unwanted motion. A value of 1.0 results in no stabilization being applied. Progressively lower values enable more aggressive stabilization. Changing this value requires you to click the Stabilize button again to reanalyze the clip.

- **Smooth:** Lets you apply mathematical smoothing to the analyzed data used to stabilize the clip, allowing camera motion in the shot while eliminating unwanted jittering. Lower values perform less smoothing, allowing more of the character of the original camera motion to show through, while higher values smooth the shot more aggressively. Changing this value requires you to click the Stabilize button again to reanalyze the clip.
- **Strength:** This value is a multiplier that lets you choose how tightly you want to use the stabilization track to eliminate motion from a shot using the current analysis. With a value of 1, stabilization is maximized. Since some clips might look more natural with looser stabilization, choosing a number lower than 1 lets a percentage of the original camera motion show through. Zero (0) disables stabilization altogether. As an additional tip, you can invert the stabilization by choosing –1 when pasting a stabilization analysis from another clip to perform a match move based on the overall motion of the scene, and you can use a negative value either lower than 0 or higher than –1 to under or overcompensate when inverting the stabilization, simulating the effects of parallax where foreground and background planes move together but at different speeds.

Lens Correction



The Lens Correction section of the Video Inspector panel

The Lens Correction group (only available in Resolve Studio) has two controls that let you correct for lens distortion in the image, or add lens distortion of your own.

- **Analyze:** Automatically analyzes the frame in the Timeline at the position of the playhead for edges that are being distorted by wide angle lens. Clicking the Analyze button moves the Distortion slider to provide an automatic correction. If you're analyzing a particularly challenging clip, a progress bar will appear to let you know how long this will take.
- **Distortion:** Dragging this slider to the right lets you manually apply a warp to the image that lets you straighten the bent areas of the picture that can be caused by wide angle lenses. If you clicked the Analyze button and the result was an overcorrection, then dragging this slider to the left lets you back off of the automatic adjustment until the image looks correct.

Retime and Scaling

The Retime and Scaling section of the Video Inspector panel

The Retime and Scaling group has four parameters that affect retiming quality and clip scale:

- **Retime Process:** Lets you choose a default method of processing clips in mixed frame rate timelines and those with speed effects (fast forward or slow motion) applied to them, on a clip-by-clip basis. The default setting is "Project Settings," so all speed-effected clips are treated the same way.

There are three options: Nearest, Frame Blend, and Optical Flow, which are explained in more detail in the Speed Effect Processing section, jump to chapter: Speed Effects.

- **Motion estimation mode:** When using Optical Flow to process speed change effects or clips with a different frame rate than that of the Timeline, the Motion Estimation pop-up lets you choose the best-looking rendering option for a particular clip. Each method has different artifacts, and the highest quality option isn't always the best choice for a particular clip. The default setting is "Project Settings," so all speed-effected clips are treated the same way. There are several options. The "Standard Faster" and "Standard Better" settings are the same options that have been available in previous versions of DaVinci Resolve. They're more processor efficient and yield good quality that are suitable for most situations. However, "Enhanced Faster" and "Enhanced Better" should yield superior results in nearly every case where the standard options exhibit artifacts, at the expense of being more computationally intensive, and thus slower on most systems.
  - The "Standard Faster" and "Standard Better" settings are the same options that have been available in previous versions of DaVinci Resolve. They're more processor efficient and yield good quality that are suitable for most situations. However, "Enhanced Faster" and "Enhanced Better" should yield superior results in nearly every case where the standard options exhibit artifacts, at the expense of being more computationally intensive, and thus slower on most systems.
  - "Speed Warp Faster and "Speed Warp Better" are available for even higher-quality slow motion effects using the DaVinci Neural Engine. Your results with this setting will vary according to the content of the clip, but in ideal circumstances this will yield higher visual quality with fewer artifacts than even the Enhanced Better setting.
  - "AI Speed Warp Metal" (macOS only) is a specifically enhanced version of Speed Warp that takes advantage of the Mac's hardware. It should dramatically speed up the DaVinci Neural Engine Speed Warp operations.
- **Scaling:** Lets you choose how clips that don't match the current project resolution are handled on a clip-by-clip basis. The default setting is "Project Settings," so that all mismatched clips use the same method of being automatically resized. However, you can also choose an individual method of automatic scaling for any clip.

  The options are Crop, Fit, Fill, and Stretch. For more information, jump to chapter: Sizing and Image Stabilization.

- **Resize Filter:** For clips that are being resized in any way, this setting lets you choose the filter method used to interpolate image pixels when resizing clips. Different settings work better for different kinds of resizing. There are four options:

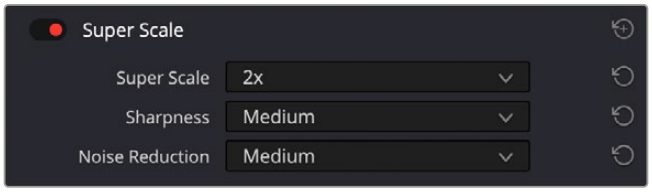
  Sharper: Usually provides the best quality in projects using clips that must be scaled up to fill a larger frame size, or scaled down to HD resolutions.

  Smoother: May provide higher quality for projects using clips that must be scaled down to fit an SD resolution frame size.

  Bicubic: While the Sharper and Smoother options are slightly higher quality, Bicubic is still an exceptionally good resizing filter and is less processor intensive than either of those options.

  Bilinear: A lower quality setting that is less processor intensive. Useful for previewing your work on a low-performance computer before rendering, when you can switch to one of the higher quality options.

  Other Resize Methods: A selection of specific resize algorithms is available if you need to match them to other VFX workflows.



- **Deinterlace Quality (Interlaced Clips Only):** Allows per clip deinterlace quality adjustments regarding how DaVinci Resolve combines the two fields of interlaced media into progressive frames.

  Normal: A high-quality deinterlacing method that is suitable for most clips. For many clips, Normal is indistinguishable from High. Normal is always used automatically during playback in DaVinci Resolve.

  High: A more processor-intensive method that can sometimes yield better results, depending on the footage, at the expense of slower rendering times.

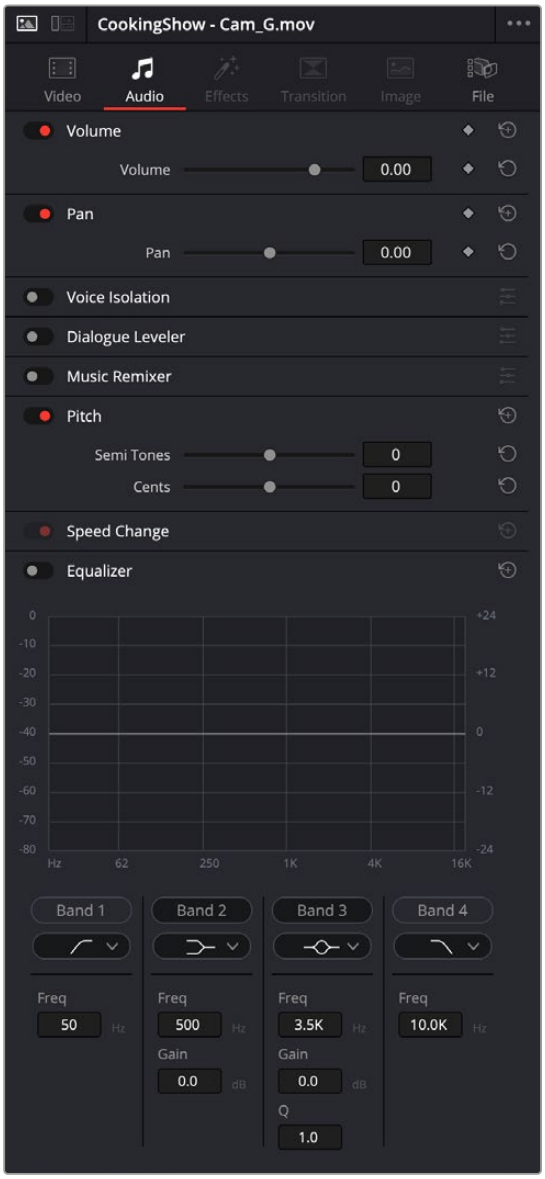
  DaVinci Neural Engine: This option uses the advanced machine learning algorithms of the DaVinci Neural Engine to analyze motion between the fields of interlaced material and reconstructs them into a single frame. This option is very computationally intensive but, ideally, will deliver an even more aesthetically pleasing result than the “high” setting.

Super Scale

The Super Scale parameters

For instances when you need higher-quality upscaling than the standard Resize Filters allow, you can now enable one of the “Super Scale” options in the Inspector. Unlike using one of the numerous scaling options in the Edit, Fusion, or Color pages, Super Scale actually increases the source resolution of the clip being processed, which means that clip will have more pixels than it did before and will be more processor-intensive to work with than before, unless you optimize the clip (which bakes in the Super Scale effect into the optimized media) or cache the clip in some way.

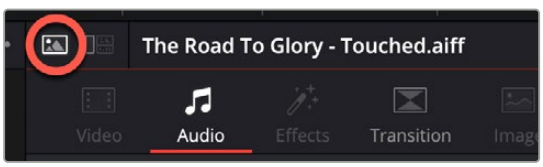
> For more information on Super Scale, Image Sizing and Resolution Independence.



Using Super Scale in the Inspector is functionally equivalent to setting the same controls for the media clip in the Clip Attributes. This means that changing this setting affects all of the additional edits referencing the selected media as well.

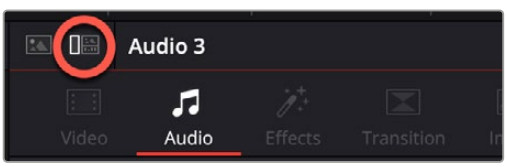
The Super Scale group has the following parameters that affect the quality and clip scale:

- **Super Scale:** Lets you choose the amount of scaling required. The options are 2-3-4x and 2-3-4x Enhanced.
- **Sharpness:** Lets you choose the amount of detail in the scaling. This is limited to Low, Medium, or High, unless the Super Scale mode is set to Enhanced, which allows you to apply variable sharpness. You will want to balance this setting against Noise Reduction.
- **Noise Reduction:** Lets you choose the amount of noise reduction in the scaling. This is limited to Low, Medium, or High, unless the Super Scale mode is set to Enhanced, which allows you to apply variable noise reduction. You will want to balance this setting against Sharpness.



Audio

The Audio Inspector can work on both individual clips or entire tracks, based on which icon is selected in the upper left of the Inspector. Normally this option automatically adjusts for you based on what you have selected in the timeline. For example, when you click on an audio clip in the timeline, the Inspector will open in Clip mode, and if you click on an audio track header in the timeline, the Inspector will switch to Track mode automatically. These can always be manually overridden simply by clicking on the appropriate icon. Clip and Track modes contain different options for audio editing.



The Audio Inspector Clip and Track parameters

The Audio Inspector in Clip mode (circled)

The Audio Inspector in Track mode (circled)

The Audio tab contains commonly used audio controls for video editing purposes, including Volume, Pan, Pitch, and Equalizer. It also contains several incredibly useful DaVinci Neural Engine powered tools like Voice Isolation, Dialog Leveler, and Music Remixer.

- **Volume:** Each clip has a single volume control that corresponds to the volume overlay over each audio clip.
- **Pan:** A simple Pan slider that controls stereo panning. While most professional mixes will restrict panning to the more robust panner found in the Fairlight page Mixer, this simple Pan control is useful for editors of visuals working in the Edit page to quickly create simple panning effects to aid in a craft edit.
- **Voice Isolation (Studio Version Only):** Voice Isolation is a plugin that can remove loud, undesirable sounds from existing voice recordings. This effect utilizes AI to provide models that let you completely remove undesired sounds. The AI model is trained for any type of human voice, male or female, young or old, so you can get incredible results that isolate dialog from background sounds in a recording, including everything from air conditioning or fans to extremely loud sounds like a jackhammer, restaurant background noise, or music playing at the same time that the subject is speaking, and so on.

  Amount: Lets you adjust the amount of voice isolation processing.

  For more information on Voice Isolation, jump to chapters: Video and Audio Effects in the Cut Page, and Fairlight FX.

- **Dialogue Leveler:** The Dialogue Leveler analyzes source material to detect dialog and then “ride down” louder areas, “lift up” softer areas, and lower background sounds that are not dialog. It works without typical dynamics processor “pumping” (compression/limiting) or other obvious side effects and produces results similar to detailed manual clip gain adjustments or by carefully “riding” the track with fader automation.

  Preset Menu: The preset menu provides the following options:

  - **Optimized for most sources:** This option is selected by default and works well for most sources.
  - **More lift for low levels:** Select this option if the source has more low level dialog that you want to boost.
  - **Lift soft whispery sources:** Select this option if the source has whispered dialog and background noise.

  Reduce Loud Dialogue: When enabled, louder dialogue is ridden downward on peaks and acts somewhat like a “perfect limiter” where you don’t have to adjust threshold or time constants. Due to the “near real time” aspect, analysis occurs prior to audible playback for optimal results.

  Lift Soft Dialogue: When enabled, finds low level dialogue and lifts and evens out material that is more variable in level and softer, but because the process is dialogue focused, it doesn’t tend to raise background sounds (unless they are happening at the same time as the dialogue itself). More often than not, the Lift Soft Dialogue option is the most useful of the three options, as it makes less audible lines of dialogue more audible and naturally smooth, while not boosting background noise.

  Background Reduction: When enabled, reduces background sounds by focusing on dialogue and gently removing them based on the internal presets (Preset menu).

  Output Gain: Adjust the Output Gain by clicking and dragging on the Output Gain control or by entering a value in the numeric field (Output Gain control in dB with 0 to +6 dB range with .1dB resolution).

- **Dialogue Separator (Track Mode Only):** The Dialogue Separator uses DaVinci Neural Engine AI to give you individual control over the level of dialogue, background sounds and “ambience,” the reverberant field, or ambient room sound. If you have a source file that contains a great roomy sound, but there is music in the background or crowd noises, you can rebalance so that the background sounds come down a bit, or adjust the room sound down a bit for better intelligibility.

  For more information on the Dialogue Separator, jump to chapter:
  Video and Audio Effects in the Cut Page

- **Music Remixer:** The Music Remixer is a DaVinci Neural Engine AI-based effect. This Track FX plugin uses AI to split music into individual basic stems: Vocals, Drums, Bass, Guitar and “Other,” which means “everything else.” You can use the level controls to rebalance or remix the sources, or the mute buttons to make instant changes and bring parts in and out of your mix. Music Remixer lets you creatively adjust a music track to suit your needs. For example, you might have a track where you need to remove the vocal or rearrange to allow for quieter moments or a build.

  For more information on the Music Remixer, jump to chapter:
  Video and Audio Effects in the Cut Page

- **Music Editor:** Allows you to seamlessly extend or shorten music to the length of your edit. You can enter a desired duration and press the Adjust button in order to shorten or extend the clip to that duration. Music Editor does not use time compression/expansion or alter the pitch of the music, but instead uses editing techniques like a music editor might to fit the material to desired length to picture. It will look for logical places to create transitions based on whether you’re extending length (by repeating sections), or removing material, and attempt to use the ending or fade of the original composition, if it times well. If the ending is abrupt, it’s up to you to manually create a fade out.

  For more information on the Music Editor, jump to chapter:
  Video and Audio Effects in the Cut Page

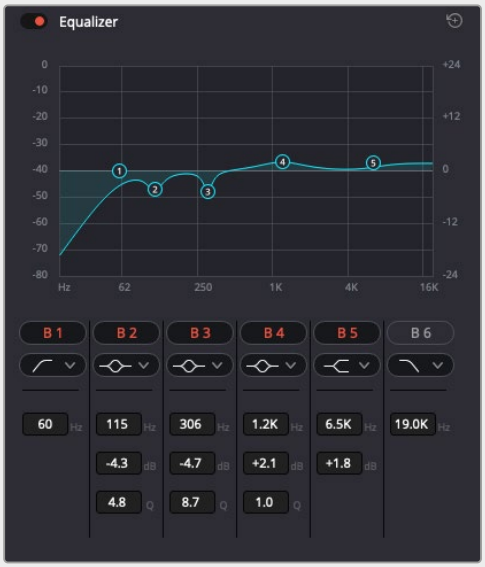
  NOTE: Music Editor is an “intelligent edit” that works effectively with beat driven music (pop, dance, etc.). It is not intended for free form, ambient, or non-beat driven material.

- **Ducker (Track Mode Only):** The Ducker Track FX plugin allows you to automatically lower the level of a track by using an external source signal – this is known as “ducking.” Most commonly, ducking is used to have dialogue or VO automatically lower a music or sound effects bed, but it can be used in many creative ways. Set up correctly, your sources can often “mix themselves,” and you can create very useful results.

  The Ducker uses changes in level only to do its work; the audio is not compressed or limited. For more information on the Ducker, jump to chapter: Video and Audio Effects in the Cut Page

Choose the target track that you want to affect (the “destination” track), and open the Ducker.

Source: This is the source track you want to use to duck the level of the target track. You can add multiple or remove additional source tracks by pressing the +/- buttons to the right.



Duck Level: Adjust the amount of “ducking” applied.

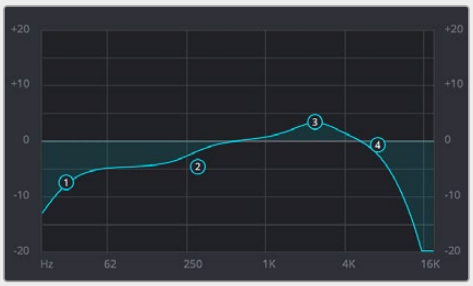
- **Pitch:** Lets you alter the pitch of a clip without changing the speed. Two sliders let you adjust clip pitch in semi tones (large adjustments, a twelfth of an octave) and cents (fine adjustments, 100th of a semi tone).

Equalizer

This six-band parametric equalizer has both graphical and numeric controls for boosting or attenuating different ranges of frequencies within that clip, before it even gets to the EQ built into the Mixer. Each band has controls for the filter type (Bell, Lo-Shelf, Hi-Shelf, Notch), Frequency, Gain, and Q-factor (sharpness of the band), with the available controls for each band of EQ changing depending on the filter type.

TIP: Clip EQ settings can be copied and pasted from one Clip EQ to another, and between Clip EQ and Track EQ instances.

Clip EQ in the Audio Inspector



Master EQ Controls

The Equalizer window has the following overall controls located in the upper-right and left corners:

- **Enable button:** Turns the overall EQ effect off and on, without resetting the controls.
- **Reset button:** Resets all controls of the EQ window to their defaults.

Clip EQ Graph

This graph displays the current EQ curve with handles that correspond to each enabled EQ band listed below. You can drag any numbered handle to boost or attenuate the range of frequencies governed by that band, using whatever type of equalization that band has been set to.

The Clip EQ graph with user-draggable handles

Dragging the numbered handles on this graph in turn modifies the parameters of the corresponding band, and changing each band's parameters will also alter the EQ graph, which serves the additional purpose of providing a graphical representation of the equalization being applied to that track.

Bands 1 and 6

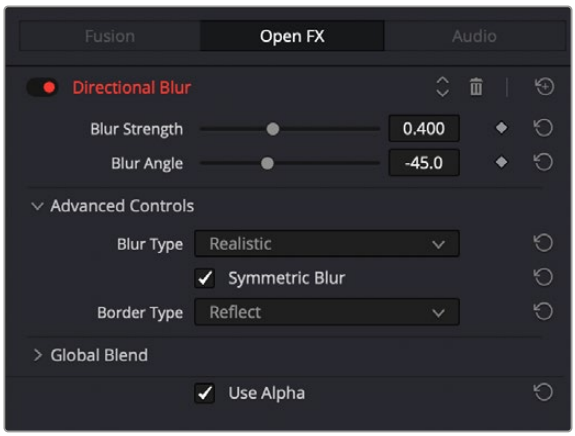
The outer two sets of band controls let you make high-pass and low-pass adjustments, if necessary.

- **Band enable button:** Turns each band of EQ on and off.
- **Band filter type:** Bands 1 and 6 can be switched among five specific filtering options for processing the lowest or highest frequencies in the signal.

  For Band 1, these include (from top to bottom): Lo-Shelf, Bell, Notch, Hi-Shelf, and Hi-Pass.

  For Band 6, the options are (from top to bottom): Lo-Pass, Lo-Shelf, Bell, Notch, and Hi-Shelf.
- **Freq:** Adjusts the center frequency of the EQ adjustment.
- **Gain:** Adjusts the amount by which the affected frequencies are impacted. Negative values attenuate those frequencies, while positive values boost those frequencies.
- **Q Factor:** This parameter adjusts the width of affected frequencies and appears whenever the Bell option is selected. Lower values include a wider range of frequencies; higher values include a narrower range of frequencies.

Bands 2 through 5



These band controls let you make a wide variety of equalization adjustments.

- **Band enable button:** Turns each band of EQ on and off.
- **Band filter type:** These Bands offer four filtering options (from top to bottom): Lo-Shelf, Bell, Notch, and Hi-Shelf.
- **Frequency:** Adjusts the center frequency of the EQ adjustment.
- **Gain:** Adjusts the amount by which the affected frequencies are impacted. Negative values attenuate those frequencies, while positive values boost those frequencies.
- **Q Factor:** This parameter appears when the Bell setting is selected. It adjusts the width of affected frequencies. Lower values include a wider range of frequencies; higher values narrow the range of frequencies.

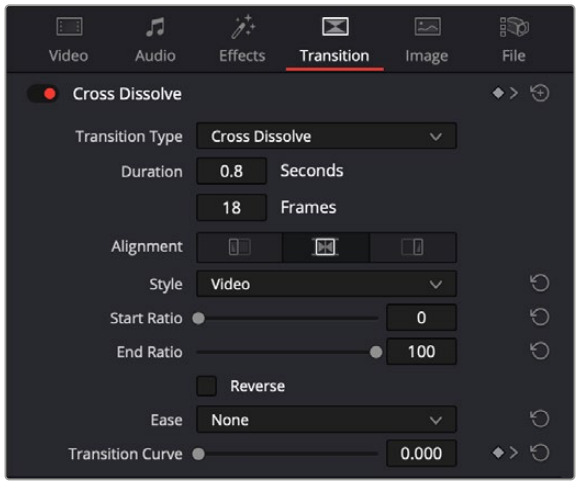
NOTE: There are many more refined plugins and effects for audio clips in the Audio FX library. If you apply any of these, the controls will appear in the Inspector's Effects tab Audio section, instead of here.

Effects

Any Fusion FX, Open FX, or Audio FX filters that have been applied to a clip can be modified here in their respective tabs. Different effects in the Timeline expose different controls in the Effects panel. Whichever panels are exposed, parameters within each panel are organized into groups, with a title bar providing the name of that group, along with other controls that let you control all parameters within that group at the same time.

The Effects Inspector controls

These controls include:



- **Enable button:** A toggle control to the left of the parameter group's name lets you disable and re-enable every parameter within that group at once. Orange means that track's enabled. Gray is disabled.
- **Parameter group title bar:** Double-clicking the title bar of any group of parameters collapses or opens them. Even more exciting than that, Option-double-clicking the title bar of one parameter group collapses or opens all parameter groups at once.
- **Keyframe and Next/Previous Keyframe buttons:** This button lets you add or remove keyframes at the position of the playhead to or from every single parameter within the group. When the button is highlighted orange, a keyframe is at the current position of the playhead. When it's dark gray, there is no keyframe. Left and right arrow buttons let you jump the playhead from keyframe to keyframe for further adjustment.
- **Reset button:** Lets you reset all parameters within that group to their default settings.
- **Use Alpha:** Checking this box applies the Open FX alpha channel to the selected clip, compositing it over any background elements that appear in lower tracks. If more than one alpha-modifying effect is applied to a single clip, the alpha channels are mixed together.

For a detailed explanation of each of the Resolve FX plugins that accompany DaVinci Resolve, jump to: Resolve FX Overview

Transition

Double-clicking a transition in the Timeline opens that Transition Panel in the Inspector. Each transition has the following properties you can edit.

- **Transition Type:** The currently selected transition. You can change to any other installed transition by selecting one in the drop-down menu.
- **Duration:** The duration of the transition, shown in both seconds and frames.
- **Alignment:** A drop-down that lets you choose the transition's position relative to the edit point it's applied to. Your choices are "Start on Edit," "Center on Edit," and "End on Edit."

The Transition Inspector controls

Additional properties that are specific to each type of transition appear in another group below. Since the Cross Dissolve transition is the most common transition used, its properties will be shown as an example.

- **Style:** The different Dissolve transitions (Cross Dissolve, Additive Dissolve, and so on) expose this drop-down that lets you choose different ways for the outgoing clip to blend into the incoming clip during the dissolve. There are six different options to choose from:

  Video: A simple linear dissolve; the outgoing clip fades out as the incoming clip fades in.

  Film: A logarithmic dissolve, simulating film dissolves as created by an optical printer.

  Additive: The outgoing and incoming clips are cross faded using the Additive composite mode. As a result, the transition seems to brighten at the halfway point.

  Subtractive: The outgoing and incoming clips are cross faded using the Subtractive composite mode. As a result, the transition seems to darken at the halfway point.

  Highlights: The outgoing and incoming clips are cross faded using the Lighten composite mode. The lightest parts of each clip are emphasized during this transition.

  Shadows: The outgoing and incoming clips are cross faded using the Darken composite mode. The darkest parts of each clip are emphasized during this transition.

- **Start Ratio:** Defines the percentage of completion for the transition at its first frame, from 0 to 100 percent. Setting the Start Ratio to anything but 0 results in the transition immediately appearing at a more fully cross-dissolved state from the very first frame.
- **End Ratio:** Defines the percentage of completion for the transition at its last frame. Setting the End Ratio to anything but 0 results in the transition never fully dissolving to the incoming shot at its last frame.
- **Reverse:** Reverses the transition. This parameter is disabled for Dissolve transitions.

- **Ease:** A drop-down that lets you apply nonlinear acceleration to the beginning, ending, or overall duration of a transition. The result is to add inertia to the transition from the outgoing clip to the incoming clip, providing a gentler change from each clip into and out of the transition.

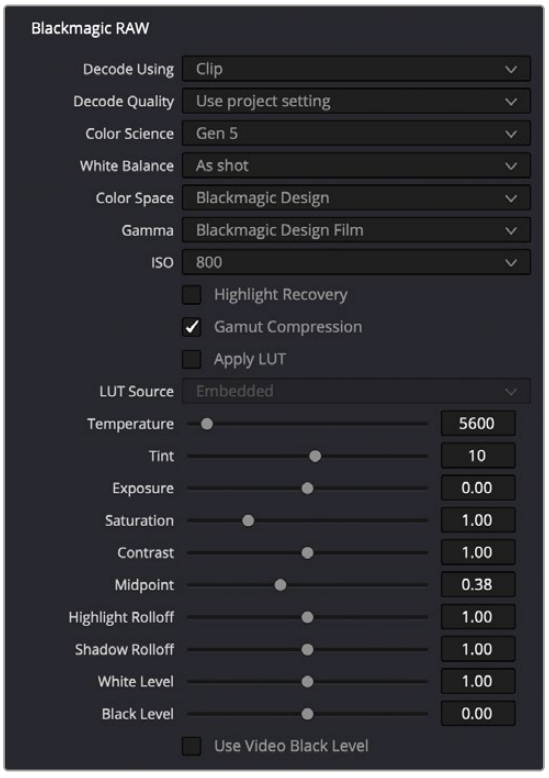
  None: The outgoing clip fades away to the next shot in a linear fashion.

  In: The outgoing clip lingers as the beginning of the transition dissolves more slowly than the end.

  Out: The outgoing clip fades away more quickly as the beginning of the transition dissolves more quickly than the end.

  In & Out: Both the outgoing and incoming clips make slower transitions at the beginning and end of the dissolve, but the very center of the transition is faster as a result.

  Custom: Lets you modify the parameters of the fade manually using the Transition Curves below.

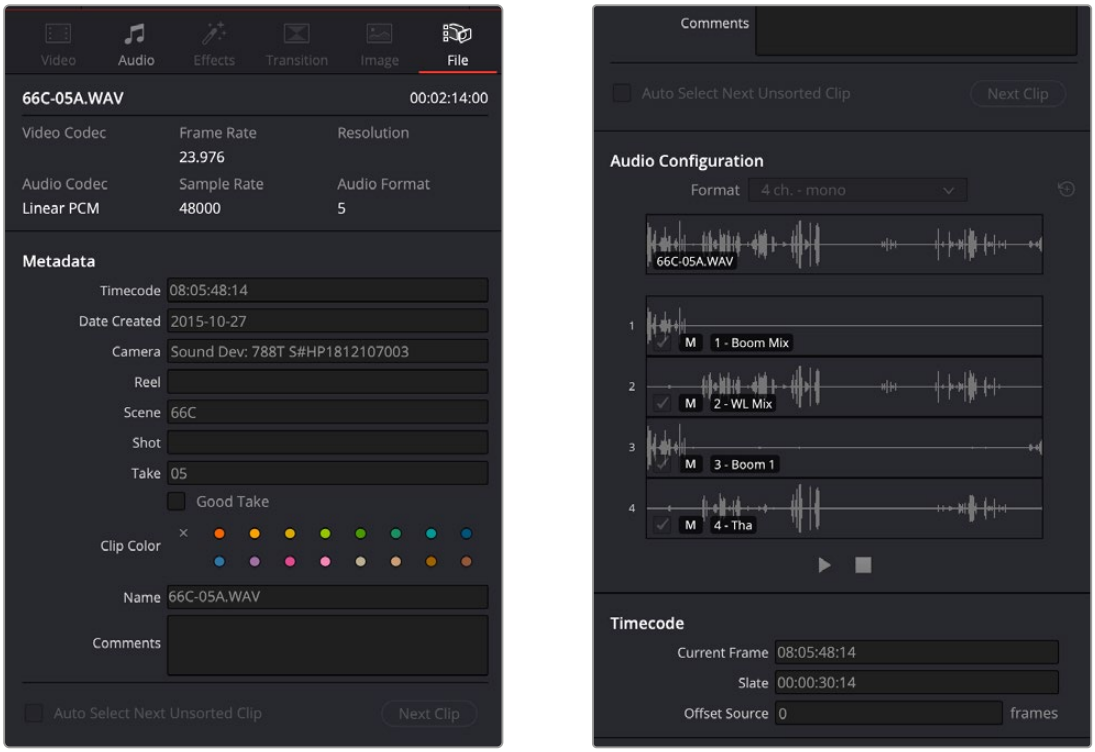


- **Transition Curve:** Allows you to manually set keyframes controlling the progress of the transition along its duration.

Other types of transitions display properties that are specific to that transition's particular effect.

For a detailed explanation of each of the transitions that accompany DaVinci Resolve, jump to chapter: Using Transitions.

Image



The Image panel contains groups of parameters that correspond to every camera raw media format that's supported by DaVinci Resolve. Using these parameters in the Image panel, you can override the original camera metadata that was written at the time of recording and make simultaneous adjustments to camera raw media throughout your project.

The Image Inspector controls for BRAW footage

For a detailed explanation of each of the RAW camera parameters supported by DaVinci Resolve, jump to chapter: Camera Raw Settings.

File

The File Inspector controls

Metadata

The File panel of the Inspector provides a consolidated way to view and edit a subsection of a clip's most commonly used media file metadata. It's easily accessible in the Inspector across the Media, Cut, Edit, and Fairlight pages.

The tab is composed of the following parts:

- **Clip Details:** Presents data about the clip's data format (codec, resolution, frame rate, etc.).
- **Metadata:** Presents a reduced set of common metadata fields for quick user entry.

  Timecode: The start timecode of the clip. This field is editable if you want to manually change the clip's starting timecode.

  Date Created: The date that the clip was created. This field is editable if you want to manually change the clip's creation date.

  Camera: Sets the Camera # metadata.

  Reel: Sets the Reel/Card ID.

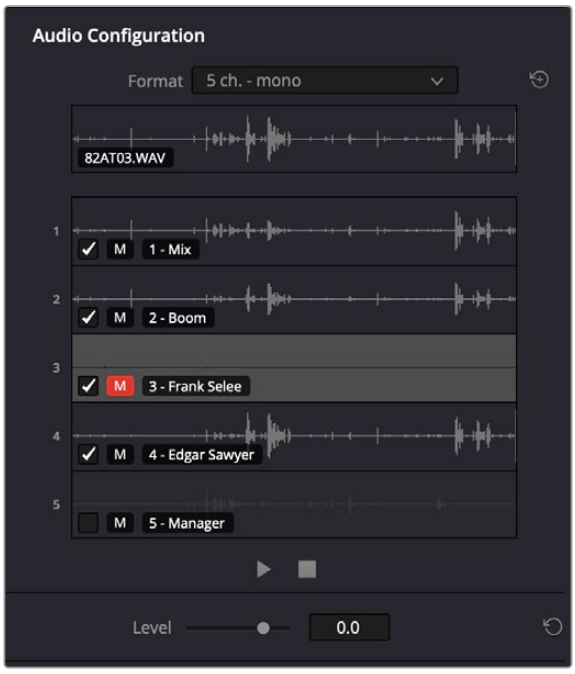
  Scene: The Scene number of the clip.

  Shot: The Shot letter/number of the clip.

  Take: The Take number of the clip.

Good Take: This checkbox indicates if the clip is a good or circled take.

Clip Color: Assign a specific color to a clip that is reflected in the Timeline.



Name: This can be entered manually and changes a clip's name in that specific timeline only.

Comments: Add a text description to the clip.

Auto Select Next Unsorted Clip: When this box is checked, the next clip in the Media Pool is selected when you hit the Return button after entering a metadata field, and the cursor is automatically placed in the same field. This allows rapid sequential metadata entry without having to manually click to load each individual clip in the Media Pool. The Next Clip button will select the next clip in the Media Pool, regardless of the checkbox status.

Audio Configuration

The File tab in the Inspector now has an Audio Configuration pane that handles the controls that were formerly handled by Clip Attributes in the Media Pool (though that option is still available). The Audio Configuration pane provides a more intuitive and visual way of changing the track properties of an audio clip. Simply click on an audio clip in the Media Pool or Timeline, and then on the File Inspector to reveal this interface.

The Audio Configuration panel. Track 3 has been muted and Track 5 has been disabled.

The pane features a per-channel waveform display for all tracks within a multichannel audio file. If the tracks have been named in the audio recorder, these names will appear over their respective tracks as well. The Audio Configuration panel can preview up to 36 tracks of audio.

At the top of the pane, a composite waveform is shown of all the tracks and is updated depending on the mute status of individual tracks. By default this composite is heard when the Play button is activated, and all channels are audible.

A format menu allows you to choose common configurations for your source audio file without cumbersome manual re-routing. Custom routing can still be accommodated by choosing custom in the drop-down, which brings up the older clip attributes for situations that require less common configurations.

Audio for a selected source or timeline clip can be played or skimmed by moving the cursor along the waveform, and the specific track is solo'ed when skimming or playing. The play position or track being monitored can also be switched dynamically during playback. For example, you can start playback on Track 1, then simply click on Track 2, and the playback continues from that position. These controls let you quickly skim through and identify exactly what audio is on which track for further adjustment.

Each track has two adjustments that can be made, an Enable/Disable checkbox and a Mute button.

Enable/Disable: Enabling a track makes that track available for use in editing operations. Disabling a track removes that track from use in editing operations. For example, if you disable Track 2 of a 4-track audio file, when you drag that audio file from the Media Pool into the timeline, only 3 tracks (1, 3, and 4) will come over.

These adjustments can only be made on Media Pool clips; audio clips already in the timeline will have these options disabled.

Mute: Clicking this icon will mute the track, so it is unheard, but leave the actual track in place when used in editing operations and dragged into the timeline. Option-clicking a Mute button on a channel will allow you to solo by muting all other channels.

Underneath the track layout is a simple transport control comprised of Play and Stop buttons to start and stop audio playback.

Adjusting Trim Levels of Individual Channels in a Source File

The level of individual source clip channels in the audio inspector can be be adjusted via a trim control. This allows source clip audio in one channel to be brought up in level, or brought down in level as needed.

The trimmed level is internal to the source clip in the Media Pool and will be inherited whenever that source clip configuration is used on a timeline, unless it is changed.

NOTE: The trim level is totally separate from clip gain in the timeline. Be aware that trimmed levels can clip if you move them too high.

Using the Trim slider

1. Select one or more channels in the Audio Configuration section of the File Inspector.
2. Adjust the Level slider at the bottom to the desired audio level.

The waveform will adjust dynamically to the level value and will display a trimmed value in dB in the channel itself. If you have multiple lanes selected, all channels will be trimmed together. Relative levels are not stored, so if you adjust one, it will then force any others in the selection to match. When no channel lanes are selected, the Level control is grayed out.

You can adjust the trim levels of individual audio channels in a multichannel clip.

Multiple Clip Selection and Adjustments

You can select multiple audio clips and adjust their properties in the Audio Configuration pane. For example, you can select a group of audio files and remove Track 2 from all of them at once. However, the following should be noted:

- In a multiple clip selection, only the last selected clip will appear in the track layout of the Audio Configuration pane. However, the top composite waveform will be named “Multiple Clips” to let you know that more than one clip has been selected.
- Any adjustments, like muting or enabling/disabling a track, will be applied to all the selected clips at once.

Timecode

The File tab in the Inspector now has a Timecode pane that handles the types of controls that were formerly handled by Clip Attributes in the Media Pool (though that option is still available). Here you can override the timecode details for a clip or clips in the Media Pool.

- **Current Frame:** Lets you assign a new time for the timecode at the currently viewed frame of the clip.
- **Slate:** In situations where source media comes from a shoot where a timecode slate was used during the shoot, then you can assign the slate timecode as a second timecode track that can be used for various operations, without changing the primary timecode of the clip, which may already be in use for program sync.

  To set appropriate Slate timecode, select a clip in the Media Pool with a visible timecode slate, and move the playhead to a frame where the timecode in the slate is clearly readable. Then, open the Timecode panel of the Clip Attributes window, and type the timecode value you see in the image into the Slate Timecode field.
- **Offset Source:** If an entire set of clips has timecode that’s merely offset, you can correct the timecode offset for as many selected clips as you like.

Chapter 38

Video and Audio Effects in the Cut Page

As you build your edit, you'll often find it necessary to add effects to clips to create titles, blend clips together with compositing, add plugins to give clips a particular look, speed clips up or slow them down, or transform clips to zoom into them or move them around the frame. The Cut page has controls to accomplish all of this and more.

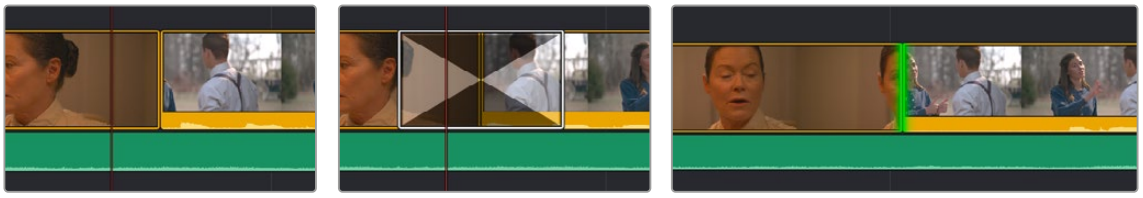
Adding Transitions

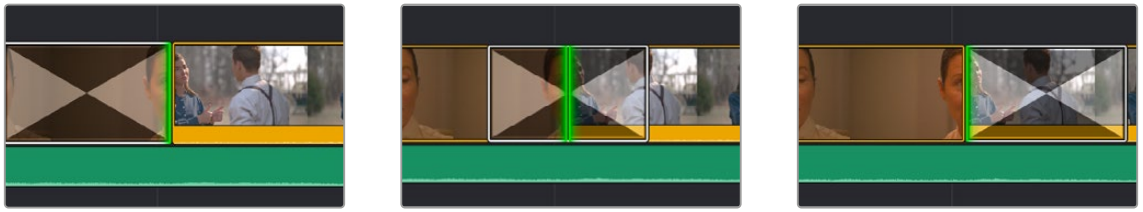


You can add transitions such as dissolves or wipes to an edit to indicate a change of topic, a change of location, or the passage of time. You can also add a Smooth Cut transition to patch unwanted cuts in interview clips or other situations where there's not a significant change in the position of the subject or background in the frame. Three buttons, at the bottom right of the Media Pool, make it easy to add and remove dissolves and Smooth Cut transitions.

The Cut, Dissolve, and Smooth Cut buttons

Adding Dissolves

Dissolves are the most standard and ubiquitous type of transition, and so they're the easiest to create. Place the playhead on or near an edit you want to turn into a dissolve, and click the Dissolve button at the bottom left of the Media Pool. A one second Cross Dissolve will be added to the edit point that's nearest to the edit point.



(Left) Moving a playhead near an edit point, (Middle) Adding a dissolve (Right) A selected edit point

Adding Dissolve Using Keyboard Shortcuts

You can also add a dissolve by selecting one or more edit points (or moving the playhead near an edit you want to select and pressing V to select the nearest edit point), then pressing Command-T to add a dissolve, which is the standard transition.

You can also add a transition that's aligned with the beginning, middle, or end of the edit point using the keyboard. To do so, select an edit point, press the U key repeatedly to cycle among selecting the start, center, or end of the edit, then press Command-T to add the standard transition. The standard transition will be added with its alignment based on the edit selection you made; selecting the start of the edit places a transition that ends on the edit; selecting the end of the edit places a transition that starts on the edit, and choosing the center of the edit places a transition that is similarly centered.

A transition that's aligned with the beginning, center, and end of an edit point

Changing a Transition to a Cut

To remove a dissolve, thereby changing a transition to a cut, move the playhead at or near the edit with the dissolve, and click the Cut button, which is fast to do when you're using the DaVinci Resolve Editor Keyboard which has a dedicated Cut button.

TIP: Alternately, you can select one or more transitions in the Timeline and press the Delete key to remove them.

Adding Smooth Cuts

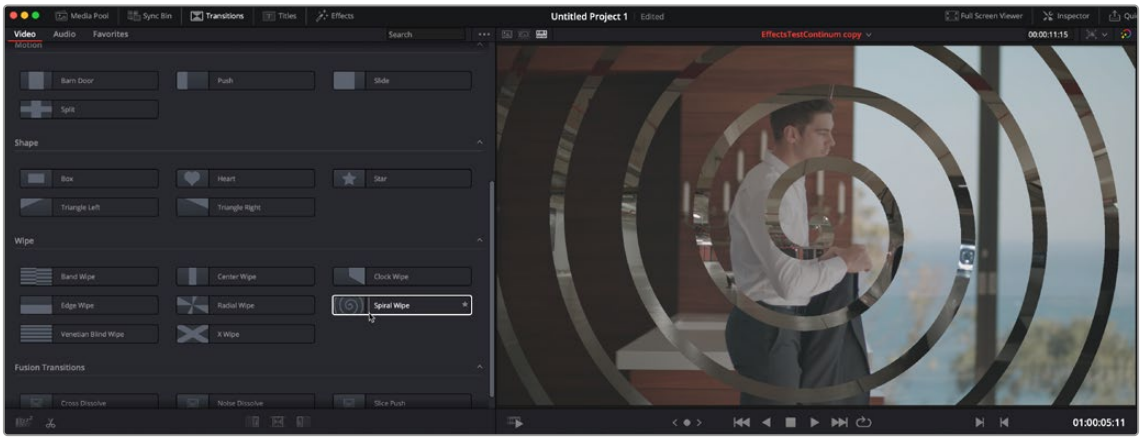
Smooth Cuts are special-purpose transitions designed to make short jump cuts in the middle of a clip unnoticeable. This is done by using AI powered Speed Warp processing to match the same features on either side of a cut in order to automatically morph a subject from one position to another over the duration of the transition.

To add a Smooth Cut:

1. Place the playhead on or near an edit.
2. Click the Smooth Cut button at the bottom left of the Media Pool. A one second Smooth Cut will be added to the edit point that's nearest to the edit point.

A Mode dropdown menu provides two options: Faster and Better. The Better option is default, with excellent quality and the capability of preserving the motion of subjects for the duration of the transition. The Faster option morphs between stills of the outgoing and incoming frames. In most practical circumstances, the Better mode will give you a superior result, but certain cuts or effects may be better addressed with the Faster option.

The Smooth Cut effect works best on clips such as sit-down interviews and close-up head shots with a minimum of background and subject motion, and where the subject's position on either side of the cut is not significantly different. A good example of when Smooth Cut is effective is when you're cutting pauses, partial repeats, filler sounds such as "um" or "you know," or other speech disfluencies out of an interview clip to tighten the dialog, and you want to eliminate the little "jump" that occurs at the cut without having to cut away to B-roll. Applying a short two or four frame Smooth Cut transition to the edit can make this kind of edit invisible, as long as the speaker doesn't change position significantly during the cut. The more motion there is in the background of the shot, and the more the speaker changes position, the harder it will be to get a useful result using Smooth Cut. Although the default duration for any transition is one second, you'll find that Smooth Cut transitions may work much better when they're short; 2- to 6-frame Smooth Cut transitions often work best to disguise jump cuts.



NOTE: As of DaVinci Resolve 20, Smooth Cut uses a new AI powered Speed Warp to perform the transition. If you would prefer to revert to the older optical flow version, simply uncheck the Speed Warp box in the Transition inspector.

Adding Other Kinds of Transitions

In order to make the selection of transitions, titles, and effects more intuitive, DaVinci Resolve shows each effect as a thumbnail representation in addition to the text name. This allows the user to quickly scan through all the numerous options to select the appropriate effect visually, rather than remembering them based on name alone. You can preview transitions and titles before you place them on the Timeline to quickly audition multiple options before making your final decision.

Transitions Thumbnails

To preview a transition before you place it into the Timeline, ensure that “Hover Scrub Preview” is checked in the Transitions option menu, then simply hover your pointer over any transition in the Transitions tab and move it across the thumbnail. The transition will preview in the Viewer using the two clips nearest the Smart Indicator in the Cut page, or the two clips nearest the playhead in the Edit page.

Scrubbing over a Transition Thumbnail previews the transition in the Viewer.

Once you’ve chosen your transition, it can be applied by to any edit point by using the methods below:

Methods of adding different transitions:

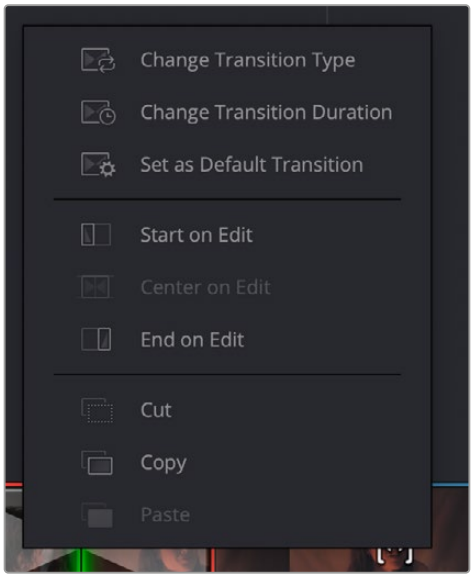
- **To add a transition by dragging it from the Transitions Browser:** Drag a video transition from the Effects Library to an edit point in the Timeline so that it’s centered at, ends at, or starts at the edit point. If there is no overlap between the heads and tails of the two clips, you may not be able to add a transition where you want.
- **To add a transition using the Transitions Browser’s contextual menu:** Select one or more edit points (one per track), then right-click a video transition in the Effects Library and choose Add to Selected Edit Points and Clips. That transition will be added to every selected edit point at once.
- **To add a transition by double-clicking in the Transition Browser:** You can double-click a transition in the Cut page’s Transitions Browser to apply it directly to the edit point referenced by the Smart Indicator.
- **To add a transition by using the transition alignment icons in the Transition Browser:** You can double-click on one of three transition alignment icons at the bottom of the in the Cut page’s Transition Browser.
- **To add a transition to all edit points on a timeline:** Click on the Timeline Actions menu and select Add Transition to All Edits. This will add the last used transition to all the edit points on a timeline.

Favorited Transitions

Any transitions you’ve marked as favorites (either by clicking on the star icon on its thumbnail or by selecting Add to Favorites from the contextual menu) can be accessed in the Favorites tab of the Effects library.

Editing and Removing Transitions

Once you've added a transition, you can edit it in a number of different ways to work best for your program, both in the Timeline and in the Transition Inspector.



Methods of editing transitions in the Timeline:

- **To change a transition's duration:** Drag the beginning or end of a transition in the Timeline to be longer or shorter symmetrically about the current edit.
- **To move a transition from one edit to another:** You can drag a transition from its current position to another edit point.
- **To copy a transition from one edit to another:** Select a transition, then option-drag it to another edit point to add a duplicate transition.
- **To change a transition's type:** Drag a different transition from the Transition Browser onto the current one in the Timeline.
- **To remove a transition:** Select a transition in the Timeline and press the Delete key.
- **To remove all transitions in a timeline:** Click on the Timeline Actions menu and select Clear Transition from All Edits.

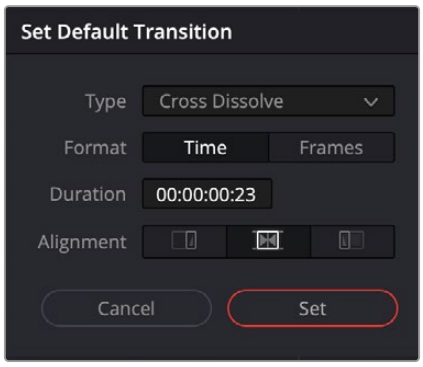
Editing transitions in the Transition Contextual menu:

You can edit the parameters of your transition, directly in the Timeline, by right-clicking on the transition and selecting one of the options from the contextual menu.

- **Change Transition Type:** You can change to any other installed transition by selecting one in the drop-down menu.
- **Change Duration:** Set the duration of the transition, shown in both seconds and frames.
- **Set as Default Transition:** Sets the currently selected transition as the Default Transition.
- **Alignment Options:** Lets you choose the transition's position relative to the edit point it's applied to. Your choices are "Start on Edit," "Center on Edit," and "End on Edit."
- **Cut/Copy/Paste:** Standard cut, copy, and paste controls for editing transitions in the timeline.

Right-clicking on a transition in the Timeline gives you the editing options above.

Editing transitions in the Transition Inspector:



For more detailed control over your transition, including modifying all transition-specific parameters, use the Transition Inspector.

For more information on each specific transition included in DaVinci Resolve, jump to chapter: Using the Inspector in the Cut Page

Setting the Default Transition

By default, the default transition is a simple cross dissolve. If you wish to change that transition to another one, simply right-click on a transition thumbnail and select Set as Standard Transition from the contextual menu.

You not only change the Default Transition type but also its duration and alignment from either the Timeline Options menu, or by right-clicking on the transition in the Timeline and selecting "Set Default Transition."

Changing the Default Transition

Titles

There's a collection of title clips in the Titles Browser that you can use to add superimposed titles, slates, interstitial titles, lower thirds, or otherwise fulfill any textual needs your program has.

Titles Thumbnails

To audition titles before you place them into the Timeline, ensure that "Hover Scrub Preview" is checked in the Titles option menu, then simply hover your pointer over any thumbnail in the Titles tab. If the title is animated (i.e., Fusion titles), moving the pointer across the thumbnail will preview the animation. Once you've chosen your title, you can drag it from the Titles tab to your Timeline in the Edit page or in the Cut page to either the upper or lower Timelines, or use the editing selection modes at the bottom of the tab.

Two categories present two different kinds of titles. The "Titles" category presents simple, bare-bones titles that you can customize in a variety of different ways. Of the available options, the Text title is the most flexible. The "Fusion Titles" category presents more complicated titles that are more visually sophisticated and have more preset animation.

Scrubbing over a Title Thumbnail previews the title in the Viewer.

Adding Titles

You can add a title to the Timeline by opening the Titles Browser and dragging and dropping titles into the Timeline wherever you want them to be, just like any other clip. The default duration of a title clip is 5 seconds. This standard “generator” duration can be customized in the Editing panel of the User Preferences.

Once edited into the Timeline, titles can be moved, resized, and superimposed much like any other clip. Furthermore, when selected, both titles and generators expose the same Transform, Cropping, Speed, and Composite controls as any other clip; these controls can be used to composite titles in various ways to create different text effects.

Editing Titles

Once you add a title to the Timeline, the original title generators that shipped with DaVinci Resolve have onscreen controls that let you edit text and transform and position blocks of text directly within the Timeline Viewer.

Positioning and Transforming Text

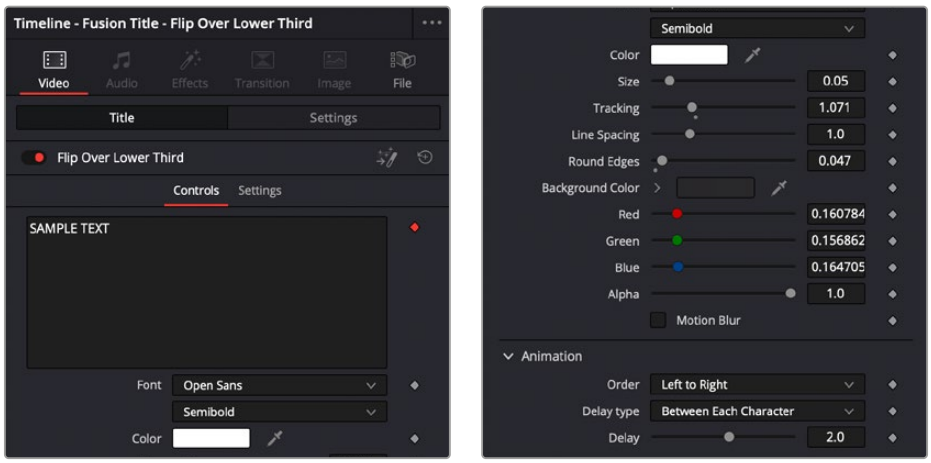
So long as the Timeline playhead is positioned over a text generator that’s on top of one or more background clips, clicking on the text in the Timeline Viewer reveals onscreen transform controls that correspond to the Position, Zoom, and Rotation parameters in the Inspector.

Transforming a title’s text box in the Viewer

While dragging text to reposition it, snapping occurs at the X and Y center of the frame, as well as around the outer third of the frame. Holding the Shift key down while dragging a text object constrains movement to just the X or Y axes. Holding the Option key down turns snapping off.

Editing Text

Double-clicking on text in the Timeline Viewer puts that text into an editable state, wherein you can insert a text cursor or select characters to edit the text as you would in any text editor.



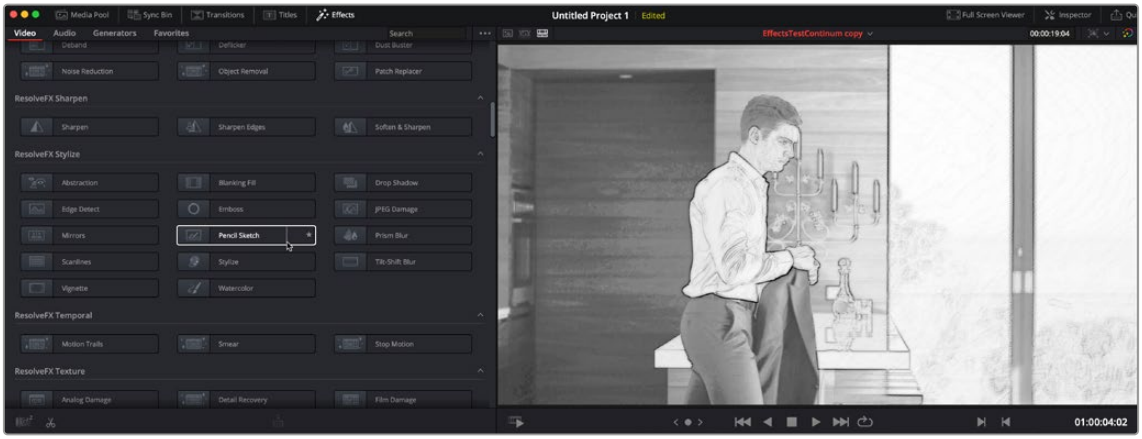
Editing the text of a title in the Viewer

Editing Titles Using the Video Inspector

For more precise control of your titles, double-clicking on any title will bring up its parameters in the Video Inspector. Here you can change fonts, colors, drop shadows, backgrounds, etc. You can also adjust basic transform parameters and cropping as well.

> For more information on Editing Titles, jump to chapter: Titles, Generators, and Stills.

The Title settinµgs of Video Inspector



Adding Resolve FX and Other Plugins

The Effects Browser reveals video and audio plugins that you can drag and drop onto to your clips. As far as video plugins go, there are several categories of Resolve FX plugins that accompany DaVinci Resolve, but if you've installed Resolve-compatible OFX plugins, those appear here as well, organized into their own categories. For audio plugins, a set of Fairlight FX plugins comes with DaVinci Resolve, but if you've installed VST plugins on macOS or Windows, or you have Audio Units installed on macOS, those will appear in the Audio category also. When you have a lot of video or audio plugins, a search field makes it easy to find the one you're looking for.

Video Effects

Each available category of video plugins creates different sorts of image effects, such as blurs, lighting effects, or stylization of different kinds. To preview a video effect before placing it on a clip, ensure that "Hover Scrub Preview" is checked in the Effects option menu, then simply hover your pointer over any thumbnail in the Effects tab and move it across the thumbnail. The effect will preview in the Viewer using its default parameters, and scrub through the clip that is selected in the Timeline. If no clip is selected then it will use the clip currently under the playhead.

To activate a specific video effect on a clip, simply drag the thumbnail of the selected effect to a clip on the Timeline. In the Cut page, you can also double-click the thumbnail to apply the effect to the selected clip. To adjust the effect's parameters, open the Effects tab in the Inspector.

Scrubbing over an Effect Thumbnail previews that effect in the Viewer.

Audio Effects

Audio plugins let you process your audio in different ways, adjusting the tone using equalization, changing dynamics with compression, or adding effects such as echo, reverb, flange, or modulation. To activate a specific audio effect on a clip, simply drag the thumbnail of the selected effect to a clip on the upper or lower Timelines in the Cut page, or onto a clip in an audio track on the Edit page. Once the effect has been dropped on a clip, its audio plugin controls will open for you to adjust the plugin's parameters.

Generators

The various video generators included in DaVinci Resolve can be previewed by hovering your pointer over any thumbnail in the Generators tab. To edit a generator into your Timeline, simply grab the thumbnail of the generator you wish to use, and place it in your Timeline in the Edit page, or in either the upper or lower Timelines in the Cut page.

For more information on using all the included video and audio effects in DaVinci Resolve, jump to chapter: Editing, Adding, and Copying Effects and Filters.

Interactive Resolve FX and Fusion Effect Overlays in the Viewer

If you've applied a Resolve or Fusion effect that uses on screen controls, you can use these controls in the Cut Page viewer. To do so, open the Tools panel in the Cut page, and select the Effects Overlay icon at the far right.

You have two options below to either manipulate the Open FX or Fusion Overlays; choose the appropriate version for your effect. The on screen controls will then appear in the Viewer.

Clicking on the Effects Overlay icon (circled) will activate the on screen controls of Resolve or Fusion effects in the Cut Screen viewer.

Clip Tools

Clicking the Tools button in the Viewer toolbar opens up additional categories of controls that let you apply various effects to the current clip, or adjust whatever effect is already applied to the current clip. Many of the parameters of these effects have corresponding onscreen controls that let you make visual adjustments directly in the Viewer.

The Tools button

Shared Controls

Every category of effect at the bottom of the Viewer has two shared controls. A toggle control at the far left lets you enable or disable an effect without losing whatever custom adjustments you've made. A reset control at the far right lets you reset every parameter within a particular category of controls to the default settings.

The Toggle button (at left) and Reset button (at right)

Transform

When you select Transform, onscreen transform controls appear that let you directly manipulate the image in the Viewer. You can drag anywhere within the clip's bounding box to adjust pan and tilt, drag any diagonal corner to proportionally resize, drag any top/bottom/left/right side to squeeze or stretch width or height, or drag the center handle to rotate.

Onscreen Transform controls in the Viewer

TIP: While dragging a clip using the onscreen controls to reposition it, holding the Shift key down constrains movement to just the X or Y axes.

The onscreen controls also correspond to the following editable parameters, which are also editable in the Video Inspector and in the Edit Sizing mode of the Sizing palette in the Color page:

Zoom Width and Height: Allows you to blow the image up or shrink it down. The X and Y parameters can be linked to lock the aspect ratio of the image, or released to stretch or squeeze the image in one direction only.

Position X and Y: Moves the image within the frame, allowing pan and scan adjustments to be made. X moves the image left or right, and Y moves the image up or down.

Rotation Angle: Rotates the image around the anchor point.

Pitch: Rotates the image toward or away from the camera along an axis running through the center of the image, from left to right. Positive values push the top of the image away and bring the bottom of the image forward. Negative values bring the top of the image forward and push the bottom of the image away. Higher values stretch the image more extremely.

Yaw: Rotates the image toward or away from the camera along an axis running through the center of the image from top to bottom. Positive values bring the left of the image forward and push the right of the image away. Negative values push the left of the image away and bring the right of the image forward. Higher values stretch the image more extremely.

Flip Image: Two buttons let you flip the image in different dimensions.

- **Flip Horizontal control:** Reverses the image along the X axis, left to right.
- **Flip Vertical control:** Reverses the clip along the Y axis, turning it upside down.

Crop

The Cut page has a set of onscreen controls you can use to directly crop the image in the Viewer. Each side of the image has an individual handle for cropping just that side. These parameters are also editable in the Video Inspector and the Color page Sizing palette.

Onscreen Crop controls in the Viewer

The Crop effects also correspond to an additional set of cropping parameters, with an additional control for softness:

Crop Left, Right, Top, and Bottom: Lets you cut off, in pixels, the four sides of the image. Cropping a clip creates transparency, so whatever is underneath shows through.

Softness: Lets you blur the edges of a crop. Setting this to a negative value softens the edges inside of the crop box, while setting this to a positive value softens the edges outside of the crop box.

Dynamic Zoom

The Dynamic Zoom controls, which are off by default, make it fast and easy to do pan and scan effects to zoom into or out of a clip. A set of two onscreen controls let you create a Dynamic Zoom effect. A green box shows the starting size and position of the animated transform, while a red box shows the ending size and position of the animated transform. Drag anywhere within either bounding box to reposition either the start or the end of the animated effect, and drag any of the corners to adjust the size at the start or end. A motion path appears to show you motion that's being created. Adjusting the Dynamic Zoom controls automatically enables dynamic zoom. These controls are also available in the Video Inspector.

Dynamic Zoom controls in the Viewer

These controls correspond to two parameters in the toolbar (Dynamic Zoom is also editable in the Video Inspector).

Zoom/Pan/Angle Presets: Let you enable or disable preset positions for the zoom level, pan location, and angle of this effect.

Swap: This button reverses the start and end transforms that create the dynamic zoom effect.

Ease Buttons: Lets you choose how the motion created by these controls accelerates. You can choose from Linear, Ease In, Ease Out, and Ease In and Out.

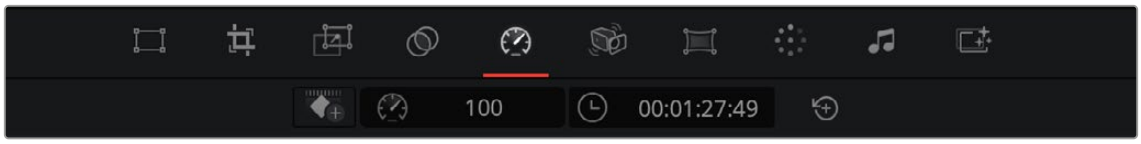
TIP: While dragging dynamic zoom outlines to reposition them, holding the Shift key down constrains movement to just the X- or Y-axis.

Composite

Two controls let you create transparency and use composite modes to create different compositing effects (also called Blend modes or Transfer modes). These controls also editable in the Video Inspector.

Composite controls in the Viewer

Composite Modes: Composite modes blend two superimposed clips together on the Timeline using different kinds of math to achieve differing results, to create transparency effects, increase image exposure, and combine multiple clips into a single image in many creative and useful ways. All Composite modes interact with the Opacity slider.



For more information on what each Composite mode does, jump to chapter: Compositing and Transforms in the Timeline.

Opacity: This slider lets you make a clip more transparent, over a range from 0 (totally transparent) to 100 (totally opaque). When set to a value less than 100, the selected clip is mixed with whatever video clip is underneath it on the Timeline, using the Composite mode that's currently selected. If no clip appears underneath the Timeline, then the clip is mixed with black and will work similarly to a fade.

TIP: If a superimposed video or still image clip in the Timeline has an alpha channel, that alpha channel automatically creates transparency within that clip, compositing it against whatever is in the track underneath. There's no need for you to do anything for this to work.

Speed

Speed effects let you speed up, slow down, or otherwise change the playback speed of clips in the Timeline. When you change the speed of a clip, that clip's duration also changes to reflect a shorter clip that plays faster, or a longer clip that plays more slowly. Speed effects change both video and audio playback, but the audio of sped up or slowed down clips is always pitch corrected. Speed effects applied in the Cut page also appear and are editable via several different methods in the Edit page timeline and the Video inspector.

Speed Effects controls in the Viewer

Add Speed Point: Lets you add a speed change point at the playhead position for speed ramping effects.

Speed: Changing this value lets you speed up or slow down playback by a simple numeric multiplier. You also have the option of choosing a negative value to create reverse speeds.

Duration: When you retime a clip, the Duration field lets you see how the change you're making affects the new duration based on the original duration of the clip with no speed effect applied.

Stabilization

The Image Stabilization controls use warping and/or translation to let you smooth out or even lock unwanted camera motion within a clip. The analysis is performed in such a way as to preserve the motion of individual subjects within the frame, as well as the overall direction of desirable camera motion, while correcting for unsteadiness.

Stabilization controls in the Viewer

To stabilize an image, all you need to do is to choose a Stabilization Method from the drop-down (see below for more information), and then click the Stabilize button. DaVinci Resolve analyzes the current clip, and applies a stabilization effect.

The rest of the stabilization controls let you refine the result. Whenever you adjust any of these parameters, you must click the Stabilize button again for the effect to be updated.

Stabilization Method: A drop-down menu provides three different options that determine how the selected clip is analyzed and transformed during stabilization. You must choose an option first, before clicking the Stabilize button, because the option you choose changes how the image analysis is performed. If you choose another option, you click the Stabilize button again to reanalyze the clip.

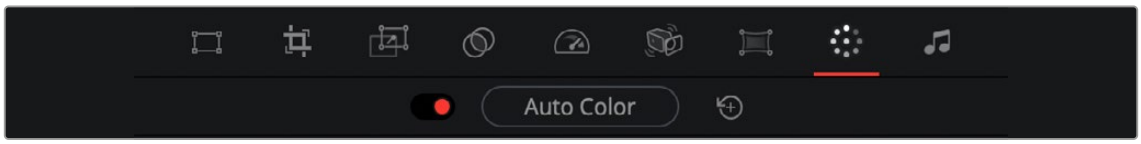
- **Perspective:** Enables perspective, pan, tilt, zoom, and rotation analysis and stabilization.
- **Similarity:** Enables pan, tilt, zoom, and rotation analysis and stabilization, for instances where perspective analysis results in unwanted motion artifacts.
- **Translation:** Enables pan and tilt analysis and stabilization only, for instances where only X and Y stabilization gives you acceptable results.

Stabilize: Clicking this button on a previously unstabilized clip analyzes the motion in that clip and applies an initial smoothing effect. Clicking this button on a clip that's already been analyzed lets you recalculate a modified stabilization effect.

TIP: These controls are identical to those found in the Video Inspector and the Color page Tracker palette, and populate the same image processing data. This means that you can use the Stabilization found on the Cut page, and then use the stabilization graph and controls found in the Color page to refine the results, if necessary.

Lens Correction

Lens Correction presents two controls that let you either correct lens distortion in the image, or add lens distortion of your own for effect. These controls are also editable in the Video Inspector and Color page Edit Sizing palette.



Lens Correction controls in the Viewer

Analyze: Automatically analyzes the frame in the Timeline at the position of the playhead for edges that are being distorted by wide angle lens. Clicking the Analyze button moves the Distortion slider to provide an automatic correction. If you're analyzing a particularly challenging clip, a progress bar will appear to let you know how long this will take.

Distortion: Dragging this slider to the right lets you manually apply a warp to the image that lets you straighten the bent areas of the picture that can be caused by wide angle lenses. If you clicked the Analyze button and the result was an overcorrection, then dragging this slider to the left lets you back off of the automatic adjustment until the image looks correct.

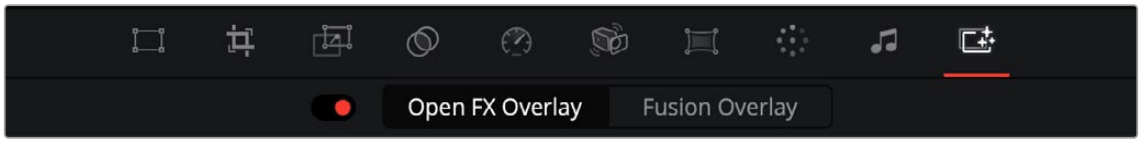
Color

The Color section of the Tools consists of only one option: Auto Color. The Auto Color command provides a quick way to automatically balance the blacks and whites of a clip based on the current frame at the position of the playhead. Using advanced algorithms, based on the DaVinci Neural Engine, it provides superior results when automatically adjusting color balance and contrast.

Color controls in the Viewer

For more details on using Auto Color, jump to chapter: Automated Grading Commands and Imported Grades.

Audio



A slider lets you adjust audio levels of the current clip in the Viewer, making the volume of that audio clips softer or louder. This is identical to each clip's volume setting in the Edit and Fairlight pages.

Audio controls in the Viewer

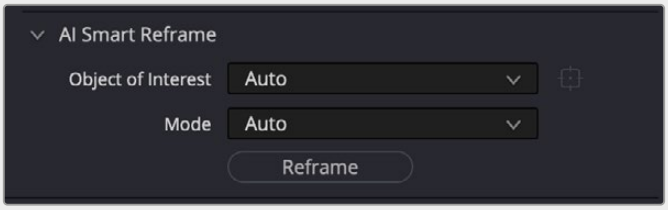
Effects Overlay

Turning on either Open FX or Fusion overlays lets you use the on screen viewer controls for those effects that use them.

The Effects overlay activates the on screen viewer controls for effects.

Smart Reframe (Studio Version Only)

The Smart Reframe feature in DaVinci Resolve makes it easier to quickly reframe material across extreme aspect ratio changes. It's useful for situations where you've shot a 16:9 horizontal video and find yourself needing to create a vertically-oriented 9:16 version for mobile phones and social media deliverables or using 4:3 archival footage in a 2.39:1 widescreen movie. Smart Reframe can be used manually or automatically executed using the DaVinci Resolve Neural Engine.

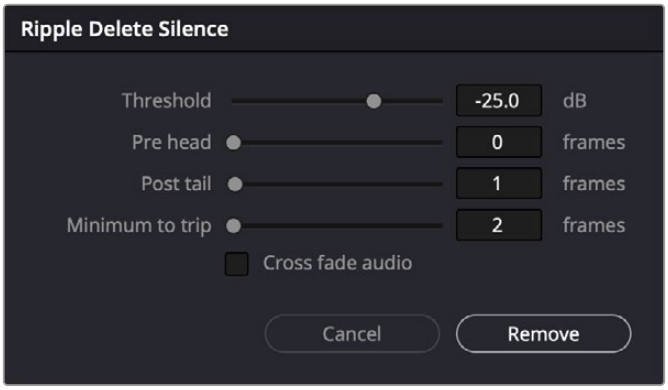


Smart Reframe in action with the Reference Point bounding box active (right)

The Smart Reframe tool is found in the Video tab of the Inspector and is available in both the Cut and Edit pages.

To use the Smart Reframe tool:

1. Duplicate your Timeline, right-click the Timeline and choose Timelines > Timeline Settings, and click Use Custom Settings to change the Timeline Resolution to the aspect ratio needed for delivery. Make sure that "Mismatched resolution files" is set to "Scale full frame with crop," and click OK.
2. Select one or more clips you want to reframe, and open the Inspector to the Video tab.
3. Open the Smart Reframe controls, leave the Object of Interest drop-down menu set to Auto (if you've selected more than one clip, Auto is the only setting available), and click "Reframe." DaVinci Resolve will analyze your footage and should automatically adjust each individual clip's position to a more aesthetically pleasing framing.
4. (Optional) If the "Auto" setting does not give you desirable results for a particular clip, you can manually select the main subject using the following steps:
    a) To manually select the subject area, choose "Reference Point" from the Object of Interest drop-down menu, and click the Target icon just to the right of the menu. This automatically sets the Viewer mode to Smart Reframe, exposing the onscreen controls for choosing a reference.
    b) Drag the Reference Point bounding box around the main subject of interest in the frame. You may use the Transform controls directly above in the Inspector to move the source clip around if your subject is outside the current framing.
5. (Optional) If you want to limit the AI to only reframing on one axis, you can select either Pan Only, or Tilt Only from the Mode selector.
6. Click Reframe.



The Inspector's Smart Reframe controls showing the manual reference point selected

DaVinci Resolve locks onto and, if necessary, tracks your subject using the reference you've selected, automatically panning and scanning the original clip as needed to keep the reference within the new aspect ratio. While involving a bit of manual adjustment, this function still dramatically reduces the time involved in pan and scanning footage by manually adjusting and keyframing the sizing controls.

Ripple Delete Silence for Selected Clip

You analyze and remove silences from a selected clip on the Edit or Cut page timeline, using the similar tool found in Fairlight. By selecting a clip, and choosing Clip > Audio Operations > Ripple Delete Silence, you can open the Ripple Delete Silence dialog.

- **Threshold:** This determines the maximum signal level of your audio (in dB) that will be recognized as silence. Audio signals below the threshold value will be treated as silence and removed. Higher threshold values result in more audio being removed.
- **Pre Head:** Sets the amount of silence or pre-roll before each audible section.
- **Post Tail:** Sets the amount of silence or post-roll after each audible section.
- **Minimum to Trip:** This parameter determines the minimum amount of silence (in frames) to be stripped from selected timeline clips. Higher values leave more silent sections in the audio. Lower values will result in more strips, but you may find that some of the remaining audio sounds "chopped up" because it abruptly cuts off.
- **Crossfade audio:** Performs a simple crossfade to the remaining audio clips to smooth out the sound if your head and tail settings permit enough length.

The Ripple Delete Silence dialog

To remove *silences* from a timeline clip:

1. Select a clip on a track.
2. Choose Clip > Audio Operations > Ripple Delete Silence.
3. The appearance of the selected audio will change to include vertical red stripes showing you the position and duration of the resulting silences based on the parameter values in the Remove Silence dialog.
4. Click Remove.

All the audio under the red stripes will be cut and removed with the remaining sections of the clip ripple deleted together on the timeline.

Voice Isolation (Studio Version Only)

Voice Isolation uses an AI model trained for any type of human voice, male or female, young or old, which lets you completely remove loud, undesirable sounds from existing voice recordings with incredible results.

The Voice Isolation plugin

You can get rid of all kinds of background noise, from air conditioners or fans to jackhammers, restaurant background noise, music playing during a featured piece of dialogue, and more.

The Amount control adjusts the mix between the original source and the isolated voice. When set to 50, the mix is roughly equal. Values between 70 and 80 work well for natural results while strongly isolating the source.

Although Voice Isolation can be used on an audio track in real time, it cannot be used on live audio input. It can be used on any mono, stereo, or dual-mono audio track, but it isn't supported on tracks with more than two channels.

Dialogue Leveler

The Dialogue Leveler analyzes source material to detect dialogue and then “rides down” louder areas, “lifts up” softer areas, and lowers background sounds that are not dialogue.

It works without the typical “pumping” or other unwanted side effects of dynamics processors (compression/limiting) to produce results like those achieved through detailed, manual clip gain adjustments or “riding” the track with fader automation.

The Dialogue Leveler can often “fix and mix” a recording made with a single boom mic, where one character is closer than another or turns away from the mic. The Dialog Leveler levels it out so that the original relative dynamics are preserved while increasing intelligibility and average level.

The Dialogue Leveler plugin

Although Dialogue Leveler can be used on an audio track in real time, it cannot be used on live audio input. It can be used on any mono, stereo, or dual-mono audio track, but it isn’t supported on tracks with more than two channels.

Dialogue Leveler controls

- **Dialogue Leveler:** Enables or disables the plugin.
- **Waveform Processing display:** This shows a scrolling waveform and a gray line indicating Dialogue Leveler processing. However, this display is not available when using the Dialogue Leveler found in the Inspector to process audio clips on the timeline.
- **Preset Menu:** This menu provides the following options:

  Allow wider dynamics: This is the default and is best for audio with a wider-ranging dynamic from loud to soft, and where the clip levels are medium to high.

  More lift for low levels: Select this option if the source has more low-level dialogue that you want to boost.

  Lift soft whispery sources: Select this option if the source has whispered dialogue and background noise.

  Optimize moderate levels: Select this option if the source is at medium levels throughout.

- **Reduce Loud Dialogue:** When enabled, louder dialogue is ridden downward when it peaks, acting like a “perfect limiter” where you don’t have to adjust the threshold or time parameters. Due to the “near real-time” functionality, analysis occurs prior to audible playback for optimal results.
- **Lift Soft Dialogue:** This setting finds and lifts low-level dialogue, evening out material that is quieter while more variable in level. Because the process is dialogue-focused, it doesn’t tend to raise background sounds unless they’re audible at the same time as the dialogue.
- The Lift Soft Dialogue option is often the most useful of the three options, as it makes quieter lines of dialogue louder and naturally smooth without boosting background noise.
- **Background Reduction:** This option gently removes background noise based on the internal preset selected in the Preset menu.
- **Output Gain:** You can use this control to adjust the output level by clicking and dragging it or entering a value in the numeric field. The range of the Output Gain control of 0.0 to +6.0 dB.

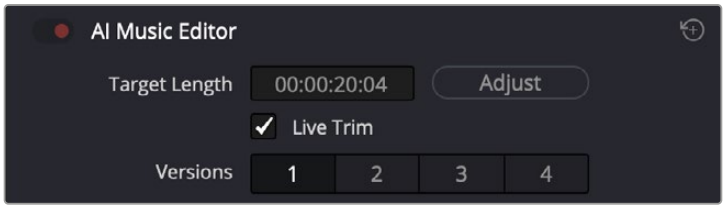
TIP: Before using the Dialogue Leveler on a track, it can be useful to set an optimum baseline level for use with the default “Allow wider dynamics” preset by normalizing the audio.

For more information on normalizing audio, jump to chapter: The Fairlight Inspector.

Music Remixer (Studio Version Only)

This DaVinci Neural Engine AI-based plugin splits music into individual stems: Vocals, Drums, Bass, Guitar, and “Other” (“everything else”), letting you creatively rebalance or remix the track.

You can use the level controls to adjust the volume of each stem and the Mute buttons to remove or bring them back into your mix. For example, you may want to remove or lower a vocal because it clashes with a featured piece of dialogue.



The Music Remixer plugin

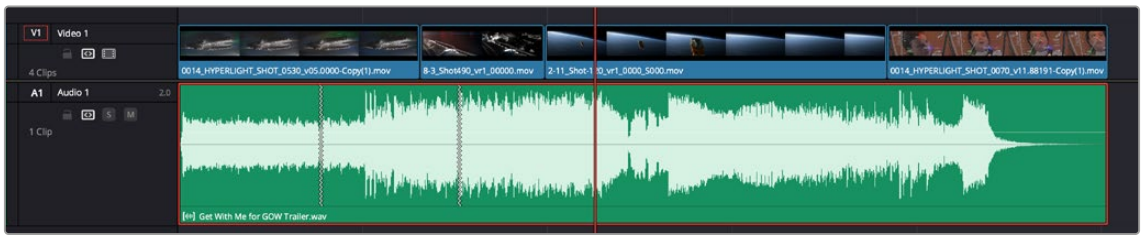
Music Editor (Studio Version Only)

DaVinci Resolve 20 supports seamlessly extending or shortening music to the length of your edit. The new AI powered Music Editor can be accessed in the Audio tab of the Inspector. You can enter a desired duration and press the Adjust button in order to shorten or extend the clip to that duration.

NOTE: Music Editor is an “intelligent edit” that works effectively with beat-driven music (pop, dance, etc.). It is not intended for free form, ambient or non-beat driven material.

Music Editor does not use time compression/expansion or alter the pitch of the music, but instead uses editing techniques like a music editor might to fit the material to desired length to picture. It will look for logical places to create transitions based on whether you’re extending length (by repeating sections), or removing material, and attempt to use the ending or fade of the original composition if it times well. If the ending is abrupt, it’s up to you to manually create a fade out.

The Music Editor in the Audio Inspector



To Use Music Editor to retime a music clip:

1. Select the clip on the timeline you wish to retime. This clip does need to be beat-driven music.
2. In the Audio Inspector under AI Music Editor, enter a new Target Length for the music duration you want.
3. Press the Adjust button.
4. Alternatively, you can check the Live Trim box to use the Trim tools to resize the clip and dynamically retime the music on the timeline. You can turn the checkbox off to return to normal editing (e.g., trimming) for that clip after the desired edit has been created.

Once the analysis is complete, four versions of potential edits you can use appear at the bottom, each with a different approach to the edit, numbered 1-4. Any subsequent editing can be done almost instantaneously. The edited pieces of music show indicators on the clip to mark the portions where cuts and transitions occur.

The initial music is too long

The Music Editor has retimed the audio clip to match the length of the video.
Note the jagged lines on the audio clip indicating where the original was cut.
In the waveform you can see the end of the music is retained in the retimed clip.

TIP: While timings can be quite close, sometimes they may not be exact. If you need to get an exact timing after working with AI Music Editor, you might use the Elastic Wave tool on the Fairlight page and choose the algorithm for general purpose (music).

The edited clip is actually a specialized Music Editor clip which allows you to further trim your edit. If you want to access the underlying edit, you can also right-click on the clip and decompose, exposing the edit points and any crossfades created. However, keep in mind that once decomposed, you can't trim the length of the clip as an entity as each editing snippet is now a separate clip.

Dialogue Separator Track FX (Studio Version Only)

Dialogue Separator uses DaVinci Neural Engine AI to give you individual control over the level of dialogue, background sounds, and the reverberant field or ambient room sound ("ambience").

The Dialogue Separator is useful when, for example, a source file has a great roomy sound, but there's music or crowd noise in the background. In this instance, you can rebalance the audio to reduce the background sounds or adjust the room sound to make the dialogue more intelligible.

Another use case would be when someone moves toward the camera in a roomy environment while speaking. You could use automation to rebalance the audio so that the ambient room sound gradually becomes "drier" as they get closer, without affecting the background.

Dialogue Separator is currently a mono-only plugin. If your source is stereo, you'll need to split it into dual-mono and process both mono tracks separately.

The Dialogue Separator plugin

Ducker Track FX

This plugin lets you use the audible signal from a track or multiple tracks to lower the level of another.

Although it can be used in many creative ways, a common use of “ducking” is automatically lowering a music or sound effects bed so that dialogue or a VO track can be heard more prominently in a mix.

This is achieved without compressing the incoming signals. When set up correctly in the Ducker interface or via the Audio tab in the Inspector, your audio tracks can practically “mix themselves.”

In a simple use case, the Ducker uses level changes of a single incoming dialogue or VO track to decrease the volume of the sound effects bed of a noisy freeway.

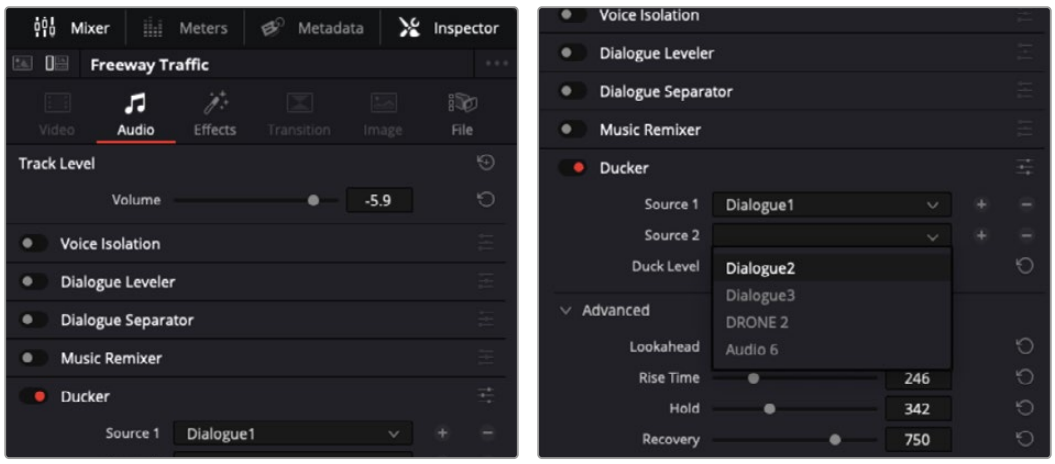
In a more complex situation, such as a scene where three characters are conversing next to the same noisy freeway, a single Ducker plugin can use the level changes of each dialogue track to attenuate the traffic noise.

With only one input source (Dialogue 1), the Ducker would only be effective when the first character speaks. However, this new feature lets you add the other two dialogue tracks (Dialogue 2 and Dialogue 3) as input sources for attenuating the traffic noise.

The Ducker plugin

Using the Ducker

Continuing with the use cases mentioned above:



1. Choose the target track that you want to attenuate (the Freeway Traffic track), and open the Ducker.
2. Click the Source dropdown and select Dialogue 1 as the input source.
    - To use additional input sources, Command-click the other track names; in this example, Dialogue2 and Dialogue3.
    - Play a bit of your sequence, and adjust the duck level and other controls to taste.

Adding Input Sources via the Inspector

If you prefer working within the Inspector:

1. Select the Freeway Traffic track, ensure the Ducker is switched on, and open the Inspector’s Audio tab.
2. Click the plus sign to the right of the Source 1 dropdown containing Dialogue1 to create a dropdown menu for Source 2, then choose Dialogue2 from the list.

3 Click the plus sign to the right of the Source 2 dropdown to create a dropdown menu for Source 3, then choose Dialogue3 from the list.

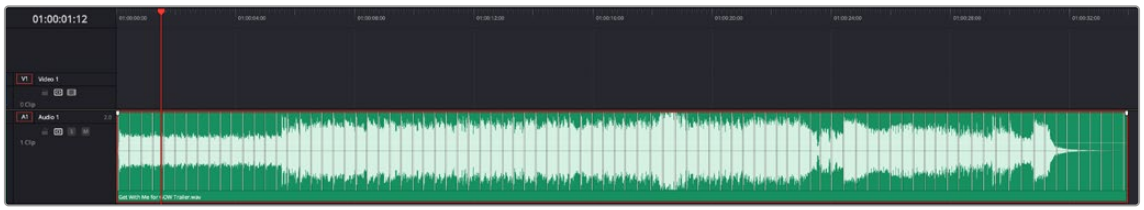
Adding Ducker input sources in the Inspector

Ducker Controls

- **Duck Amount:** This control determines level attenuation on the target track in dB with a default value of 2.7 dB. Most of the time, a value between 2.0 dB and 5.0 dB works best.
- **Lookahead:** Adjusts the amount of lookahead time in milliseconds, with a default value of 15ms. Lookahead allows the Ducker to start attenuating the destination track before the source track is audible.

  The larger the value, the more the Ducker will “pre-anticipate” the source track. If you want the Ducker to start lowering the sound before a line of dialogue or VO begins, you can experiment with higher values, but the default will usually produce good results.
- **Rise Time:** This determines how many milliseconds it takes for the Ducker to reach the amount of reduction specified by the Duck Amount. The default value is 10 milliseconds, which should work for most situations. Longer Rise Times may be useful with higher Duck Amount values and longer gaps in the source track.
- **Hold:** This parameter determines how long the target signal will be attenuated. The default is 150ms.
- **Recovery Time:** This value indicates how quickly the target signal will return to its previous level after attenuation. The default time value is 750ms, but setting the correct Recovery time is crucial to a natural-sounding ducking process, so you should try different values to find the best results.

Ducker Graph Display

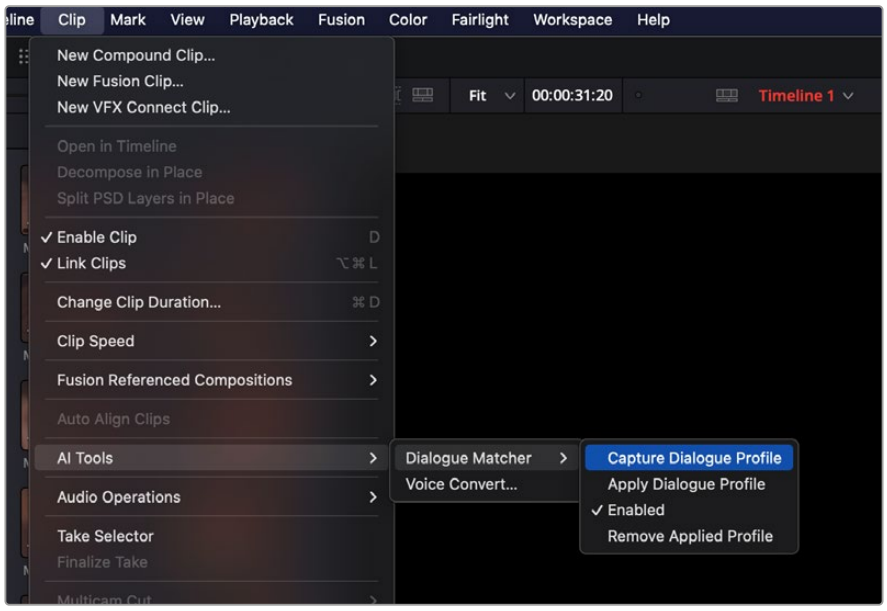


This area shows a gray line representing the incoming signal against the action of the Ducker, shown in yellow. Dips in the yellow line signify attenuation of the target track based on the Duck Amount in combination with the other parameters.

Beat Detector (Studio Version Only)

DaVinci Resolve can automatically detect beats for a piece of music on the timeline, and supports snapping to these beat marker locations. This can be especially useful when trying to make edits to the beat.

NOTE: The Beat Detector will only work effectively with beat-driven music, and with 4/4 or 3/4 time signatures at this time.



To detect beats, right-click on the timeline audio clip and select Detect Music Beats from the context menu. Once analyzed, the timeline clip displays beat indicator overlays that you can snap other timeline elements to.

A music track with the Beat Detector applied. The lined overlays match up with the beat of the music.

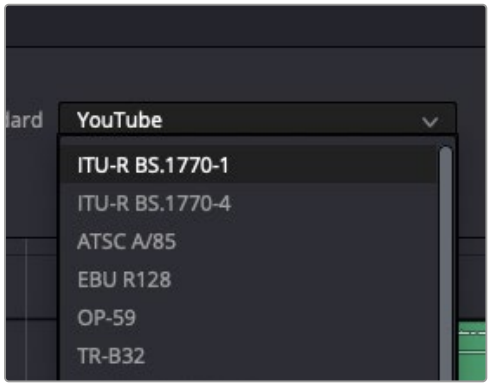
Dialogue Matcher (Studio Version Only)

Dialogue Matcher allows you to match one piece of dialogue to another, matching level, EQ, and reverb. This can help with situations where new recordings may not match the environment of existing ones. The Dialogue Matcher is a fully automated tool that only requires the user to capture a tone profile from a clip and then to apply it to another.

Capturing a Dialogue Profile from a clip using the main menu

To Use Dialogue Matcher:

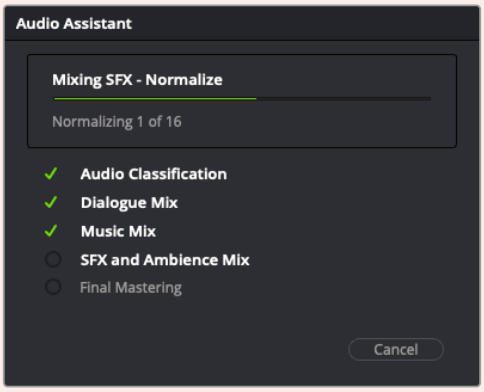
1. Select a reference clip whose dialogue you want to match, right-click, and choose Clip > AI Tools > Dialogue Matcher > Capture Dialogue Profile.
2. Select the clip whose dialogue you want to change, right-click and choose Clip > AI Tools > Dialogue Matcher > Apply Dialogue Profile.
3. You can enable or disable the Dialogue Matcher on a clip by right-clicking and choosing Clip > AI Tools > Dialogue Matcher > Enable.
4. You can Remove the Dialogue Matcher on a clip by right-clicking and choosing Clip > AI Tools > Dialogue Matcher > Remove Applied Profile.



Audio Assistant (Studio Version Only)

With the Audio Assistant, DaVinci Resolve can automatically organize and color code your tracks, even out your dialogue levels, and adjust the mixer faders to create a professional-quality mix of your music, sound effects, and dialogue.

During this process, your dialogue will also be cleaned up, and if needed, Voice Isolation and De-Essing will be applied. Ducking will be applied to music tracks, any required automation will be written, and the appropriate mastering and finalizing plugins will be added and adjusted to help achieve the correct loudness level for your chosen delivery standard.



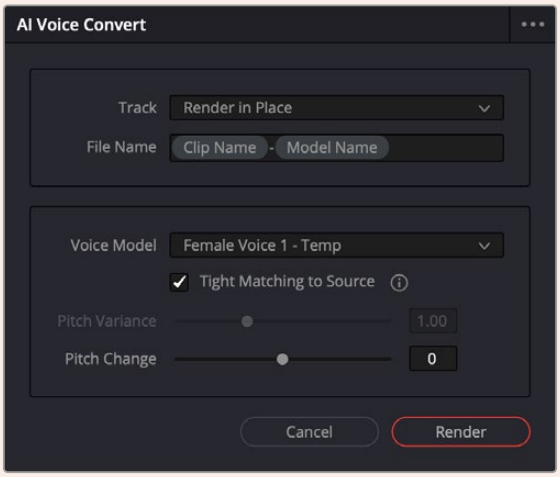
To use AI Audio Assistant:

1. Open a timeline containing unmixed audio. The initial fader levels really don't matter as Audio Assistant will handle all fader adjustments during the mixing process.
2. To begin the automatic mixing process, choose Timeline > AI Tools > Audio Assistant from the Timeline menu, select the Delivery Standard for your mix from the dropdown menu, and click the Auto Mix button.

Audio Assistant dialog - Delivery Standard

3. The Audio Assistant dialog changes to display the progress of the mixing process with an option to cancel it.
4. When the mixing process has concluded, you can play back the mix and, if needed, make further adjustments or completely undo it.

Audio Assistant dialog - Mix Progress



NOTE: If a track is in the wrong category, right-click the corresponding track header and choose the correct category from the Track Category section of the contextual menu, and then rerun the Audio Assistant.

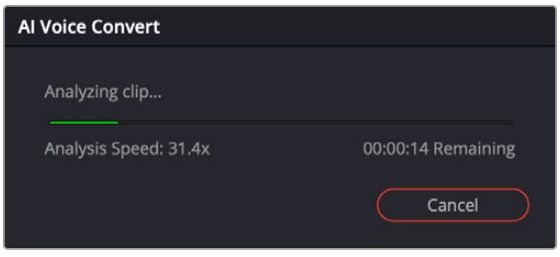
Voice Convert (Studio Version Only)

DaVinci Resolve has an incredibly sophisticated AI-driven voice conversion tool that allows you to essentially swap one speaking voice for another. The use cases for this tool are wide reaching and even somewhat controversial, however this Voice Convert toolset can be an invaluable resource in a post production. It allows you to take a generated voice model that has been captured by DaVinci Resolve and “drive” that voice model using another voice recording as its foundation.

In simple cases, you can replace your own voiceover tracks with a voice that has more depth and gravitas to it, or even switch the gender of your own voice if you feel it’s more appropriate for the subject matter. Perhaps you recorded audio in a noisy environment and wanted to make a pristine version instead, by using your own voice as a model, to replace your original noisy tracks. In more complicated scenarios you can train your own voice convert model on your actor’s voice patterns and use that to change and replace their previous voiceover, without having to get them back into the recording booth. Finally, it is even possible to change the voice of an actor completely to another voice all while staying perfectly in sync with the picture. The inflection, pitch variations, and emotion of the original all remain; it just sounds like someone else.

Needless to say, using this powerful tool requires a certain level of responsibility on the part of the user. Privacy, copyright, and union laws and rules are all in flux at the moment around AI-generated content, and it’s necessary to carefully navigate the ethics involved in its professional use.

The Voice Convert tool



NOTE: Using Voice Convert is very processor intensive and requires your system to have a minimum of 8 GB of video RAM before it will activate, to avoid crashes and system instability. Even with a strong system, creating a Voice Model will require prolonged intensive CPU and GPU power, so multi-tasking while it's working may be challenging.

Using Voice Convert

Like most of DaVinci Resolve's AI tools, using Voice Convert is very simple, with all of the complex processing involved handled by the voice model.

To use Voice Convert to change one voice to another:

1. Place the clip or clips you want to change the voice of in the timeline, and select them.
2. Right-click on the clip and select Voice Convert from the context menu, or select Clip > AI Tools > Voice Convert in the main menu.
3. Select the track that you want the new audio to appear in (including overwriting the original).
4. Select the file name you want the new audio to be named.
5. Select the Voice Model you want to use for the new audio (you can make your own custom voice models as explained below) and its parameters.
6. Click Render to start the Voice Convert process.

Voice Convert analyzing a clip

At this point the Voice Convert dialog will appear, showing you the progress of the conversion. Depending on the length and number of clips selected, this can take some time. When the process is done, the new audio will appear in the timeline in the exact same place as the original audio (or on the same place in another track if that option was selected). The new audio clips will also appear in the Media Pool.

Simply play back the timeline to audition the new voice. You can change the audio back to the original by right-clicking on a clip and selecting Revert to Original Voice from the context menu.

TIP: While you can drive voices with different accents, Voice Convert generally can't recreate another accent. For example, if you have a voice model that is a speaker with a British accent and drive that voice with an American accent, you get more of an American version of the British accented speaker. But if you speak with a British accent when driving the British voice model, it will work well.

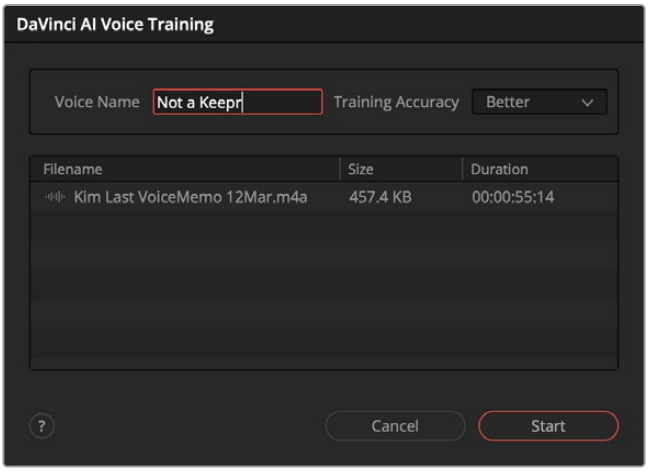
Voice Convert Settings

Each voice conversion requires selecting set up parameters to drive the model.

- **Track:** Select which track you want the new audio to be placed on. The default is Render in Place, which will overwrite the original audio.
- **File Name:** Set the file name for the new audio clip. You can enter a specific name, or use the metadata variables to create a template for file naming. By default the name is ClipName-(Voice Model Name).
- **Voice Model:** Select which voice model you wish to use for the new audio. There are some built-in options that come with DaVinci Resolve, and any custom options you create will also be available here.
- **Tight Matching to Source:** Check this box to tightly follow the pitch, intonation, and volume variance of the source voice. Uncheck this box to have a looser interpretation using the Pitch Variance tool.
- **Pitch Variance:** When the Tight Matching to Source box is unchecked, this tool becomes active. Lower values create a more monotone interpretation, while higher values have more variance in pitch.
- **Pitch Change:** Use this slider to create a deeper (negative values), or higher (positive values) voice based on the model. The values are in semitones and can be adjusted in 100 cents (.1 semitone) increments.

Creating Your Own Voice Models

It is possible to create your own voice models for use with Voice Convert. These can be of your own voice or even someone else's that you have the rights to. This section goes over some best practices to get a clean and usable voice model.



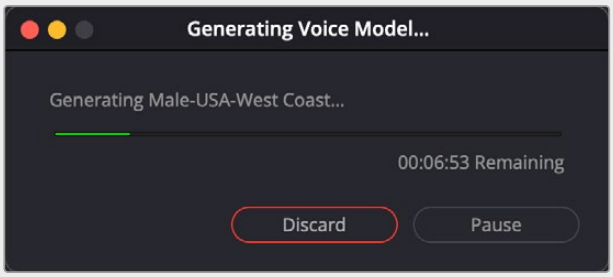
Preparing the Voice Model Assets

You will get the best results using ten minutes or so of clean, high-quality recordings of the voice to be modeled. The audio should be free of excessive ambiance and noise, with little to no dynamics processing. You will want consistent material that sounds natural. It can be useful to have a variety of emotions expressed as well, if you want to hear those results for the driven voice. Treat it like a voice over audition; show your range.

These voice assets do not necessarily need to be in one long clip, though if there are a lot of separate files, it can be helpful to consolidate them all in a single bin for organization. The multiple clips should be of consistent quality, without audio variations in the recorded sources.

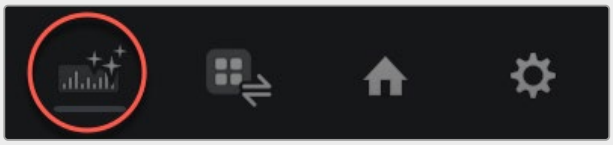
Creating the Voice Model

To generate your own voice model, select one or more clips for analysis in the Media Pool, right-click and choose AI Tools > DaVinci AI Tools Voice Training from the context menu. If this is the first time you've run this tool, DaVinci Resolve will open up the Resolve Extras Download Manager to install the required support files.



Voice Model Generation

Initially a warning splash screen appears, to ensure you assume full responsibility for how you will use this tool. Once you hit accept, the DaVinci AI Voice Training dialog appears, and there are two options to set.



- **Voice Model Name:** Enter a descriptive name for your new model.
- **Quality:** Choose Faster or Better mode for analysis. Better takes about 3x the time as faster, and 10 minutes or so of material can take a few hours to complete, depending on your computer's power.

Initially creating a voice model launches a foreground process, then once the initial analysis is complete, it will switch to a background process, allowing you to continue to use DaVinci Resolve for other purposes or other apps while it finishes.

Voice Model progress

You can see the progress of the model in the Voice Model Generation Progress indicator in the bottom-right corner, or by selecting Workspace > Voice Model Progress.

The Voice Model Generation Progress indicator will slowly fill blue as the voice model finishes. Hover over the top to get an ETA and progress finished tooltip.

You can also alternatively choose to pause or discard the in-progress model instead. Quitting DaVinci Resolve will also pause the background process, and it will automatically start up again the next time DaVinci Resolve is launched.

Once the model is complete, the new voice preset will appear for use in the Voice Convert Dialog.

Speech Generator (Studio Version Only)

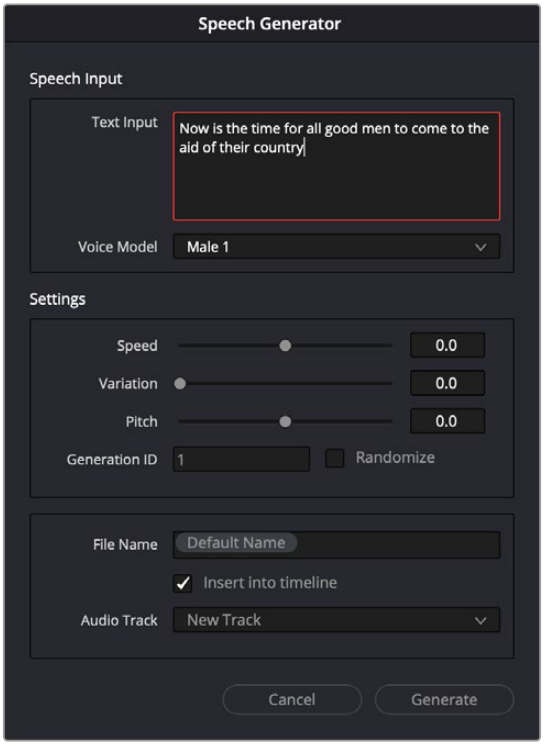
Speech Generator generates high quality spoken word output from written text, letting you create your own natural sounding VO or narrations for your projects with different voices and performances that you can tailor to your edit.

- Timeline > AI Tools > Speech Generator

Downloading the Speech Generator Model

As an AI based tool, you will need to download the Speech Generator Model before use. You can download the Speech Generator model from DaVinci Resolve > Extras Download Manager.

Using AI Speech Generator



Launch the AI Speech Generator by going to Timeline > AI Tools > Speech Generator.

Next type in the text you want to generate in the Text Input field. Speech Generator does best with shorter sentences or paragraphs. If the text you input is too long, the generated voice can start to drift into strange territory after a while. So keep it brief, or if you have a large amount of text, break it into smaller pieces.

Then choose the Voice Model you want to read your text. There are four built in voices that are licensed for use, or you can also create your own custom voice as described below. You can modulate the voice by adjusting the parameters in the settings section.

Finally you can set the generated audio clip's file name, and decide which audio track to insert the clip into.

When you press the Generate button, the Speech Generator will process and create a new audio clip based on your input, and put it in your Media Pool.

The Speech Generator tool

- **Speech Input:** This section inputs the text and decides which voice you want it to read in.

  Text Input: Type in the text you want the Speech Generator to read here. Shorter sentences and paragraphs are better. Punctuation does affect the timing of the reading. Periods (full stops) are longer pauses, and commas shorter. Carriage returns may make a pause longer coming after a period.

  Voice Model: Choose a voice model to read your text from the dropdown list. Selecting Custom will open a file requester to load an audio file with the voice you wish to use (see Creating a Custom Voice below).

- **Settings:** These settings control the modulation and performance of the voice.

  Speed: Adjusts the speed of the reading.

  Variation: Controls variation of the reading prosody (the rhythm and intonation of speech) and emotion with 0 being closest to prosody of the reference voice source.

  Pitch: Controls how high or low the voice is. Positive values are higher pitched, and negative values are lower.

  Generation ID: You can think of this number like a performance or take. Each number represents a different reading with varying prosody. Choosing the exact same number will give you the exact same performance, so this can be useful when you want to try other variations but keep the same prosody including emotional emphasis.

  Randomize: Check this box to use a random number for the Generation ID.

- **File Name:** The name of the new Speech Generator audio file. A default name is supplied and a numerical suffix is automatically added. You can enter your own name instead for the start of the string. Speech Generator audio files are stored in the DaVinci Resolve Media location you've set under their project name.
- **Insert into Timeline:** Checking this box will automatically insert the reading at the playhead position in your timeline.
- **Audio Track:** Choose which audio track in your timeline the reading will be inserted into.

Creating a Custom Voice for the Speech Generator

You can easily create a custom voice for use in the Speech Generator. All you need is an audio file of the person talking for about twenty seconds, that's been recorded in a clean and high fidelity signal. Then simply load that file into the Speech Generator using the Custom setting in the Voice Model dropdown menu.

Tips for getting the best voice sample:

- The recording only needs to be 10-20 seconds long. In fact, longer recordings are truncated to the first 20 seconds for Speech Generator analysis.
- Make sure the voice recording is clean, with good levels and low noise.
- Try to keep your spacing even, no long gaps, or extremes in volume and emotion if you want an even result.
- If you're at a loss what to record, try reading the "Harvard Sentences" out loud for twenty seconds or so. They are designed to be phonetically balanced for the frequency of the English language.
- Experiment to see what works.

IMPORTANT: Ensure you get permission for using a real person's voice and are fairly compensating the creative voice talent!

Speech Generator vs. Voice Convert

While similar in overall effect, the input driving the two AI speech tools is very different. Speech Generator creates a new audio file and performance from written text, while Voice Convert uses an existing audio file and tries to match the tonality and performance of that exact clip, just using a different voice.

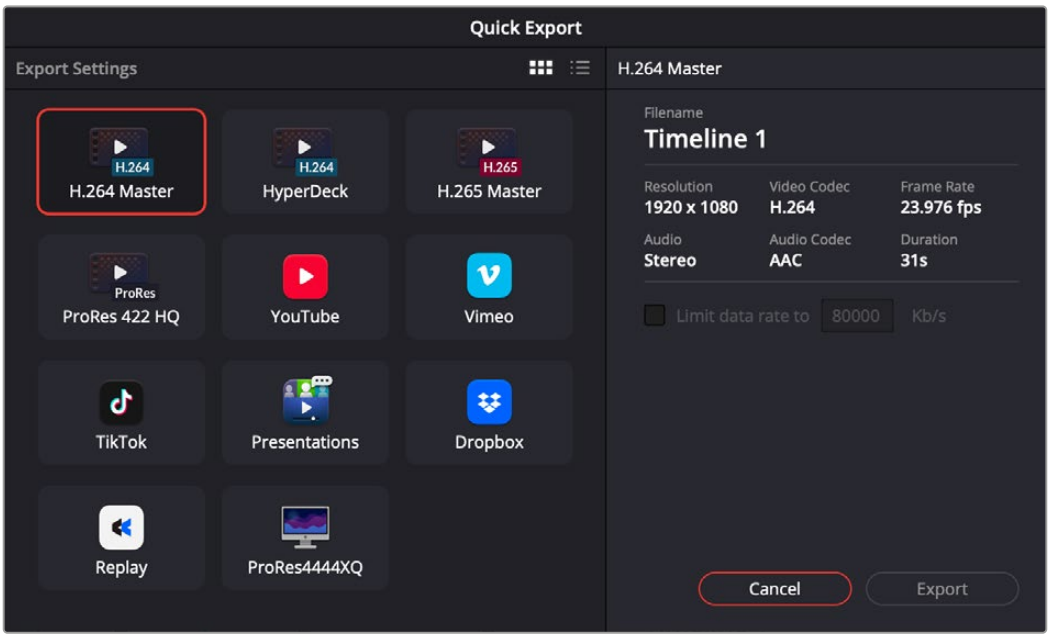
In addition, Speech Generator's voices can be generated using only a short snippet of audio, so it can be used quickly, while Voice Convert requires a longer source file and analysis time to build a voice model.

Chapter 39

Quick Export

Once you've finished your program and you want to share it with others, you can use the Quick Export button to output the contents of the Timeline as a self-contained file in one of a variety of different formats in order to share it with people.

Contents



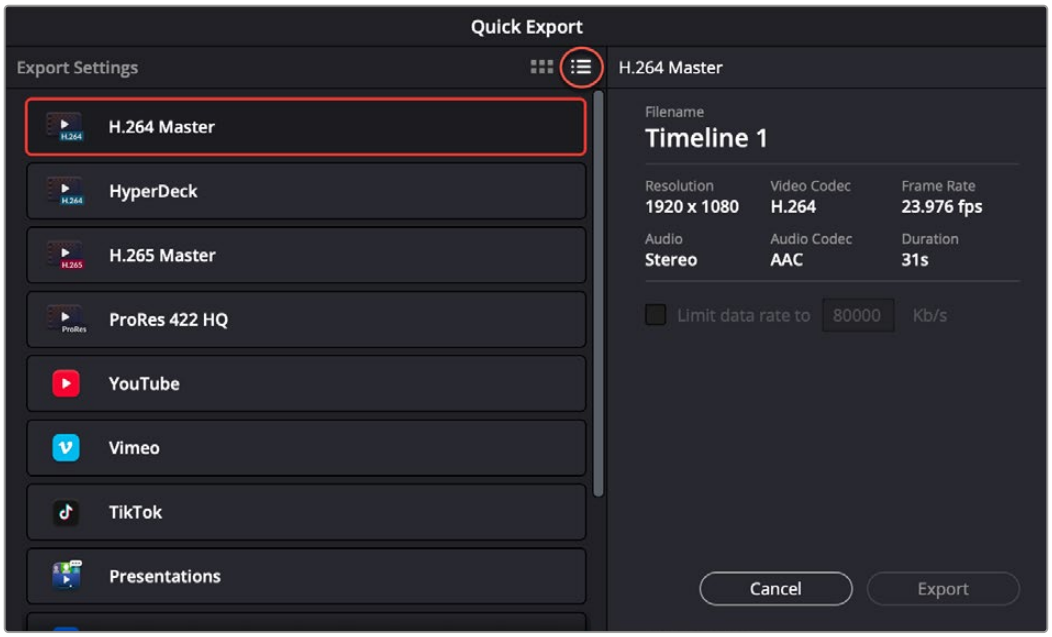
Quick Export 811
Assign Icons to User Presets 812

Quick Export

You can choose File > Quick Export to use one of a variety of export presets to export your program from any page of DaVinci Resolve. You can even use Quick Export to export and upload your program to one of the supported video sharing services, including YouTube, Vimeo, and Dropbox.

To use Quick Export:

1. (Optional) In the Cut, Edit, Fairlight, or Color page, set In and Out points in the Timeline to choose a range of the current program to export. If no timeline In or Out points have been set, the entire timeline will be exported.
2. Choose File > Quick Export.
3. Select a preset to use from the top row of icons in the Quick Export dialog, and click Export.
4. Choose a directory location and enter a file name using the Export dialog, then click Save. A progress bar dialog appears to let you know how long the export will take.

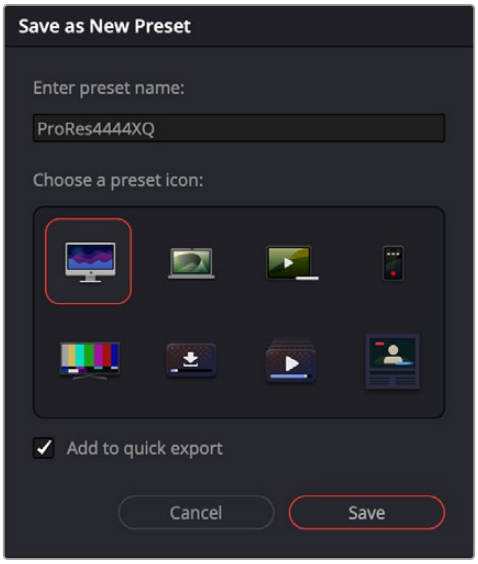


The Quick Export dialog showing a custom preset

To Create a New Custom Preset and Add it to Quick Export:

1. On the Deliver page, select Custom Export from the Render Settings, and adjust the Video, Audio, and File settings for your new preset. Only Single Clip settings can be made Custom Presets, not Individual Clips.
2. In the Render Settings 3-Dot Option Menu, select Save as New Preset.
3. Type in a name for your new Preset, and choose a preset icon to represent it.
4. Check the Add to quick export box.
5. Click Save.

Your preset and icon will now be added to the Quick Export dialog across all pages of DaVinci Resolve and also be added to the Render Settings in the Deliver page.



The List View icon (circled) in the Quick Export dialog

To View the Quick Export Options in List View:

1. Open the Quick Export dialog.
2. Click on the List View icon in the Render Settings.

Assign Icons to User Presets

When you create a new Custom Preset in the Deliver page, in addition to entering a name, you can now choose an icon from the list to represent it in the Render Settings and Quick Export dialog.

Creating a new Custom Preset in the Deliver page

Chapter 40

Using the Edit Page

In this chapter, you'll learn how to use and configure the Edit page user interface to prepare for editing projects in DaVinci Resolve.

For more information on how to use the Edit page to import and conform projects edited in other applications for color correction and finishing in DaVinci Resolve, jump to this section: Conforming and Relinking Media.

The Edit Page User Interface

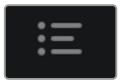
The Edit page has evolved into a source-record style NLE that contains nearly every editorial tool you need for creative editing through finishing. The Edit page is divided into three main regions: the browsers found at the left, the Viewers at the top, and the Timeline at the bottom, all of which work together to let you import, edit, and trim timelines with a flexible variety of tools and methods.

The Edit Page in its entirety

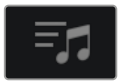
The Interface Toolbar

At the very top of the Edit page is a toolbar with buttons that let you show and hide different parts of the user interface. These buttons are as follows, from left to right:

The Interface toolbar



Media Pool/Effects Library/Edit Index height button: Lets you set the area used by the Media Pool, Effects Library, and/or Edit Index to take up the full height of your display (you can display two at a time), giving you more area for browsing at the expense of a narrower timeline. At half height, the Media Pool/Effects Library/Edit Index are restricted to the top of the UI (you can only show one at a time), and the timeline takes up the full width of your display.



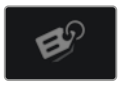
Media Pool: Opens or hides a smaller version of the full Media Pool page, allowing access to all the video clips, audio clips, and images used in the project.

Effects Library: Opens or hides the repository of all transitions, generators, OpenFX, and audio filters available to use in the Edit page.

Index: Opens or hides the Edit, Tracks, and Markers indexes.

Sound Library: Opens or hides the libraries of sound effects and music registered with DaVinci Resolve.

> For more information on using the Sound Library, jump to this chapter: Using the Fairlight Page.



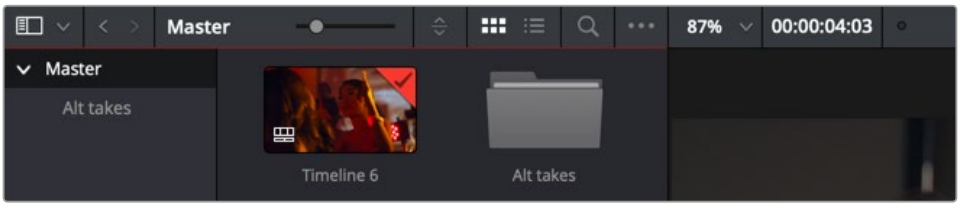
Keyframes: Opens the Keyframes and Curves Editor.

Quick Export: Opens the Quick Export Dialog to simply deliver an export of your timeline.

Mixer: Opens or hides the Audio Mixer, giving you graphical controls to adjust your sound mix.

Metadata: Shows or hides the Metadata Editor.

Inspector: Shows or hides the Inspector, which shows you the transform and compositing effects of selected clips, or the editable options of selected effects such as transitions or generators.

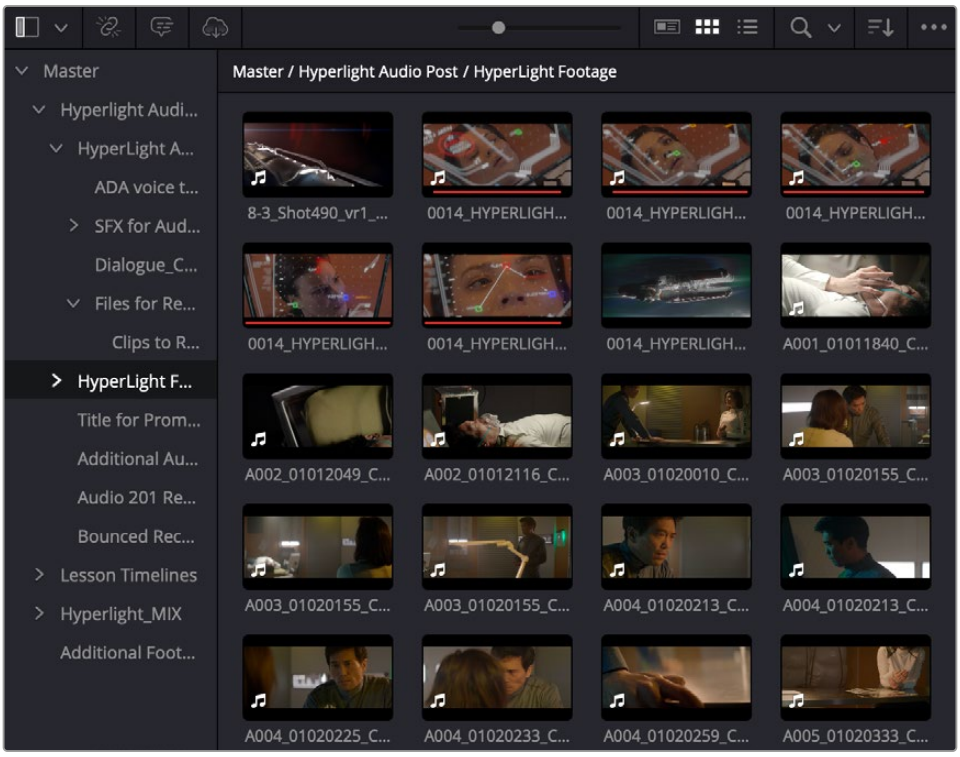


Navigating the Edit Page

Each of the panels in the Edit page user interface can be given focus via the Workspace > Active Panel Selection submenu. Additionally, the following keyboard shortcuts can be used to give focus to select bins, clips, the Source and Timeline Viewers, the Timeline, the Effects Library, Edit Index, and Inspector.

Key	Function
Command-1	Media Folders
Command-2	Media Clips
Command-3	Source Viewer
Command-4	Timeline
Command-5	Timeline Viewer
Command-6	Effects
Command-7	Edit Index
Command-8	n/a
Command-9	Inspector
Q	Toggle between Source and Timeline Viewers

Showing Which Panel Has Focus



Each panel you use has “focus,” meaning that clicking an item or control within a particular panel makes that panel the active panel, which serves to direct keyboard shortcuts that are shared among many panels to the particular panel you’re using. If you want to see which panel is in focus, you can turn on the “Show focus indicators in the User Interface” checkbox in the UI Settings panel of the User Preferences. When on, a red line at the top of the active panel indicates that it has focus.

The focus indicator shown at the top edge of the Media Pool, shown next to a viewer that doesn’t have focus

The Media Pool

In the Edit page, the Media Pool contains all of the video, audio, and still image media you’ve imported for editing into the project at hand, as well as all of the timelines that you’re going to be editing into. The Media Pool is also mirrored on the Media, Cut, Fusion, Color, and Fairlight pages, so you can access any audio or video clip, graphic, or timeline from any page where they can be used.

The Media Pool in Thumbnail mode

The Bin list at the left shows a hierarchical list of bins used for organizing your media, which is also used to organize your timelines. By default, the Media Pool consists of a single bin, named “Master,” but you can add more bins as necessary to organize timelines and clips by right-clicking anywhere

in the empty area of the Media Pool and choosing Add Bin. You can rename any custom bin by double-clicking on its name and typing a new one, or by right-clicking a bin's name and choosing Rename Bin. The Bin list can be hidden or shown via the button at the upper left-hand corner of the Edit page toolbar.

The browser area to the right shows the contents of the currently selected folder. Every timeline you create, and every AAF, XML, or EDL file you import, appears here. You can create or import as many timelines as you need within a single project.

As in the Media page, the Media Pool can be displayed in either Metadata, Icon, or List view. In List view, you can sort the contents by any one of a subset of the total metadata that's available in the Metadata Editor of the Media page. Of particular interest to editors are columns for Name, Reel Name, different timecode streams, Description, Comments, Keyword, Shot, Scene, Take, Angle, Circled, Start KeyKode, Flags, Usage, Resolution, and Frames Per Second.

For more information on using the myriad features of the Media Pool, jump to this chapter: Adding and Organizing Media with the Media Pool.

In the sections that follow, some key features of the Media Pool are summarized for your convenience.

Importing Media Into the Media Pool on the Edit Page

While adding clips to the Media Pool in the Media page provides the most organizational flexibility and features, if you find yourself in the Edit, Cut, Fusion, Color, or Fairlight page and you need to quickly import a few clips for immediate use, you can do so in a couple of different ways.

To add media by dragging one or more clips from the Finder to the Edit page Media Pool (macOS only):

1. Select one or more clips in the Finder.
2. Drag those clips into the Media Pool of DaVinci Resolve or to a bin in the Bin list.

   Those clips are added to the Media Pool of your project.

To use the Import Media command in the Edit page Media Pool:

1. With the Edit page open, right-click anywhere in the Media Pool, and choose Import Media.
2. Use the Import dialog to select one or more clips to import, and click Open.

   Those clips are added to the Media Pool of your project.

For more information on using the myriad features of the Media Pool, jump to this chapter: Adding and Organizing Media with the Media Pool.

Below, some key features of the Media Pool are summarized for your convenience.

Bins, Power Bins, and Smart Bins

There are actually three kinds of bins in the Media Pool, and each appears in its own section of the Bin list. The Power Bin and Smart Bin areas of the Bin list can be shown or hidden by selecting/deselecting in the Media Pool option menu Show Smart Bins, and Show Power Bins. Here are the differences between the different kinds of bins:

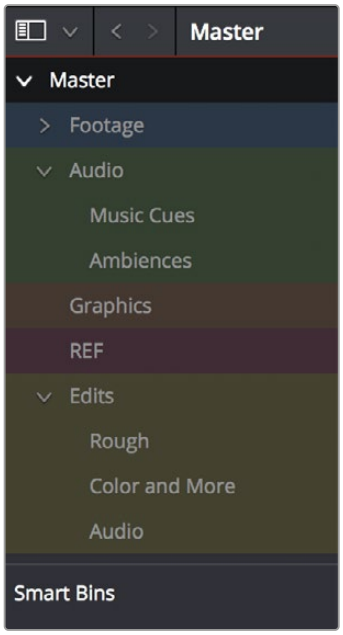
- **Bins:** Simple, manually populated bins. Drag and drop anything you like into a bin, and that's where it lives, until you decide to move it to another bin. Bins may be hierarchically organized, so you can create a Russian dolls nest of bins if you like. Creating new bins is as easy as right-clicking within the bin list and choosing Add Bin from the contextual menu.
- **Power Bins:** Hidden by default. These are also manually populated bins, but these bins are shared among all of the projects in your current project library, making them ideal for shared title generators, graphics movies and stills, sound effects library files, music files, and other media that you want to be able to quickly and easily access from any project. To create a new Power Bin, show the Power Bins area of the Bin list, then right-click within it and choose Add Bin.
- **Smart Bins:** These are procedurally populated bins, meaning that custom rules employing metadata are used to dynamically filter the contents of the Media Pool whenever you select a Smart Bin. This makes Smart Bins fast ways of organizing the contents of projects for which you (or an assistant) has taken the time to add metadata to your clips using the Metadata Editor, adding Scene, Shot, and Take information, keywords, comments and description text, and myriad other pieces of information to make it faster to find what you're looking for when you need it. To create a new Smart Bin, show the Smart Bin area of the Bin list (if necessary), then right-click within it and choose Add Smart Bin. A dialog appears in which you can edit the name of that bin and the rules it uses to filter clips, and click Create Smart Bin.

Showing Bins in Separate Windows

If you right-click a bin in the Bin List, you can choose "Open As New Window" to open that bin into its own window. Each window is its own Media Pool, complete with its own Bin List, Power Bins and Smart Bins lists, and display controls.

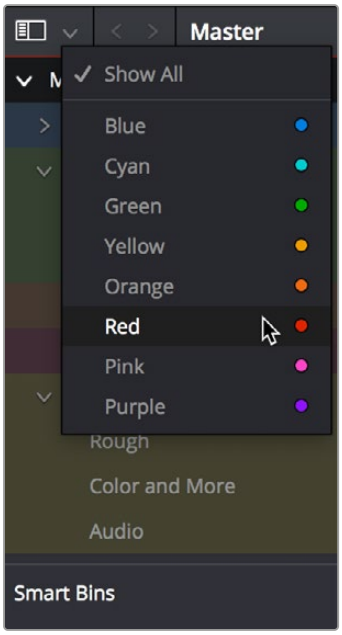
Media Pool bins opened as new windows

This is most useful when you have two displays connected to your workstation, as you can drag these separate bins to the second display while DaVinci Resolve is in single screen mode. If you hide the Bin list, not only do you get more room for clips, but you also prevent accidentally switching bins if you really want to only view a particular bin's contents in that window. You can as many additional Bin windows open as you care to, in addition to the main Media Pool that's docked in the primary window interface.



Filtering Bins Using Color Tags

If you're working on a project that has a lot of bins, you can apply color tags to identify particular bins with one of eight colors. Tagging bins is as easy as right-clicking any bin and choosing the color you want from the Color Tag submenu.

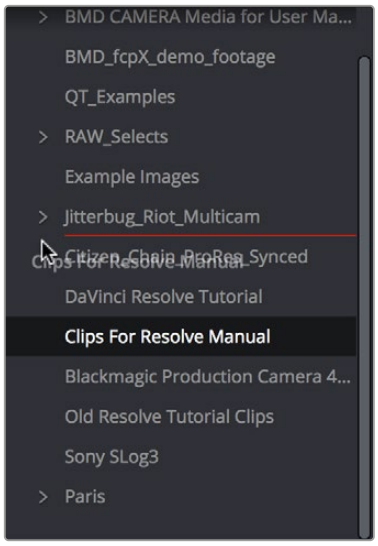


For example, you can identify the bins that have clips you're using most frequently with a red tag. A bin's color tag then appears as a colored background behind that bin's name.

Once you've tagged one or more Media Pool bins, you can use the Color Tag Filter drop-down menu (the drop-down control to the right of the Bin List button) to filter out all but a single color of bin.

To go back to seeing all available bins, choose Show All from the Color Tag Filter drop-down.

Using Color Tags to identify bins



Using color tag filtering to isolate the red bins

Sorting the Bin List

The Bin list (and Smart Bin list) of the Media Pool can be sorted by Bin Name, Date Created, or Date Modified, in either ascending or descending order. Simply right-click anywhere within the Bin list and choose the options you want from the Sort by submenu of the contextual menu.

You can also choose User Sort from the same contextual menu, which lets you manually drag all bins in the Bin list to be in whatever order you like. As you drag bins in this mode, a highlighted line indicates the new position that bin will occupy when dropped.

Dragging a bin to a new position in the Bin list in User Sort mode

If you use User Sort in the Bin list to rearrange your bins manually, you can switch back and forth between any of the other sorting methods (Name, Date Created, Date Modified) and User Sort and your manual User Sort order will be remembered, making it easy to use whatever method of bin sorting is most useful at the time, without losing your customized bin organization.

More About Timelines and Grading

DaVinci Resolve projects contain one or more edited timelines (sometimes called a sequence in other applications) which are also organized in the Media Pool, and displayed in the Timeline Editor (referred to as “the Timeline”). Timelines contain clips, the source media of which is kept in the Media Pool, and which also appear as edit events in the Edit Index that can be shown at the right of the Timeline.

Timelines, Grades, and Versions

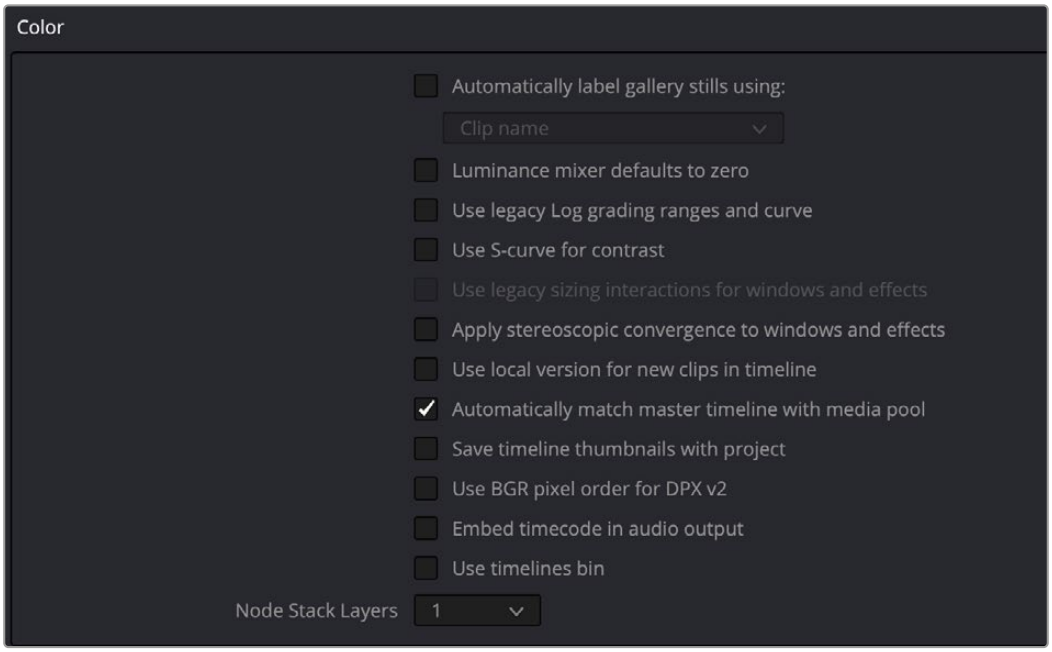
Within any given timeline, grades are associated with the timecode of the source clip they’re applied to. That means that as you alter the timeline, each clip’s grade moves along with it, making it extremely easy to move back and forth between editing and grading as your needs require. By default, each timeline in a project has independent sets of grades using local versions; this is true even if your timelines are duplicates. That means each clip within every timeline has a completely independent grade.

However, if you switch the clips in one or more timelines to use Remote versions, a clip’s grades are shared by every instance of that clip in all timelines with clips that also use Remote versions. If you import a new timeline that rearranges clips into a different order and switch it to using Remote versions, then grades will automatically follow the clips, so that the clips within each new timeline inherits the grades applied to those same clips in other timelines.

You can switch a timeline between using Local and Remote grades at any time.

For more information on using Local versus Remote versions, jump to this chapter: Grade Management. You can also copy grades from one timeline to another using the ColorTrace feature.

For more information on ColorTrace, jump to this chapter: Copying and Importing Grades Using ColorTrace



Enabling the Use of a Master Timeline

Previous versions of DaVinci Resolve had a Master Timeline, which consisted of one long timeline containing every clip in the Media Pool, arranged by default in ascending order by timecode. While the Master Timeline was useful for a variety of tasks, architectural improvements have rendered it unnecessary, and by default the Master Timeline does not appear in new projects created by DaVinci Resolve version 10 or later.

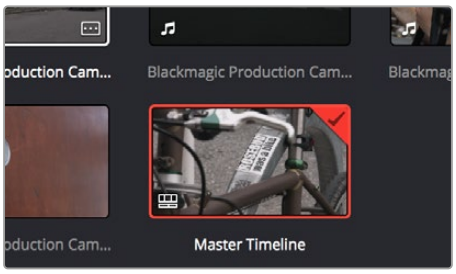
However, if you want a Master Timeline in order to have a single timeline that always contains all clips currently in the Media Pool, there's a way you can create one. You need to do it immediately upon creating a new project, before adding any media to the Media Pool. Once you've added one or more clips to the Media Pool, the option you need to do so will be disabled.

To create a new Master Timeline:

1 Create a new project, open the General Options panel of the Project Settings, and turn on the "Automatically match master timeline with media pool" checkbox. If you also want all clips to use Remote versions as you grade by default as in previous versions of DaVinci Resolve, you can turn off the "Use local version for new clips in timeline."

The option to use a Master Timeline is in the Color section of the General Options panel of the Project Settings

2 Click Save to close the Project Settings window.



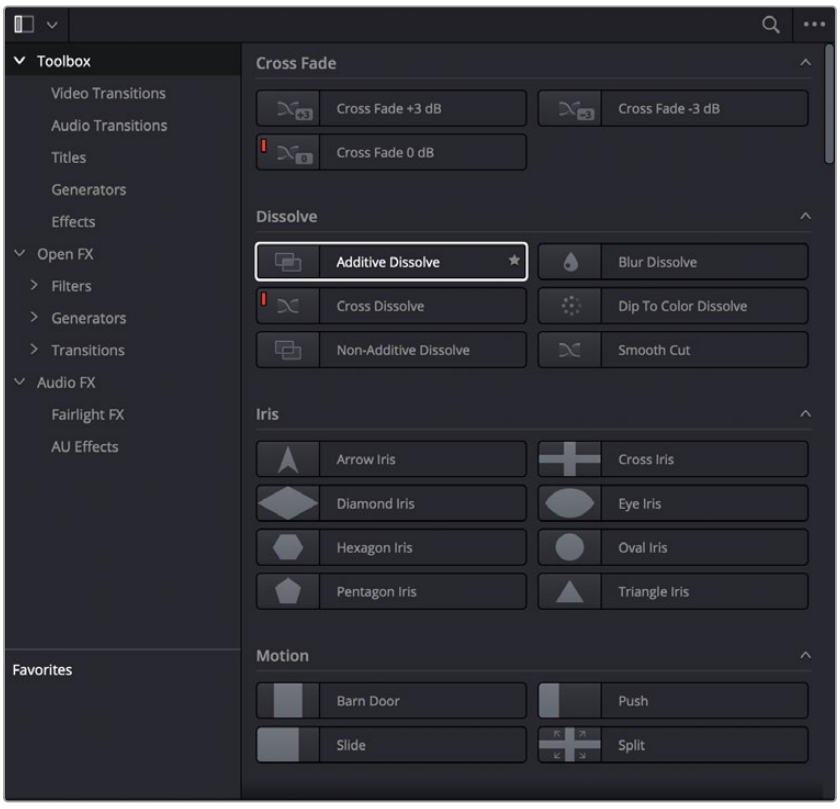
3 Open the Edit page, and choose File > New Timeline (Command-N).

4 When the New Timeline Properties window appears, turn the Empty Timeline checkbox off, and click Create New Timeline.

Now, in addition to the new timeline, a Master Timeline appears in the Timeline list.

TIP: If you want to make sure that you always have a Master Timeline when you create new projects, you can alter the Project Setting preset for your user account to reflect these settings, or you can create a new Project Setting preset with these settings that you can easily switch to.

The Master Timeline consists of one long sequence of every clip in the Media Pool, arranged in ascending order by timecode. Each clip in the Master Timeline appears at its full duration, regardless of the duration of corresponding clips in an EDL-, AAF-, or XML-imported timeline. Whenever you add more clips to the Media Pool, they're automatically added to the Master Timeline.



Creating a Master Timeline

The Master Timeline is useful for organizing media for which no editing has yet been done, such as when grading digital dailies. The Master Timeline is also useful for identifying a range of similar clips, based on their similar ranges of timecode. For example, you could find all the talking head shots from a particular section of tape clustered together in the Master Timeline.

Using the Effects Library

All effects that you can add to your edit, including filters, transitions, titles, and generators, are found in the Effects Library, which is split into two parts. To the left is a bin list that shows a hierarchical list of all of the different Transitions, Title Effects, Generators, and Filters that are available, sorted by category. To the right is a browsing area in which you can see the contents of whichever bins are selected.

Similar to the Media Pool, the Effects Library's bin list can be opened or closed using a button at the top left, while a menu just to the right of this button lets you sort the list into different categories.

The Effects Library

The Toolbox

All of the video and audio transitions, titles, and generators that ship along with DaVinci Resolve appear in the Toolbox category of the Effects Library.

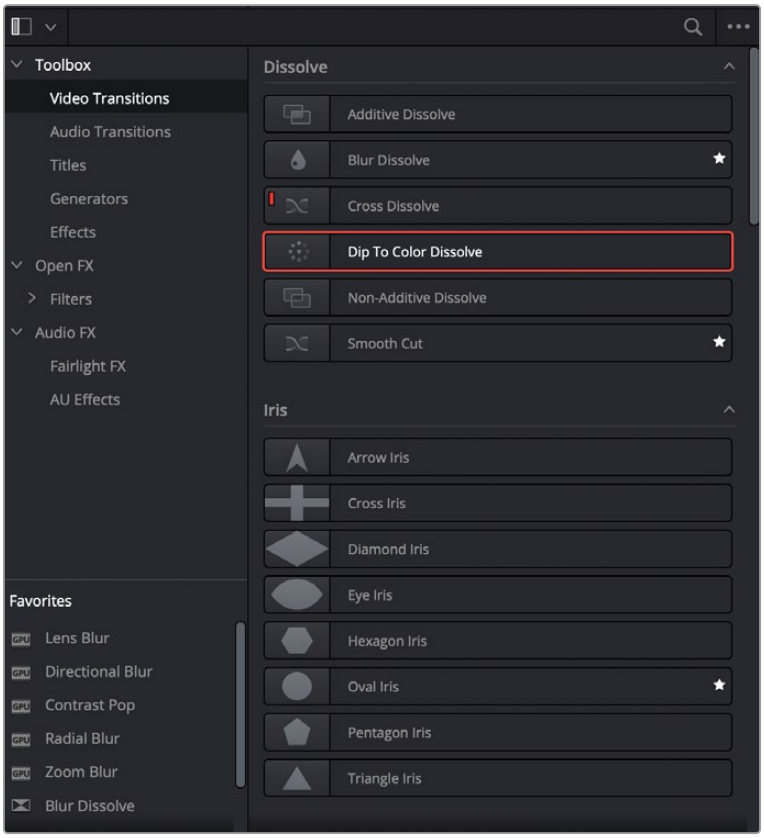
- **Toolbox:** Exposes all Transitions, Titles, Generators, and Effects at once.
- **Video Transitions:** Contains all of the built-in transitions that are available from DaVinci Resolve. You can drag any video transition to any edit point in the Timeline that has overlapping clip handles to add it to your edit; you have the option to drag the transition so that it ends on, is centered on, or starts on the edit point.

  For more information, jump to this chapter: Using Transitions.

- **Audio Transitions:** Contains audio transitions for creating crossfades.
- **Titles:** Titles can be edited into the Timeline like any other clip. Once edited into the Timeline, you can edit the title text and position directly in the Timeline Viewer, or you can access its controls in the Inspector for further customization.
- **Generators:** Generators can also be edited into the Timeline like any other clip. Selecting a generator and opening the Inspector lets you access its controls for further customization. You can also choose a standard duration for generators to appear with in the Editing panel of the User Preferences.
- **Effects:** Contains unique placeholder effects like Adjustment Clip, and Fusion Composition, that can be customized to apply sophisticated effects to your programs.

OpenFX

DaVinci Resolve supports the use of third-party OpenFX filters, transitions, and generators in the Edit page. Once you install these effects on your workstation, they appear in this section of the Effects Library, organized by type and group depending on the metadata within each effect.



- **OpenFX:** Exposes all Resolve FX and third-party OpenFX installed on your workstation at once.
- **Filters:** Contains the Resolve FX filters that ship with DaVinci Resolve, as well as any third-party OFX plugins you've installed on your workstation. Filters can be dragged onto video clips to apply an effect to that clip. Once applied, filters can be edited and customized by opening the OpenFX panel of the Inspector.
- **Transitions:** Contains any third-party OFX transitions you have installed on your workstation. OFX transitions can be used similarly to any other transition, but they also expose an OpenFX panel next to the Transition panel in the Inspector, where you can customize settings that are unique to that transition.
- **Generators:** Contains any third-party OFX generators you have installed on your workstation. Can be edited into the Timeline just like the native generators that ship with DaVinci Resolve, but they also expose an OpenFX panel next to the Transition panel in the Inspector, where you can customize settings that are unique to that transition.

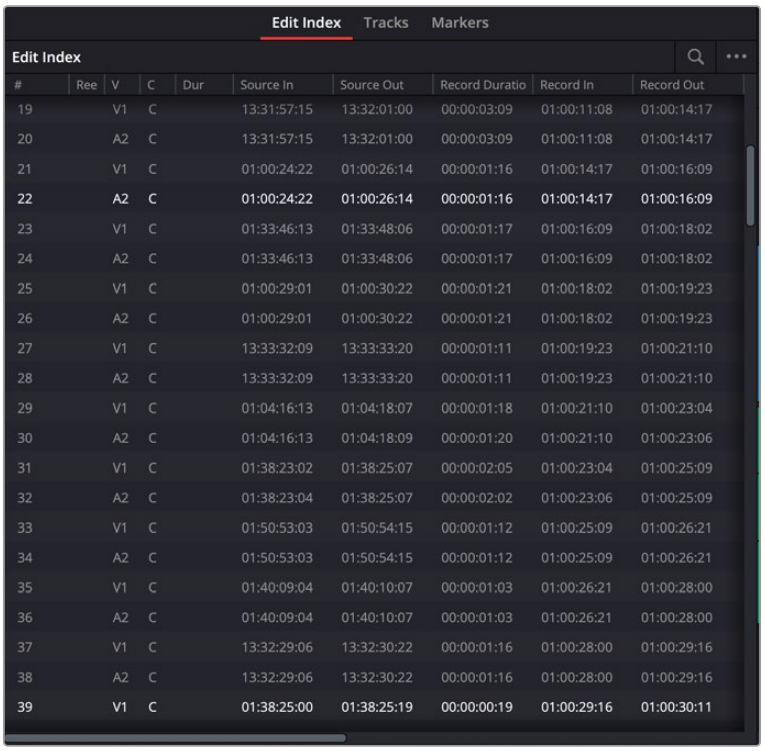
Audio FX

On all platforms, DaVinci Resolve supports Fairlight FX, which are built-in audio plugins that come with DaVinci Resolve. Additionally, DaVinci Resolve supports the use of third-party VST audio plugins on macOS and Windows, and Audio Unit (AU) audio plugins on macOS. Once you install these effects on your workstation, they appear in this panel of the Effects Library. Audio plugins let you apply effects to audio clips or an entire track's worth of audio to add creative qualities such as echo or reverb, or to take care of mastering issues using noise reduction, compression, or EQ.

Effects Library Favorites

You can click on the far right of any transition, title, or generator to flag that effect with a star as a favorite effect. When you do so, the favorited effects appear in a separate Favorites area at the bottom of the Effects Library Bin list.

Stars indicate a flagged favorite effect; all favorites are currently filtered.



Index

The index provides information about your timeline in a simplified spreadsheet format; it is used for both reference and timeline navigation. The index is broken up into the Edit Index, Tracks, and Markers tabs.

Edit Index

Clicking the Edit Index button opens the Edit Index. By default, this shows an EDL-style list view of all the edit events in the current timeline. Whichever timeline is selected in the Timeline list displays its events here. However, the contents of the Edit Index can be filtered using commands found in the Option drop-down, described later in this section.

Each clip and transition is shown as an individual event, each of which contains multiple columns of information. If you re-edit a timeline, your changes are also reflected in this list. The Edit Index is useful for creative editors that are looking for specific effects that are used in the current timeline, or for finishing editors that need more information about a specific clip, or who might need to filter the entire edit by specific criteria in order to troubleshoot various issues.

Edit Index List shown open

Navigating the Timeline Using the Edit Index

Whenever you move the Timeline playhead to intersect a clip, the Edit Index updates to show only the clips on the video track the intersecting clip is on, and that clip's event is highlighted in the Edit Index. This makes it easy to see the correspondence between a clip in the Timeline and its event, which is helpful when troubleshooting problems. There are also commands available in the Option menu to display only clips on enabled tracks, only video clips, and only audio clips.

Edit Index Columns

Each event populates several columns of information. These columns can be rearranged by dragging them to the left or right, depending on what information is most important to you.

The available columns of information are:

- **#:** The event number (which corresponds to the clip number shown in the Thumbnail timeline of the Color page).
- **Reel:** The reel name of the corresponding clip.
- **Match:** Flags clips that have clip conflicts, which display a question mark in this column. Once the clip conflict has been resolved, this flag disappears.
- **V:** Video event.
- **C:** The event type (C for cut, D for dissolve or transition).
- **Dur:** A number showing the duration of a transition in frames.
- **Source In/Source Out:** The Source In and Source Out timecode indicating the range of timecode referenced by that clip; corresponds to the timecode locations of each clip's In and Out point relative to the source media it comes from.
- **Record Duration:** The duration of the clip in the Timeline, determined by the Record In/Out timecodes.
- **Record In/Record Out:** Record In and Record Out timecode indicating that clip's position in the Timeline.
- **Name:** The name of the clip.
- **Comments:** Whatever comments were present in the EDL that was imported. For example, clip names exported from the original NLE to be used as reel names in RED workflows using EDL import.
- **Source Start/ Source End:** The very first and last frame of media available in the Source Media for that clip.
- **Source Duration:** The duration, in timecode, of the total source media available in that clip.
- **Codec:** The codec of the corresponding clip.
- **Source FPS:** The frame rate of the corresponding clip.
- **Resolution:** The frame size of the corresponding clip.
- **Color:** The color of flags or markers applied to that clip.
- **Notes:** Notes entered inside of markers applied to clips or the Timeline.
- **EDL Clip Name:** Shows the name of the imported EDL. Clicking in this column lets you edit the Clip Name in the text field.
- **Marker Keywords:** Lists all keywords found in a particular marker.

The columns in the Edit Index can be customized to prioritize the information that's important to you.

Methods of customizing metadata columns in the Edit Index:

To show or hide columns: Right-click at the top of any column in the Edit Index and select an item in the contextual menu list to check or uncheck a particular column. Unchecked columns cannot be seen.

To rearrange column order: Drag any column header to the left or right to rearrange the column order.

To resize any column: Drag the border between any two columns to the right or left to narrow or widen that column.

You can also customize column layouts in the Edit Index. Once you've customized a column layout that works for your particular purpose, you can save it for future recall.

Methods of saving and using custom column layout:

To create a column layout: Show, hide, resize, and rearrange the columns you need for a particular task, then right-click any column header in the Media Pool and choose Create Column Layout. Enter a name in the Create Column Layout dialog, and click OK.

To recall a column layout: Right-click any column header in the Media Pool and choose the name of the column layout you want to use. All custom column layouts are at the top of the list.

To delete a column layout: Right-click any column header in the Media Pool and choose the name of the column layout you want to delete from the Delete Column Layout submenu.

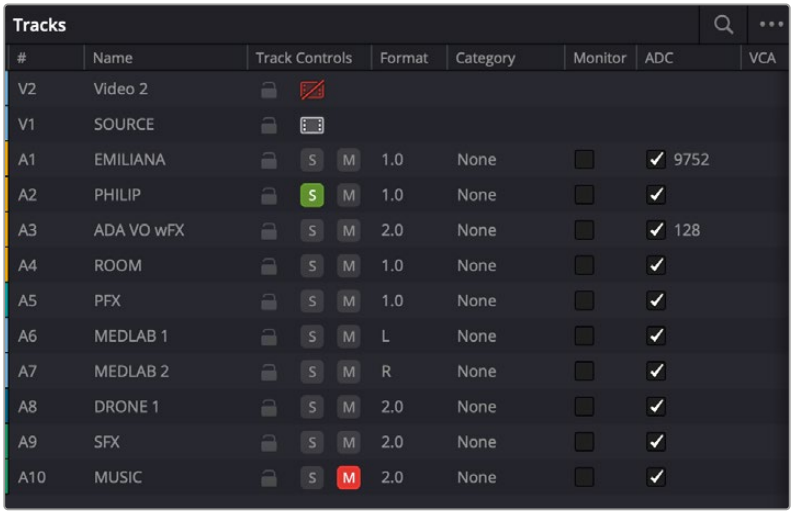
Filtering the Edit Index

You can use options found in the Edit Index's option menu to filter specific things that you want to check out, whether to go through all of the marked clips to see if there are any notes you need to address, or to isolate all offline clips, or to go through edits to see if there's anything you need to fix. You can filter the Edit Index in the following ways:

- **Show All:** Shows all entries in the list. Choose this option after using any of the other options to go back to seeing the entire timeline.
- **Show Active Track Items:** Filters out all clips that appear on tracks above or below tracks identified with a destination control. For example, if you have three video tracks and the destination control is on track V2, then all clips on tracks V1 and V3 will be hidden from the Edit Index.
- **Show Video Track Items:** Filters out all audio clips so only video clips appear in the list.
- **Show Audio Track Items:** Filters out all video clips so only audio clips appear in the list.
- **Show Flags:** Isolates clips with flags in the list. A submenu lets you choose to show all clips with flags or only clips with a particular color of flag.
- **Show Markers:** Isolates all clips with markers in the list. A submenu lets you choose to show all clips with markers or only clips with a particular color of marker.
- **Show Clip Colors:** Isolates all clips that have been labelled with clip colors in the list. A submenu lets you choose to show all clips that are labelled using any clip color or only clips labelled with a particular color.
- **Show Through Edits:** Filters only clips that have through edits, or cuts where continuous timecode appears from the outgoing to the incoming half of the edit, that you may or may not want to remove, depending on why they're there.
- **Show Offline Clips:** Isolates all offline clips (clips that have become unlinked from the corresponding source media on disk) in the Timeline, so you can quickly navigate to each one and troubleshoot the issue.
- **Show Clip Conflicts:** Filters all clips with clip conflict warning badges (indicating there is reel, name, and timecode metadata that overlap that of another clip) in the Timeline, so you can quickly navigate to each one and check whether they're using the correct clip.
- **Show Clips With Speed Effects:** Filters all clips with linear or variable Speed Effects in the Timeline.
- **Show Clips With Composite Effects:** Filters all clips with Composite mode or Opacity settings other than the default (Normal, 100).
- **Show Clips With Transform Effects:** Filters all clips with altered Transform settings.

- **Show Clips With Filters:** Filters all clips with Resolve FX or OFX filters applied to them.
- **Show Stills and Freeze Frames:** Filters all clips that are stills or that have freeze frame speed effects applied to them.
- **Show Compound Clips and Nested Timelines:** Filters all compound clips and nested timelines in the Timeline.
- **Show VFX Connect Clips:** Filters all Fusion Connect Clips.

Exporting the Edit Index



If you've filtered a series of edits in the Edit Index that you'd like to share with someone else, this is easy to do. For example, you might filter the Edit Index to show a list of all the offline clips in the current timeline, and then export a list as either a .csv or .txt file to give to your assistant editor so they can chase down the necessary media. Both types of files are widely compatible with spreadsheet and database software in the event you want to import the data into another application.

To export the Edit Index:

1. Click on the Edit Index option menu, and choose Export Edit Index from the contextual menu.
2. Use the Export Edit Index window to choose a location to save the exported file, and choose a format from the drop-down menu at the bottom. You can export either a Comma Separated Values (.csv) file, or a Tab Delimited Values (.txt) file.
3. Click Save.

Tracks

Several of the most common track controls can be found together in the Track Index. The Track Index is accessed by clicking on the Index Pane, and selecting the Tracks Tab. The index shows all the current tracks in your timeline and their position and attributes. These are all modifiable right inside the Track Index.

The Tracks Index

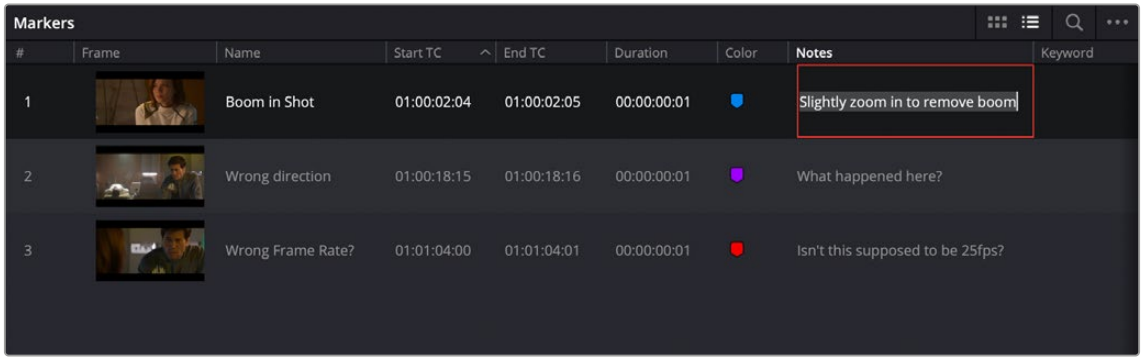
Tracks Index Columns

Each track reveals several columns of information. These columns can be rearranged by dragging the column headers to the left or right, depending on what information is most important to you. Clicking on a track row selects the track for modification.

The available columns of information are:

- **Color:** The current color of the track is shown. Right-click anywhere in the row and choose Change Track Color to choose a new one.
- **#:** Displays the current track order. You can rearrange the order of the tracks by dragging the number in this column up or down in the track hierarchy and releasing the mouse button. Note that the actual absolute track number (V1, A1, etc.) does not change, but the track that is assigned to that number will have changed.
- **Name:** The name of the Track. You can click in this field to rename the track.
- **Track Controls:** The same track controls that are found in the Track Header in the Timeline can also be accessed here: Lock/Unlock, Disable/Enable Video Track, Solo, and Mute.
- **Format (audio track only):** Shows the current format of the audio track. You can change this format to any other by right-clicking anywhere in the row of an audio track and choosing Change Track Type to, and then selecting a new format from the contextual menu.
- **Monitor (audio track only):** Selects which tracks can be selected in the monitor drop-down menu in the upper right of the Edit Timeline or Fairlight page windows.
- **ADC (audio track only):** Checking this box turns on Automatic Delay Compensation (ADC) for the track.

Right-clicking on a track or multiple tracks in the track index allows you to delete all selected tracks by choosing Delete Tracks from the contextual menu.



Clicking on the Tracks Index's option menu lets you include or exclude track types (video, audio, subtitle) from the tracks.

Markers

You can use the Marker Index to easily view, edit, and organize all your timeline and clip markers in one convenient location. The Marker Index can be found by clicking on the Index panel and selecting the Markers tab.

Methods of working with markers in the Marker Index:

- **To filter markers in the Marker Index:** Click the Option menu of the Marker Index, and choose Show All or Show Only to choose a specific color. Each clip with a matching marker appears in a list, with columns corresponding to the color(s), information, and notes of each timeline and clip marker. Columns can be sorted in ascending or descending order by clicking on the column header. Individual columns can be turned on or off by right-clicking on the column header and checking or unchecking the column name.
- **To move the playhead to the position of a marker in the Marker Index:** Double-click that marker's entry in the list.
- **To edit marker information:** You can change the values of a marker by clicking in the Name, Notes, or Keyword fields and modifying the text field. Other values are not editable in the Marker Index and should be changed in the timeline marker's Edit dialog.
- **To search for a specific marker:** Click on the Search icon (magnifying glass), and type in your search terms. Currently the search only queries the Marker Name column; you cannot search by notes and keywords.
- **To switch between Thumbnail and List view:** Click on either the Thumbnail or List View icons in the top bar of the Marker Index.

The Marker Index in List View mode lets you edit and organize all your timeline's markers in one place.

Source and Timeline Viewers

By default, the Edit page presents a traditional source/record style editing experience. The Source Viewer lets you view individual clips from the Media Pool to prepare them for editing. Meanwhile, the Timeline Viewer lets you play through your program, showing you the frame at the position of the playhead in the Timeline.

Source and Timeline Viewers

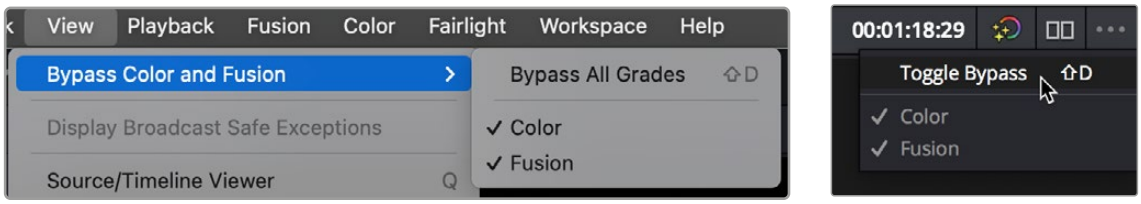
You can select either viewer by clicking with the pointer, or by pressing Q (Source/Timeline Viewer), and the name of the viewer that currently has focus appears in orange.

How Each Clip's Grade Looks in Each Viewer

Because of DaVinci Resolve's deep color and effects tools, the state of the image you see in each viewer of the Edit page depends on a number of things.

The Source Viewer

The Source Viewer shows each clip as it looks at the source. If you have Resolve Color Management (RCM) turned on or source LUTs applied, then the Source Viewer will show your clips as they're being processed by RCM and/or the source LUTs, since those are source-level color operations. However, in the absence of RCM and source LUTs, the image in the Source Viewer looks exactly the same as it does on disk. If you have log-encoded media that looks flat and low-contrast, then that's how it's going to look in the Source Viewer.



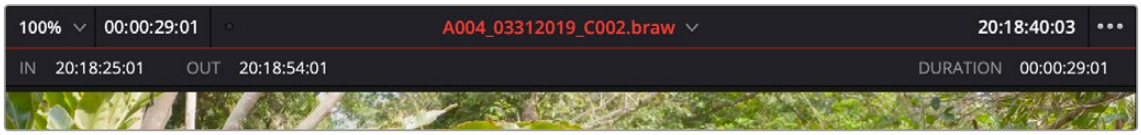
The Timeline Viewer

The Timeline Viewer follows all of the same rules as the Source Viewer, with the addition that the Timeline Viewer also shows you how each clip in the Timeline looks with Fusion page and/or Color page operations applied, since the Timeline Viewer is actually showing you the output of the Color page, so you can see every clip of your program in context of how the image is being affected by the DaVinci Resolve image processing pipeline.

> **NOTE:** The Color Viewer Lookup Table options in the Color Management panel of the Project Settings only affect the GUI Viewer in the Color page. They do not affect the viewers in the Edit page.

Turning Grades and/or Fusion Effects Off in the Timeline Viewer

The Bypass Color Grades and Fusion Effects button/drop-down from the Color page is also available on the Edit page either via the View > Bypass Color and Fusion drop-down, or via a toggle button/drop-down menu in the Timeline Viewer. If you choose Bypass All Grades or click the Viewer control, you'll turn off whatever is checked in the optional menu, which lets you choose whether or not you want to bypass both Color and Fusion, or just one or the other.

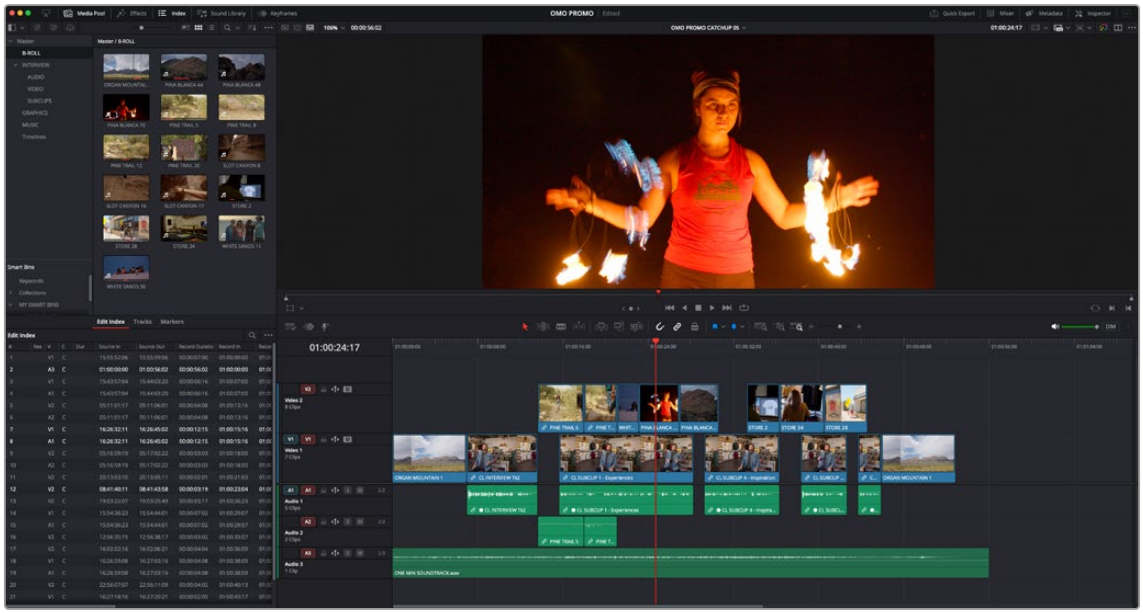


(Left) Menu commands for bypassing Color and Fusion, (Right) Edit page Timeline Viewer controls

Turning off color grades and Fusion effects is an easy way to improve playback performance on low power systems when you just need to make a quick set of edits, and it's also a convenient way to quickly evaluate the original source media.

Timecode Toolbar on Edit Viewers

You can enable the same Timecode toolbar from the Media page in the Edit page. In the Edit page Source or Timeline Viewer, select the Option (3-dot) menu, and select Show Timecode Toolbar from the drop-down. The Timecode Toolbar shows the In/Out point timecodes, as well as the total duration set.

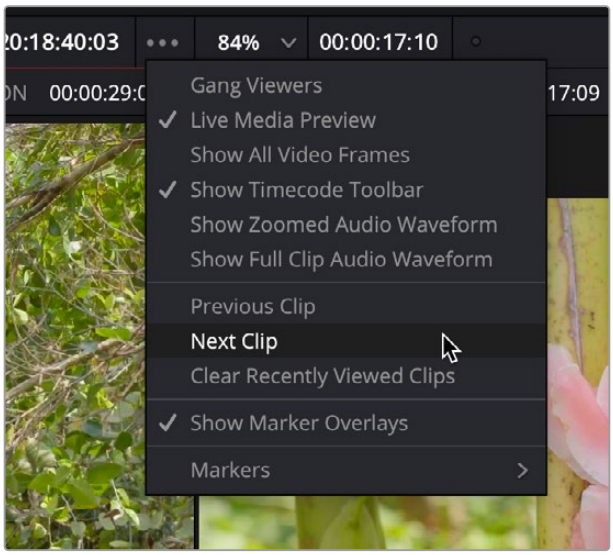


The Timecode toolbar activated in the Source monitor

Source and Timeline Viewers vs. Single Viewer Mode

If you want to change the Edit page layout to hide the Source Viewer, you can choose Workspace > Single Viewer Mode to instead use just a single viewer to contextually display either a selected Source Clip or the current frame of the Timeline.

In Single Viewer mode, whatever you select in the Media Pool or Timeline determines which controls appear in the Viewer, which lets you do nearly everything you can do with two simultaneously open viewers.



Single Viewer mode turned on

Previous and Next Clips or Timelines in Viewers

In the Viewer's Option (3-dot) menu in the Media. Edit and Color pages, you can navigate to the recent next/previous clip or timeline directly from the submenu.

- **Edit page Source Viewer:** Previous/Next Clip
- **Edit page Timeline Viewer:** Previous/Next Timeline

Selecting the next clip from the Viewer Option menu

Viewer Controls

Both viewers share the following onscreen controls:

- **Zoom drop-down menu:** Choosing Fit fits the currently visible frame to the available size of the Viewer. Choosing a percentage zooms the visible frame to that size. You can also use the scroll wheel functionality of your mouse, trackpad, or tablet to zoom in and out of the Viewer..
- **Duration field:** At the top left-hand side of the Source Viewer, this displays the total duration of the clip, or the duration from the In to the Out point, if these have been placed. In the Timeline tab, this displays the total duration of the currently selected timeline.
- **GPU Status Display:** Every viewer in DaVinci Resolve exposes a GPU status indicator and a frame-per-second (FPS) meter, which appears in the Viewer's title bar, which shows you your workstation's performance whenever playback is initiated. Since DaVinci Resolve uses one or more GPUs (graphics processing units) to handle all image processing and effects, the GPU status display shows you how much processing power is being used by whichever clip is playing.
- **Clip Name:** The clip name is displayed at the center of the Source Viewer title bar.

  The Source Viewer: Displays a drop-down at the top of the Source Viewer, next to the name of the currently open clip, which lets you open a menu containing a list of the last 10 clips you opened in the Source Viewer. This list is first in, first out, with the most recently opened clips appearing at the top. If you wish to clear the visual history in the menu, you can remove unwanted entires and start a new queue by clicking on the Viewer's option menu and selecting Clear Recently Viewed Clips.

  The Timeline Viewer: Displays the timeline name and is also a drop-down menu that lets you switch among other timelines in the current project. The clip/timeline name is highlighted orange when either the Source or Timeline Viewer has focus.

- **Bypass Color Grades and Fusion Effects:** The Bypass Color Grades and Fusion Effects button/drop-down from the Color page is also available on the Edit page either via the View > Bypass Color and Fusion drop-down, or via a toggle button/drop-down menu in the Timeline Viewer. Turning off color grades and Fusion effects is an easy way to improve playback performance on low power systems when you just need to make a quick set of edits, and it's also a convenient way to quickly evaluate the original source media.
- **Source/Timeline Timecode/Frame/Keykode Display:** At the top right-hand side of the Source Viewer, this field shows the timecode of the current frame at the position of the playhead in the Source Viewer's jog bar, and can be switched between source timecode, source frame, and keykode by right-clicking and choosing from the contextual menu. In the Timeline Viewer, this field shows the record timecode of the current frame at the position of the playhead in the Timeline, and can be switched between source and record timecode, source and record frames, and keykode by right-clicking and choosing from the contextual menu.
- **Source Viewer Option menu:** Contains the following commands:

  Gang Viewers: With Gang Viewers enabled, the movement of the Source and Timeline Viewer playheads is locked together, so that they move in unison. This is useful when you're matching the timing of part of a clip in the Source Viewer to match an event in the Timeline.

  Live Media Preview: Enabled by default, makes it possible for thumbnails that you're skimming in the Media Pool to show the skimmed frame in the Viewer. When skimming with Live Media Preview enabled, the playhead that appears in the thumbnail is locked to the playhead displayed in the Viewer's jog bar.

  Show Timecode Toolbar: The Timecode toolbar shows the In/Out point timecodes, as well as the total duration set.

Show All Video Frames: When available processing power is insufficient to play the clip or clips at the position of the playhead due to the grade, transforms, or effects that are applied at that moment in the Timeline, you have the ability to choose exactly how performance in DaVinci Resolve degrades. When off, DaVinci Resolve prioritizes audio playback at the expense of dropping video frames when processing power is tight, resulting in a more conventional playback experience. When on, audio quality is compromised while every frame of video plays in slower-than-real time to maintain playback.

Show Zoomed Audio Waveform: When enabled, shows an audio waveform overlay at the bottom of the Source Viewer with a zoomed in section of the audio surrounding the current position of the playhead.

Show Full Clip Audio Waveform: When enabled, shows an audio waveform overlay at the bottom of the Source Viewer that displays the audio over the entire duration of the clip.

Previous Clip: Goes to the previous clip in the Media Pool.

Next Clip: Goes to the next clip in the Media Pool.

Clear Recently Viewed Clips: Clears the memory of the recent clips in the Source Viewer.

Show Marker Overlays: Enabled by default, markers that intercept the playhead when playback is paused appear superimposed in the Viewer.

Markers submenu: When one or more markers are applied to the clip in the Source Viewer, they appear in this list in chronological order, listed by Name and Note. Choosing a marker from this menu jumps the playhead to that marker in the Source Viewer.

- **Timeline Viewer Option menu:** Contains the following commands:

Gang Viewers: With Gang Viewers enabled, the movement of the Source and Timeline Viewer playheads is locked together, so that they move in unison. This is useful when you're matching the timing of part of a clip in the Source Viewer to match an event in the Timeline.

Show All Video Frames: When available processing power is insufficient to play the clip or clips at the position of the playhead due to the grade, transforms, or effects that are applied at that moment in the Timeline, you have the ability to choose exactly how performance in DaVinci Resolve degrades. When off, DaVinci Resolve prioritizes audio playback at the expense of dropping video frames when processing power is tight, resulting in a more conventional playback experience. When on, audio quality is compromised while every frame of video plays in slower-than-real time to maintain playback.

Show Timecode Toolbar: The Timecode toolbar shows the In/Out point timecodes, as well as the total duration set.

Timeline Sort Order: These options allow you to set the sort order that timelines use in the timeline selector in the top middle of the Viewer. Options are: Alphabetical, Creation Date, or Recently Used (shows the last 10 actively used timelines).

Previous Timeline: Goes to the previous timeline in the Media Pool.

Next Timeline: Goes to the next timeline in the Media Pool.

Show Marker Overlays: Enabled by default, markers that intercept the playhead when playback is paused appear superimposed in the Viewer.

Show Timecode Overlays: When enabled, shows the source timecode of the video and audio clips under the position of the playhead when playback is paused.

Show Overlays During Playback: When enabled, shows timecode and marker overlays on the Viewer constantly during playback. When disabled, overlays are only visible while playback is paused.

Markers submenu: When one or more markers are applied to a Timeline, they appear in this list in chronological order, listed by Name and Note. Choosing a marker from this menu jumps the playhead to that marker in the Timeline.

- **Source Viewer Mode drop-down (Source Viewer only):** This drop-down menu lets you set the Source Viewer to display different views of the clips you're working on, depending on what you need to do.

  Source: Shows the video of the currently open clip in the Source Viewer.

  Offline Reference Movie button: If you've assigned an offline reference movie to the currently selected timeline, clicking the Offline Mode button lets you display the offline movie so you can compare it with the currently open timeline. In this mode, Source and Timeline playback are synced; an Offset field replaces the duration field, letting you re-sync the offline reference movie, if necessary.

  Audio Track: Shows the audio waveforms corresponding to all channels of the currently open clip in the Source Viewer. The top of this audio-only view shows the waveform for the entire duration of the clip, while the main region of the viewer shows a zoomed in section of the audio waveform. The level of zoom displayed is controlled by the zoom drop-down at the upper left-hand corner of the Source Viewer.

  Multicam: Shows you the multi-angle Multicam Viewer that you can use to switch among different angles of video and audio while multicam editing a clip in the Timeline.

  > For more information on multicam editing, jump to this chapter: Multicam Editing.

  Annotations: Allows you to draw directly onto the current frame to highlight areas for further attention.

- **Transform Mode drop-down (Timeline Viewer Only):** This functions as both a toggle switch and a drop-down menu. Clicking the button control to the left enables or disables onscreen controls that you can use to transform the clip right in the viewer. Clicking the drop-down control to the right lets you switch between two modes of transforms:

  Transform: Exposes controls for Pan (X) and Tilt (Y), Scale X and Y, and Rotation.

  Crop: Exposes controls to crop from the top, bottom, left, and right.

  Dynamic Zoom: Shows controls to do quick pan and scan effects on the selected clip.

  OpenFX Overlay: Exposes the onscreen controls of an applied OpenFX filter.

  Fusion Overlay: Exposes the onscreen controls of an applied Fusion FX or Title filter.

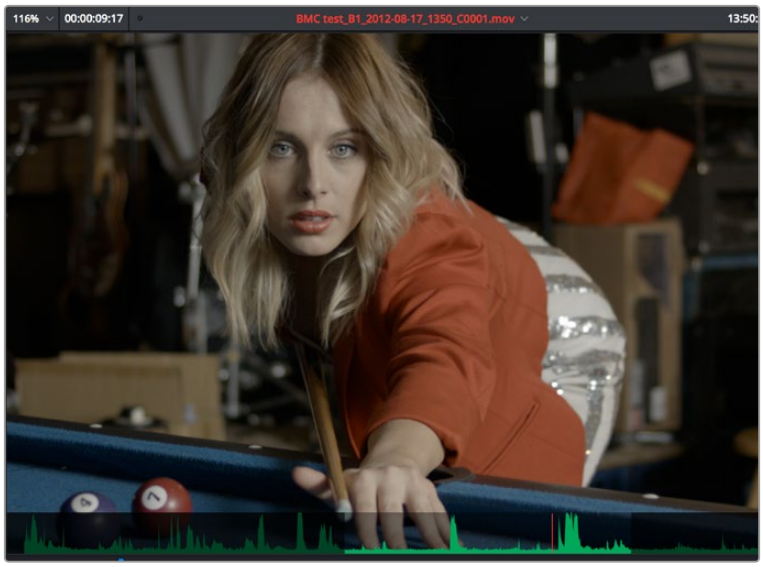
  Annotations: Allows you to draw directly onto the current frame to highlight areas for further attention. Right-clicking in the viewer will let you select a specific control from the dropdown list. You can also Tab and Shift-Tab through the Fusion controls in the inspector to select a control.

  Smart Reframe: Exposes the onscreen controls of the Smart Reframe.

- **Jog control:** Clicking the Jog control and dragging left and right lets you move slowly through a clip or the Timeline a frame at a time.
- **Transport controls:** These controls include, from left to right, Jump to First Frame, Play Reverse, Stop, Play Forward, Jump to Last Frame.
- **Loop Playback:** Enables or disables looped playback. Looping is also controllable via the Playback > Loop/Unloop command (Command-/). When enabled, each playback command loops back to the beginning when the end of that command's range is reached. In and Out points in the Source or Timeline Viewers do not trigger looping. For example, when enabled, the Play command will play through the entire clip or timeline, and then loop back to the beginning when the end is reached and start playing automatically. The Play Around command, on the other hand, will start at the beginning of pre-roll, play through the post-roll, and then immediately loop back around to the beginning of pre-roll, continuing playback in this manner until you stop it.

- **Match Frame:** In the Source Viewer, Match Frame attempts to move the playhead in the Timeline to match the current frame of the clip in the Source Viewer. In the Record Viewer, Match Frame opens the Media Pool clip corresponding to the clip at the current position of the playhead into the Source Viewer, setting In and Out points and the playhead position to match those of the clip in the Timeline.
- **In/Out buttons:** Places In and Out points with which to define a range of the clip, or of the Timeline, in preparation for making different kinds of edits.
- **Jog bar:** In the Source Viewer, drag within the jog bar to reposition the Source playhead, scrubbing through the clip. In the Timeline tab, drag to reposition the playhead throughout the entire program.
- **Skim Playhead:** You can skim footage in any viewer in the Media, Cut, Edit, Color, and Deliver pages by holding down the C key, and scrubbing the pointer back and forth in the viewer.

Transport Controls and Important Playback Controls



While the operation of the main transport controls is probably obvious, there are additional playback controls of interest to the editor that may not be so readily found.

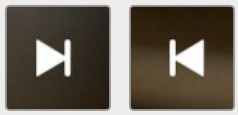
For more information on transport controls,jump to this chapter: Preparing Clips for Editing and Viewer Playback.

Simultaneous Audio Waveform Display in the Source Viewer

When the Source Viewer is set to Source, two options in the Option menu let you see a superimposed audio waveform running along the bottom of the viewer, over the video of the currently selected clip.

- **Show Zoomed Audio Waveform:** Shows a zoomed-in section of audio that scrolls as you play the clip. Useful for seeing dialog and music cues as you play through a clip.
- **Show Full Clip Audio Waveform:** Shows the audio waveform for the entire source media of that clip. The section of audio from the In to Out points you've set in the Source Viewer are highlighted. Useful for using the audio waveform to navigate throughout that clip using the waveform as a reference.

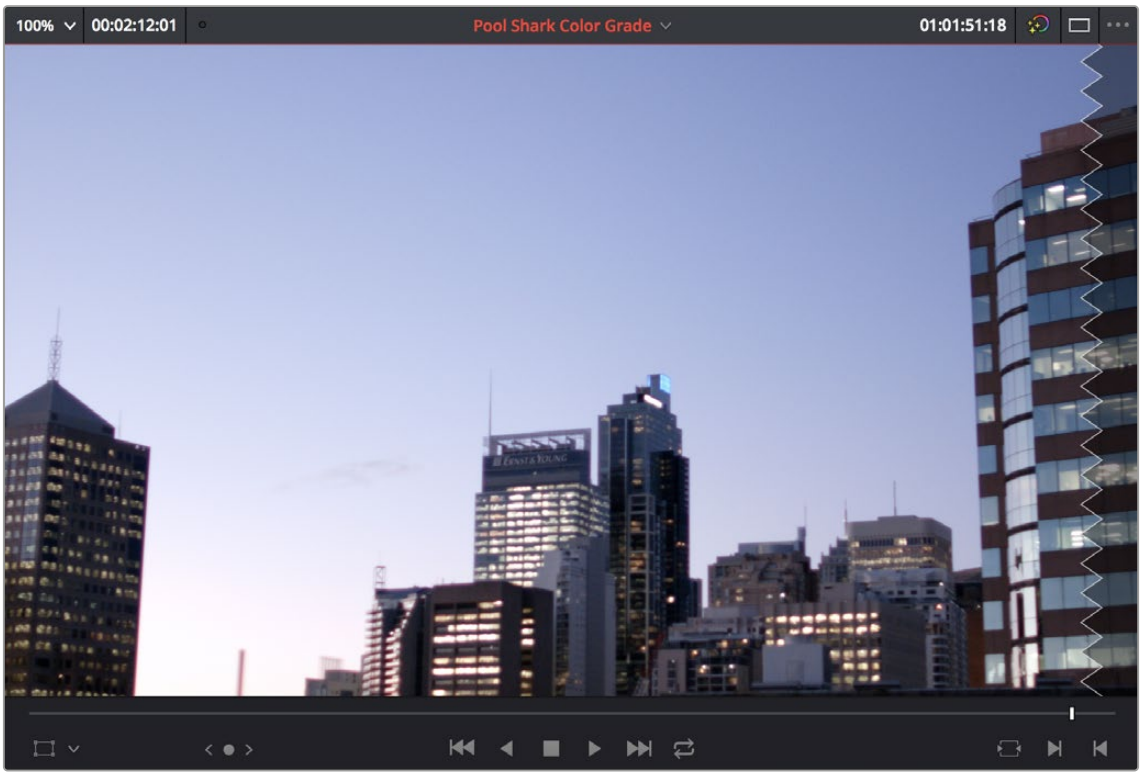
The Source Viewer with "Show Full Clip Audio Waveform" enabled



Cinema Viewer Mode

You can also put either the Source or Timeline Viewers into Cinema Viewer mode by choosing Workspace > Viewer Mode > Cinema Viewer (P), causing whichever viewer is currently selected to fill the entire screen, which is good for doing a test viewing of your edit without the distractions of the DaVinci Resolve Edit Page UI. This command toggles Cinema Viewer mode on and off.

Viewer Indicators



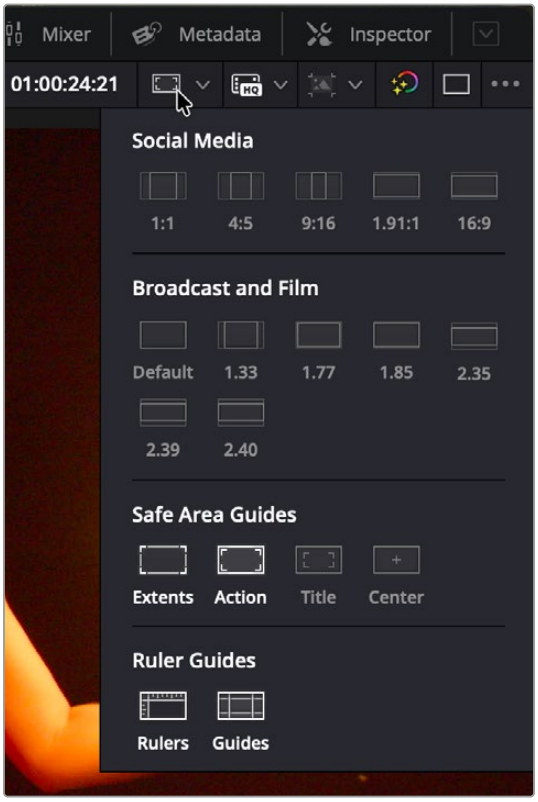
Certain frames trigger visible indicators in either the Source or Timeline viewers.

For example, if the playhead is at the very first or last frame of media available to a particular clip, indicators appear in the lower-left or right corner of the frame to let you know there's no more media in that direction.

The first and last frame clip indicators

If the playhead in the Timeline is on the first frame of black immediately after the last video clip in the Timeline, an end of sequence indicator appears in the Timeline Viewer to let you know that you're viewing the last frame of the current sequence of clips, even though the playhead is actually on a frame of black. This makes it easy to see what you're doing while you're first assembling clips together.

The end-of-sequence indicator



Other Viewer Options

There are additional overlays and options you can use to customize how the viewer appears.

- **Safe Area and Guides:** In the upper-right corner of the Timeline Viewer, you can turn on and select one or multiple Safe Area guides to be overlayed on the Viewer.

  This allows you to easily see if the important action in the frame still is composed adequately for different delivery requirements.

- **Show Checkerboard, Black, Gray, or Alert Red Backgrounds in Viewers:** Selecting Viewer Background in the Timeline View options changes the empty area of the Viewer (if there is any) to the selected option, making it easier to see which parts of the Viewer are black because of blanking and which parts are simply empty because of the way the image is zoomed or panned.

The Safe Area selector

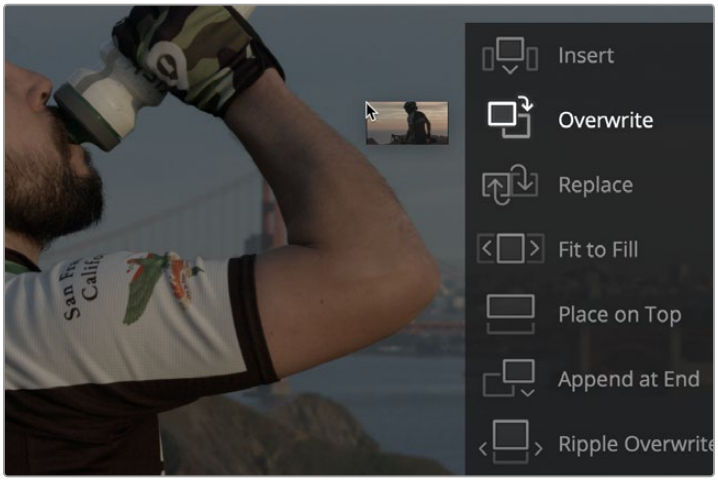
Fast Review in the Timeline Viewer

Fast Review plays back your timeline at variable fast forward speeds where the speed of playback is dependent on the length of each clip on the Timeline. Longer clips play back at faster speeds than shorter ones. This feature is designed to allow you to quickly scan through a large amount of material on a timeline.

To use the Fast Review feature on your Edit page Timeline, select Playback > Fast Review. Pressing K or the spacebar will return you to the normal JKL playback mode. If you use this feature often you can bind Fast Review to a specific key in the Keyboard Customization window.

NOTE: Fast Review does not work for clips in the Source Viewer, only for timelines in the Timeline Viewer.

Opening Clips in the Source Viewer



There are two methods of opening clips into the Source Viewer. Which is enabled depends on the “Live Media Preview” setting found in the Viewer options menu (the three-dots menu found at the upper right-hand corner of the Viewer).

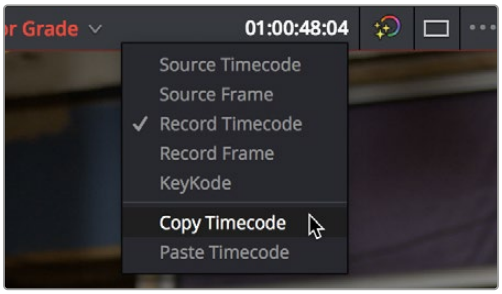
- When Live Media Preview is enabled (by default), skimming a thumbnail in the Media Pool also shows the skimmed frame in the Source Viewer, effectively opening each clip you skim in the Media Pool into the Source Viewer. As you skim, the playhead that appears in the thumbnail is locked to the playhead that’s displayed in the Viewer’s jog bar.
- When Live Media Preview is disabled, you must either double-click a clip in the Media Pool to open it into the Source Viewer, or you can select a clip in the Media Pool and press the Return key to open it into the Source Viewer.

  Which method is best is purely a matter of preference.

Timeline Viewer Edit Overlays

Dragging a clip from the Media Pool or Source Viewer onto the Timeline Viewer also exposes edit overlays that let you choose what kind of edit you want to make by choosing which overlay to drop the clip onto.

The overlay that appears when you drag a clip onto the Timeline Viewer lets you choose from a variety of edits



This overlay exposes every type of edit that’s available in DaVinci Resolve, including the Insert, Overwrite, Replace, Fit to Fill, Place On Top, Ripple Overwrite, and Append at End edits, all of which are also available from the Edit menu. It’s a useful method of making three-point edits if you like drag and drop editing, but it also provides a nice reminder of what types of edits are available, given all the different options that are available.

By default, the larger empty area to the left of these overlays defaults to the highlighted Overwrite overlay, while all the smaller buttons let you perform each of the other edit types that are available.

However, the “Timeline overlay retains the last performed action” checkbox in the Editing panel of the User Preferences can be turned on if you want DaVinci Resolve to always remember the last edit type you used, and highlight it on this overlay whenever you drag another clip over the Timeline Viewer to let you know that the last edit you performed is the new default edit if you drop clips to the left of the overlay. For example, with this option enabled, if you perform a place on top edit, then the next time you drop a clip into the empty area to the left of the overlays, the result will be another place on top edit. This option is off by default.

Copy and Paste Timecode in Viewer Timecode Fields

You can right-click on most Viewer timecode fields in the Media, Edit, and Color pages to choose Copy and Paste commands from a contextual menu for copying and pasting timecode values. You can also click in the timecode fields and use the normal Copy (Command-C), and Paste (Command-V) keyboard commands. This works even between pages. The timecode value you're pasting must be valid timecode, for example you can't paste 0 hour timecode onto a 1 hour timeline.

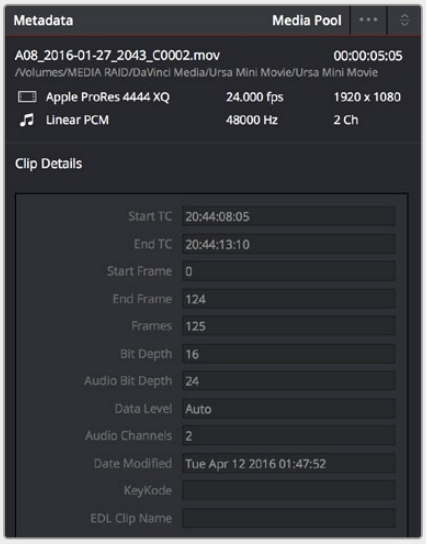
Right-clicking on a timecode field to use the Copy Timecode command

Export The Current Frame from The Viewer

You can now export a still frame from the Viewer in the Media, Cut, and Edit pages.

To Export a Still Frame from the Viewer:

1. Select either the Source or Timeline viewer for export.
2. Use the Viewer's playback controls to navigate to the frame you want to export.
3. Select File > Export > Current Frame as Still.
4. Enter the name of the still frame in the File System viewer.
5. Enter the desired format of the still frame in the File System viewer.
6. Click on the Export button.



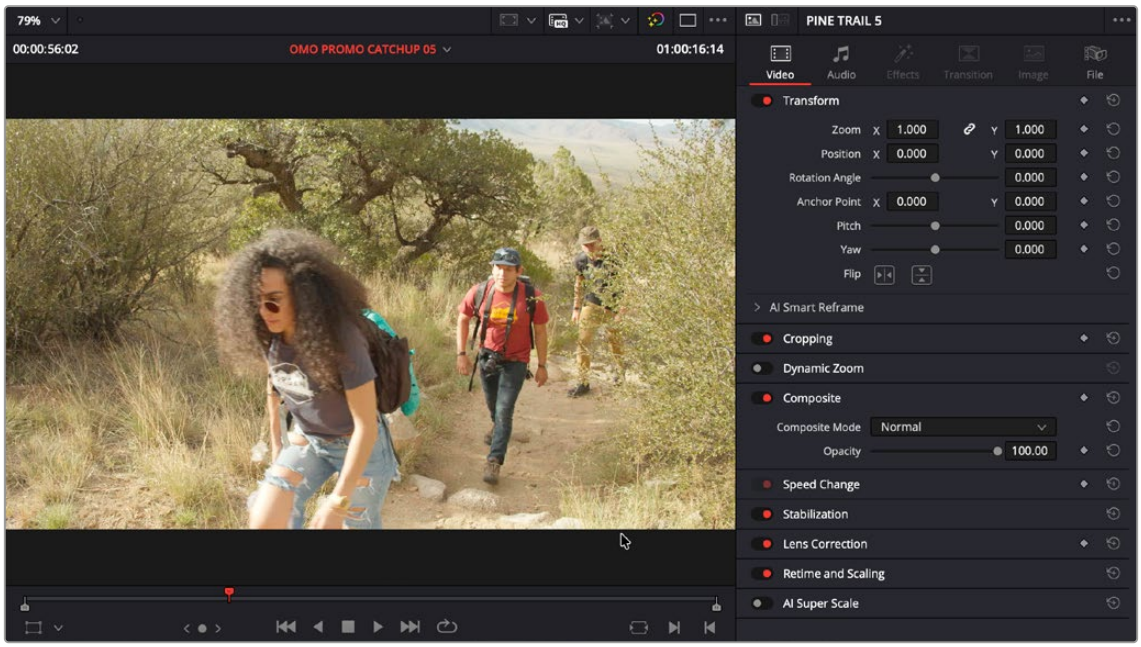
Metadata Editor

Both the Media and Edit pages have a Metadata Editor. In the Edit page, the Metadata Editor opens in the same place as the Inspector, to the right of the Source and Timeline Viewers. When you select a clip in the Media Pool or Timeline, its metadata is displayed within the Metadata Editor, and the title bar indicates whether you're evaluating a clip in the Timeline or Media Pool. If you select multiple clips, only the last clip's information appears. The Metadata Editor's header contains uneditable information about the selected clip, including the file name, directory, duration, frame rate, resolution, and codec.

Because there are so very many metadata fields available, two drop-down menus at the top let you change which set of metadata is displayed in the Metadata Editor.

- **Metadata Presets (to the left):** If you've used the Metadata panel of the User Preferences to create your own custom sets of metadata, you can use this drop-down to choose which one to expose. Surprisingly enough, this is set to "Default" by default.
- **Metadata Groups (to the right):** This drop-down menu lets you switch among the various groups of metadata that are available, grouped for specific tasks or workflows.

  The heart of the Metadata Editor is a series of editable fields underneath the header that let you review and edit the different metadata criteria that are available.



Clip Metadata Editor showing the
Clip Details panel for a clip in the Timeline

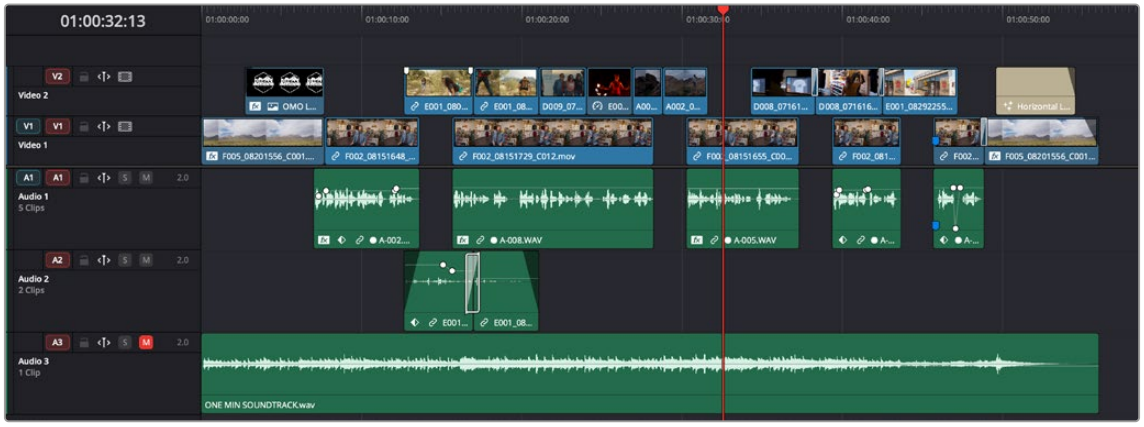
For more information on editing clip metadata, and on creating custom metadata presets, jump to this chapter: Using Clip Metadata.

Inspector

The Inspector can be opened to let you customize compositing, transform, and cropping parameters for clips, as well as clip-specific retime and scaling options. Furthermore, the Inspector lets you edit the parameters of transitions, titles, and generators used in the Timeline, in order to customize their effect.

The Inspector, opened and showing a clip's parameters

When the Inspector is open, the Source and Timeline viewers move to the left, to sit alongside the Inspector showing the selected clip's parameters. However, if your computer display's resolution is not high enough, opening the Inspector may result in the Source Viewer being hidden.

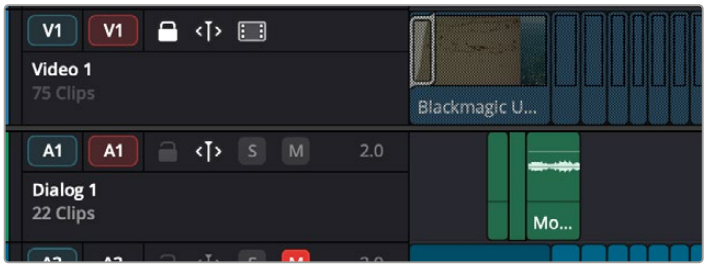


Methods of showing parameters in the Inspector:

- **To open a video or audio clip's transform settings when the Inspector is closed:** Select that clip, and then click the Inspector button at the far right of the Edit page toolbar.
- **If the Inspector is already open:** You need only select a clip or effect to reveal its controls in the Inspector.
- **If the Inspector is closed:** Double-clicking any transition will automatically open it.

The Inspector shows different buttons at the top that let you switch among different pages of parameters. For example, when you select a clip with both audio and video components, the Inspector shows Video and Audio buttons at the top that let you switch among each set of controls.

Timeline



The Timeline shows whichever timeline you've double-clicked in the Timelines browser. It's where you either edit programs together from scratch, or import sequences from other applications. For imported programs, the Timeline provides a visual representation of the edited program that's helpful for verifying that the project was imported correctly, checking the media corresponding to each clip in the program, and performing whatever editorial tasks are necessary to prepare a project for grading (such as replacing or adding clips, superimposing composites, and modifying composite modes or transitions).

An edited timeline

- **Timeline Ruler:** The Timeline Ruler shows the program's timecode, and the playhead indicates the current frame of the current clip. Whichever clip intersects the playhead is the one that you'll be working on in the Color page. Dragging within the Timeline Ruler moves the playhead. When you add markers to the timeline, these markers appear within the Timeline Ruler, as well.
- **Playhead:** The playhead automatically syncs with the Timeline Viewer's jog bar playhead, the playheads in the Mini-Timeline and Thumbnail timeline of the Color page, Cut page, and the playhead on the Deliver page. Furthermore, the Edit Index event that corresponds to the clip intersecting the playhead is automatically highlighted.

- **Timecode field:** Shows the current timecode value corresponding to the position of the playhead.
- **Video Tracks:** DaVinci Resolve supports multiple video tracks. At the left of each track is a header area that contains a number of controls.
- **Track Header:** The Track Header contains different controls for selecting, locking/unlocking, and enabling/disabling tracks. Each track header also lists how many clips appear on that track. The Track Header contains the following five controls, from left to right:

Track Header area showing the controls for each track that are located within

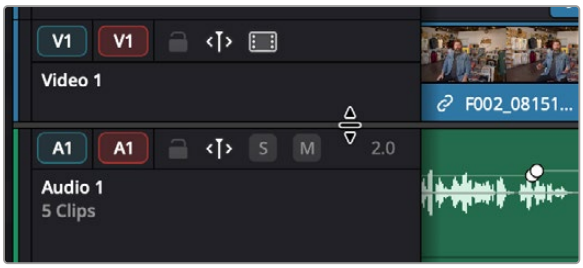
Track Color: Each track can be color-coded with one of 16 different colors. These color codes correspond to the Edit page Mixer, and to the Fairlight page Mixer and Audio Meters. You can choose a new color for any track by right-clicking the track header and choosing from the Change Track Color submenu.

Source Track Selector: Two rectangular icons in columns labeled V1, A1, A2 etc. The left side column (in blue) represents the tracks found in source clips selected in the media pool or loaded in the source viewer. The right side column (in red) represents the destination tracks on your timeline. The Source Track Selector lets you choose which track of the source clip is edited into which track on the timeline. Click any track's number to select that track for different editing functions; the selected track is highlighted in red or blue, while a deselected track has no highlight.

Lock Track button: White when turned on, dark grey when turned off. When a track is locked, clips can't be replaced, moved, or otherwise edited, although clips on locked tracks can be graded. In the timeline, the track has a grey mesh pattern overlayed onto it, letting you know it can't be modified.

Sync Lock: On by default, white when that track is selected, dark grey when that track is not selected. This icon determines the behavior of the clips in that track during a ripple edit. When enabled, it ripples with other tracks (for example, where an item is ripple deleted, and the rest of the timeline slides left to fill in the gap), when disabled, ripple works as a solo on the track but does not ripple with edit operations on other tracks.

Solo (Audio Track Only): Clicking on this icon "S" will mute all other audio tracks, and only play the selected track. You can have multiple Solo tracks selected, in order to hear just those selected tracks.



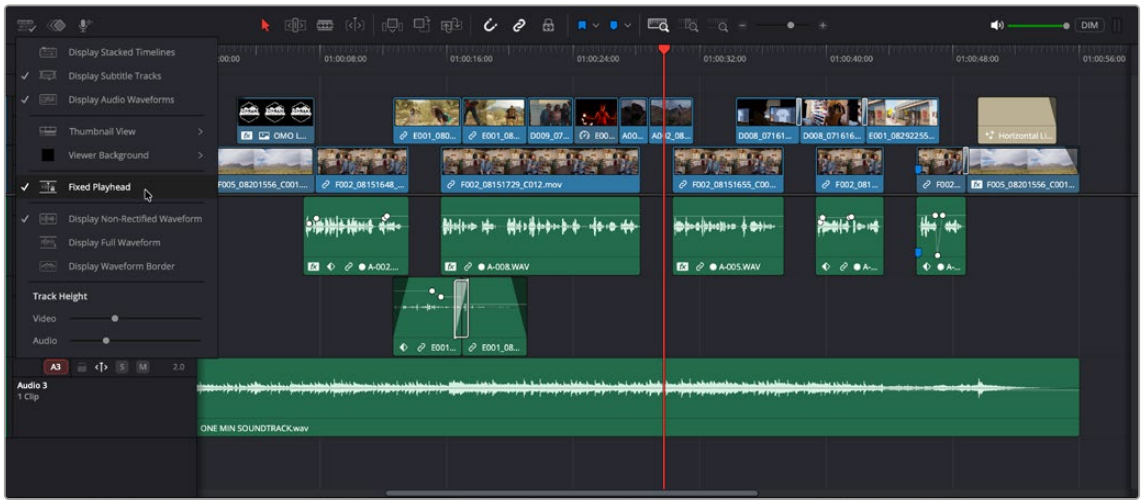
Enable Track/Mute button: A small film icon is on by default (enabled), and slash through it and a grey overlay on the track itself indicates when a track is disabled. This control lets you turn tracks on and off. Clips on tracks that are turned off aren't visible in the viewer, don't show up in the Color page, and aren't available for rendering or output. For Audio tracks this is the Mute button (M).

Audio Channel Type indicator: Audio tracks also show which channel configuration that track uses, listing the number of channels for mono, stereo, 5.1, 7.1, and adaptive.

Track Name: Each track has a name that defaults to the type of track and the track number, such as Video 1, Audio 1. However, you can click any track's name and edit it to be whatever you like. For example, you can rename each audio track with the type of audio you're editing onto it, such as Production, Ambience, SFX, or Music. These track names are also used to identify each track's channel in the Edit page Mixer and in the Fairlight page Mixer.

Number of clips: The number of clips on that particular track of the Timeline is listed, but only if the track is tall enough to have room for them.

- **Vertical and horizontal scroll bars:** If your project is longer than the current width of the Timeline, or the number of video tracks is taller than the current height of the Timeline, these scroll bars let you drag to navigate around your program.
- **Individual Timeline track resizing:** Any track in the Timeline can be individually resized by dragging its top divider in the Track Header area.



Resizing an individual timeline track by dragging its top border in the Track Header

Timeline Options

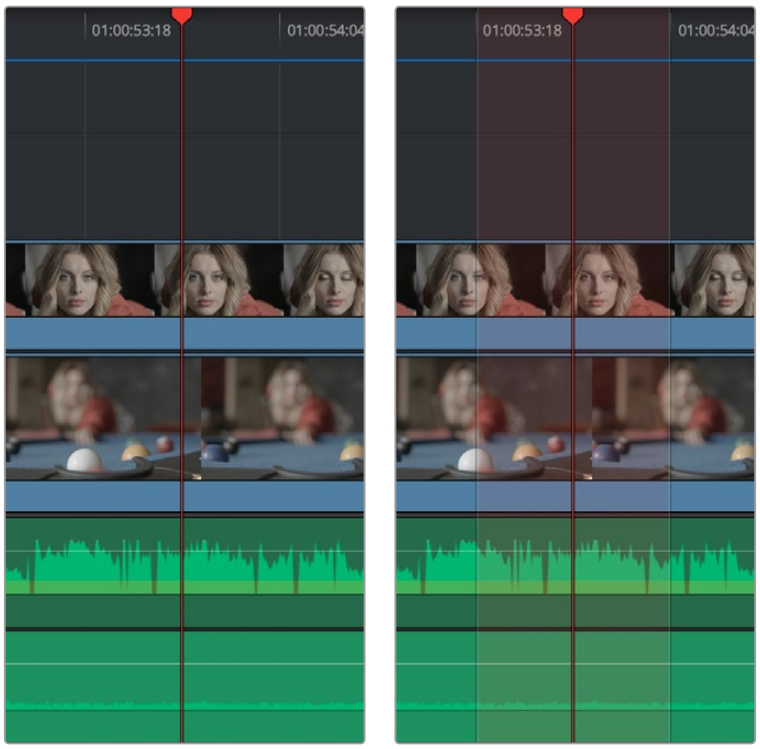
Specific elements and behaviors within the Timeline can be customized in various ways.

Fixed Playhead Mode in the Timeline

You can select the fixed playhead mode from the Timeline View options in the Edit page. This view option will keep the playhead static in the middle of the timeline, while the tracks on the timeline move underneath it, similar to the Cut page.

Selecting the Fixed Playhead mode in the Timeline View options

Selection Follows Playhead



As of DaVinci Resolve 17, the Clip selection no longer automatically moves along with the playhead. Instead, a new set of commands lets you create and move a selection by holding down the Command key and pressing the Up, Down, Left, and Right Arrow keys. This allows you to select clips above and below the current track and to the left and right, independently of the playhead.

You can return the Clip Selection mode back to its previous behavior of automatically selecting the top clip it's intersecting by choosing the option Timeline > Selection Follows Playhead.

Show Playhead Shadow

Ordinarily, the playhead is shown in the Timeline as a single line that indicates the beginning of the frame that you're viewing in the Timeline Viewer. However, you can choose Show Playhead Shadow from the User Preferences UI Settings to display an orange-ish background surrounding the playhead.

This shadow can make it easier to see the playhead's position, and it can also serve as a measuring tool for projects where you have an interest in visualizing a specific offset, in frames, both before and after the current position of the playhead. This offset can be adjusted by changing the Pre- and Post-Playhead Shadow Length parameters in the Editing panel of the User Preferences, which let you specify the number of frames to shadow both before and after the playhead. The default length of the playhead shadow is 5 frames.

(Left) The playhead's default look, (Right) The playhead showing the optional playhead shadow

TIP: You can set the "Pre-playhead shadow length" to 0, and the "Post-playhead shadow length" to 1 if you want to display a "Media Composer-style" playhead that shows the duration of the current frame.

Enabling and Disabling Audio Scrubbing

Audio scrubbing is enabled by default, meaning that you'll hear audio when dragging the playhead with the mouse back and forth. While this can be useful when you're searching for audio cues, it can also be distracting if you're just focused on the picture.

To enable or disable audio scrubbing:

Choose Timeline > Audio Scrubbing (Shift-S)

Playback Post-Roll

Enables the playhead to continue playing past the last clip in the Timeline for a duration equal to the "Post-roll time" Project Setting in the Editing panel. This is good for editors that want to experience a few moments of playback after cutting or fading to black after the last frame of audio and video in the Timeline.

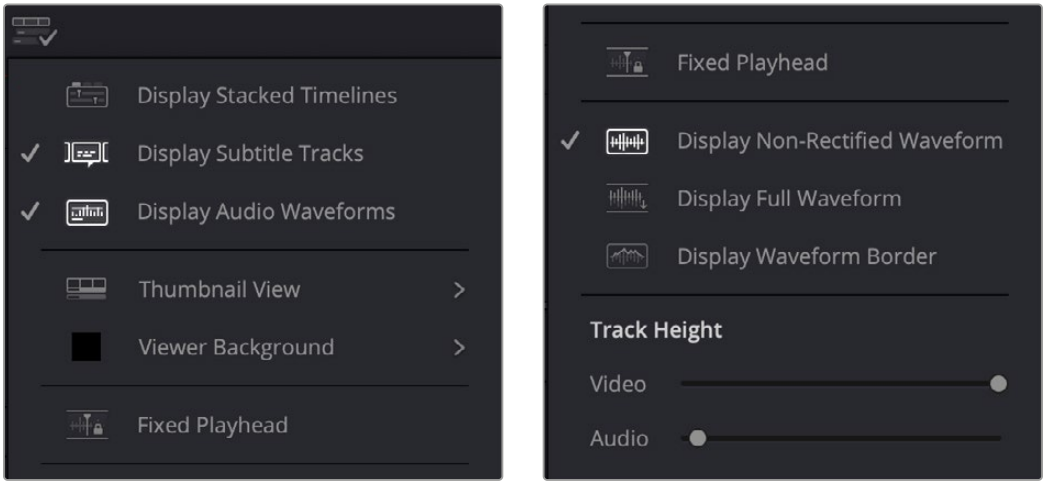
To enable or disable playback post-roll:

Choose Timeline > Playback post-roll

Switching Among Multiple Timelines

Timelines can be organized like any other clip in the Media Pool. To open or switch among timelines, use the following procedures.

To switch timelines, do one of the following:



- Double-click a timeline in the Media Pool on any page.
- Turn on Stacked Timelines in the Timeline View Options menu of the Edit page toolbar, so that all timelines you open appear as tabs. Clicking different tabs switches to that timeline.
- In the Edit page Timeline Viewer, choose a timeline from the Timelines drop-down menu at the top of the viewer.
- In the Color page, choose a timeline from the Timelines drop-down menu at the top of the Viewer.
- In the Fairlight page, choose a timeline from the Timelines drop-down menu to the left of the transport controls.

Toolbar

At the center of the toolbar that sits above the Timeline, several buttons let you choose different tools and options for performing various editing functions.

Buttons in the toolbar

Selecting the Timeline View options

Timeline View Options: The controls let you customize the look of the clips on the tracks (Filmstrip, Thumbnail, or Minimized), audio waveform displays, stacked timelines, subtitles, and the adjustable height of the video and audio tracks.

Keyframe Editor: Opens the Keyframe Editor in the timeline.

Voiceover: Opens the Voiceover tools to record directly into the timeline.

Selection Mode: The default mode in which you can move and resize clips in the Timeline, roll edits, and do other basic editing tasks. In this mode, making specific selections in the Timeline and using the nudge commands of Comma and Period resizes, moves, or rolls the selection, as does absolute or relative timecode entry.

Trim Edit Mode: In this mode, the Trim tool lets you make slip, slide, ripple, and roll edits by dragging different parts of clips in the Timeline, by making specific selections and using the “nudge” keyboard shortcuts of Comma and Period to move the selection left or right, or by making specific selections and using timecode entry to make relative or absolute adjustments.

Dynamic Trim Mode: This mode works in conjunction with either the Selection or Edit modes. With Dynamic Trim mode enabled, you can either resize and move clips (in Selection mode), or ripple, slip, or slide them (in Trim mode) using the JKL keyboard shortcuts that play forward and backward through the Timeline. While enabled, the spacebar triggers the Play Around Current Selection command. The Toolbar button for this mode also changes to show you whether you’re in slip or slide mode for nudging, timecode-entry adjustment, or dynamic trim (set by pressing the S key).

Blade Edit Mode: Lets you add cuts to clips at the playhead in the Timeline by clicking.

Insert Clip: Performs an insert edit to the Timeline with whatever clip is in the Source Viewer.

Overwrite Clip: Performs an overwrite edit to the Timeline with whatever clip is in the Source Viewer.

Replace Clip: Performs a replace edit to the Timeline with whatever clip is in the Source Viewer.

Snapping: Enables or disables clip snapping. When turned on, clip In and Out points, markers, and the playhead all snap to one another for reference while you're editing.

Linked Selection: Enables or disables audio/video linking. When turned on, clicking a video clip in the Timeline automatically selects the corresponding audio clip if they're linked together. When turned off, clicking a video clip won't select its audio. Clip linking can be toggled while you work by pressing the Option key while clicking to make selections in the Timeline.

Position Lock: Prevents clips from being moved to the left or right, and it prevents all ripple operations. Essentially ensures all the Timeline elements stay in sync and can't be adjusted accidentally.

Flag Clip/Flag Colors drop-down menu: Flags identify clips, and indicate all clips that correspond to the same item of media in the Media Pool. Clips can have multiple flags. Clicking the Flag button automatically adds a flag to whichever clip is currently selected in the Timeline. A drop-down menu to the right lets you choose differently colored flags, and clear all flags from the currently selected clip.

Add Marker/Marker Colors drop-down menu: Markers identify specific frames of individual clips. Clicking the Add Marker button adds a marker of the currently displayed color to the clip at the position of the playhead in the Timeline. A drop-down menu to the right lets you choose differently colored markers, and clear all markers from the currently selected clip.

Full Extent Zoom: Dynamically adjusts the zoom level to encompass the whole Timeline as you add or remove clips.

Detail Zoom: Zooms the Timeline in on the Playhead to the frame level.

Custom Zoom: Zooms the Timeline to the level selected by the Zoom slider to its immediate right.

Zoom Slider: Lets you zoom into or out of the clips in the Timeline. Use the scroll wheel of your mouse to horizontally zoom into and out of the Timeline. Scrolling up zooms in, while scrolling down zooms out. You can also use Command-Plus to zoom in, and Command-Minus to zoom out, and Shift-Z to fit every clip in your program into the available width of the Timeline.

These functions are described in greater detail in the following sections of this chapter.

Toolbar Audio Monitoring Controls

At the far right of the toolbar, a set of three monitoring controls lets you quickly control the output volume of your mix. An audio Enable/Disable button lets you turn audio playback on and off, while a slider lets you change the volume, and a DIM button lets you temporarily duck the monitored volume being output in order to have a quick chat with your client about sports or the state of the world while keeping half an ear on the mix.

The monitoring controls in the Edit page

When there are multiple audio Mains defined for a project, an additional drop-down dialog appears with the audio monitoring controls in the toolbar that lets you choose which Main you're listening to.

The Mixer and Meters

The Audio Mixer provides a set of graphical controls you can use to set track levels, pan stereo audio, and mute and solo tracks, all while you continue to edit.

The Audio Mixer, with four channel strips corresponding to the four tracks in the Timeline

To open the Audio Mixer:

Click the Mixer button on the Interface toolbar.

The Audio Mixer exposes a set of channel strips with controls that correspond to the tracks in the Timeline, and each channel strip displays a number of audio meters equal to the number of channels within that track. By default, a Main 1 channel strip appears all the way to the right that lets you adjust the overall level of the mix. However, if you add subs and mains on the Fairlight page, those will appear at the right of the mixer as well.

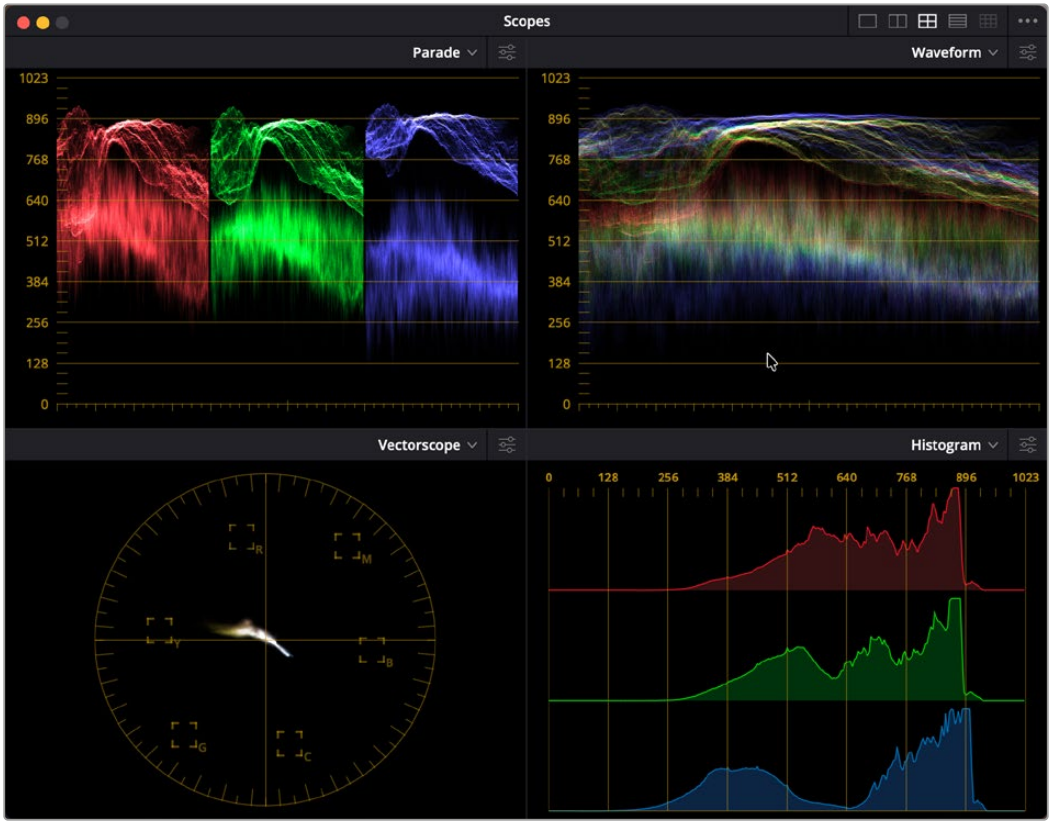
For more information on the use of the Mixer in the Edit page, jump to this chapter: Working with Audio in the Edit Page.

For more information on using the Mixer in the Fairlight page, jump to this chapter: Mixing in the Fairlight Page.

Displaying Audio Meters

If you just want to see your program's levels, you can also switch to display the "Control Room" audio meters instead of the Mixer. How many audio meters appear depends on the current speaker configuration in the Video and Audio I/O panel of the System Preferences.

To show the Audio Meters:



Click the Mixer button on the Interface toolbar to display the audio panel, and then choose Meters from the option menu at the upper right-hand corner.

Using Video Scopes

DaVinci Resolve has a set of four real-time video scopes that you can use to monitor the internal data levels of clips in your project as you work. Each scope provides an unambiguous graphical analysis of the various characteristics of the video signal, showing you the relative strength and range of individual color components including luma, chroma, saturation, hue, and the red, green, and blue channels that, together, comprise the color and contrast of the images in your program.

To open video scopes from the Media, Cut, Edit, Color, or Deliver pages, do one of the following:

- Choose Workspace > Video Scopes > On/Off (Command-Shift-W) to open video scopes into a floating window.
- Choose Workspace > Dual Screen > On to open video scopes as part of a dual screen layout.

Video scopes in a floating window

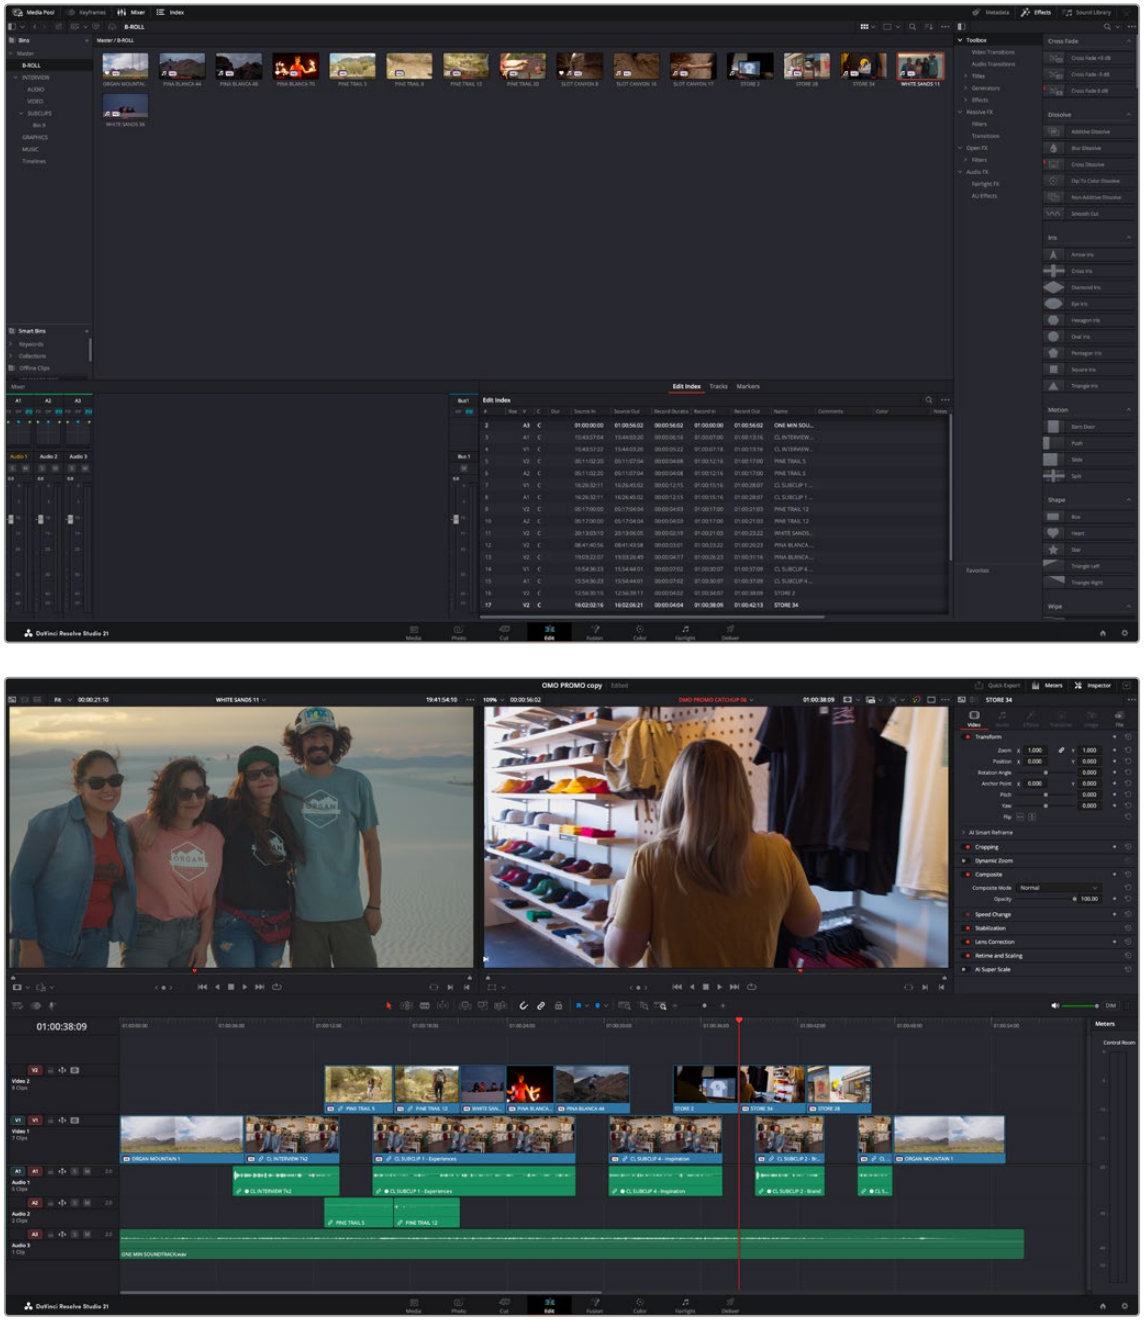
The video scopes aren't just available in the Color page. They're also available in the Media, Cut, Edit, and Deliver pages for whenever you need to evaluate the video signal more objectively, such as when you're setting up to capture from tape or scan from film, or when you're setting up for output.

For more information on using the video scopes, jump to this chapter: Using the Color Page.

Floating Timecode Window

A Timecode Window is available from the Workspace menu on every page except Fusion. Choosing this option displays a floating timecode window that shows the timecode of the Viewer or Timeline that currently has focus. This window is resizable so you can make the timecode larger or smaller.

The floating timecode window



Dual-Monitor Layout

The Edit page has a dual-monitor layout that provides maximum space for the Timeline and Viewers on the primary monitor, and an enlarged Media Pool, simultaneously displayed Timelines browser, Edit Index, Effects Library, and Metadata Editor on the secondary monitor. The second screen of a dual-screen layout can be resized but not reorganized.

If you have an single ultra-wide monitor, you can also use the dual-monitor layout, and DaVinci Resolve will scale the interface as if you had two normal monitors side by side.

To enter dual-screen mode:

Choose Workspace > Dual Screen > On.

The Edit page in dual-screen mode

To switch which UI elements appear on which monitors:

Choose Workspace > Primary Display > (Monitor Name), which reverses the contents of both monitors in dual screen mode.

To view only the timeline in a monitor:

Choose Workspace > Full Screen Timeline.

Customizing the Edit Page

The default layout is quite efficient for a number of tasks on most displays. You can always return to the default layout by choosing Workspace > Reset UI Layout. However, the Edit page can be customized to create more room for specific areas of the interface to accommodate different tasks.

To resize any area of the Edit page:

Drag the vertical or horizontal border between any two panels to enlarge one and shrink the other.

To expand the width of the Timeline:

Click the Media Pool/Effects Library/Edit Index height button to reduce the area used by the Media Pool, Effects Library, and/or Edit Index to shrink to half height. At this size, the Media Pool/Effects Library/Edit Index are restricted to the top of the UI (you can only show one at a time), and the Timeline takes up the full width of your display.

Hiding the Edit Index and the Effects Library causes the Timeline to expand to the full width of your screen.

To resize the height of individual video or audio tracks:

Move the pointer to the top border of any video track header, or the bottom border of any audio track header, and when it becomes a resize cursor, drag that border up or down to resize that track. Each track can have an independent size when you do this.

To enable a full-screen timeline in Dual Screen mode:

Choose Workspace > Dual Screen > Full Screen Timeline, which causes the Timeline to fully occupy the primary display, while the Browser, Viewers, Audio Mixer, Edit Index, and Effects Library appear on the secondary display.

To customize the columns in the Edit Index:

To show or hide columns in the Edit Index: Right-click any column header, and choose the column you want to show or hide from the contextual menu.

Checked columns are shown, unchecked columns are hidden.

To resize any column of the Edit Index:

Move your pointer over the divider between any two columns and drag when the horizontal resize cursor appears.

To sort the Edit Index by any column:

Click the Option button at the top right to display all active tracks, just the video, or just the audio tracks.

To rearrange Edit Index columns:

Drag the header of any column to the left and right to move that column.

To show and hide the Audio Meters or Audio Mixer:

Click the Mixer button in the UI toolbar.

To switch between the Audio Meters and the Audio Mixer:

Choose Meters or Mixer from the Option menu at the top right corner of the Mixer.

Undo and Redo in DaVinci Resolve

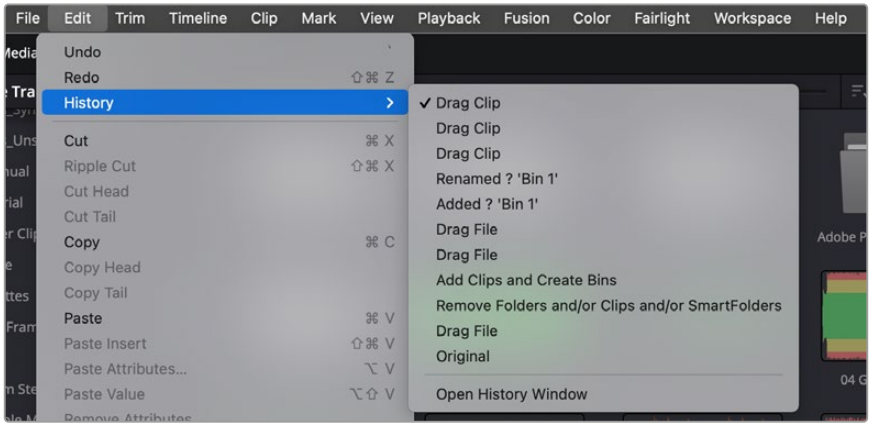
No matter where you are in DaVinci Resolve, Undo and Redo commands let you back out of steps you've taken or commands you've executed and reapply them if you change your mind. DaVinci Resolve is capable of undoing the entire history of things you've done since creating or opening a particular project. When you close a project, its entire undo history is purged. The next time you begin work on a project, its undo history starts anew.

Because DaVinci Resolve integrates so much functionality in one application, there are three separate sets of undo "stacks" to help you manage your work.

- The Media, Edit and Fairlight pages share the same multiple-undo stack, which lets you backtrack out of changes made in the Media Pool, the Timeline, the Metadata Editor, and the Viewers.
- Each clip in the Fusion page has its own undo stack so that you can undo changes you make to the composition of each clip, independently.
- Each clip in the Color page has its own undo stack so that you can undo changes you make to grades in each clip, independently.

In all cases, there is no practical limit to the number of steps that are undoable (although there may be a limit to what you can remember). To take advantage of this, there are three ways you can undo work to go to a previous state of your project, no matter what page you're in.

To simply undo or redo changes you've made one at a time:



- Choose Edit > Undo (Command-Z) to undo the previous change.
- Choose Edit > Redo (Shift-Command-Z) to redo to the next change.

You can also undo several steps at a time using the History submenu and window. At the time of this writing, this only works for multiple undo steps in the Media, Cut, Edit, and Fairlight pages.

To undo and redo using the History submenu:

1. Open the Edit > History submenu, which shows (up to) the last twenty things you've done.
2. Choose an item on the list to undo back to that point. The most recent thing you've done appears at the top of this list, and the change you've just made appears with a check next to it. Steps that have been undone but that can still be redone remain in this menu, so you can see what's possible. However, if you've undone several changes at once and then you make a new change, you cannot undo any more and those steps disappear from the menu.

   Once you've selected a step to undo to, the menu closes and the project updates to show you its current state.

The History submenu, which lets you undo several steps at once

To undo and redo using the Undo window:

1. Choose Edit > History > Open History Window.
2. When the History dialog appears, click an item on the list to undo back to that point. Unlike the menu, in this window the most recent thing you've done appears at the bottom of this list. Selecting a change here grays out changes that can still be redone, as the project updates to show you its current state.
3. When you're done, close the History window.

The Undo history window that lets you browse the entire available undo stack of the current page

Chapter 41

Creating and Working with Timelines

EDIT

In this chapter, you'll learn how to create and modify the timelines into which you edit clips to create the edited sequences that are your programs.

Contents

Creating and Duplicating Timelines 860
Individual Timeline Settings for Format, Monitoring, Output, and Color 860
Creating Blank and Stringout Timelines 861

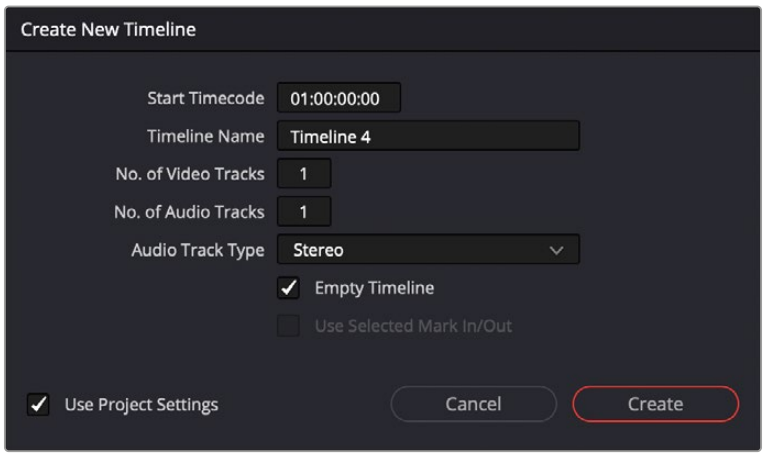
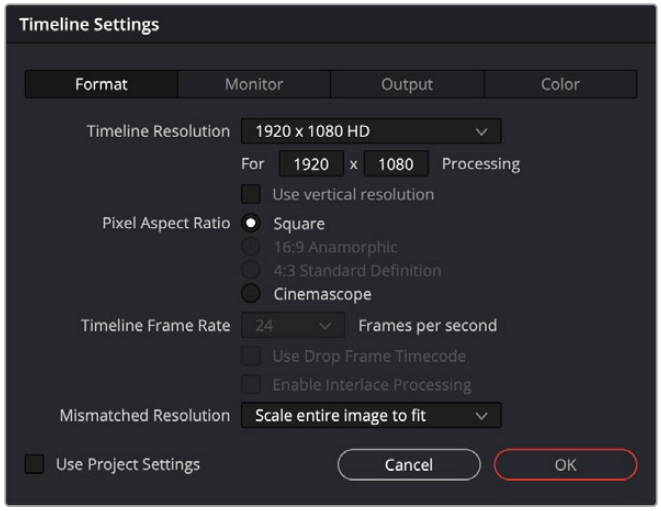
Tabbed Timelines 877
Stacked Timelines 878
View and Edit Dual Timelines Using the Source Viewer 879
Duplicate Frame Detection 881
Comparing Timelines 881
The Timeline Comparison Window 881



Creating and Duplicating Timelines

If you're not importing a project that's been edited elsewhere, you can create a new timeline to cut together a new edit from scratch, to use to assemble clips for use in a Fusion composition, to grade a set of dailies, or to put together an audio program within the Fairlight page. When you create a new timeline, you can either create a timeline that contains all clips found in the Media Pool to quickly create a big batch of offline dailies, or an empty timeline that's ready for you to add specific clips to. Timelines you create are stored in the currently selected Media Pool bin.

If you'd like an easy way to browse all the timelines in your project at once, regardless of their diverse locations, you can enable the "Smart Bin for Timelines" option, which is in the Editing panel of the User Preferences. This creates a Smart Bin in the Bin list of the Media Pool that filters all timelines in your project, making it easy to see all your timelines without altering your original organization.



Individual Timeline Settings for Format, Monitoring, Output, and Color

When you create a new timeline, there are a number of ways you can customize it, but by default it will mirror the current project-wide timeline settings for resolution, frame rate, and other format and monitoring parameters.

The Create New Timeline dialog with standard customization settings

However, you have the option of creating separate timelines with individual Format, Monitoring, Output Sizing, and Color Management settings for situations where you need to set up multiple timelines to create multiple deliverables with different resolutions, pixel aspect ratios, frame rates, monitoring, or output scaling options, and color management than the overall project, including "Mismatched Resolution Files" settings. To choose individual settings, uncheck the Use Project Settings box in the New Timeline dialog, and additional controls will appear.

Clicking Use Custom Settings exposes additional panels for individualized timeline settings

Once you've created a timeline with individual settings, you can edit its settings by right-clicking that timeline in the Media Pool, and choose Timelines > Timeline Settings from the contextual menu. An Edit Timeline dialog appears, with separate panels for Format, Monitor, Output, and Color settings that you can choose. You can also click Use Project Settings to have that timeline use the project-wide timeline settings instead.

It is also possible to change the starting timecode for multiple timelines at the same time using the custom timeline settings.

To change the start timecode for multiple timelines at once:

1. Select the Timelines whose timecode you want to modify.
2. Right-click on one of the selected Timelines and choose Timelines > Starting Timecode from the contextual menu.
3. Enter the new timecode in the Time Start field.
4. Click on OK.

Creating Blank and Stringout Timelines

If you're cutting a new video or audio program, you'll usually want a blank timeline. However, the same command can be used to create stringout timelines when putting together dailies by turning the "Empty Timeline" checkbox off.

To create a new blank timeline:

1. (Optional) Select or create a folder in the Bin list in which to put the new timeline.
2. Do one of the following:
   - Choose File > New Timeline (Command-N).
   - Right-click within the Media Pool, and choose Timelines > Create New Timeline.
3. When the New Timeline Options window opens, set the following options:

   Start Timecode: You can change the Start Timecode if a specific start time is required.

   Timeline Name: Enter a name into the Timeline Name field.

   No. of Video Tracks: Enter how many video tracks you want to have. You can also drag within this field to adjust the number of video tracks with a virtual slider.

Use Fairlight Preset: If this box is checked, it creates a timeline with pre-assigned audio tracks using a previously created Fairlight Configuration preset. A drop-down menu then appears, allowing you to select the specific preset for the Timeline. The preset is used in lieu of the No. Of Audio Tracks setting below. You can create Fairlight Configuration presets using the Fairlight Presets Library, available from the Fairlight menu.

> For more information, jump to this chapter: Setting Up Tracks, Busses, and Patching.
> If you have no Fairlight Configuration presets saved, this option will not appear.

No. of Audio Tracks: Enter how many audio tracks you want to have. You can also drag within this field to adjust the number of audio tracks with a virtual slider.

Audio Track Type: Choose the channel mapping you want the new audio tracks to use.

Empty Timeline: Checked by default, this sets new timelines to be created empty. If you turn off the Empty Timeline checkbox, the new Timeline that's created will contain all media found in every bin within the Media Pool, effectively creating a stringout of everything you've imported.

Use Selected Mark In/Out: Only available when "Empty Timeline" is turned off. When you turn this checkbox on, each clip's duration in the new Timeline is defined by the In and Out points saved within each clip. If there are no In/Out points in a clip, the clip's entire duration is used.

Use Custom Settings: Click this button if you want to expose the Format, Monitor, and Output tabs that can expose unique settings for each timeline.

4 Click Create New Timeline.

A new timeline is created. If necessary, you can duplicate an existing timeline in order to alter an edit or create an alternate grade.

> **TIP:** If you're going to be creating several new timelines with a specific set of parameters, you can open the User pane of the Preferences and edit the New Timeline Settings, found in the Editing panel. This will define new presets that populate the New Timeline Options window from that point forward.

Creating Timelines by Drag and Drop

When you first create a new project, no timeline inhabits the Timeline Editor, and you have an opportunity to create a new timeline by drag and drop.

To create a timeline by dragging and dropping a clip:

Drag any clip into the empty Timeline Editor area underneath the Viewers on the Edit page, and a new timeline will automatically be created.

Creating Timelines From Bins and Selections

The "Create Timeline Using Bin" and "Create Timeline Using Selected Clips" commands let you quickly assemble a timeline using the contents of the Media Pool, using whatever In and Out points have been added to each clip, and using the sort order of the enclosing bin to determine the order in which the clips will be assembled.

TIP: These commands are especially useful for putting together quick assembly edits if you have metadata-rich media with scene, shot, and take information that you can use to sort clips into the proper order, and In and Out points that you've already logged.

To create a timeline using the full contents of a bin:

1. (Optional) Put the Media Pool into List mode, set In and Out points for each clip in your Bin, and sort the Media Pool by the column that will put all clips in the order you want them to be assembled.
2. Right-click the bin in the Bin list, and choose Create Timeline Using Bin.
3. Type the name of the new timeline in the New Timeline Properties dialog. If you want to use the In and Out points of each clip, make sure "Use Selected Mark In/Out" is checked, and click Create New Timeline.

To create a timeline using manually selected clips:

1. (Optional) Put the Media Pool into List mode, set In and Out points for each clip in your Bin, and sort the Media Pool by the column that will put all clips in the order you want them to be assembled.
2. Select one or more clips you want to assemble into a new timeline.
3. Right-click one of the selected clips, and choose Create Timeline Using Selected Clips.
4. Type the name of the new timeline in the New Timeline Properties dialog. If you want to use the In and Out points of each clip, make sure "Use Selected Mark In/Out" is checked, and click Create New Timeline. By default, Audio Track Type is set to "Based on selected media," so the timeline audio tracks reflect the track mapping of the clips you've selected, but you can manually choose other specific mappings if you need to.

Creating Timelines Using an IMF or DCP Composition Playlist (CPL)

You can create a timeline in DaVinci Resolve that exactly replicates the Composition Playlist (CPL) of a DCP or IMF package. This is currently a DaVinci Resolve Studio only feature.

To create a timeline using a Composition Playlist (CPL):

1. Import an IMF or DCP package into the Media Pool, like any other piece of media.
2. Right-click on the imported clip and choose "Create New Timeline Using Composition Playlist" from the contextual menu.
3. In the New Timeline dialog box, choose a specific CPL from the package in the "Composition Playlist" drop-down menu.
4. Make any other normal new Timeline adjustments you may need (such as Resolution, Aspect Ratio, etc.), then click the "Create" button.

Duplicating Timelines

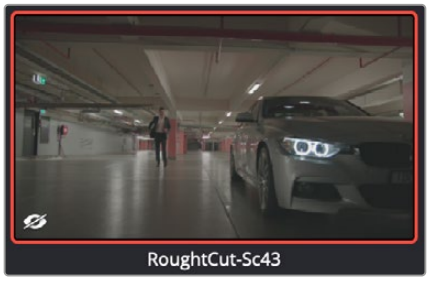
You can also duplicate existing timelines in preparation for saving a copy prior to making modifications, or as a starting point for a different version of your content.

To duplicate a Timeline, do one of the following:

- Select a timeline in the Media Pool, and choose Edit > Duplicate Timeline. The duplicate timeline appears with “copy” appended to the name.
- Right-click a timeline in the Media Pool, and choose Duplicate Timeline from the contextual menu.

Disabling Timelines

You can disable/enable timelines in the Media Pool for both performance and organizational purposes. This is particularly useful for editors who like to maintain a history of a program’s editing via an ongoing series of periodically duplicated timelines. Since having a large number of timelines within a single project file can affect performance, having the ability to disable timelines lets you maintain these backup/alternate timelines without any penalty.



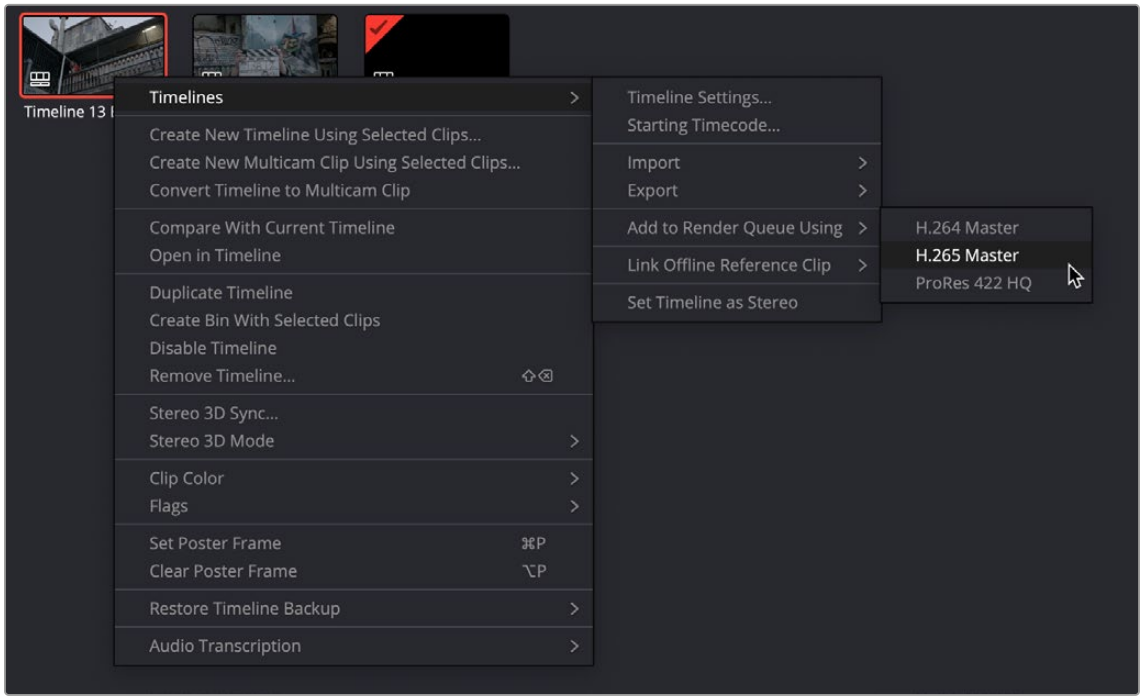
Disabled timelines are never loaded into RAM, have no effect on the speed at which a project opens, saves, exports, or loads, and have no effect on program performance. A disabled timeline also hides the timeline from the viewer drop-down menus throughout the program. Disabled timelines are still visible in the Media Pool, but have a crossed out eye icon in the lower left to show the status. A disabled timeline cannot be opened in any page of DaVinci Resolve.

To disable a timeline:

Select the Timeline, right-click on it and choose “Disable Timeline” from the drop-down menu.

To enable a timeline:

Select the Timeline, right-click on it and choose “Enable Timeline” from the drop-down menu.



The crossed-out eye in the lower left of the thumbnail indicates this Timeline is disabled.

TIP: Enabled and Disabled timelines can be easily grouped and organized across the entire project by creating a Smart Bin with the MediaPool Properties > Timeline fields, and choosing “is Enabled/Disabled.”

Adding Media Pool Timelines Directly to the Render Queue

You can add a timeline directly to the Deliver page's Render Queue by right-clicking on the timeline and hovering over the Add to Render Queue Using, and making a selection from the list of presets. You can add your own presets to this list by saving a new custom preset in the Deliver page.

You will then be prompted for the location to render the file. The timeline will be added to the Render Queue in the Deliver page but will not start rendering until the Render All button is pressed.

Select a Preset from the "Add to Render Queue Using" menu option to directly send the timeline to the Render Queue

Import and Export DaVinci Resolve Timelines (.drt)

You can export and import individual timelines from one DaVinci Resolve project into another previously existing DaVinci Resolve project, allowing you to pass timelines quickly between projects and workstations, without creating additional imported project files. Just the timeline and its associated clip information are exported; none of the actual media files are included.

To export a timeline from the Media Pool:

1. Select a timeline from the Media Pool.
2. Choose File > Export > Export AAF, XML, DRT (Shift-Command-O).
3. Choose "DaVinci Resolve Timeline Files (*.drt)" from the format options popup in the file system dialog.
4. Choose where to save the DaVinci Resolve Timeline file (.drt) in the file system dialog, and click Save.

To export multiple timelines from the Media Pool:

1. Select multiple timelines from the Media Pool.
2. Right-click on a timeline and choose Timelines > Export > DaVinci Resolve Timeline Files.
3. Select the folder where you wish to save them from your file browser.

Unlike exporting individual timelines, when exporting multiple timelines, you will not be able to rename the .drt files on export. They will retain the timeline name they have in the Media Pool.

To import a timeline into the Media Pool:

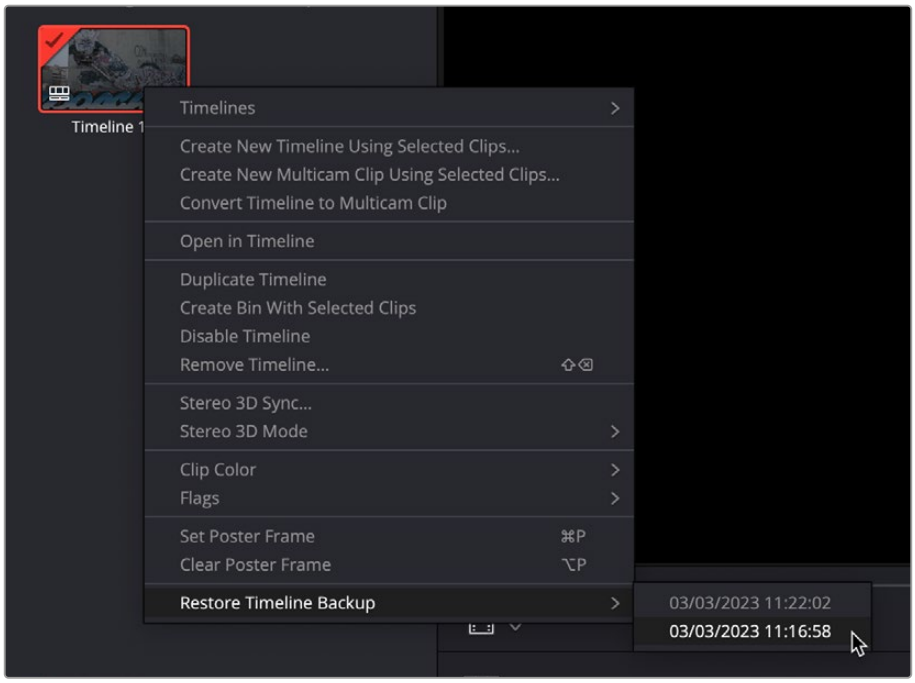
1. Choose a bin in the Media Pool in which you want the imported timeline to be saved.
2. Do one of the following:
   - Choose File > Import Timeline > Import AAF, XML, DRT (Shift-Command-I), then Select a DaVinci Resolve Timeline file (.drt) from the file system dialog, and click Open.
   - Double click the .drt file in your file system.

The timeline will appear in the Media Pool, along with all of the clips associated with it, including any media sync information. Any timelines imported this way will have the word "import" appended to their name, to avoid duplicate names. The imported timeline will be automatically conformed to corresponding media that's already in the Media Pool. However, if the timeline has been moved to another computer, you may have to reimport or relink missing or offline media in to bring the imported timeline fully online.

NOTE: Only a single timeline can be imported and exported at a time using this method. To import or export multiple timelines, use the Import/Export Bin function instead.

Backing Up and Restoring Timelines

Turning on the Timeline Backups checkbox in the Project Save and Load panel of the User Preferences enables DaVinci Resolve to save multiple backups of a timeline at periodic intervals, using a method that's analogous to a GFS (grandfather-father-son) backup scheme. This can be done regardless of whether or not Live Save is turned on.



If you want to revert to a previous backup of a timeline, simply right-click on the timeline in the Media Pool, select Restore Timeline Backup from the contextual menu, and choose the backup from the list of options. Backups are organized by date and time, making it easy to find the specific timeline you want to restore.

There are certain times in the editing process where it makes sense to manually create a backup point before radically changing the remainder of your timeline. This can be done by duplicating the timeline (which is generally the safest), or you can also manually set a backup point for recall with the rest of your timeline backups.

To manually create a backup point with a custom name for a timeline, either:

- Select File > Create Timeline Backup (Option-Command-S).
- Right-click on your timeline in the Media Pool, and select Create Timeline Backup from the context menu.

Restoring a timeline backup does not overwrite your current timeline. Instead the selected backup will be brought into the Media Pool as a new timeline, with the name “Backup” appended to it.

Restoring a timeline backup in the Media Pool

Timeline backups are only saved when changes have been made to a project. If DaVinci Resolve sits idle for any period of time, such as when your smart watch tells you to go outside and walk around the block, no additional project backups are saved, preventing DaVinci Resolve from overwriting useful backups with unnecessary ones.

Three fields let you specify how often to save a new backup, while the fourth lets you choose where the backups will be saved. These settings apply to both Project and Timeline backups.

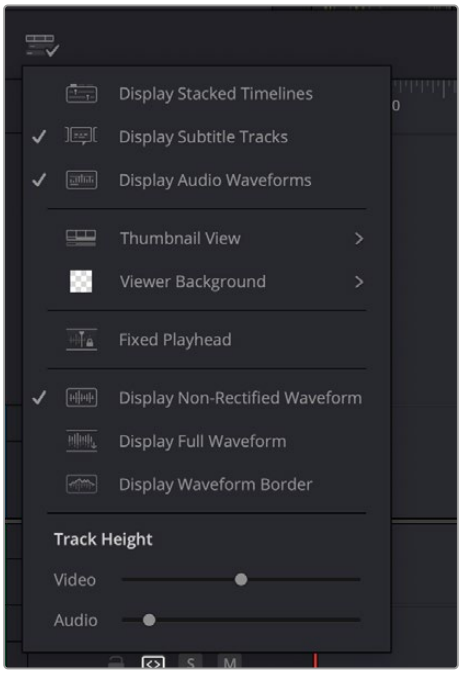
- **Perform backups every X minutes:** The first field specifies how often to save a new backup within the last hour you’ve worked. By default, a new backup is saved every 10 minutes, resulting in six backups within the last hour. Once an hour of working has passed, an hourly backup is saved and the per-minute backups begin to be discarded on a first in, first out basis. By default, this means that you’ll only ever have six backups at a time that represent the last hour’s worth of work.
- **Hourly backups for the past X hours:** The second field specifies how many hourly project backups you want to save. By default, two hourly backups will be saved for the current day. Past that number, hourly backups will begin to be discarded on a first in, first out basis.
- **Daily backups for the past X days:** The third field specifies for how many days you want to save backups. The very last backup saved on any given day is preserved as the daily backup for that day, and by default daily backups are only saved for two days. Past that number, daily backups will begin to be discarded on a first in, first out basis. If you’re working on a project over a longer stretch of time, you can always raise this number.
- **Project backup location:** Click the Browse button to choose a location for these backups to be saved. By default they’re saved to a “Project Backup” directory on your scratch disk, although you could change this to a volume that better fits into your data backup methodology. This folder contains both Project and Timeline backups.

Restoring Deleted Timeline Backups

From the Media Pool Options menu, you can select Deleted Timeline Backups and examine deleted timelines and available backup files for each timeline. You can select backups to be restored or choose to permanently delete selected backups.

Compare Timelines with Timeline Backup Snapshots

To view the timeline changes you've made against other previously backed up timelines, right-click on the timeline and select **Compare with Timeline Backup** to open up the **Compare Timeline** window.



The **Compare Timeline** window shows the two timelines stacked together, highlighting their differences. You can choose which backup to compare it to from the dropdown menu at the top of the window.

Comparing the current timeline against a previous timeline backup.

Timeline View Options

As you're working on an edit, it can often be useful to modify the appearance of the Timeline, changing the height of video or audio clips, choosing whether audio waveforms are drawn or not, and so on. Using the Timeline View Options dropdown at the far left of the Timeline, you can make these kinds of changes as you work.

The Timeline View Options dropdown

You have the following options:

- **Timeline View Options:** Three buttons let you choose to show or hide specific Timeline interface elements, including the following:

  Display Stacked Timelines: This option lets you show stacked timelines for simultaneous display of timelines one on top of another.

  Display Subtitle Tracks: Lets you display or hide the subtitle tracks region of the timeline. Hiding subtitle tracks does not disable subtitle display; to do that you must disable the currently displayed subtitle track.

  Display Audio Waveforms: Lets you turn Audio Waveform viewing off and on. When Audio Waveform is turned off, audio tracks are minimized.

- **Thumbnail View Options:** Three buttons let you choose the overall appearance of the video track. From left to right:

  Filmstrip: Displays each clip as a series of frames along its length. The number of frames displayed depends on the current zoom level of the clip in the timeline.

  Thumbnail: Displays each clip as a solid color with a thumbnail image of the clip's In point at the beginning of the clip and a thumbnail image of the Out point at the end. The thumbnails displayed depend on the current zoom level and track height of the clip in the timeline. If the clip does not have enough room for both, only the In point thumbnail will appear.

  None: Displays each clip as a solid color along its length.

- **Viewer Background:** Four options: Checkerboard, Black, Grey, or Alert Red let you determine what color the transparent background will be in the Viewer.
- **Fixed Playhead:** This option lets you toggle between a fixed playhead, keeping the playhead static in the middle of the timeline, while the tracks on the timeline move underneath it, or Free Playhead, where the playhead travels along the timeline as it is played back.

  When using the Fixed Playhead option, you can choose where to set the location of the Fixed Playhead in the timeline, rather than just have it in the center. To do so, hover the pointer over the top of the playhead in the Timeline Ruler and drag it to the new location you want to use.

  Moving the Fixed Playhead can be useful in increasing the amount of timeline working area for clips before or after the current position.

- **Audio View Options:** Three buttons govern the look of audio waveforms in the Timeline, when visible.

  Display Non-Rectified Waveform: Lets you toggle between the waveform being drawn from the bottom of the audio track up, or centered and mirrored about itself.

  Display Full Waveform: Hides the divider bar that keeps the waveform separate from the file name area of each audio clip, so the waveform occupies the full space of each audio bar in the Timeline.

  Display Waveform Border: Draws a dark border around the edges of each waveform to make them easier to see.

- **Video track height slider:** Lets you resize the size of all video tracks at once, independently of the audio tracks.
- **Audio track height slider:** Lets you resize the size of all audio tracks at once, independently of the video tracks.

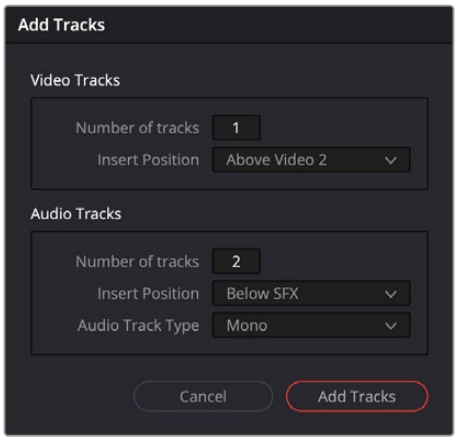
In addition, any track in the Timeline can be individually resized by dragging its top divider in the Track Header area. Track heights in the Edit page are independent of the Thumbnail and Waveform view settings in the Timeline View options. Previously, specific Timeline viewing options such as Filmstrip or Thumbnail view had minimum track height settings. Now you can freely change track height no matter what options you've chosen, and resizing one or more tracks below the minimum height for filmstrips or thumbnails automatically collapses those tracks into Simple view to avoid clutter.

Resizing an individual timeline track by dragging its top border in the Track Header

Modifying Timeline Tracks

When you're getting ready to edit clips into the Timeline, you need to make sure you've got enough tracks to do the job. The following procedures cover the different methods available for adding, removing, and rearranging tracks as you work. These commands are all available via the contextual menu that appears when you right-click anywhere in the Timeline header area (the header of the Timeline is the area to the left where each track's various buttons and controls are located).

Keyboard Shortcuts can be assigned for track header context menu actions to add, delete, move, change color, and link tracks. Tracks can be selected in the Track index, or the Edit and Fairlight timelines. For example, you can assign a keyboard shortcut to add a new Audio Track in the Edit page by navigating to Commands > Edit Timeline > Track Controls > Add Track > Audio in the Keyboard Customization window.



Methods for adding, deleting, and rearranging tracks:

- **To add a track to the Timeline:** Right-click on a Track Timeline header and choose Add Track. A new video track will be created immediately above the track you right-clicked on. A new audio track will be created immediately below the track you right-clicked on. If you add an audio track, you can choose what type of channel mapping you want.

  For more information about audio track channel mappings, jump to this chapter: Working with Audio in the Edit Page.

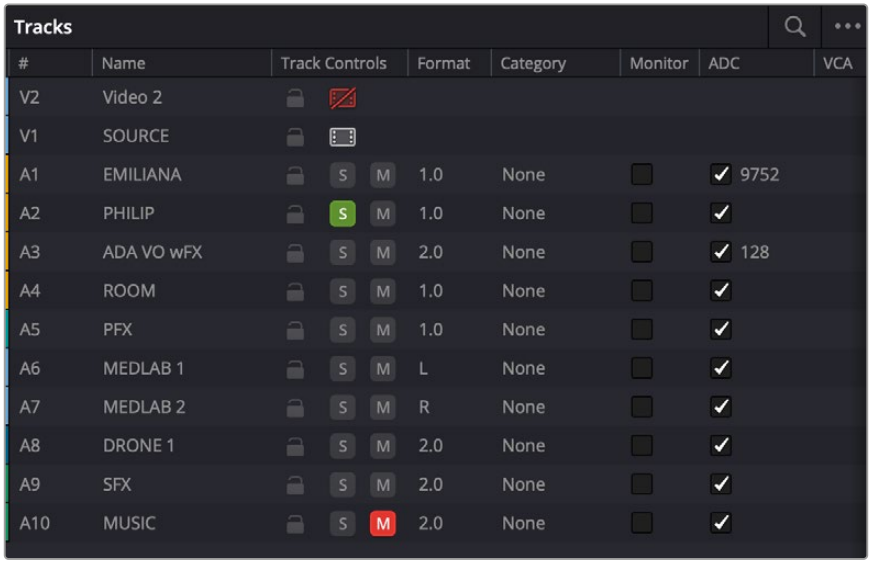
- **To add multiple tracks to the Timeline at a specific position:** Right-click anywhere in the Timeline header and choose Add Tracks. When the Add Tracks dialog appears, choose the number of video and audio tracks you want to add, choose the position you want to insert the tracks above or below, and choose the Audio Track Type you want to add if you're adding audio tracks. When you're done, click "Add Tracks."

- **To delete a track from the Timeline:** Right-click within a track's Timeline header and choose Delete Track. If there are clips on a track you remove, they are deleted from the Timeline.
- **To delete all unused tracks in the Timeline:** Right-click anywhere in the track header area and choose Delete Empty Tracks. All tracks without clips will be deleted at once.
- **To move tracks and the clips on them up and down:** Right-click within a track's Timeline header and choose Move Track Up or Move Track Down from the contextual menu. That track, along with all clips on it, will be moved up or down relative to the other tracks in the Timeline. You can also rearrange track order from the Tracks Index. Simply click on the track in the # field and drag the track to its new position.

The Add Tracks Dialog lets you add multiple tracks at once and set their locations in the timeline.

Naming Timeline Tracks

If you're a stickler for organization, you can also name the tracks on a timeline to identify its purpose.



To rename a track:

1. Make sure the Timeline View Options are set to either the Filmstrip view or the Thumbnail view, and that audio tracks are tall enough, so that track names are visible.
2. To edit the name of any track, click the default "Video X" or "Audio X" track name to select it, then type your preferred name and press the Return key.

Using the Tracks Index

The Tracks Index presents an easy to use track list that lets you view and control all your track headers in one place. It also gives more audio information than the track header section of the Timeline. The Tracks Index is especially useful for controlling projects with a large number of video and audio tracks. It is accessed by clicking on the Index pane and selecting the Tracks tab.

The resulting list shows all the current tracks in your timeline and their position and attributes. These are all modifiable right inside the Track Index.

The Tracks Index

Tracks Index Columns

Each track reveals several columns of information. These columns can be rearranged by dragging the column headers to the left or right, depending on what information is most important to you. Clicking on a track row selects the track for modification. Right-clicking on a track or tracks allows you to delete them from the contextual menu.

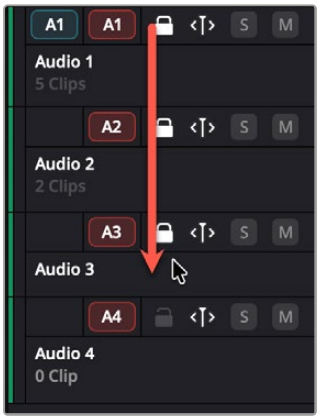
Using the Tracks Index for video tracks:

- **Color:** Shows a bar of the track's assigned color. To change its color, right-click on the track
- **Visibility:** Clicking on the eye icon toggle will show or hide tracks.
- **#:** Shows the track's number.
- **Name:** Shows the track's name. This field is editable.
- **Track Controls:** Exposes the Lock and the Enable/Disable Video track toggle. All of these controls are active.

Using the Tracks Index for audio tracks:

- **Color:** Shows a bar of the track's assigned color. You can right-click on the track to change its color.
- **Visibility:** Click on the eye icon toggle to show or hide tracks.
- **#:** Shows the track's number.
- **Name:** Shows the track's name. This field is editable.
- **Track Controls:** Exposes the Lock Solo, and Mute controls. All of these controls are active.
- **Format:** Shows the audio track type. Right-clicking on this field lets you change the audio track type.
- **ADC:** Shows the current amount of Automatic Delay Compensation on the track. Clicking on the checkbox toggles the automatic delay compensation on or off.
- **VCA:** Shows the track's VCA group number.
- **Tags:** Shows any tags assigned to the track.

Using the Tracks Index for subtitle tracks:



- **Color:** Shows a bar of the track's assigned color. To change its color, right-click on the track.
- **Visibility:** Click on the eye icon toggle to show or hide tracks.
- **#:** Shows the track's number.
- **Name:** Shows the track's name. This field is editable.
- **Track Controls:** Exposes the Lock and the Enable/Disable Subtitle toggle. All of these controls are active.

Using the Tracks Index options:

- **To search for a specific track:** Click on the search icon (magnifying glass) and type in your search terms.
- **To select which type of tracks are included in the Tracks Index:** Click on the Option menu to choose which type of tracks will be included in the list. The options are: Video, Audio, and Subtitle.

Toggle Track Header Control States by Clicking and Dragging

You can change multiple Track Header controls in the Edit page (Lock Track, Visibility etc.) by simply clicking on an icon and dragging your pointer up or down across the track headers. You can do this for one type of control at a time and not across Audio and Video tracks.

Clicking on the Lock icon on A1, then dragging the pointer down to A3, will lock all audio tracks in between

Using Timeline Snapping and Zooming

When preparing to make an edit into the Timeline, you can set the snapping and zoom controls to whichever state is most useful for the operation you need to perform. For example, if you're editing an insert shot into a rapid-fire section of edits in the Timeline, you may want to zoom in to better see the exact place where you want to place the incoming clip. Since there are many edits at that point, disabling snapping might make it useful to avoid having the clip jump to the nearest edit point if you need to move the incoming clip to a very specific frame.

Playhead Snapping:

To turn clip and playhead snapping on and off: Click the Snapping button in the toolbar, or press N. When snapping is turned on, the In and Out points and markers of clips all snap to one another and to the playhead. You can also press N to temporarily turn snapping on or off while dragging a clip in the Timeline, or while scrubbing the playhead using the pointer (snapping reverts to its previous state when you finish the operation).

Timeline Zoom presets:

From left to right: Full Extent, Detail, and Custom Zoom controls

Full Extent Zoom: This mode dynamically adjusts the zoom level to encompass the whole Timeline as you add or remove clips. As your timeline grows by adding clips, the zoom level decreases automatically to fit the new clips into your Timeline Viewer. Conversely, the zoom level will increase automatically as you remove clips.

Detail Zoom: This setting zooms the Timeline in on the Playhead to the frame level to quickly make fine timing adjustments.

Custom Zoom: Zooms the Timeline to the level selected by the Zoom Slider to its immediate right.

Zoom Slider: Drag the zoom slider to the left to zoom out, and right to zoom in. You can also press Command-Minus (–) and Command-Equal (=) to zoom out and in. Either way, zooming is always centered on the current position of the playhead, even if the playhead is off screen.

To frame every clip into the width of the Timeline: Press Shift-Z. This is a toggle, so pressing Shift-Z frames your whole edited sequence to the width of the Timeline, and then pressing Shift-Z again returns the Timeline to whatever level of zoom you were using previously. Using this keyboard shortcut makes it really easy to navigate the Timeline when you're zoomed in, as you can press Shift-Z, move the playhead to another part of the Timeline you want to work on, and then press Shift-Z again to zoom back into the new location of the Timeline.

Zoom Around Mouse Pointer

You can set up the Edit Timeline zoom controls to stay centered on the pointer as you zoom in or out, instead of staying centered on the Timeline playhead as usual, by selecting View > Zoom Around Mouse Pointer. This can be helpful when navigating longer timelines.

With this option enabled, zooming in and out of the Timeline using the scroll control of your pointing device while holding the Option key down keeps the Timeline centered on the pointer. Deselect this option to return to the behavior of only zooming in or out centered on the playhead position.

Scrolling Through the Timeline

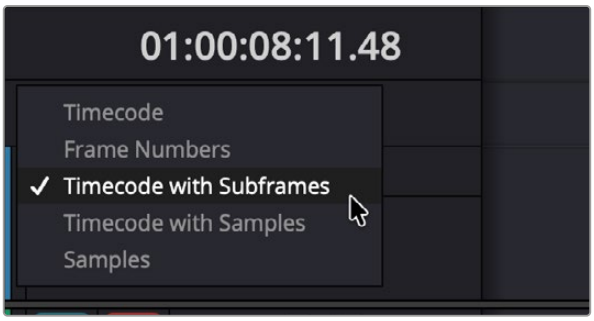
When you're zoomed into the Timeline, there are several methods you can use to scroll around as you work.

- You can scroll left and right, or up and down, by dragging the Timeline's horizontal and vertical scroll bars.
- You can scroll left and right through the Timeline, one "page" at a time at the current zoom level, by selecting Playback > Next/Previous > Timeline Page. If you use these often, you can assign them a keyboard shortcut.
- You can also scroll up and down the tracks of the Timeline using the scroll wheel, scroll ball, or scroll gestures of your mouse, trackball, trackpad, or other pointing device.
- You can also scroll within the Timeline by middle-clicking and dragging in any direction, which works the same as panning around a viewer that you've zoomed into. This frees you from having to use the scroll bars as you move around your edited clips.

  If you scroll past the position of the playhead, a small playhead indicator appears in the bottom scroll bar to let you know where it is relative to the entire duration of your edited sequence.

A small indicator shows the position of the playhead if it's outside of the visible area of the Timeline.

Scroll Wheel Controls on Timeline



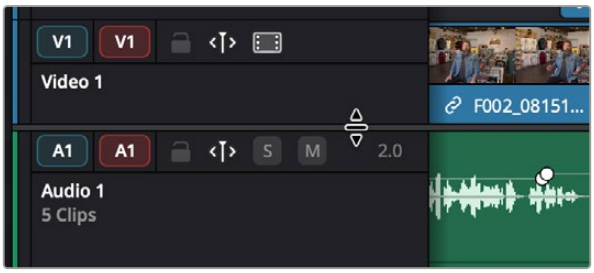
Additional scroll wheel and key presses can be used to manipulate the Timeline on the Edit page.

To manipulate the Timeline, rotate the scroll wheel while holding down:

- **Shift:** Expands or contracts all the Video or Audio track heights, depending on what section the pointer is located at when you scroll.
- **Option:** Zooms in and out the view of the Timeline.
- **Command:** Navigates forward and backward in the Timeline.

Timecode Display can Show Frames, Subframes or Audio Samples

You can view timecode in the Edit page timeline with Frames, Subframes, and Audio Sample information instead of just timecode. To change the display, right-click on the Timecode display in the Timeline, and select your option from the dropdown menu.



Choose a different timecode display by right-clicking on the timecode box.

Move Playhead to Mouse Pointer Using the C key

In the Edit page, you can instantly snap the playhead to wherever your pointer is on the timeline by pressing the “C” key on the keyboard. This lets you quickly move around the timeline without having to maneuver the mouse to click on the upper timeline ruler. You can also use a menu action: Playback > Go To > Mouse Pointer.

Resizing the Timeline’s Video and Audio Track Regions

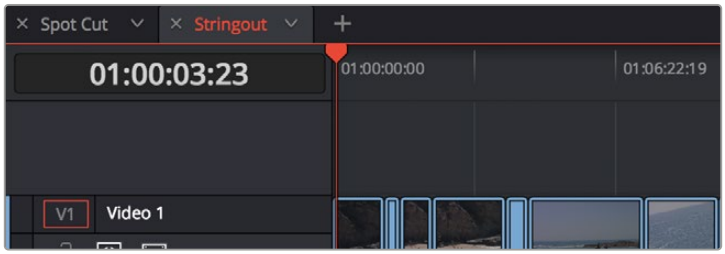
If you need to see more of the video or audio tracks in the available area of the Timeline, you can drag the horizontal divider that separates the audio and video tracks up or down to create room where you need it.

Dragging the Timeline center divider to make more room for audio or video tracks

Tabbed and Stacked Timelines

The Timeline now supports the option to have tabs that let you browse multiple timelines quickly. With tabbed timeline browsing enabled, a second option lets you open up stacked timelines to simultaneously display two (or more) timelines one on top of another.

Tabbed Timelines

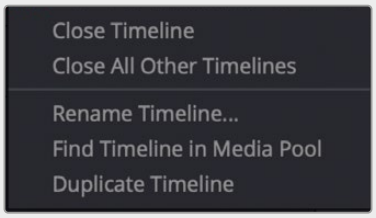


The Timeline View Options menu in the toolbar has a button that lets you enable tabbed browsing and the stacking of timelines.

A button in the Timeline View Options enables tabbed timelines.

When you first turn this on, a Timeline tab bar appears above the Timeline, displaying a tab for the currently open timeline that contains a Close button and a Timeline drop-down menu. Once you enable Tab mode, opening another timeline from the Media Pool opens it into a new tab.

To the right of the currently existing tabs, an Add Tab button lets you create additional tabs that default to “Select Timeline.” Click any tab’s drop-down menu to choose which timeline to display in that tab.



Tabs above the Timeline Editor let you switch among multiple timelines quickly

Right-clicking a tab opens a contextual menu that gives access to several commonly used Timeline functions.

Tabbed timeline contextual menu options:

- **Close Timeline:** Closes the current tab’s timeline, and removes the tab. The same as clicking on the “x” inside the tab.
- **Close All Other Timelines:** Closes all open timelines and tabs except for the one that you right clicked and chose this option on.
- **Rename Timeline:** Opens the tab’s text editing field, allowing you to change the name of the timeline inside the tab. This will change the timeline’s name across the project in the Media Pool as well.
- **Find Timeline in Media Pool:** Opens the bin where the timeline is stored in the Media Pool, and highlights the timeline in orange.

- **Duplicate TImeline:** Creates a duplicate of the selected timeline in the same bin, with the word “copy” appended to the timeline name. It also automatically opens the copied timeline in a new tab.

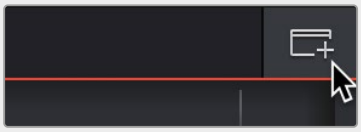
Right-clicking on a tab will show the timeline options.

Methods of working with tabbed timelines:

- Click any tab to switch to that timeline.
- Use the drop-down menu within any tab to switch that tab to display another timeline from the Media Pool. Each tab’s drop-down menu shows all timelines within that project, in alphabetical order, but a timeline can only be open in one tab or stack at a time.
- Drag any tab left or right to rearrange the order of timeline tabs.
- Click any tab’s Close button to close that timeline and remove that tab.
- Middle-click any tab to close that timeline and remove that tab.

Stacked Timelines

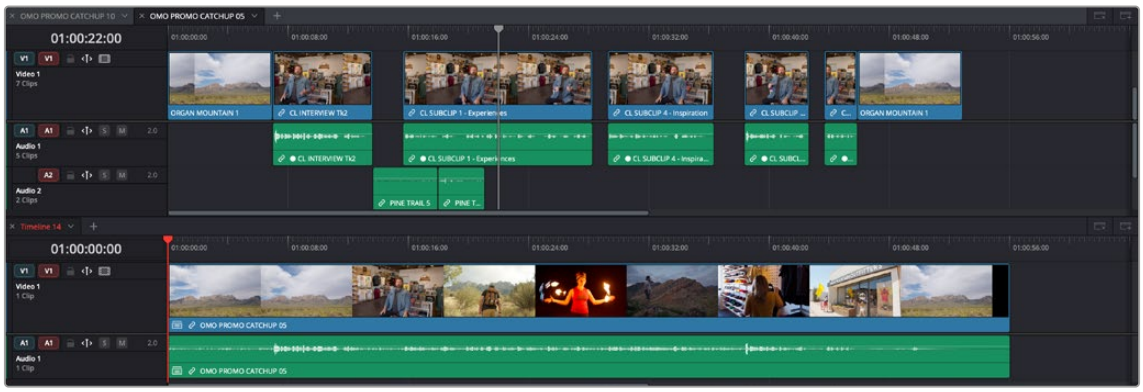
While tabbed browsing is turned on, an Add Timeline button appears on the far right of the tab bar that enables you to stack two (or more) timelines one on top of another. This lets you have two (or more) timelines open at the same time, making it easy to edit clips from one timeline to another.



A good example of when this is useful is when you’ve created a timeline that contains a stringout of selects from a particular interview. You can stack two Timeline Editors, one on top of another, and then open the Selects Timeline at the top and the Timeline you’re editing into at the bottom. With this arrangement, it’s easy to play through the top timeline to find clips you want to use, to drag and drop into the bottom timeline to edit into your program.

The button for closing a stacked timeline

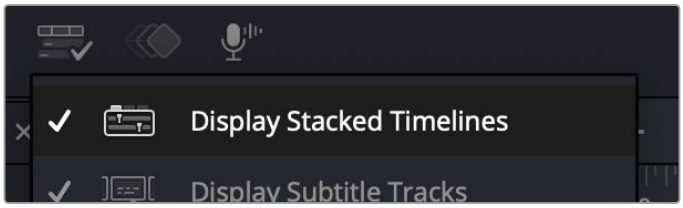
To enable or disable stacked timelines:



Click the Add Timeline button at the right of the Timeline tab bar.

The button for adding a stacked timeline

Once you've enabled stacked timelines, each timeline has its own tab bar and an orange underline shows which timeline is currently selected.



At the right of each Timeline tab bar, a Close Timeline button appears next to the Add Timeline button, which lets you close any timeline and remove that timeline browsing area from the stack.

Stacked Timelines

View and Edit Dual Timelines Using the Source Viewer

You can now work on two timelines simultaneously in the Edit page, one loaded in the Source Viewer and one in the Timeline Viewer. This allows you to easily compare two timelines or copy content between one timeline to another.

Enable Display Stacked Timelines in the Timeline View options to use dual timelines

To get the best use from this feature, you should first enable Display Stacked Timelines in the Timeline View Options icon in the upper left of the timeline. Enabling this view will allow each timeline to appear in its own tab, and the Viewer will automatically switch focus, depending on which tab is selected.

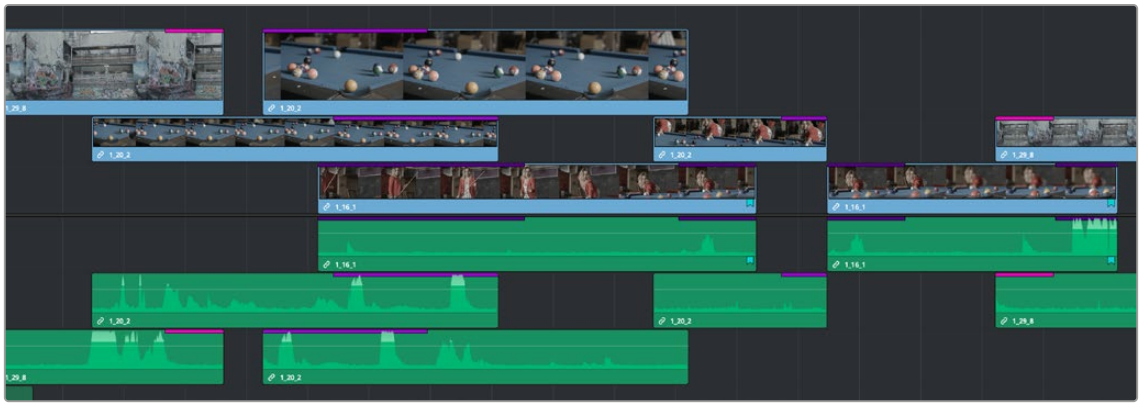
Then, in order to load a timeline into the Source Viewer, right-click on a timeline in the Media Pool and choose "Open in Timeline with Source Viewer." The timeline will appear in the Source Viewer, as a new tab with the name and playhead turning blue to help you keep track of what timeline is in what Viewer. The timeline in the Source Viewer is read only. You can switch between the timelines by clicking on the tabs, pressing Q, or by clicking in the appropriate Viewer.

You can change the timeline that appears in the Source Viewer either by right-clicking another timeline in the Media Pool and selecting the "Open in Timeline with Source Viewer" option, or by selecting one of the timelines in the dropdown menu at the top of the Source Viewer.

You can perform standard cut and copy operations from the read-only source timeline to the actual timeline, as well as drag from the Source Timeline viewer (left) into the Timeline viewer (right) to make an edit. As with a normal clip, editing operations between timelines can be limited by using the destination track selectors.

A dual timeline editing setup, with one timeline in the Source Viewer (blue), and another timeline in the Timeline Viewer. Switching tabs automatically focuses the appropriate viewer.

TIP: You can solo a specific track in the Source Timeline Viewer timeline for playback purposes. For example, you just might want to hear the boom mix track, or a specific ISO of a character's wireless mic while you're cutting from the Source Timeline. To do so, simply click on the "S" solo button on the audio track you want to solo.



There are also shortcuts that make focusing between viewers that much quicker:

- To toggle between the Source and Timeline viewers, press Q.
- To turn on and off the Source Timeline view, press Option-Q.
- To load a specific timeline into the source viewer, right click on its tab and select Load Timeline to Source Viewer.

TIP: You can also right-click on a normal media clip and select Open in Timeline with Source Viewer to load that clip into the Viewer as a timeline. These "timelines" will be read only, but will otherwise allow the same timeline to timeline editing operations currently possible. This mode is useful for very long clips like interviews.

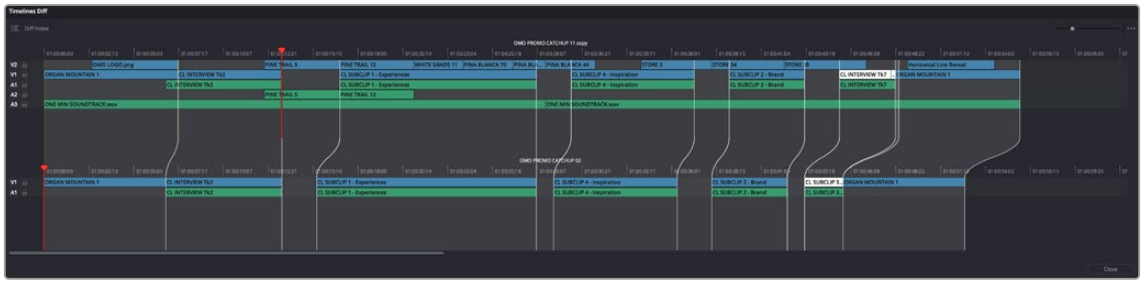
Duplicate Frame Detection

You can turn on Duplicate Frame Detection (often referred to as Dupe Detection) for clips in the Timeline by choosing View > Show Duplicate Frames. Doing so shows colored bars at the top of clips in the Timeline whenever a range of frames has been used more than once.

Duplicate Frame Detection shows colored bars where a range of frames is used more than once in a timeline.

Comparing Timelines

For instances where you're importing multiple versions of a timeline that's been edited in another application, or where you're working with multiple editors on different versions of the same Timeline in either collaborative mode or on multiple separate DaVinci Resolve installations, DaVinci Resolve provides a method of comparing two timelines with one another. Using the Timeline Comparison window, you can both see a visual comparison of which sections of two timelines differ, and you can derive a more traditional change list by opening up the Difference Index.



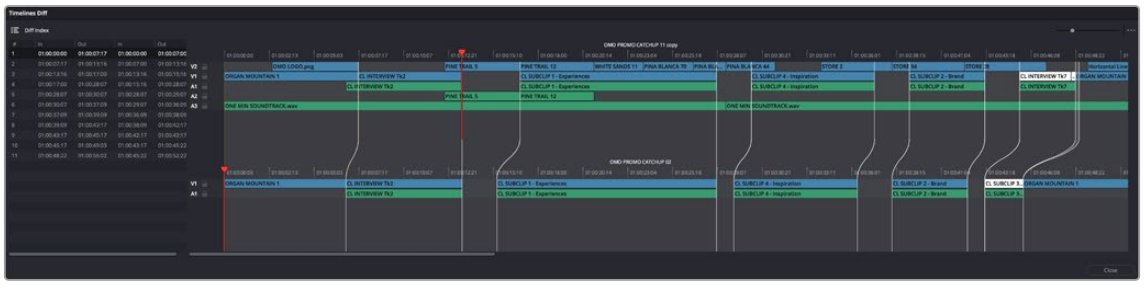
To compare two timelines:

1. Open the first timeline you want to compare.
2. Right-click a second timeline in the Media Pool, and choose Compare With Current Timeline.

A Timeline Comparison window appears, showing you the currently opened Timeline at the bottom and the Timeline you right-clicked at the top.

The Timeline Comparison Window

When you first open the Timeline Comparison window, the first thing you see is a pair of miniature timelines. The currently open Timeline appears at the bottom and the Timeline you right-clicked appears at the top.



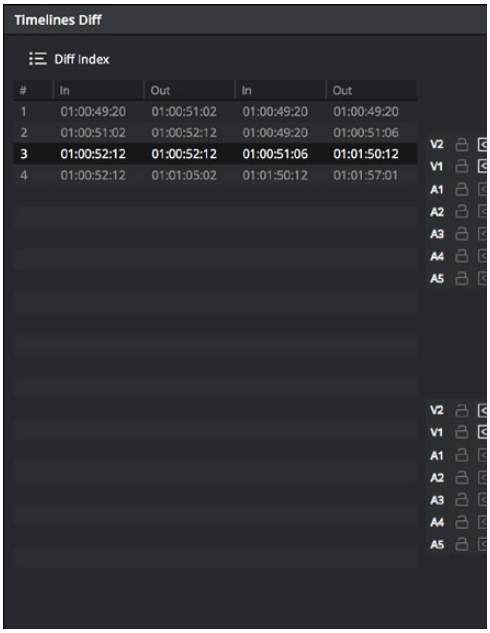
The Timeline Comparison window

Comparison Window Playhead Output

By default, the two playheads are ganged together, with the top playhead being displayed in the Source Viewer, and the bottom playhead being displayed in the Timeline Viewer. These playheads can be unganged if you want to compare different areas of both timelines, simply by turning off Sync Playheads in the option menu.

Highlighting Differences

Special highlights indicate sections of both timelines that are different. Individual changes are not individually highlighted, although they can be seen, on the premise that you're more interested in a section by section analysis of what your collaborating editor has been doing, for purposes of deciding whether to incorporate changes or reversions based on this comparison.



Each section of differences between the two timelines are highlighted

When using this tool, you can change the bottom Timeline to match the top Timeline, on a section by section basis, by right-clicking a highlighted section and choosing Accept Change from the contextual menu. When you do this, the currently open Timeline is immediately changed to incorporate the altered section from the Timeline you're comparing to. If necessary, you can undo this.

The Change List

Clicking the Diff Index button opens the change list, which shows you a more conventional item by item comparison of the differences between the two timelines.

The change list of the Timeline Comparison window

Chapter 42

Preparing Clips for Editing and Viewer Playback

EDIT

Before you start editing, there are a wide variety of things you can do to prepare your clips for editing.

In this chapter, you'll learn how to browse, select, and play through clips that you need to log, adding markers, setting In and Out points, and creating subclips as you identify pieces you'll be using later as you edit.

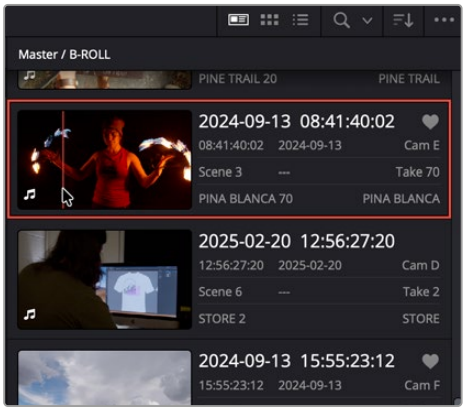
Keyboard Shortcuts in This Chapter

Here's a list of of keyboard shortcuts you might find helpful that relate to topics found in this chapter.

Key Shortcut	Function
Arrow Keys (Media Pool)	Move selection in Media Pool; left and right arrow keys also open and close bins in the Bin list
Shift (modifier)	Hold Shift down when clicking-to-select clips to select a contiguous range
Command (modifier)	Hold Command down when clicking-to-select clips to select non-contiguous clips
Command-A	Select all; selects all clips in the Media Pool browser area
Return or Enter	Opens selected clip or timeline into the Source Viewer (in dual viewer mode) or Viewer
I, O	Set in/out point in Media Pool, Source Viewer, or Timeline
Option-Shift-I, O	Set video-only in/out point in Media Pool, Source Viewer, or Timeline
Command-Shift-I, O	Set audio-only in/out point in Media Pool, Source Viewer, or Timeline
Shift-I, O	Move playhead to in/out point
Spacebar	Play and stop
J, K, L	Play reverse, stop, play forward; more uses covered later in this chapter
Option-L	Play again
Option-K	Stop and go to last position (of playhead)
/	Play around current selection
Up, Down Arrow	Go to previous clip/edit, go to next clip/edit
M	Add marker; doesn't stop playback
Command-M	Add marker, open modify marker while pausing playback, then continue playback
Shift-M	Modify marker
Option-M	Delete marker
Shift-Up, Down Arrow	Go to previous/next marker
Option-B	Create subclip (in currently selected Media Pool bin)



Browsing Clips in the Media Pool

The following procedures show how to select one or more clips in the Media Pool to accomplish various editing tasks, either by opening a clip in the Source Viewer, or selecting a group of clips with which you want to do drag and drop editing. This section starts by presenting different ways you can browse the contents of the Media Pool to find clips you want to use, in preparation for making a selection for your next operation.

Methods of browsing clips in the Media Pool:

In the Metadata View mode, each clip is represented by its own card with a thumbnail and basic clip metadata information visible. This view is designed to have more metadata information than a thumbnail but more targeted information than the List view. This feature, combined with its Sort modes, is a powerful way to organize and reorganize your clips in the Media Pool.

- **Using thumbnail hover scrub in the Media Pool's Metadata view:** Drag the pointer over a thumbnail to scrub through its contents.

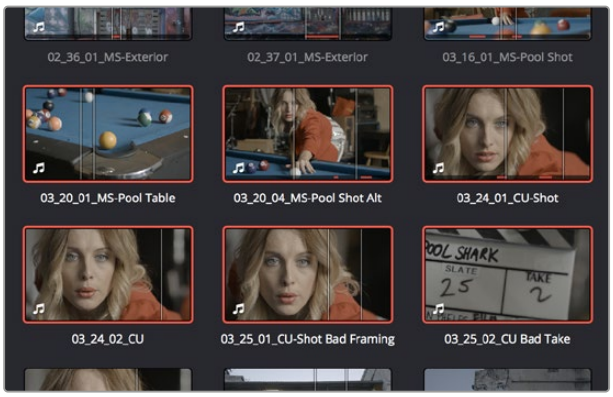
The Metadata View icon view (highlighted icon in the top bar), showing the thumbnail being scrubbed next to the clip's metadata

- **Using thumbnail hover scrub in the Media Pool's Thumbnail view:** Drag the pointer over a thumbnail to scrub through its contents.

Thumbnail hover scrubbing

- **Using the Media Pool Filmstrip in the Media Pool's List view:** Select "Show Filmstrip" in the Media Pool's option menu. Select a clip to expose it in the Filmstrip at the top of the Media Pool, and hover the pointer over the Filmstrip to watch it play. At any time, you can double-click a clip in the Filmstrip to open it into the Source Viewer.

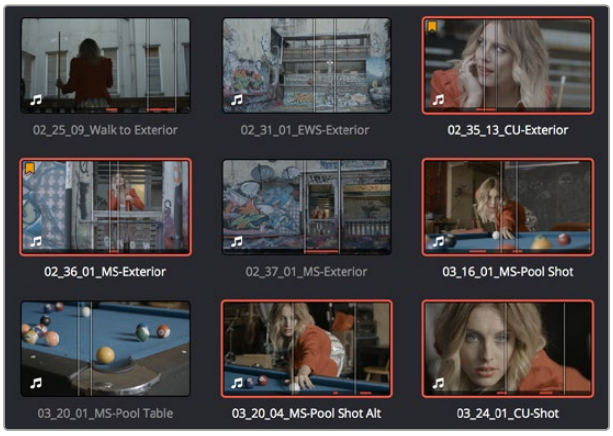
Using the Filmstrip when the Media Pool is in List view



TIP: When browsing media, you can open clips you want to have a closer look at in the Source Viewer by double-clicking them in the Media Pool. Meanwhile, you can continue to open other clips in the Filmstrip with a single clip in order to compare different clips with your main selection that remains in the Viewer.

Selecting Clips in the Media Pool to Edit

Once you've found one or more clips that you want to use in your edit, you'll need to make a selection in preparation for performing an edit.



Methods of selecting clips in the Media Pool using the mouse:

- **To select a single clip:** Click a clip in the Media Pool.
- **To select a contiguous range of clips:** In either Metadata, Thumbnail, or List view, drag a selection box over all the clips you want to select, or click to select the first clip in a series, then Shift-click the last clip to select those clips and everything in between.

Selecting a contiguous range of clips

- **To select a noncontiguous range of clips:** Command-click each clip you want to include in the selection. Or, you can hold the Command key down while you drag bounding boxes over unselected clips to add them to the current selection, or over selected clips to remove them from the selection.

Selecting a noncontiguous range of clips

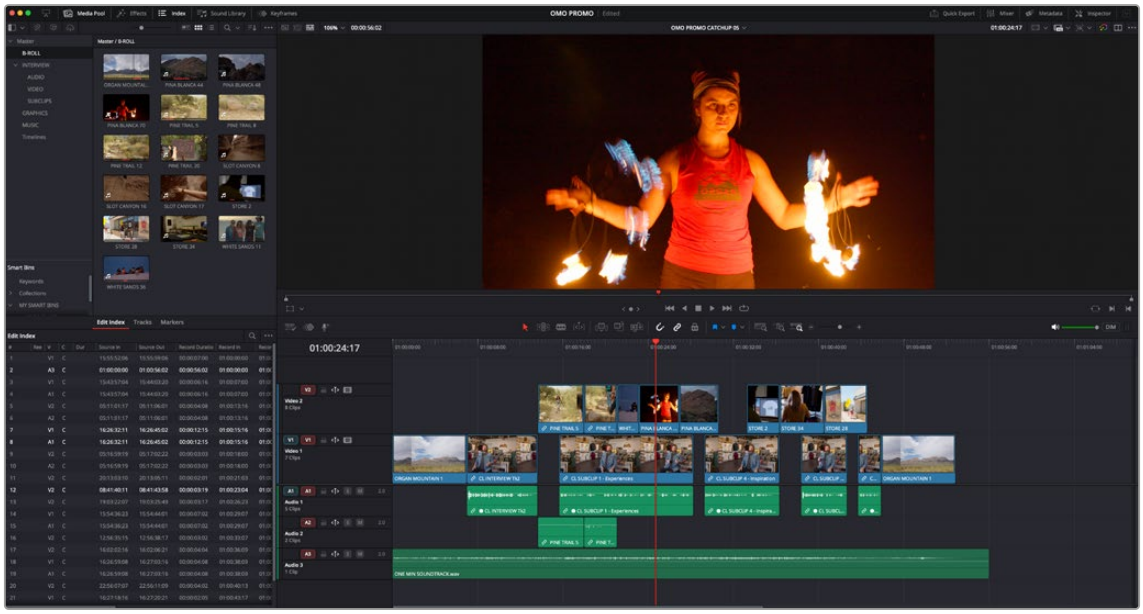
Methods of selecting clips using the keyboard:

- **To navigate the Bin list:** Either click any bin in the Bin list to the left of the Media Pool, or press Command-1 to make the Bin list the active pane of the Edit page, then use the Up and Down Arrow keys to to move up and down among the available bins. Use the Right Arrow key to open a bin that's closed, and use the Left Arrow key to close the bin again.
- **To select a single clip:** Press Command-1 to make the Media Pool Bin list the active area, and use the arrow keys to select and open bins. Then press Command-2 to select the clip browser area and use the Arrow keys to move the selection from clip to clip. Once a clip is selected, you can use any of the edit keyboard shortcuts to edit the selected Media Pool clip straight to the currently open Timeline.
- **To select multiple clips:** Hold the Shift key down while you're using the Arrow keys to move the selection to expand or contract a continuous selection in the Media Pool.
- **To select all clips in the Media Pool:** Make sure the Media Pool has focus by clicking a clip or clicking anywhere in the background of the Media Pool, then press Command-A to select all clips.
- **To open a selected clip or timeline into the Source Viewer:** Press the Return key. Once you've opened a clip into the Source Viewer, you can use the transport controls to play through it.

Duplicating Clips in the Media Pool

If you want to create duplicates of clips in the Media Pool, you can Option-drag one or more clips to another bin. You can also select the clip or clips you want to duplicate and select Edit > Duplicate Clips. The duplicated clips will appear in the same bin as the original media. The duplicate clips have their own individual links to the source media on disk.

Viewer Playback and Navigation



By default, the Edit page presents a traditional source/record style editing experience. The Source Viewer lets you view individual clips from the Media Pool to prepare them for editing. Meanwhile, the Timeline Viewer lets you play through your program, showing you the frame at the position of the playhead in the Timeline.

Source and Timeline Viewers

Source and Timeline Viewers vs. Single Viewer Mode

If you want to change the Edit page layout to hide the Source Viewer, you can choose Workspace > Single Viewer Mode to instead use just a single viewer to contextually display either a selected Source Clip or the current frame of the Timeline.

Single Viewer mode

In Single Viewer mode, whatever you select in the Media Pool or Timeline determines which controls appear in the Viewer, which lets you do nearly everything you can do with two simultaneously open viewers.

Opening Clips Into the Source Viewer to Prepare for Editing

Once you've decided which clips you want to use in your program, you can open them into the Source Viewer to review them more completely. How this works depends on the Source Viewer's Live Media Preview setting.

To skim through a Media Pool metadata or thumbnail and view clips in the Source Viewer using Live Media Preview:

1. Turn on Live Media Preview (if necessary) by clicking the Source Viewer option menu and choosing Live Media Preview.
2. With the Media Pool open and in Metadata or Thumbnail mode, position the pointer over a clip, and after a few moments when that clip's thumbnail starts to skim, you can see the clip you're scrubbing in the Source Viewer. Do one of the following:
    a) As you skim within the thumbnail, the playhead that appears in the thumbnail is locked to the playhead displayed in the Viewer's jog bar. While skimming, you can add markers and set In and Out points
    b) Leaving the pointer positioned over that clip, use the JKL keyboard shortcuts to play through the clip, adding markers and setting In and Out points as you like
3. It takes a moment for skimming to begin, which allows you to quickly move the pointer from that clip back to the Source Viewer without opening any other clip.

    Turning off Live Media Preview lets you use more traditional and controlled methods of opening clips into the Source Viewer.

To open a clip into the Source Viewer using the mouse:

Double-click any clip in the Media Pool, or in the Filmstrip of the Media Pool, to open it into the Source Viewer.

To load the previous or next clip in the bin into the Source Viewer:

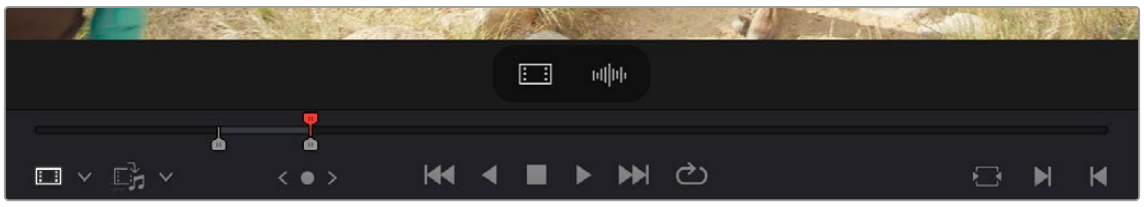
1. Click inside the Source Viewer to bring it into focus.
2. Press the Up Arrow key to navigate to the previous clip in the currently open bin, and load it into the Source Viewer.
3. Press the Down Arrow key to navigate to the next clip in the currently open bin, and load it into the Source Viewer.

To open a clip into the Source Viewer using the keyboard:

1. If necessary, press Command-1 to select the Bin list, and press the Up and Down arrows to choose a folder to view its contents. Press the Right Arrow key to open folders and show any nested folders within, or the Left Arrow key to close folders and hide their nested contents.
2. Press Command-2 to select the Media Pool browser, and use the Arrow keys to change the selection from clip to clip in the Media Pool, up, down, left, and right.
3. When the clip you want is highlighted, press Return to open it into the Source Viewer.

To open a timeline into the Source Viewer:

Drag and drop any timeline into the Source Viewer in preparation for either ganging it to the existing Timeline, or editing it, in whole or in part using In and Out points, into the currently open Timeline.



Monitoring with an External Video Display

While working in the Edit page, the image that's displayed on an external video display (if one is connected) is determined either by the current selection in the Media Pool, or by which part of the Edit page interface has focus. For example, if you select a clip in the Media Pool so it's displayed within the Filmstrip, that clip is output to video. If you then open it into the Source Viewer, then the contents of the Source Viewer are output to video. If you switch to the Timeline Viewer, then your timeline is output to video.

Viewer Transport Controls

The Edit page has two Viewers. The left Viewer, when you're editing, should be set to show either source video or source audio, so it shows the source clip in any edit you're setting up. At right is the Timeline Viewer, that shows the frame at the current position of the playhead in the Timeline. Using the Source and Timeline Viewers, you can set up a wide variety of edits.

There are transport controls underneath each of the Viewers.

The transport controls at the bottom of the Source Viewer

A jog bar appears directly underneath the transport controls, letting you drag the playhead directly with the pointer. The full width of the Source Viewer's jog bar represents the full duration of a clip, while the full width of the Timeline Viewer's jog bar represents the full duration of the current timeline. The current position of each playhead is shown in the timecode field at the upper right-hand corner of each viewer.

A separate jog control (<o>), to the left of the other transport controls, provides a way to jog more slowly through long clips or a long timeline. Click and drag to the left and right to move through a clip or the Timeline a frame at a time.

Transport controls appear below the jog bar. In the Source Viewer, these controls let you Jump to the First Frame, Play Reverse, Stop, Play Forward, and Jump to the Last Frame. In the Timeline Viewer, these controls move to the Previous Edit, Play Reverse, Stop, Play Forward, and move to the Next Edit. A loop control governs the looping behavior during playback.

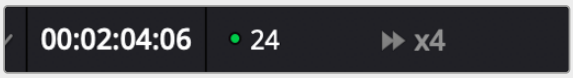
Simple Keyboard Shortcuts for Playback and Navigation

There are many different keyboard shortcuts you can use to simply navigate clips and timelines, and control playback.

- **Spacebar:** You can use the Spacebar to start and stop playback.
- **Skim Playhead:** You can skim footage in any viewer in the Media, Cut, Edit, Color, and Deliver pages by holding down the C key, and scrubbing the pointer back and forth in the viewer.
- **Play Again:** Press Option-L to immediately restart playback from where the playhead began without stopping; for instances where you quickly want to replay the beginning of what you're listening to.
- **Step One Frame Forward/Step One Frame Back:** The Left Arrow and Right Arrow keys move the playhead back and forth one frame at a time, while Shift-Left Arrow and Shift-Right Arrow move the playhead in one-second increments.
- **Step One Second Forward/Step One Second Reverse:** Shift-Left Arrow and Shift-Right Arrow moves the playhead back and forth one second at a time.
- **Next Edit/Previous Edit:** Up Arrow moves the playhead to the previous edit and selects the edit point, while Down Arrow moves the playhead to the next edit and selects the edit point.
- **First Frame/Last Frame of the Current Clip:** The Semicolon key moves the playhead to the first frame of the clip intersecting the playhead, while the Apostrophe key moves the playhead to the last frame of the clip intersecting the playhead.
- **Previous Keyframe/Next Keyframe:** Shift-Semicolon moves the playhead to the next previous keyframe on the left when keyframes are displayed in the Timeline, while Shift-Apostrophe moves the playhead to the next keyframe to the right.
- **Previous Marker/Next Marker:** If there are markers in either the Timeline Ruler or within clips in the Timeline, Shift-Up Arrow and Shift-Down Arrow moves the playhead left and right from one marker to the next.
- **Previous Gap/Next Gap:** If any tracks of the Timeline that have Auto Select control enabled have gaps between clips, Option-Command-Semicolon and Option-Command-Apostrophe moves the playhead left and right from one gap to the next.
- **Timeline Start/Timeline End:** The Home key moves the playhead to the first frame of the Source or Timeline Viewer, while the End key moves the playhead to the last frame of the Source or Timeline Viewer.

  Go to

- **In Point/Go to Out Point:** Shift-I moves the playhead to the In point set in either the Viewer or the Timeline. Shift-O moves the playhead to the Out point.



TIP: One of the options in the Editing panel of the User Preferences window, "Always highlight current clip in the media pool," lets you decide whether the current selection in the Timeline is mirrored in the Media Pool.

Using JKL to Control Playback

The JKL keyboard shortcuts are common to many editing applications, and experienced editors know these to be some of the most useful controls for playback and editing there are. Here's a list of the many different ways you can use these three keyboard shortcuts to play through clips and timelines as you work.

J	Plays 100% backward
K	Stops playback
L	Plays 100% forward
Press J repeatedly	Increases backward play speed each time you press J, for a range of fast-reverse speeds
Press L repeatedly	Increases forward play speed each time you press L, for a range of fast-forward speeds
Shift-J	Plays in fast reverse
Shift-L	Plays in fast forward
Shift-K	Play Slow at 1/2, 1/4 or 1/8 speeds
Press and hold K+J	Plays backward at slow motion (with slow motion audio playback)
Press and hold K+L	Plays forward at slow motion (with pitch-corrected audio playback on macOS)
Pressing K while tapping J	Moves the playhead back one frame
Pressing K while tapping L	Moves the playhead forward one frame
Command-J and Command-L	Holding the Command key down while using the J and L keyboard shortcuts lets you dynamically resize or trim selected edit points or clips at 100 percent or faster speed, depending on whether the Selection or Trim tool is enabled. For more information on dynamic trimming, jump to this chapter: Trimming.

When you're playing back at faster or slower than real-time speed using the JKL commands, a speed indicator appears to the right of the frame per second indicator of the Viewer.

A speed indicator above the Viewer shows that you're playing at 4x speed

Once you learn all the different methods of JKL playback, they will probably become one of the main ways you move the playhead around in DaVinci Resolve.

Special-Purpose Playback Commands

In addition to the standard transport controls, there are some additional playback controls, available via keyboard shortcuts or the Playback menu, that let you perform different playback operations.

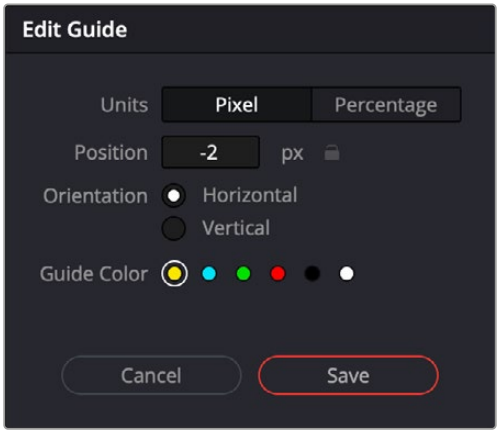
- **Loop:** Command-Forward Slash (/). Toggles looped playback off and on. While looped playback is on, playback initiated with any of the following commands will loop automatically until you stop playback.
- **Play around selection:** Forward Slash (/). This command works contextually depending on what's selected in the Timeline. Plays a section of the Timeline from x frames before to y frames after (a) the playhead (if nothing's selected), (b) the currently selected edit point, (c) the currently selected clip, (d) the currently selected transition, (e) a selection of multiple clips. This command is useful for previewing how the current selection plays within the context of the clips immediately surrounding it. The pre-roll and post-roll time is customizable in the Editing panel of the User Preferences.
- **Play around current frame:** Plays a section of the Timeline from x frames before to y frames after the current position of the playhead. This command is useful for previewing how edits play within the context of the clips immediately surrounding them. The pre-roll and post-roll time is customizable in the Editing panel of the User Preferences.
- **Play around current clip:** (no default key assigned). Plays a section of the Timeline from x frames before to y frames after the current clip intersecting the position of the playhead. The pre-roll and post-roll time is customizable in the Editing panel of the User Preferences.
- **Play Around In:** Option-Space. Plays a section of the Timeline from x frames before to y frames after the current assigned In point, letting you preview the transition from one clip to the next. The pre-roll and post-roll time is customizable in the Editing panel of the User Preferences.
- **Play Around Out:** Shift-Space. Plays a section of the Timeline from x frames before to y frames after the current assigned Out point, letting you preview the transition from one clip to the next. The pre-roll and post-roll time is customizable in the Editing panel of the User Preferences.
- **Play In to Out:** Option-Forward Slash (/). If you've marked a section of a clip or timeline with In and Out points, this command lets you preview how it will play.
- **Play to In:** (no default key assigned). Initiates playback and stops at the current In point.
- **Play to Out:** Option-Command-Forward Slash (/). Initiates playback and stops at the current Out point.

Custom Guides and Snapping in the Timeline Viewer

You can create your own custom guides in the timeline viewer. This lets you fully customize and create specific geographic locations in the frame, and then have the image snap to those locations in other operations. You can create Guides, which are colored lines that cross the frame horizontally or vertically, and Rulers, which provide measurement metrics along the edges of the frame. Both Guides and Rulers are overlay tools for adjusting your video position, and only show in the viewer, not your final project output.

The Timeline Viewer with Guides and Rulers enabled

Both Guides and Rulers can be shown independently by clicking on their icon in the Ruler Guides section of the Viewer Guides dropdown menu on the Timeline viewer. They can also be independently activated in the View > Rulers, and View > Guides menus.



The Ruler Guides section of the Viewer Guides dropdown

To Show and Modify a Ruler:

1. Activate the Ruler by choosing View > Rulers > On, or clicking on the Ruler Icon in the Viewer Guides dropdown in the Timeline Viewer.
2. Choose which metric you want the Ruler to use in View > Rulers, or by right-clicking on the Ruler in the Viewer.

   Pixel: Shows the ruler in number of pixels from the origin point (0,0) in the middle of the frame using a standard x/y cartesian coordinate graph, that reflects the Position field in the Video Inspector.

   Percentage: Shows the ruler in percentage distance from the origin point (0%, 0%) in the top-left of the frame. The top ruler runs from 0% at the left to 100% at the right, while the side ruler measures 0% from the top to 100% at the bottom. For example a point at the exact center of the frame would be at (50%, 50%).

The Add/Edit Guide dialog

To Show and Create a Guide Line:

1. Activate the Guides by choosing View > Guides > On, or clicking on the Guides Icon in the Viewer Guides dropdown in the Timeline Viewer.
2. Create a new Guide by choosing View > Guides > Add Guide, or by right-clicking on the Ruler in the Viewer and selecting Add Guides.
3. in the Add Guide dialog, choose the position and orientation you want the new guide to be, and click Add.

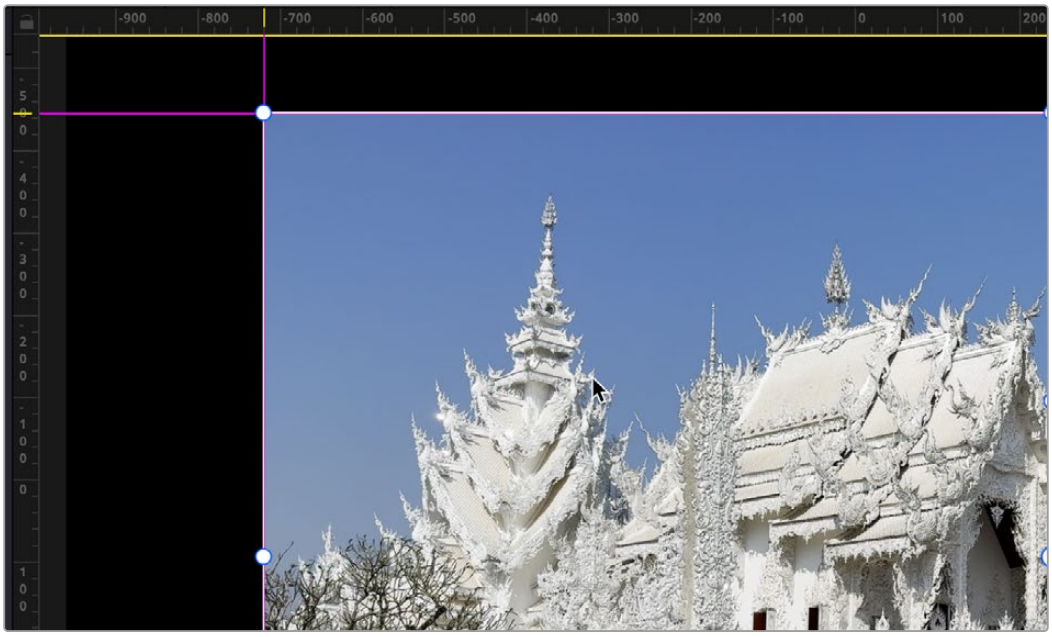
   Units: Choose which metric you want the guide line to use. Pixel shows the number of pixels from the guide's origin point, while Percentage shows the percentage distance from the top left of the frame at 0%, 0%.

   Position: Enter a value for where in the frame you want the guide line to intersect. You can also click and drag this line in the viewer to position it by eye (a small popup will reveal the exact position value as you move it). Optionally you can click the lock icon to prevent this guide from being moved accidentally.

   Orientation: Choose either a horizontal or vertical orientation for the line.

   Color: Choose the color of the guide line from the available options.

To Modify a Guide Line:

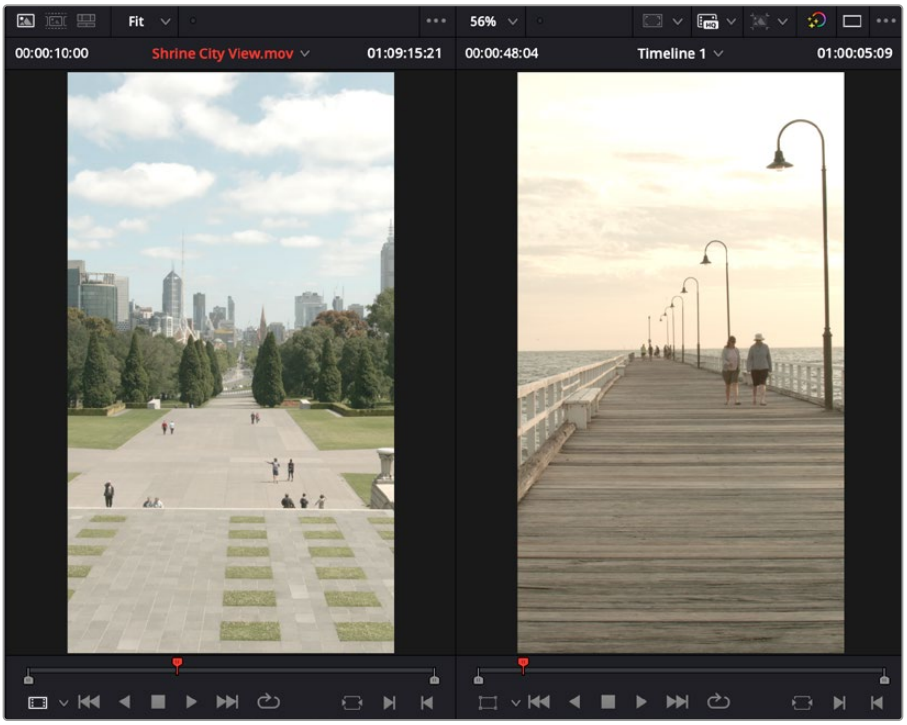


- Click and Drag the line to any position in the viewer, a small pop up window will appear to show you the exact position value.
- You can change the color of the Guide Lines for legibility by right-clicking in the Ruler and selecting a new color from the Guide Color context menu.
- You can delete a line by right-clicking on the line in the viewer and choosing Remove Guide.
- You can change an existing line's position and orientation by right-clicking on it in the viewer and choosing Edit Guide.
- You can delete all, only horizontal, or only vertical lines, by choosing View > Guides > and selecting the appropriate lines to remove. You can also do this by right-clicking on the ruler.
- Guides can be locked in place to avoid accidental movement by clicking on the small lock icon in the upper-left of the ruler, or by choosing View > Guides > Lock Guides.

Right-clicking on the Ruler opens a context menu
letting you adjust all parameters of the Rulers and Guide lines

Snapping to Guide Lines

By default, when moving the clip inside the frame using the Transform Viewer controls, whenever the edge of the image gets near a guideline it will automatically snap the image edge to it, turning the guide line purple so you know that it is exactly placed. If you want to disable this behavior, simply hold down the option key while moving the image in the viewer to bypass the snapping.



The Guide Lines turn purple when the edge of the image snaps to that location.

Optimized UI Layouts for Vertical Editing

Optimized layouts for vertical timelines and projects are supported in DaVinci Resolve. When a vertical timeline or project is loaded, the UI automatically switches to a layout optimized for vertical viewers on the Cut, Edit and Color pages. When loading a normal landscape timeline or project, UI automatically switches back to the original layout. No additional user intervention is needed.

You can change this behavior in Preferences > User > UI Settings > Use optimized UI layouts for vertical video. Unchecking this box retains the normal horizontal layout, even for vertical video timelines.

The UI now changes format to accommodate vertical video timelines automatically.

Option to “Stop and Go to Last Position”

Playback > Stop and Go to Last Position lets you set DaVinci Resolve to a mode where the playhead returns to where playback began whenever you stop. This option is most useful when editing audio, although it’s available any time. When using the JKL keys to navigate the Viewer in this mode, “K” will pause the playhead in place, while the space bar (stop) will go to last position.

This option is also available when you right-click on the Stop button in the transport controls of any viewer. A contextual menu appears where you can turn “Stop and go to last position” on or off as the default behavior.

Enabling and Disabling Audio Scrubbing

Audio scrubbing is enabled by default, meaning that you’ll hear audio when dragging the playhead with the mouse back and forth. While this can be useful when you’re searching for audio cues, it can also be distracting if you’re just focused on the picture.

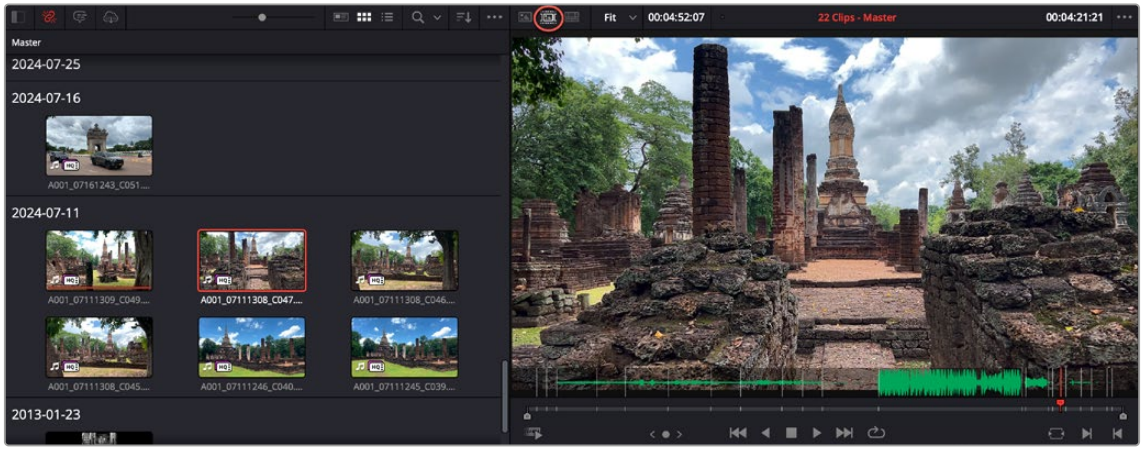
To enable or disable audio scrubbing:

Choose Timeline > Audio Scrubbing (Shift-S).

Playback Post-Roll

Enables the playhead to continue playing past the last clip in the Timeline for a duration equal to the “Post-roll time” Project Setting in the Editing panel. This is good for editors that want to experience a few moments of playback after cutting or fading to black after the last frame of audio and video in the Timeline.

To enable or disable Playback Post-Roll:



Choose Timeline > Playback Post-Roll.

Source Tape in the Edit Page Source Viewer

The Cut page’s Source Tape is also available in the Edit Page Source Viewer. To enable it, simply select a bin and then click on the Source Tape icon in the upper right of the Source Viewer, or press Shift-Q.

Using this option, every single clip in the currently open bin, and any subfolders in that bin, of the Media Pool is shown in the Source Viewer as a “stringout” in the scroll area at the bottom of the Viewer. In the scroll area, each clip appears one after the other in a long strip, with the order determined by the sort order. This makes it easy to scrub through a whole collection of clips while you’re figuring out what you want to use.

As you play through, whichever clip the playhead intersects is selected in the Media Pool, so you know which clip you’re looking at, and you have the ability to set In and Out points for any clip in the Source Tape.

You can also edit using the Source Tape in the Edit page. To do so, click on the Source Tape icon in the Source Viewer (circled red).

For watching and reviewing a large amount of footage, the Fast Review button is also now available in the lower left of the Source Viewer. Pressing this button will automatically adjust to a faster playback speed, depending on the length of the clip being viewed in the Source Tape.

Limiting the Source Tape Scope by Folder Structure

As your project grows, it can become unwieldy to constantly have an entire film's worth of media in the Source Tape. It is possible to limit the scope of the Source Tape at the bin level. By clicking directly on bins in the Bin list, you can quickly broaden or narrow the scope of the Source Tape. If you click on a bin named Scene02, the Source Tape will then zoom in to only show you clips in that folder. Clicking back on Master will zoom out the Source Tape to show the clips in all folders again.

This is also useful when navigating bin structures that reflect the original camera file system. For example, you may have a camera that records to each memory card as a separate folder, and then each individual clip is saved as a separate folder inside that folder. When you bring this file system into the Media Pool using the Create Bins option, these nested levels are mirrored in the Media Pool bin structure. Now when you click on a card bin in the Source tape, it will directly show you all the clips on that card, rather than show many individual sub-bins.

Moving the Playhead Using Timecode

You can use absolute or relative timecode entry to either move the playhead in both the Source and Timeline Viewers, or to move or trim selected edit points or clips. When navigating the Timeline, timecode entry lets you move the playhead very precisely, or jump to specific timecode values really quickly.

TIP: The method of timecode entry described here is used for many different commands that require timecode entry and is designed for fast and efficient editing.

How to Enter Timecode Values

When entering timecode, type each pair of hour, minute, second, and frame values from left to right, with a period representing a pair of zeros for fast entry. The numbers you enter appear in the timecode field at the upper right-hand corner of the Viewer with focus. When you're finished typing, press the Enter key to execute the timecode command. The rules for timecode entry are as follows:

- The right-most pair of timecode values (or period) you enter is always the frame number.
- A period to the left or to the right of any number you type is considered to be a pair of zeroes.
- A single period between two numbers is considered to either be a single zero, or ignored if it's between two pairs of numbers.
- Any untyped pairs of values to the left of what you enter are assumed to be whatever those values were prior to the timecode you entered; this makes it easy to type partial timecode values even when the Timeline starts at hour one.
- It's not necessary to enter colons or semicolons.

IMPORTANT: With full length keyboards, you can use the number pad for implicit timecode entry without invoking the Go To Timecode action (=). When using a multicam or printer light operation, any already mapped number pad key will continue to invoke actions like switching angles or incrementing color values.

When using the number keys above the letters on a keyboard, you must first select Go To Timecode (=), or click in the field you wish to change before entering a new value.

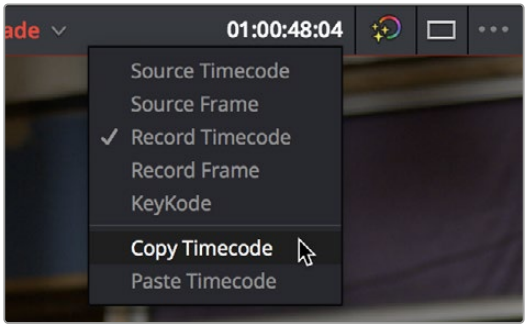
Absolute Timecode Entry

Absolute timecode is entered simply by typing in a timecode value. So long as no clips or edit points are selected when you press the Return key, the playhead will move to that timecode value. If an edit point or clip is selected, those will be moved or trimmed to the corresponding timecode value, if possible.

Here are some examples of absolute timecode entry using this method:

Original TC Value	User-Typed Value	New TC Value
01:10:10:10	15245218	15:24:52:18
01:10:10:10	2..	01:02:00:00
01:10:10:10	15	01:10:10:15
01:10:10:10	12	01:10:10:12
01:10:10:10	1.2	01:10:01:02
01:10:10:10	1115..	11:15:00:00
01:10:10:10	23...	23:00:00:00

Relative Timecode Entry



Relative timecode is entered by starting the timecode value with a plus (+) or minus (–). Adding a plus results in the value you type being added to the current timecode value for purposes of offsetting the playhead or moving a selection. Adding a minus will subtract the value you type from the current timecode value.

Here are two examples of relative timecode entry:

User-Typed Value	Result
+20.	00:00:20:00 is added to the current timecode value.
+3..	00:03:00:00 is added to the current timecode value.
-5	00:00:00:05 is subtracted from the current timecode value.

Copy and Paste Timecode in Viewer Timecode Fields

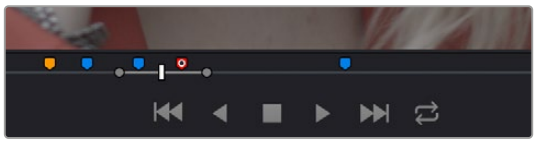
You can right-click on most Viewer timecode fields in the Media, Edit, and Color pages to choose Copy and Paste commands from a contextual menu for copying and pasting timecode values. You can also click in the timecode fields and use the normal Copy (Command-C), and Paste (Command-V) keyboard commands. This works even between pages. The timecode value you're pasting must be valid timecode, for example you can't paste 0 hour timecode onto a 1 hour timeline.

Right-clicking on a timecode field
to use the Copy Timecode command

Gang Viewers (Playhead Ganging)

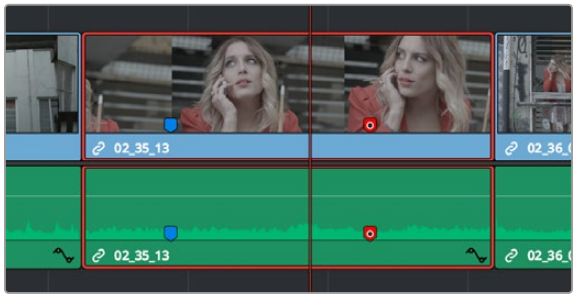
Ordinarily, the playhead movement in the Source and Timeline Viewers is independent. However, if you click the Option menu at the upper right-hand corner of either Viewer and turn Gang Viewers on, the movement of the Source and Timeline Viewer playheads is locked together, so that they move in unison. This is useful when you're marking the In and Out points of a clip in the Source Viewer to match the duration of a clip or other event in the Timeline.

When the Source and Timeline Viewers are ganged, you can still switch focus back and forth between the Source and Timeline Viewers, and your video output device will consistently switch to output whichever Viewer is in focus.



Adding Markers

While markers, flags, and clip labels are covered in much more detail elsewhere in the editing section, the use of markers is so important that a summary of how to add and edit markers appears here. Markers are used to call attention to a particular frame within a specific clip. Markers can be individually colored, and can have customized name and note text. Whenever you enter text into a marker, that marker displays a small dot that indicates there's more information inside of it.



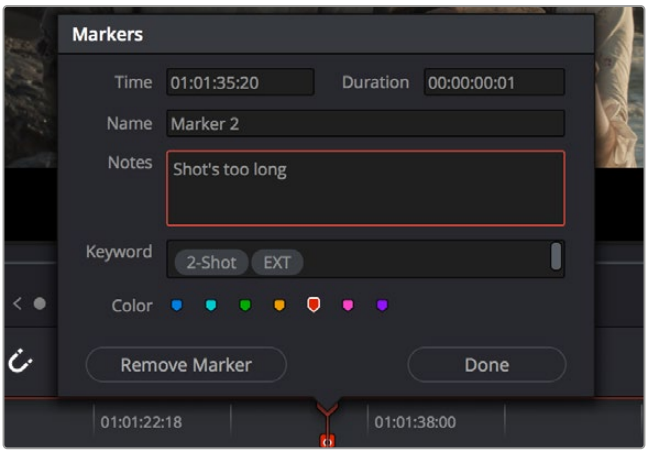
Once placed, markers snap to In and Out points, edit points, the playhead, and other markers whenever snapping is enabled, making it easy to use markers to "measure" edits and trims that you make in the Timeline.

Adding Markers to Clips

You can place markers on the jog bar of source clips in the Source Viewer (or in the Media Page Viewer) and on clips that are selected within a timeline.

Markers placed on a source clip

Markers placed on a clip in the Timeline



To mark a source clip in the Source Viewer or Media Page Viewer, do one of the following:

- To place a marker without doing anything else, move the playhead to the frame you want to mark, and then press M.
- To place a marker and immediately open the marker dialog to enter a name or note within it during playback, press Command-M. Playback pauses until you enter the text you want to and close the marker dialog again, at which point playback continues.
- Move the playhead to the frame you want to mark, then right-click in the jog bar and choose a marker color from the Add Marker submenu of the contextual menu.

Once you've added some markers, you may want to edit their contents to make them more useful.

To open a marker's edit dialog to alter its properties:

1. Do one of the following:
   - Press Command-M to add a marker during playback and immediately open its edit dialog.
   - Double-click any marker you want to edit.
   - Move the playhead to the frame containing the marker you want to annotate using Shift-Up Arrow/Down Arrow and press M.
   - Select a marker anywhere in the Source Viewer or Timeline, and press Shift-M.
2. When the marker dialog opens, you can modify several properties.

The properties found in the marker dialog

For much more information on markers, jump to this chapter: Marking and Finding Clips in the Timeline.

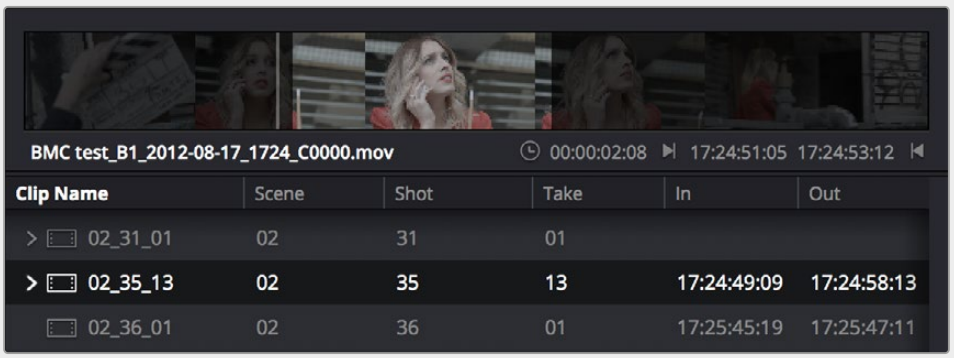
Setting In and Out Points

Now that you've used playback commands to review your clips, you can place In and Out points to set the range of each clip that you want to edit into the Timeline. If you don't set In or Out points, then the entire clip will be edited into the Timeline. If you do set In and Out points, those points will be saved in the Media Pool and used the next time you edit that clip.

Setting Clip In and Out Points in the Media Pool

You can set In and Out points right in the Media Pool to prepare for editing.

To set In and Out points while skimming a thumbnail in the Media Pool's Metadata view:



Set the Media Pool to Metadata view, then move the pointer over the Thumbnail and wait a moment until dragging the pointer begins to skim through that clip. As you skim, press I and O to set In and Out points to encompass the part of that clip you're going to want to use.

To set In and Out points while skimming a thumbnail in the Media Pool's Thumbnail view:

Set the Media Pool to Thumbnail view, then move the pointer over a clip and wait a moment until dragging the pointer begins to skim through that clip. As you skim, press I and O to set In and Out points to encompass the part of that clip you're going to want to use. When you're finished, that clip's thumbnail will show a range indicator at the bottom to show how much of the clip you've selected.

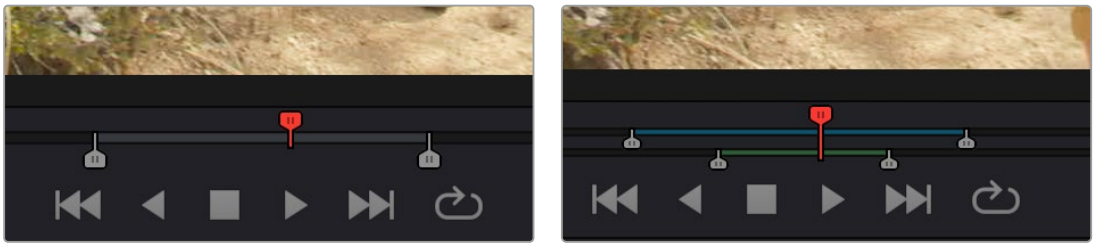
To set In and Out points using the Media Pool's List view Filmstrip:

Set the Media Pool to List view, then select a clip to expose it in the Filmstrip at the top of the Media Pool, drag the pointer through the Filmstrip to watch it play, and press I and O to set In and Out points to the appropriate range.

Marking In and Out points in the Filmstrip of the Media Pool in List view

The Filmstrip will dim the heads and tails to let you see the range of media you've marked. Once you've marked In and Out points in the Filmstrip, you can drag them to the left and right to move them.

Setting Clip In and Out Points in the Source Viewer



For a better look at your footage, you can set In and Out points in the Source Viewer in preparation for editing.

To set In and Out points in the Source Viewer:

1. Either skim a Media Pool thumbnail with Live Media Preview enabled in the Source Viewer's option menu, or open a clip into the Source Viewer.
2. Use JKL, the Spacebar, the transport controls, or drag in the jog bar to move the playhead to where you want to set an In or Out point.
3. Do one of the following:

   To mark simple In and Out points: Use the In and Out buttons to the right of the transport controls, or press the I or O keys.

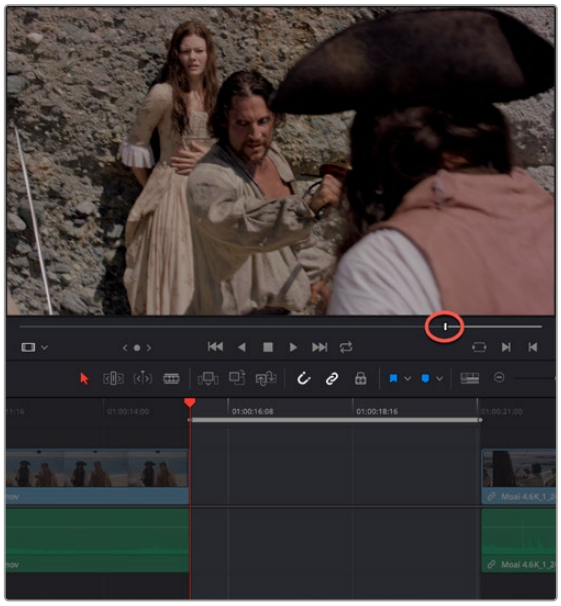
   To mark split In and Out points in preparation for making a split edit: Right-click the Jog Bar and choose Mark Split > Mark Video In (Shift-Option-I) / Mark Audio In (Command-Option-I) / Mark Video Out (Shift-Option-O) / Mark Audio Out (Command-Option-O).

Marking In and Out points in the Source Viewer, both as simple (Left) and split edits (Right)

Simple In and Out points let you join the audio and video of two clips at a single edit point in the Timeline. However, setting split In or Out points sets you up to create split edits where the video is offset from the audio in a single step.

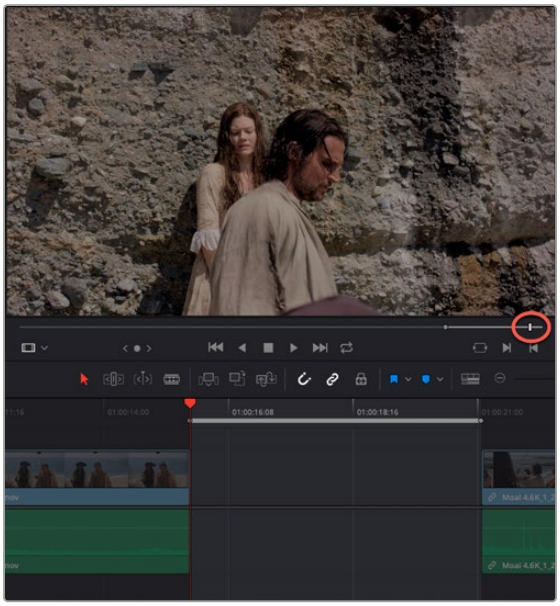
Clearing and Navigating In and Out Points

Once placed, you can also clear In and Out points you don't want and move the playhead to In and Out points you might want to edit.



To clear In and Out points:

- **To clear In or Out points:** Move the pointer over a marked thumbnail in the Media Pool or over the Media Pool film strip, or open a clip in the Source Viewer, and then press Option-I to clear the current In point, or Option-O to clear the current Out point.
- **To clear Split In or Split Out points:** Press Shift-Option-X to clear the Video In and Video Out points. Press Command-Option-X to clear Audio In and Audio Out points.
- **To clear both the In and Out points at once:** With the pointer over a marked thumbnail in the Media Pool or over the Media Pool film strip, or with the Source Viewer selected, press Option-X.



To jump the playhead to the current In or Out points in the Source or Timeline Viewer:

- Press Shift-I to move the playhead to the current In point (Playback > Go To > In).
- Press Shift-O to move the playhead to the current Out point (Playback > Go To > Out).

The Go to In and Go to Out commands are capable of placing the playhead at the implicit (but unmarked) In and Out points defined by a three point edit you're setting up, even when Preview Marks have not been enabled. For example, if you mark In and Out points in the Timeline, and you then mark an In point for a clip in the Source Viewer, pressing Shift-O (Go to Out) automatically moves the Source Viewer playhead to the frame that will be the Out point of that clip were you to execute this edit.

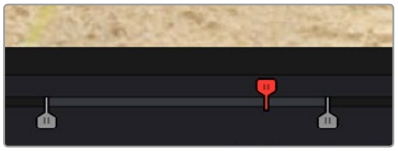
In and Out points set in the Timeline and an In point set in the Source Viewer set up a three point edit,

Using Go to Out to move the Source Viewer playhead to the implicit Out point defined by a three point edit

Clip Edit Points Are Saved

Once set, In and Out points remain in place within each source clip or timeline until you set new ones. If you quit DaVinci Resolve and later reopen the same project, each clip's In and Out points are saved for future reference.

Turning In and Out Points into Markers With Duration and Back Again



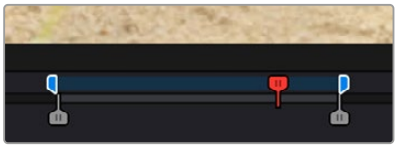
If you want to log the most important sections of clips using In and Out points, you can only log a single section at a time, as In and Out points are used to identify the next section of a clip to be edited in a three point edit. However, two commands in the contextual menu of the Source Viewer jog bar work together to let you turn In and Out points into Markers with Duration, and vice versa:

- **Convert In and Out to Duration Marker:** Turns a pair of In and Out points into a duration marker. By default, no key shortcut is mapped to this command, but you can map one if you like.
- **Convert Duration Marker to In and Out:** Turns a duration marker into a pair of In and Out points, while retaining the marker. By default, no key shortcut is mapped to this command, but you can map one if you like.

Using these two commands, you can easily use markers with duration to mark regions of clips that you want to log for future use, turning each region into an In and Out point when necessary for editing. By default, these commands don't have keyboard shortcuts assigned to them, but you can assign them if you use them frequently.

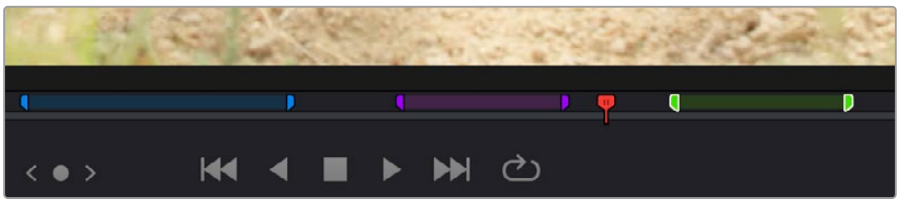
To turn In and Out points into a duration marker:

1 Set In and Out points in the Source Viewer jog bar to identify a region you want to log for future reference.



Marking In and Out points in preparation to log that section of the clip

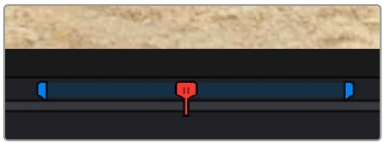
2 Do one of the following:



- Right-click the jog bar and choose Convert In and Out to Duration Marker.
- Choose Mark > Convert In and Out Into Duration Marker.

A duration marker appears above the In and Out points.
To edit its name or notes, double-click the marker, press Shift-M, or choose Mark > Modify Marker.

A duration marker is created from the In and Out points

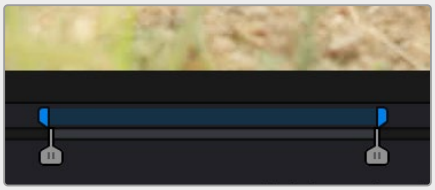


In this way, you can log several regions within a single clip for future use.

A clip with multiple logged sections identified via markers with duration

To turn a duration marker into an In and Out point:

1 Find a duration marker you want to convert into In and Out points..



Finding a duration marker to convert into In and Out points

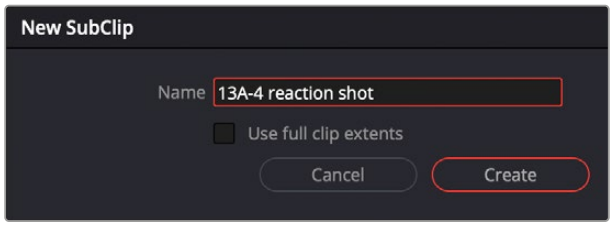
2 Do one of the following,

- Right-click the jog bar and choose Set In and Out from Duration Marker.
- Position the playhead over the duration marker and choose Mark > Set In and Out from Duration Marker.

In and Out points appear under the duration marker.

In and Out points are created from the duration marker

In this way, you can turn a duration marker that you've logged into In and Out points in preparation for executing a three-point edit.



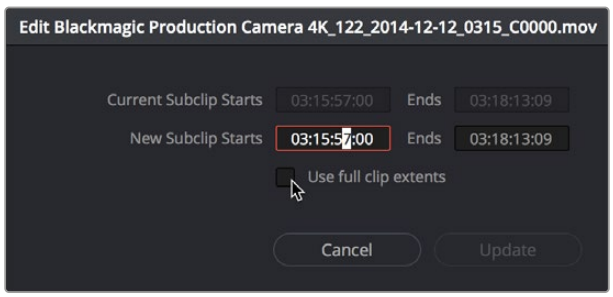
These are extremely useful logging techniques for three reasons. First, markers with duration can be searched for in the Media Pool using the All Fields, Marker Name, and Marker Notes Filter by options. Second, they can be filtered with Smart Bins using the Marker Name and Marker Notes Media Pool Properties options. Lastly, once one or more duration markers have been added to a clip, they can quickly be used to perform three-point edits into the timeline.

Organizing Media by Creating Subclips

Subclips give you another way of organizing media in the Media Pool, letting you break excessively long clips into shorter ones. For example, if the director of a project is fond of “rolling takes” where multiple takes are all recorded within a single clip, you can break these takes up by making them into subclips.

To create a subclip in the Edit page:

1. Do one of the following to open a clip into the Source Viewer in either the Media page or the Edit page, in preparation for creating subclips.
   - Double-click any clip in the Media Pool.
   - Single-click any clip in the Media Library of the Media page to create a subclip without needing to first import that clip into the Media Pool.
2. Set In and Out points in the Source Viewer to define the section you want to turn into a subclip.
3. Do one of the following:
   - Choose Mark > Create Subclip.
   - Press Option-B.
   - Right-click the jog bar and choose Create Subclip from the contextual menu.
   - Drag a clip from the Source Viewer to the Media Pool.
4. A new subclip dialog appears, allowing you to name the subclip and decide to use its full extents by turning on the checkbox.



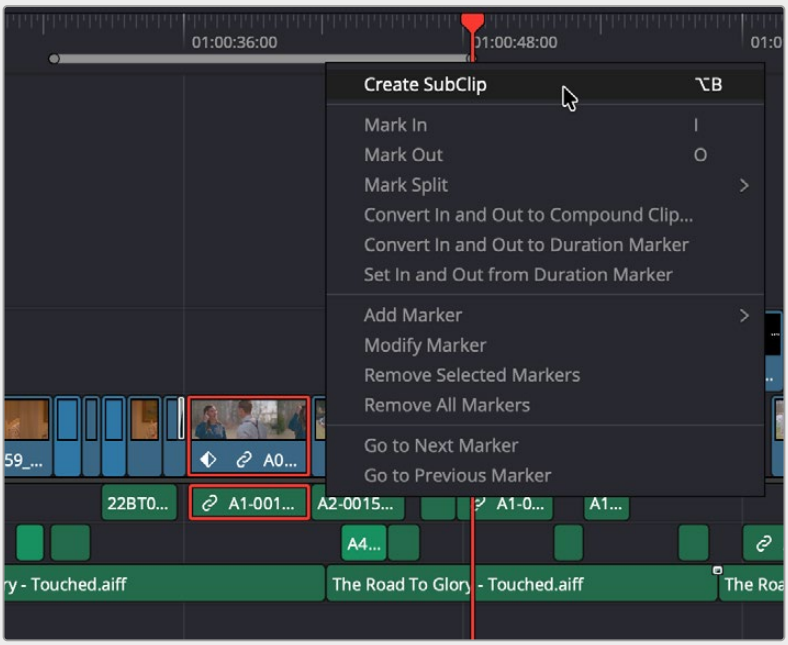
The New SubClip dialog

Once created, subclips appear and work like any other clip in DaVinci Resolve. You can also create subclips in the Media page while performing other organizational tasks there.

Removing or Changing Subclip Limits

Once created, you can right-click any subclip in the Media Pool or a timeline and choose Edit Subclip to open a dialog in which you can turn on a checkbox to use the subclip’s full extents, or to change the start or end timecode of the subclip via timecode fields, before clicking Update to modify the subclip.

The Edit Subclip dialog



Create a Timeline Subclip from In / Out Range

You can also make a subclip of multiple clips from the active timeline in the Edit page. This lets you pick just a section out of a timeline and isolate it in its own new timeline for further modification without changing the original.

To create a Timeline Subclip in the Edit page:

1. Set the In and Out points where you want the subclip to begin and end on the timeline.
2. Right-click on the selected range at the bottom of the Timeline viewer or the Timeline ruler bar, and choose Create Subclip from the context menu. Alternatively you can press Option-B.

This creates a new timeline with just the range chosen from the original timeline. It is named "<timeline name> Subclip" in the Media Pool to differentiate it from the original.

Right-clicking on the ruler bar in the timeline also lets you choose Create SubClip from the list of options.

Chapter 43

Editing Basics

In this chapter, you'll learn many of the fundamental methods and commands you'll use when beginning to assemble clips into the Timeline.

This includes drag and drop operations to begin assembling a timeline, different ways of selecting and deselecting the clips you've edited in preparation for different tasks, maintaining sync between the audio and video components of clips you're editing, and deleting clips and gaps you don't want.

Keyboard Shortcuts in This Chapter

Here's a list of of keyboard shortcuts you might find helpful that relate to topics found in this chapter.

Key Shortcut	Function
V	Select nearest edit to playhead
Shift-V	Select clip intersecting playhead
U	Select incoming, outgoing, or centered part of edit
Option-U	Toggle selection among video+audio, video only, and audio only
Option-Y	Select clips forward (of the playhead) on all tracks
Command-Option-Y	Select clips backward (of the playhead) on all tracks
Y	Select clips forward (of the playhead) on current track
Command-Y	Select clips backward (of the playhead) on current track
Up, Down Arrow Keys	Move selection to previous/next edit or clip
Delete	Delete clip and leave gap (lift edit)
Forward Delete	Ripple delete; deletes a clip and moves the rest of the timeline left to fill the gap
Command-Backslash (\)	Insert edit; adds a cut to the clip(s) at the position of the playhead
N	Toggle timeline snapping off and on
Command-Shift-L	Toggle linked selection off and on
Option-1 through 8	Set video destination control to that track number; press again to enable/disable
Command-Option-1 thorugh 8	Set audio destination control to that track number; press again to enable/disable
Option-Shift-1 through 8	Toggle lock for individual video tracks
Option-Shift-9	Toggle lock for all video tracks
Option-Shift-F1 through F8	Toggle lock for individual audio tracks
Option-Shift-F9	Toggle lock for all audio tracks
F9	Insert Edit selected clip(s) from Media Pool or Source Viewer to the Timeline
F10	Overwrite Edit selected clip(s) from Media Pool or Source Viewer to the Timeline
F11	Replace Edit the first of selected clip(s) from Media Pool or Source Viewer to the Timeline

Key Shortcut	Function
F12	Place On Top Edit from Media Pool or Source Viewer to the Timeline
Shift-F10	Ripple Overwrite from Media Pool or Source Viewer to the Timeline
Shift-F11	Fit to Fill from Media Pool or Source Viewer to the Timeline
Shift-F12	Append To End Edit from Media Pool or Source Viewer to the Timeline
Undo	Command-Z
Redo	Command-Shift-Z

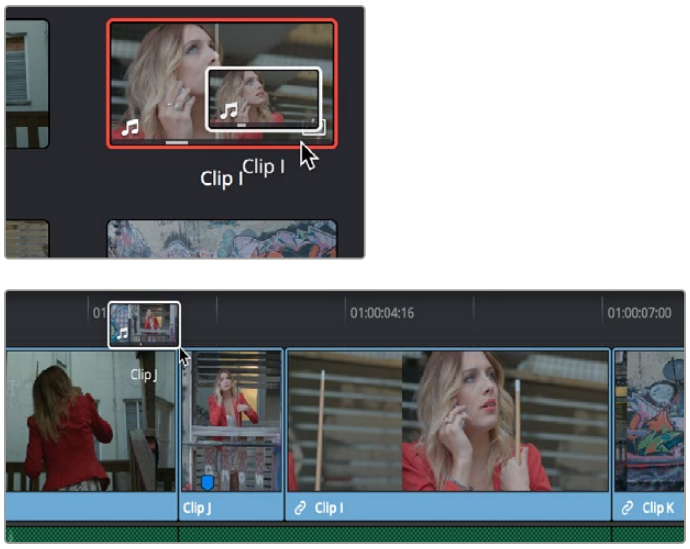
Drag and Drop Editing

If you've already used other editing programs, the procedures in this section will almost certainly be remedial, but if you're new to editing, this section covers the most basic methods of editing a series of clips into the Timeline to get you started. The absolute simplest method of editing is to drag clips from the Media Pool and drop them into the Timeline. You can do this with individual clips, or with selected groups of clips.

Drag and Drop Editing of Individual Clips Into the Timeline

If you're just editing one clip at a time to create an edited sequence in a timeline, this is how that works.

1 If you need to edit specific ranges of the clips you're editing, you can set In and Out points in source clips first by doing one of the following:



Setting In and Out points while skimming a thumbnail in the Metadata View: As you're skimming over a clip's thumbnail in the Viewer, press I and O to set In and Out points to encompass the part of that clip you're going to want to use. If you've turned on Live Media Preview in the Source Viewer, then the Source Viewer will show what you're skimming so you can get a closer look. If you don't like the current In and Out points, you can press Option-X to clear them both.

Setting In and Out points while skimming a thumbnail in the Media Pool: As you're skimming over a clip's thumbnail in the Viewer, press I and O to set In and Out points to encompass the part of that clip you're going to want to use. If you've turned on Live Media Preview in the Source Viewer, then the Source Viewer will show what you're skimming so you can get a closer look. When you're finished, that clip's thumbnail will show a range indicator at the bottom to show how much of the clip you've selected. If you don't like the current In and Out points, you can press Option-X to clear them both.

Using the Media Pool Filmstrip in the Media Pool's List view: Set the Media Pool to List view, select Show Filmstrip in the option menu, then select a clip to expose it in the Filmstrip at the top of the Media Pool, drag the pointer through the Filmstrip to watch it play and press I and O to set In and Out points to the appropriate range. The Filmstrip will dim the heads and tails to let you see the range of media you've marked. If you've turned on Live Media Preview in the Source Viewer, then the Source Viewer will show what you're skimming so you can get a closer look. If you don't like the current In and Out points, you can press Option-X to clear them both.

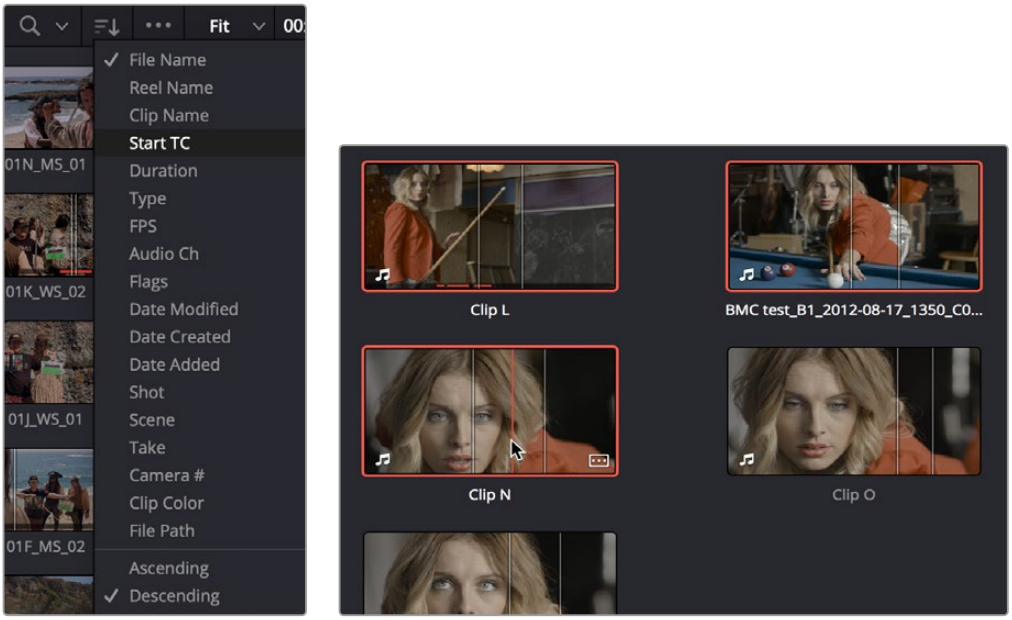
Using the Source Viewer: Open a clip in the Viewer by double-clicking it in the Media Pool, or by selecting it in the Media Pool and pressing the Return or Enter key. Then use the transport controls, jog bar, control panel buttons, Spacebar, or JKL commands to move the playhead, and place In and Out points using the In and Out buttons to the right of the transport controls, or by pressing the I or O keys. If you don't like the current In and Out points, you can press Option-X to clear them both.

2 Drag the clip you want to edit from either the Media Pool or the Source Viewer, and drop it onto the desired position in the Timeline to perform an overwrite edit. If you drag a clip on top of another clip that's already in the Timeline, the clip you're dragging will overwrite the part of the clip that it overlaps.

Dragging a clip from the Media Pool to overwrite a clip in the Timeline

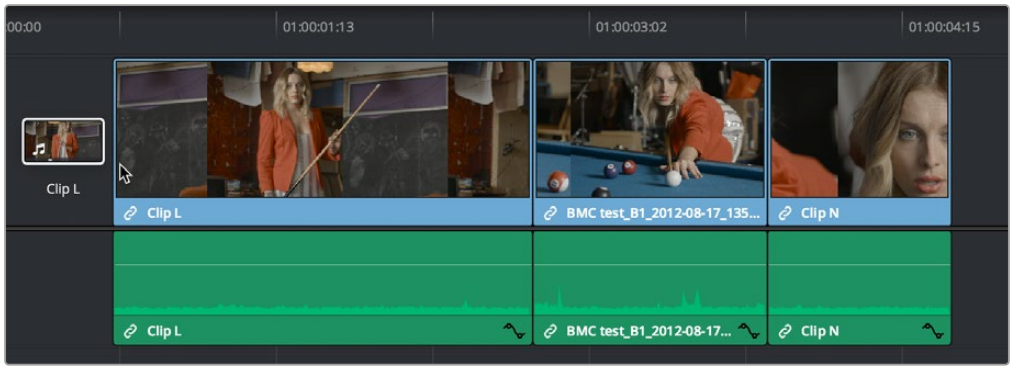
TIP: If you drag a clip into the blank area above an existing video track or below an existing audio track, a new track will automatically be created.

Drag and Drop Editing of Several Clips Into the Timeline At Once



The procedure above also works when you want to edit several clips into the Timeline at once by dragging them from the Media Pool.

1 Change the sort order of the Media Pool's browser area to put the clips into the order in which you want them to appear. In Thumbnail view you can use the Sort Order menu, but in List view you can click the header of any metadata column to sort by that column's data. If you've used the Metadata Editor to add Scene, Shot, Take, or other information to identify each clip, you can sort by these metadata criteria.

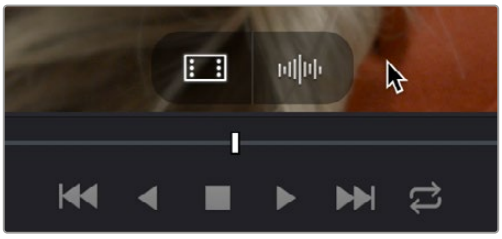


2 Use the Media Pool thumbnails, the Media Pool List view Filmstrip, or the Source Viewer to set In and Out points to define the part of each clip that you want to edit into the Timeline.

3 Select the Media Pool clips you want to edit into the Timeline by dragging a bounding box, Command-dragging multiple bounding boxes over different sets of clips, by Shift-clicking a range of clips, or by Command-clicking individual non-contiguous clips.

4 Drag any of the selected clips to the desired position in the Timeline to perform an overwrite edit.

Using the Sort Order menu to change the sort order of clips in the Media Pool



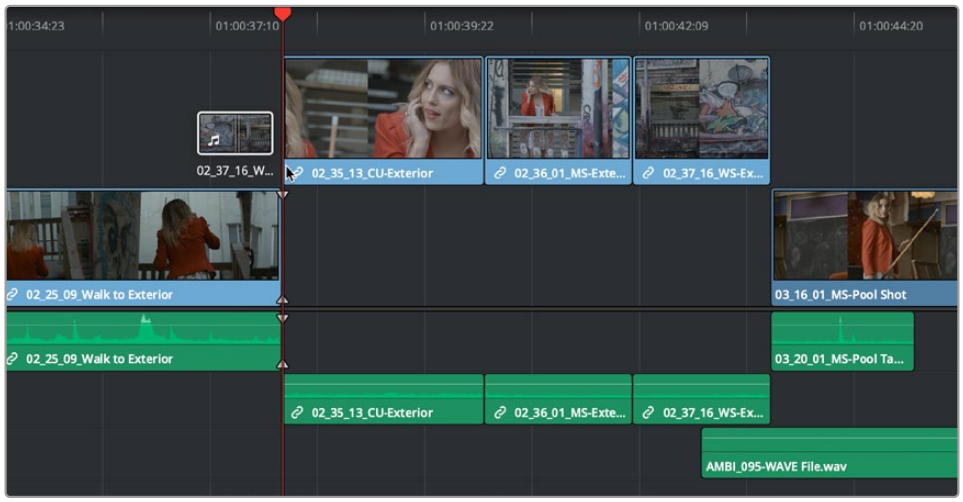
Dragging multiple clips into the Timeline in the sort order of the Media Pool

The clip(s) you drag overwrite whatever other clips they overlap in the Timeline. Multiple clips dragged from the Media Pool will be edited in the order in which they're sorted in the Media Pool, using each clip's In and Out points.

Drag and Drop Editing of Video-Only or Audio-Only Edits

While it's easy to edit just the video or just the audio of a clip by disabling the audio or video destination control in the Timeline prior to doing any sort of edit (described later in Chapter 39, "Three- and Four-Point Editing"), there's also a pair of keyboard modifiers you can use to do the very same thing while you're dragging.

- **To edit only the video of a clip from the Media Pool:** Option-drag clips from the Media Pool/Filmstrip, Source Viewer, or Finder into the Timeline.
- **To edit only the audio of a clip from the Media Pool:** Shift-drag clips from the Media Pool/Filmstrip, Source Viewer, or Finder into the Timeline.
- **To edit only the video or audio of a clip from the Source Viewer:** Open a clip into the Source Viewer, then move the pointer over the Source Viewer and drag from either the Video-only or Audio-only overlays that appear over the bottom of the image.

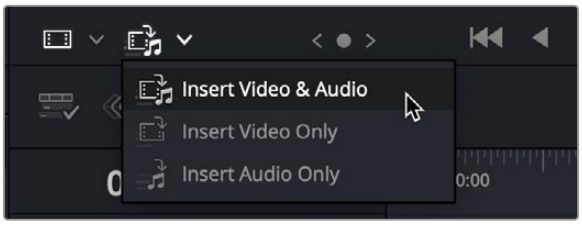


Video and Audio-only overlay controls appear in the Source Viewer that let you drag just the video or just the audio into the Timeline

Drag and Drop Insert Editing

You can also drag multiple clips from the Timeline, or a single clip from the Source Viewer, at any frame of the current timeline to either insert the selection between any two clips or to insert it in the middle of an existing clip, moving (actually rippling) all media to the right of the new edit point you create to make room for the new incoming media.

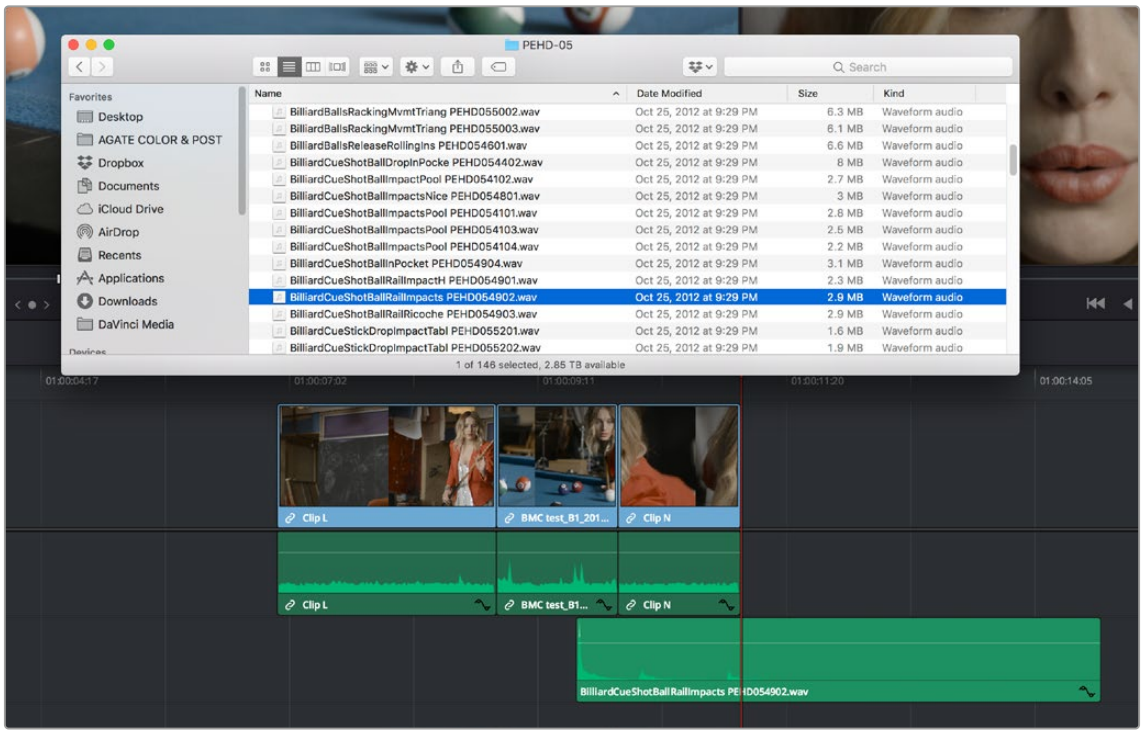
To shuffle insert multiple clips from the Media Pool or Source Viewer into the Timeline:



1. Select one or more clips in the Media Pool (the sort order dictates the final order of the edited clips), or open a clip in the Source Viewer.
2. Press and hold the Command and Shift keys, and drag the selection from the Media Pool or Source Viewer into the Timeline.
3. As you drag, the clips you're dragging will be inserted into the Timeline at the pointer location. Release the mouse to finish making the edit.

Making an Insert Edit while dragging clips from the Media Pool

Audio-Only and Video-Only Insert Controls in the Source Viewer



In the Edit page, you can persistently select Video and Audio, Video-Only, and Audio-Only inserts of a source clip from a drop-down menu under the Source Viewer.

The new persistent Video / Audio insert controls at the bottom of the Source Viewer

Dragging Clips From the File System Into the Timeline

You can also drag a clip directly from your file system to the Timeline on supported platforms.

Dragging multiple clips into the Timeline from the macOS Finder

Inserting Multiple Clips into the Timeline From the Media Pool

For certain large volume editing projects, you can insert multiple clips from the Media Pool into a timeline all at once. The parameters for the order and positioning of the clips depend on the method used.

Insert Selected Clips to Timeline Using Timecode

Clips can now be edited directly from the Media Pool into a timeline, such that each clip's source timecode is aligned with an identical record timecode value in the Timeline. This can be useful for long form multi-camera events, like weddings or concerts, where all cameras are linked by the same timecode to ensure all edits are perfectly synced. This function matches the Source Overwrite edit on the Cut page.

IMPORTANT: The timecode of the Timeline must overlap the timecode of the clip(s) for this edit to function. This can be set in the Start Timecode field of the New Timeline settings.

To insert selected clips to timeline using timecode:

1. Select one or more clips to edit into the Timeline in the Media Pool. If there are In and Out points set on the clip, the edit will respect those boundaries. If no In/Out points are set, each selected clip's full duration will be edited in its entirety.
2. Set a destination control to determine which track in the Timeline you want to edit to.
3. Right-click one of the selected clips and choose "Insert Selected Clips to Timeline Using Timecode" from the drop-down menu.
4. All of the selected clips will be overwritten into the Timeline at their appropriate timecode locations onto the destination track.

IMPORTANT: If multiple selected clips have overlapping timecode, no edit will occur.

Insert Selected Clips to Timeline With Handles

This command inserts multiple clips into the Timeline serially, using the current sort order of the Media Pool, with handles subtracted from the current In and Out points of each clip (using the Default Handles Length in the Editing panel of the User Preferences). Combined with the Add Transition tool (Command-T), this function is useful when quickly creating montages from multiple clips.

To insert clips with handles to the Timeline:

1. Select the clips to insert into the Timeline with handles in the Media Pool.
2. Right-click any selected clip, then choose "Insert Selected Clips to Timeline With Handles." The clips will be inserted starting at the Timeline In point with the default handles length already calculated.

TIP: To finish creating the montage, select the clips in the Timeline, then choose "Add Transition" (Command-T) from the Timeline menu. This will apply the default transition to all of the clips at once.

Audio Track Creation While Editing

When dragging an audio clip to the undefined gray area of the Timeline below currently existing audio tracks in order to create a new track, the new track is set to a channel mapping that reflects the number of channels of the audio clip you're dragging.

This also means that if you've used Clip Attributes to map a clip's audio to consist of multiple tracks where each track has a different channel mapping, for example, one 5.1 track, one stereo track, and six mono tracks, then editing that clip into the Timeline so that the audio portion creates new tracks will automatically create eight tracks: one that's 5.1, one that's stereo, and six that are mono.

Not Creating New Tracks when Adding Clips to a Timeline

There is a menu item in Edit > Edit Options called Automatically Create Tracks on Edit. This option is on by default and preserves DaVinci Resolve's default behavior of automatically adding new tracks to the timeline if your source material has more audio tracks than your timeline does.

When disabled, you have the ability to drag source clips on to the timeline without the timeline automatically creating new tracks for the additional audio or video elements. In situations where your source camera files have more audio tracks than on your timeline, disabling this option will not create additional new tracks and will only bring elements visible in the track destination controls.

This can be useful if, for example, you wanted to only bring a single mixed track in with a clip from a multitrack recorder and exclude the independent microphone tracks.

Using Keyboard Shortcuts and Three-Point Editing to Assemble a Program

While drag and drop editing is intuitive enough, there are other methods of editing clips into the Timeline by using the playhead to define where those clips will start that can be more efficient and precise. These examples all use "overwrite" edits, which delete unwanted media from the Timeline as you're adding clips that you do want. Here are two examples of how to do this.

Example: Assembling Clips Into the Timeline From the Source Viewer

The following example shows how you can use the Edit page to assemble a quick first cut of edits using different features of the Media Pool, Viewers, and Timeline. Written out with every possible option, this may seem like a lot of steps, but once you learn these fundamentals and develop some muscle memory for the keyboard shortcuts in use, these methods become really fast to do.

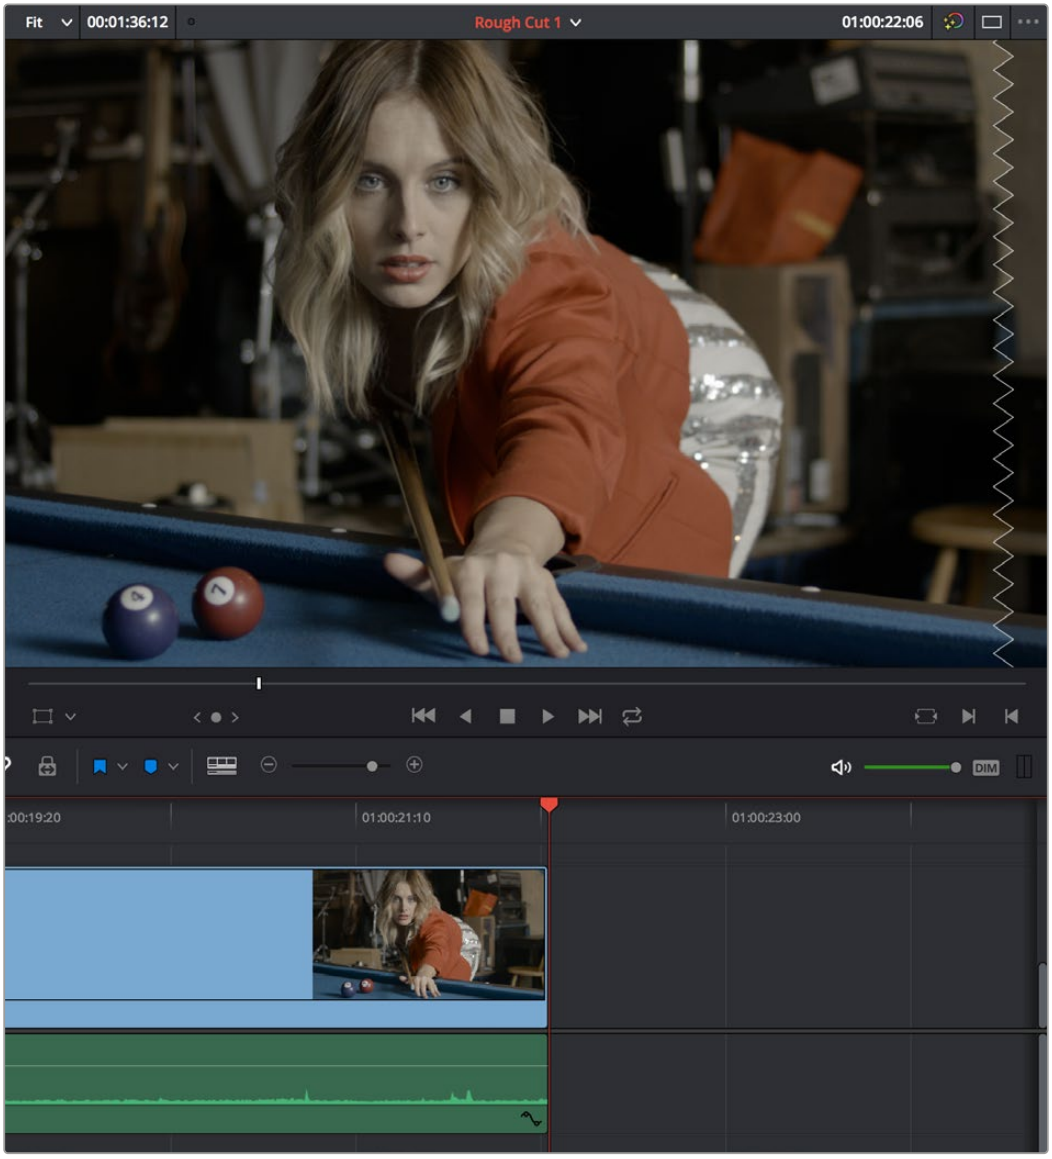
1. Press Command-1 to open the Media Pool, and use the Arrow keys to select a bin (Up and Down to change the selection, Right and Left to open and close bins). Then press Command-2 to choose the clip browser, and use the Arrow keys to select a specific clip.
2. Press the Return or Enter key to open the selected clip into the Source Viewer.
3. Drag the playhead with the pointer or use the Spacebar or JKL keys to move the playhead and set In and Out points (I and O) to define the section of that clip you want to edit into your program.

4 By default, the source destination controls are assigned to tracks V1 and A1. If necessary, choose different video and audio tracks to edit the clip to in the Timeline by doing one of the following:

- Drag the source destination controls from where they are now to where you want them to be in the Source Track Selector.
- Right-click in an empty source destination control in the Source Track Selector, and select the source destination from the context menu.
- Use the Command-Option Up and Down Arrow (for audio) and Command-Shift Up and Down Arrow (for video) shortcuts to move the source destination controls up and down.
- Use the Option-1–8 (for video) and Command-Option-1–8 (for audio) key shortcuts to assign the video and audio source destination controls to specific tracks.

5 By default, all source destination controls are enabled. If you want to edit clips into the Timeline as audio or video only, you can do one of the following:

- Click any source destination control itself to disable the video or audio component.
- Press Option-1–8 (for video) or Command-Option-1–8 (for audio) for the currently assigned tracks to toggle the destination controls on those tracks on and off.
- Select Video and Audio, Video-Only, and Audio-Only inserts of a source clip from the drop-down menu under the Source Viewer.



6 In the Timeline Viewer or the Timeline itself, use the pointer, Spacebar, or JKL controls to move the Timeline playhead to the frame you want the beginning of the clip you're about to edit to start. If no In or Out points are set in the Timeline, the playhead position is used as the In point by default.

7 To perform an overwrite edit, do one of the following:

- Drag the clip from the Source Viewer to the Timeline Viewer and drop it on the Overwrite overlay. If you're in single viewer mode, this overlay only appears when you drag a clip from the Media Pool to the Timeline Viewer.
- Click the Overwrite Clip button in the toolbar.
- Choose Edit > Overwrite (or press F10).

The selected clip(s) are overwritten to the selected track at the position of the playhead, and the playhead automatically moves to the end of the newly edited clip, ready for you to perform another edit. If that clip is the last one on the Timeline, you'll see the last frame to the left of the playhead (with a jagged overlay at the right-hand side of the Timeline Viewer) instead of the black that is the actual frame after that clip. This makes it easier for you to line up the next edit. Otherwise, the playhead will show whatever frame happens to be at that point in time.

8 To edit another clip, open the next clip you want to edit into the Source Viewer, set In and Out points, and use the Overwrite Clip button or command to edit it into the Timeline. Continue this process until you've edited together the assembly of edits you want.

The Timeline playhead at the first frame after the clip you've just edited;
the Timeline Viewer shows a jagged overlay at the right to let you know this isn't a real frame

Example: Assembling Clips Into the Timeline From the Media Pool

If you want, you can also edit clips directly into the Timeline from the Media Pool using a variety of commands. This can be a fast way of appending clips to the end of the Timeline (although you can also perform insert edits this way).

To edit one or more clips from the Media Pool to the Timeline:

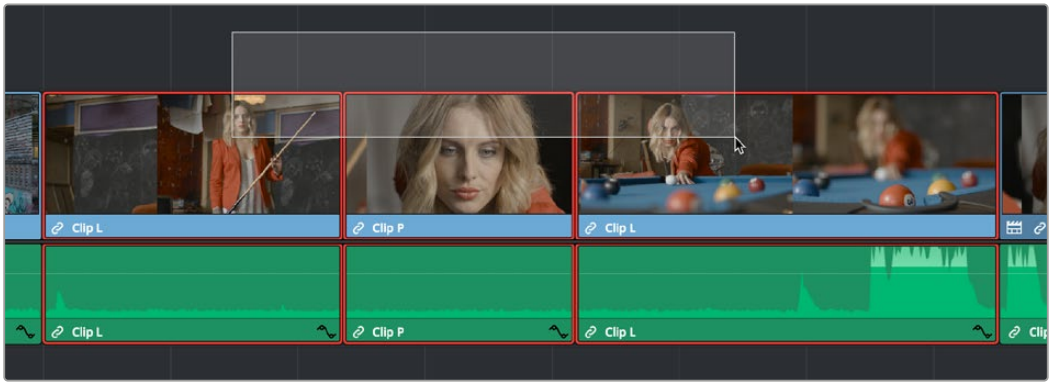
1. Click with the pointer to choose a clip in the Media Pool.
2. Set In and Out points for one or more clips in the Media Pool by doing one of the following:
   - In Metadata view, drag the pointer over a clip's thumbnail and use the I and O keys. If Live Media Preview is enabled in the Source Viewer, dragging over a clip's thumbnail mirrors the content in the Source Viewer.

- In Thumbnail view, drag the pointer over a clip's thumbnail and use the I and O keys. If Live Media Preview is enabled in the Source Viewer, dragging over a clip's thumbnail mirrors the content in the Source Viewer.
- In List view, drag over the Media Pool Filmstrip Viewer and use the I and O keys. If Live Media Preview is enabled in the Source Viewer, dragging over the filmstrip mirrors the content in the Source Viewer.

3. Change the sort order of the Media Pool's browser area to put the clips into the order in which you want them to appear. In Thumbnail view you can use the Sort Order menu, but in List view you can click the header of any metadata column to sort by that column's data.
4. Click, drag, use the Command-Option and Command-Shift Up and Down Arrow Key shortcuts, or use the Option-1–8 and Command-Option-1–8 key shortcuts to assign the video and audio source destination controls to the tracks you want to edit the video and audio of the incoming clip(s) to. Click any source destination control itself to disable it if you want to edit clips into the Timeline as audio or video only.
5. Select one or more clips you want to edit. Insert, overwrite, place on top, ripple overwrite, and append at end edits are all capable of editing multiple clips at once, while replace and fit to fill edits can only edit one clip at a time, and will only edit the first of multiple selected clips into the Timeline.
6. To perform the edit, do one of the following:
   - Use any of the editing commands in the Edit menu.
   - Use the equivalent keyboard shortcuts to Insert (F9), Overwrite (F10), Replace (F11), Place On Top (F12), Ripple Overwrite (Shift-F10), Fit to Fill (Shift-F11), or Append To End of Timeline (Shift-F12) the selected clips into the Timeline.
   - Right-click one or more selected clips in the Media Pool, and choose "Insert Selected Clips to Timeline" or "Append Selected Clips to Timeline."

   The selected clip(s) are edited into the Timeline.

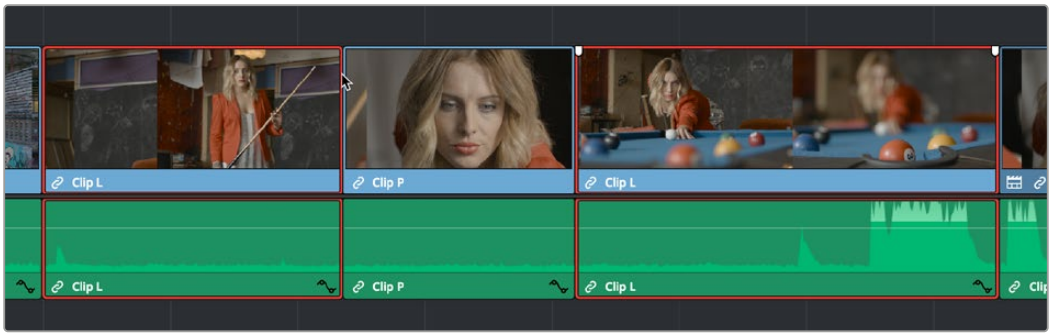
Making Selections in the Timeline



Once you've assembled a sequence of clips in the Timeline, you'll probably need to manipulate them further, moving, deleting, trimming, or otherwise adjusting the clips in the Timeline to make the edit play with the pacing and verve you require.

Manually Selecting Clips in the Timeline

Many operations require you to make a selection first, to define the scope of what you're about to do. There are many ways to do so.



Selections you can make using the mouse:

- **To select one clip:** Click a clip with the mouse.
- **To select all clips under the playhead:** You can select all the clips under the playhead at once, regardless of how many tracks they are spread across by selecting Trim > Select All Clips Under Playhead (Option-Shift-V).
- **To select a continuous range of clips by dragging:** Drag a bounding box from an empty area of the Timeline to surround a group of clips.

Dragging a bounding box to select a continuous range of clips in the Timeline

- **To select a continuous range of clips by Shift-clicking:** Click the first clip you want to select, and then Shift-click the last clip you want to select, and all clips in-between will automatically be selected as well.
- **To select a discontinuous range of clips:** Command-click any clips to select them no matter where they appear on the Timeline. Command-clicking a selected clip deselects it.

Command-clicking to select a discontinuous range of clips in the Timeline

Selecting clips using the keyboard or menu commands:

- **To select one clip:** Using the keyboard, make sure the Source Track Selector button for the track the clip is on is enabled, then move the playhead over that clip and press Shift-V.
- **To select a clip using keyboard navigation:** Holding down the Command key and pressing the Up, Down, Left, and Right Arrow keys allows you to select clips above and below the current track and to the left and right, independently of the playhead.
- **To select all clips forward of the playhead on the current track:** Move the playhead to the first clip you want to include in the selection, then press the Y key (Timeline > Select Clips Forward > On This Track) to select that clip and every clip to its right in the same track of the Timeline.
- **To select all clips forward of the playhead on all tracks:** Move the playhead to the first clip you want to include in the selection, then press Option-Y (Timeline > Select Clips Forward > On All Tracks) to select that clip and every clip to its right in all tracks of the Timeline.
- **To select all clips backward from the playhead on the current track:** Move the playhead to the last clip you want to include in the selection, then press Command-Y (Timeline > Select Clips Backward > On This Track) to select that clip and every clip to its left in the same track of the Timeline.
- **To select all clips backward from the playhead on all tracks:** Move the playhead to the last clip you want to include in the selection, then choose Command-Option-Y (Timeline > Select Clips Backward > On All Tracks) to select that clip and every clip to its left in all tracks of the Timeline.
- **To select all clips in the Timeline:** Make sure the Timeline has focus, then press Command-A.

To change which clip is selected using the keyboard:

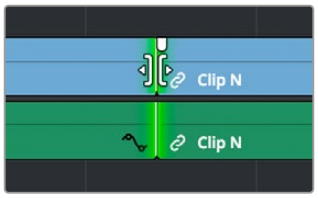
Select a clip, then use the Command-Up/Down/Left/Right Arrow keys to change the selection to the above, below, previous or next clip among all tracks.

Selecting Clips Based on Markers, Flags, and Clip Color

It's also possible to select multiple clips that have a particular color of marker, flag, or clip coloration. This is useful in any situation where you're using these organizational tools to keep track of clips with specific characteristics that you might need to later select for multi-clip operations.

For example, you might add purple markers to a series of audio clips that might need special EQ settings. Later, you can choose Timeline > Select Clips By Marker Color > Purple to select all of those clips in order to move them to another track, where you can apply the same EQ to all of them using an audio filter applied to the track. There are three ways of selecting groups of clips.

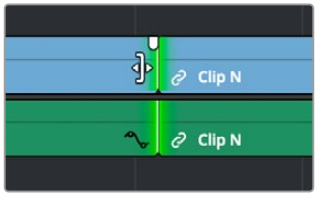
To select groups of clips based on marker, flag, or clip color:



- Choose Timeline > Select Clips By Flag Color > Blue – Cream
- Choose Timeline > Select Clips By Marker Color > Blue – Cream
- Choose Timeline > Select Clips By Clip Color > Orange – Chocolate

Selecting Edits in the Timeline

A variety of editing and trimming methods require you to select an edit point, or part of an edit point, in order to resize, ripple, or roll an edit. You can do so using the mouse or using the keyboard.



Methods for selecting edit points using the mouse:

- **To select an edit to roll:** Move the mouse to the center of an edit point, and when the ripple cursor appears, click to select the edit.

Selecting an edit point to roll

- **To select just the incoming or outgoing half of an edit point to resize or ripple:** Move the mouse to the left or right of the center of an edit, and when the resize/ripple cursor appears, click to select that portion of the edit.

Selecting incoming or outgoing halves of an edit point to resize or ripple

To select multiple edit points, do one of the following:

- **To select multiple roll points:** Command-click the center of multiple edit points. Command-click a selected edit point to deselect it.

Command-clicking the center of several edits to prepare to roll them all

- **To select multiple ripple points:** Command-click the left or right sides of multiple edit points.

Command-clicking the left or right of several edits to ripple them all

- **To drag to select many edit points:** Select the Trim tool (T), and drag a bounding-box over the edit points you want to select. You can press U to switch all selected edit points among rippling incoming edits, rippling outgoing edits, and rolling edits.

Using the Trim tool, you can drag a bounding box to select multiple edits

There is also a flexible set of keyboard shortcuts that makes it easy to select edit points in preparation for various operations if you like to avoid using the mouse.

Keyboard shortcuts for selecting edits:

V: Selects the nearest edit point to the playhead on the lowest track with Source Track Selector enabled. Selects both the audio and video edit points of a clip together.

Option-E: Selects the nearest video edit point to the playhead on the lowest track with Source Track Selector enabled. Linked audio edit points are not selected.

Shift-E: Selects the nearest audio edit point to the playhead on the lowest track with Source Track Selector enabled. Linked video edit points are not selected.

U: Once you've selected an edit point, this shortcut toggles among selecting the outgoing half, incoming half, or the entire edit.

Option-U: Once you've selected an edit point, this shortcut toggles among selecting the video+audio of the edit, just the video, or just the audio.

To move the selection to another edit:

- Select a single edit point, then use the Up Arrow key (Previous Edit) or Down Arrow key (Next Edit) to change the selection to the previous or next edit point among all tracks.

To deselect all edit points:

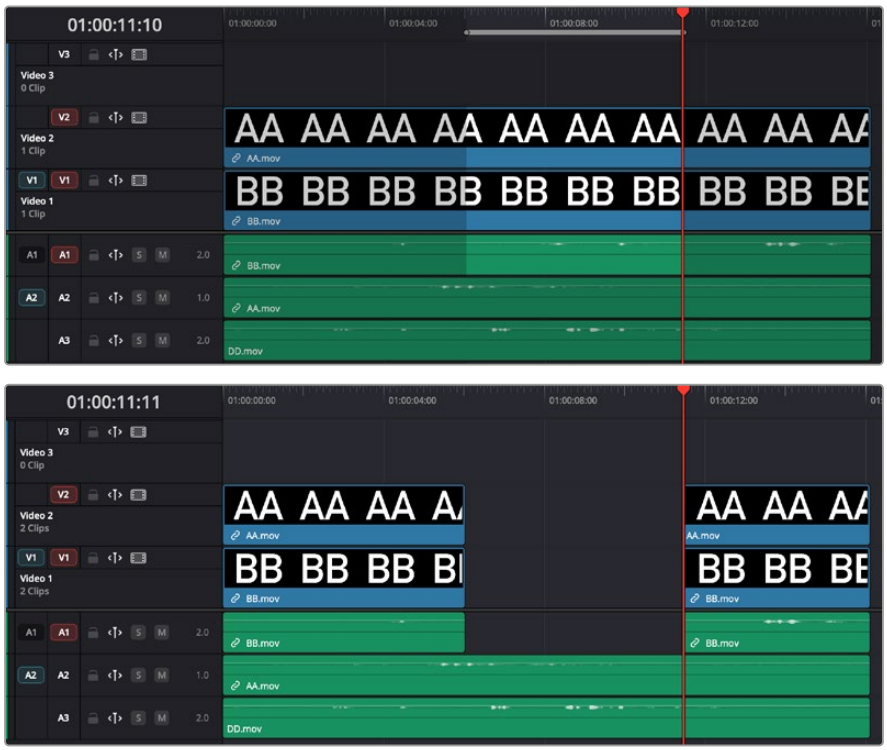
- **Using the mouse:** Click any empty area of the Timeline.
- **Using the keyboard:** Press Shift-Command-A.

A Practical Example of Keyboard-Driven Selections

Here's an example of how you would use these keyboard shortcuts together as a sequence of operations.

To select an edit point using the keyboard:

1. Press Command-4 to give focus to the Timeline.
2. Move the Timeline playhead close to the edit point you want to select using the JKL keys.
3. Press the V key to select the nearest edit point to the playhead on the lowest track with Destination Track Selector enabled. If there are overlapping superimposed clips on multiple tracks, turn off the Destination Track Selector controls of tracks with edits you don't want to select using Option-F1 through Option-F8 corresponding to the Destination Track Selector controls on tracks 1–8. Using the mouse, you can solo a track's Destination Track Selector state by Option-clicking its Destination Track Selector button. (Option-F9 toggles the Destination Track Selector controls of all video tracks.)
4. Initially, the entire edit is selected, in preparation for a roll edit. To toggle among selecting the outgoing half, incoming half, and the entire edit, press the U key.
5. To toggle among selecting the video+audio of the edit, just the video, or just the audio, press Option-U.
6. Perform whatever operation you need to. When you're finished, using Up-Arrow or Down-Arrow to move the selection backward or forward in the Timeline, or press Command-Shift-A to deselect it.



Using Destination Track Selector Controls to Define Selections

The Timeline Destination Track Selector controls are extremely useful and versatile controls that serve many purposes. In short, they give you a way to specify which tracks will be affected or considered when you're performing an operation upon multiple superimposed clips on multiple tracks of the Timeline.

Also, the Timeline Destination Track Selector controls are particularly convenient when you're using keyboard shortcuts to edit and you don't want to have to grab your mouse to explicitly select a single clip, since you can turn Destination Track Selectors on or off via keyboard shortcuts.

Defining Selections With the Help of Destination Track Selector Controls

Here is the easiest example of when the Destination Track Selector controls are indispensable. In the following example, there are two superimposed video clips and three superimposed audio clips. Supposing you only want to delete the media from tracks V2, V1, and A1, but you want to leave the media on A2 and A3 alone, you can turn off the Destination Track Selector controls for tracks A2 and-A3, and set Timeline In and Out points to define the range of the clips you want to delete. When you press the Delete key, only the media on the Destination Track Selector-enabled tracks is deleted.

Before and After deleting a clip with Destination Track Selectors (red) for Tracks V2, V1, and A1 turned on, and Tracks A2, and A3 turned off

TIP: If you set In and Out points to perform an operation and you don't see any shading in the Timeline to indicate which parts of the Timeline will be affected and which won't, chances are you have another selected clip in the Timeline somewhere you can't see that's overriding the Destination Track Selectors. Press Command-Shift-A to de-select all and things should go back to normal.

Overriding Automatic Selections by Making Manual Selections

It's important to note that manual selections that you make which highlight specific clips in the Timeline always override whatever the Destination Track Selector control of a track is set to. In the following example, three clips are superimposed and the Destination Track Selector control of every track except V2 has been turned off. Setting Timeline In and Out points now automatically defines that region of the clip on track V2 to be deleted were you to press the Delete key. You can see the affected part of the Timeline because it's highlighted while the rest of the Timeline is dimmed.

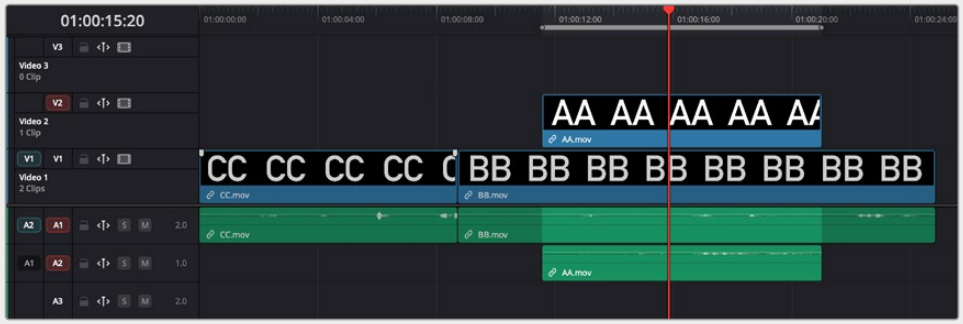
Soloing the Destination Track Selector control on track V2 to limit a Delete operation

However, if you clicked the clip on track V1 to select it manually, the automatic selection defined by the In and Out points disappears in favor of the highlighted clip you just clicked. This is because manual selections almost always take precedence over automatic selections you define using the In and Out points and Destination Track Selector controls.

Making a manual selection overrides the Destination Track Selector controls

This is good to keep in mind for situations where the fastest way to do the operation you need to do is to simply manually select the clip you want to define the operation.

Using Destination Track Selector Controls to Control Other Operations



Other operations that are affected by the Destination Track Selector controls include any command that uses “the clip on the lowest-numbered track with Destination Track Selector enabled” to define what happens. This includes Copy and Paste, Mark Clip, Go To Next Edit/Previous Edit, the Selection Follows Playhead mode, Next Gap/Previous Gap, and so on (a full list of affected operations appears later).

A common example of when this is important is whenever you use the Mark Clip command to automatically set In and Out points to match the duration of a clip on the Timeline. If that clip happens to be at a section of the Timeline where there are multiple superimposed clips, each of which has a different duration, then by default the In and Out points (first and last frames) of the clip on the lowest numbered track is used to set Timeline In and Out points when you use Mark Clip.

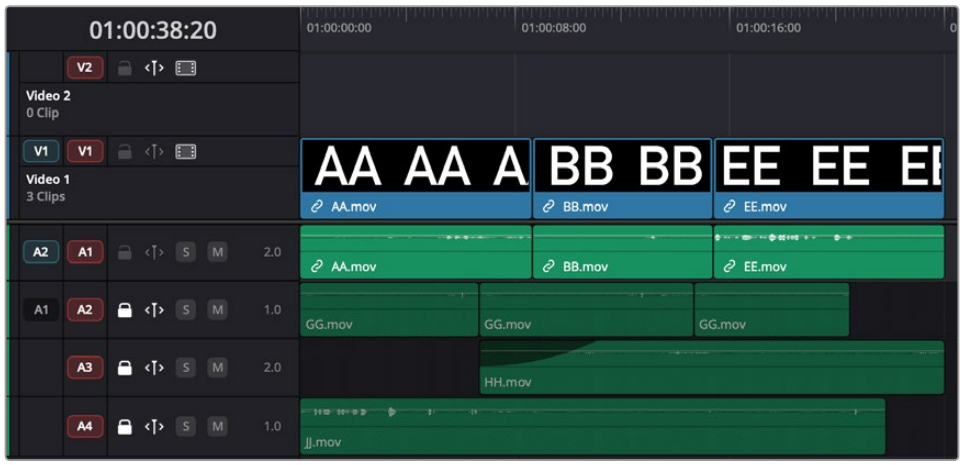
Using Mark Clip with all Destination Track Selector controls enabled, the clip on the lowest-numbered video track with Destination Track Selector enabled defines the result

However, if you disable the Destination Track Selector control of track V1, then whichever clip is on the lowest video track with the Destination Track Selector still enabled is used as the target clip for the Mark Clip operation. In this example, the shorter clip on track V2 now sets the locations of the In and Out points.

Using Mark Clip with Destination Track Selector controls enabled

Methods of enabling and disabling the Destination Track Selector controls:

- **To toggle Destination Track Selector for any track:** Click any track's Destination Track Selector control.
- **To toggle Destination Track Selector for video tracks:** Press Option-F1 through F8 to toggle Destination Track Selector on the corresponding tracks.
- **To toggle Destination Track Selector for audio tracks:** Press Option-Command-F1 through F8 to toggle Destination Track Selector on the corresponding tracks.
- **To toggle all video track Destination Track Selector tracks off and on:** Press Option-F9.
- **To toggle all audio track Destination Track Selector tracks off and on:** Press Option-Command-F9.
- **To "solo" Destination Track Selector for a track and disable Destination Track Selector on all other tracks:** Option-click any Destination Track Selector control to leave that control on while turning off all other Destination Track Selector controls of that type (video or audio).
- **To turn all audio or video Destination Track Selector controls on and off:** Shift-click any video or audio Destination Track Selector control to toggle on or off all Destination Track Selector controls of that type (video or audio).



The following operations are affected by the state of each track's Destination Track Selector control:

- **Cutting, copying, or deleting clips:** When using Timeline In and Out points to delete a range of media from the Timeline, only media on tracks with an enabled Destination Track Selector control will be cut, copied, or deleted.
- **Deleting gaps:** When selecting and deleting gaps in the Timeline, clips on other tracks that overlap the selected gap will also be deleted on tracks with an enabled Destination Track Selector control. Media to the right of affected tracks will ripple left to close the gap.
- **Selecting edit points using the keyboard:** When you press V to select the nearest edit point, the edit point on the lowest track with Destination Track Selector enabled is selected. When pressing the Up Arrow and Down Arrow keys to move the selection from edit point to edit point, edit points on tracks with a disabled Destination Track Selector control are ignored.
- **Selecting clips using the keyboard:** When a clip is selected, you can press the Up Arrow and Down Arrow keys to move the selection from clip to edit clip, but clips on tracks with a disabled Destination Track Selector control are not seen by this operation.

- **Using Mark Clip:** When using the Mark Clip command, clips on tracks with disabled Destination Track Selector controls are ignored. This lets you choose a target clip to use for marking the clip when there are multiple overlapping superimposed clips.
- **Match Frame:** When making a Match Frame operation, clips on tracks with disabled Destination Track Selector controls are ignored. This lets you choose a target clip to use for matching a frame when there are multiple overlapping superimposed clips.
- **Pasting clips:** All copied clips will be pasted to the lowest numbered track with Destination Control enabled. If all tracks of a particular type have their Destination Track Selector controls turned off, then no clips of that type will be pasted at all.
- **Finding gaps:** When using Playback > Previous Gap (Command-Option-Semicolon) or Next Gap (Command-Option-Apostrophe), gaps on tracks with Destination Track Selector disabled will be ignored.
- **Using Selection Follows Playhead:** When you turn on "Selection Follows Playhead" so that the clip intersecting the position of the playhead is automatically selected. If multiple clips are intersecting the playhead, the clip on the highest track will be selected. Clips on tracks with Destination Track Selector disabled will not be selected.

Locking Tracks You Don't Want to Change

Another step you can take to prepare before performing any kind of editorial operation is to lock tracks with media that you don't want to be affected by whatever it is you're about to do. For example, if you have a complex set of music edits on track A3 that you don't want to be affected by operations that will ripple the Timeline, you can lock track A3 so those clips remain unaffected.

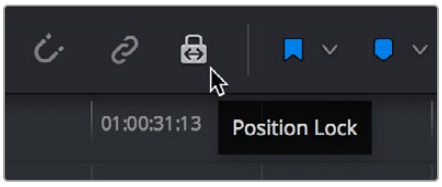
Tracks V2, V1, and A1 are unlocked, while tracks A2, A3, and A4 are locked

Clips on locked tracks cannot be moved, deleted, cut, or otherwise affected by editorial operations. Furthermore, parameters of locked clips cannot be edited in the Inspector. However, clips on locked tracks can be graded and otherwise modified in the Color page.

To toggle the lock or unlock state of tracks, do one of the following:

- Click any track's lock control to toggle lock on and off.
- Shift-click any track's lock control to toggle locking on and off for all tracks.
- Press Option-Shift-1 through 8 to lock or unlock tracks V1 through V8.
- Press Option-Shift-9 to lock or unlock all video tracks.
- Press Option-Shift-F1 through F8 to lock or unlock tracks A1 through A8.
- Press Option-Shift-F9 to lock or unlock all audio tracks.

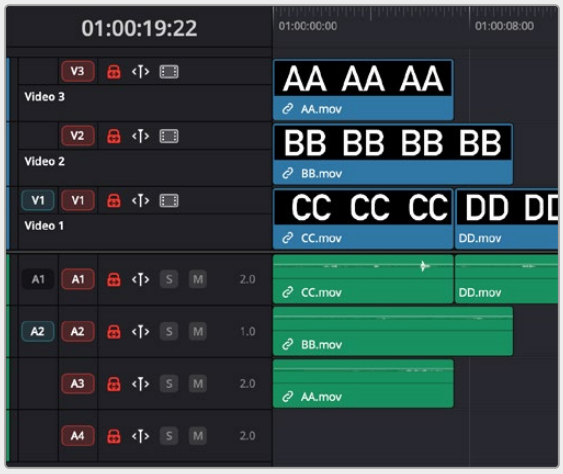
Position Lock for Finishing



In a nutshell, turning position lock on prevents clips from being moved to the left or right, and it prevents all ripple operations. This is primarily useful when you're near the end of post on a project for which the cut has been locked (or at least as "locked" as directors and producers allow any more), but you still need to make surgical changes that don't risk throwing the video out of sync with audio that may be being edited and mixed elsewhere because of an accidentally rippled edit.

With position lock on, you can still make edits (such as Replace), slip clips, roll edits, add Resolve FX and other Open FX, and alter all manner of effects in the Inspector. You just can't do anything that alters the position of clips in the Timeline, or ripples entire sections of the Timeline.

There are two ways you can enable Position Lock.



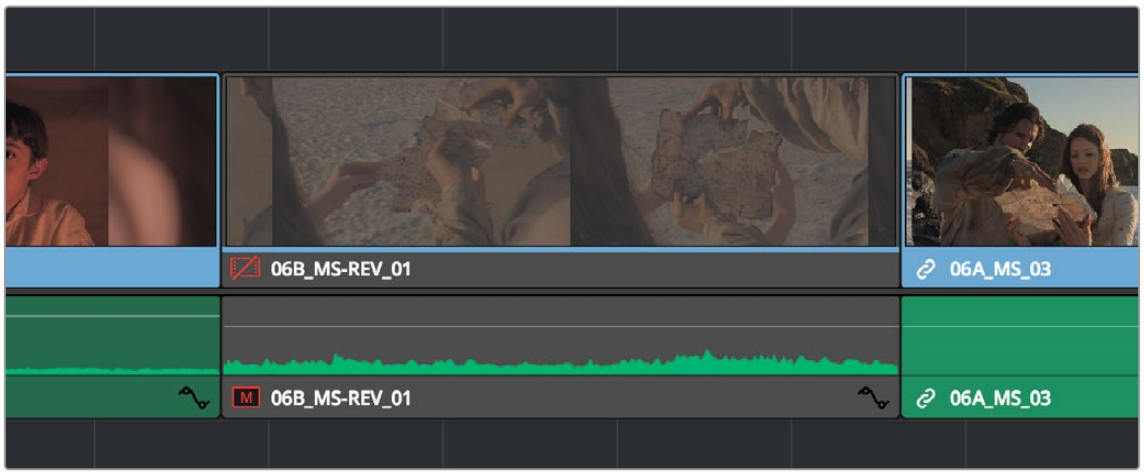
Position Locking All Tracks

You can turn Position Lock on and off for all tracks via a button in the toolbar above the Timeline.

The Position Lock button on the toolbar

When you turn position lock on, the Lock button of all tracks changes to red to show that position lock is enabled instead.

Position lock indicated by each track's Lock icon changing to red.



Position Locking Individual Tracks

You can also be extra tricky and enable position lock on a track-by-track basis by Command-clicking any track's Lock button. Position lock can be released by simply clicking that track's Lock icon.

Disabling and Re-Enabling Clips in the Timeline

Sometimes there's one or more video or audio clips in the Timeline that you don't want to play along with the rest of the edited sequence, but you don't want to remove from the Timeline either, in case you change your mind later. For this reason, it's possible to Disable clips, effectively turning them off without removing them.

Disabled clips appear dimmed in the Timeline. They don't play back, they're not rendered, and they're not output to video. However, their position is preserved in the Timeline, so you can always re-enable them at a later time if you change your mind and decide you want to use them.

A clip that's been disabled between two enabled clips; the disabled clip is dimmed

To disable or re-enable one or more selected clips:

- Right-click part of the selection and choose Enable Clip from the contextual menu.
- Choose Clip > Enable/Disable Clip.
- Press D.

NOTE: There are now specific Enable and Disable clip actions that can be assigned to keyboard shortcuts in the Keyboard Customization Dialog. The enable / disable clip toggle shortcut is still "D", but assigning these specific actions prevents the issue of having disabled and enabled clips in the same selection simply swapping on / off states, rather than all being enabled or disabled.

1. Go to DaVinci Resolve > Keyboard Customization.
2. Under Commands, select Clip.
3. Type in "able" in the search box.
4. Assign a keyboard shortcut for Disable Clip and Enable Clip.

Deleting Clips From the Timeline

There are two ways you can delete clips you don't want in the Timeline. Using the Delete key, you can perform what's sometimes called a "lift edit," removing the unwanted clips and leaving a gap. Using the Forward Delete key, you can perform a "ripple delete," removing unwanted clips and closing the gap by rippling the rest of the edited Timeline to the right of the deleted clip(s) by moving it to the left.

Deleting clips as a "lift edit" operation:

- **To remove one or more clips from the Timeline, leaving a gap:** Select a clip in the Timeline, or Shift-click or Command-click to select the clips you want to remove, and press the Delete key (or right-click the selection and choose Delete).
- **To remove a range of media from the Timeline on multiple tracks, leaving a gap:** Set Timeline In and Out points defining the range of media you want to delete, then turn off the Destination Track Selector controls of any tracks with media you want to preserve, and press the Delete key (or right-click the selection and choose Delete).

Deleting Clip using the Backspace or Delete key and leaving a gap on V1, A1

Deleting clips as a "ripple delete" operation:

- **To delete one or more clips and close the gap by rippling the Timeline left:** Select a clip in the Timeline, or Shift-click or Command-click to select the clips you want to remove, and press the Forward Delete key.
- **To delete a range of media and close the gap by rippling the Timeline left:** Set Timeline In and Out points defining the range of media you want to delete, then turn off the Sync locks of any tracks with media you want to preserve, and press the Forward Delete key.

Deleting a Clip using the Forward Delete key to ripple all clips with In points to the right in the Timeline to close the gap. Note no rippling of tracks A2, A3 as their Sync Locks have been turned off in their track headers.

As with any ripple operation, all clips with Sync Locks enabled are rippled to close the gap.

Gaps in the Timeline

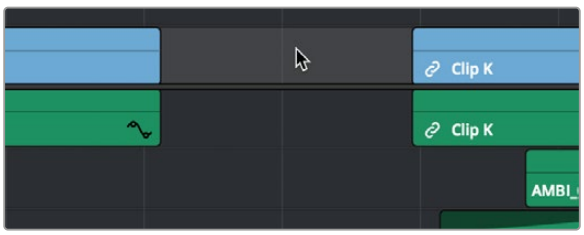
EDIT

A gap is defined as a space between any two clips on the same track. Often gaps are desirable as they allow audio or video clips to be spaced apart from one another very specifically, but sometimes they're not. If you want to find accidental gaps in your timeline that may be too small to see, a pair of commands lets you do this.

To move the playhead to the next gap on the Timeline:

1. Turn off the Destination Track Selector controls of any tracks you want to omit from this operation.
2. Do one of the following:
   - Choose Playback > Previous > Gap, or press Option-Command-Semicolon (;) to move the playhead to the next gap to the left of the playhead's current position.
   - Choose Playback > Next > Gap, or press Option-Command-Apostrophe (') to move the playhead to the next gap to the right of the playhead's current position..

There are times when you may want to add a gap intentionally in the timeline, whether as a flag to reserve space for a clip, or to split up a section into smaller pieces.



To insert a gap:

1. Place the playhead at the edit point you want the gap to appear.
2. Select Edit > Insert Gap.
3. Alternatively, you can right-click in a blank section of the timeline and choose Insert Gap from the context menu, to add a gap at the current playhead position.

To select or deselect a gap:

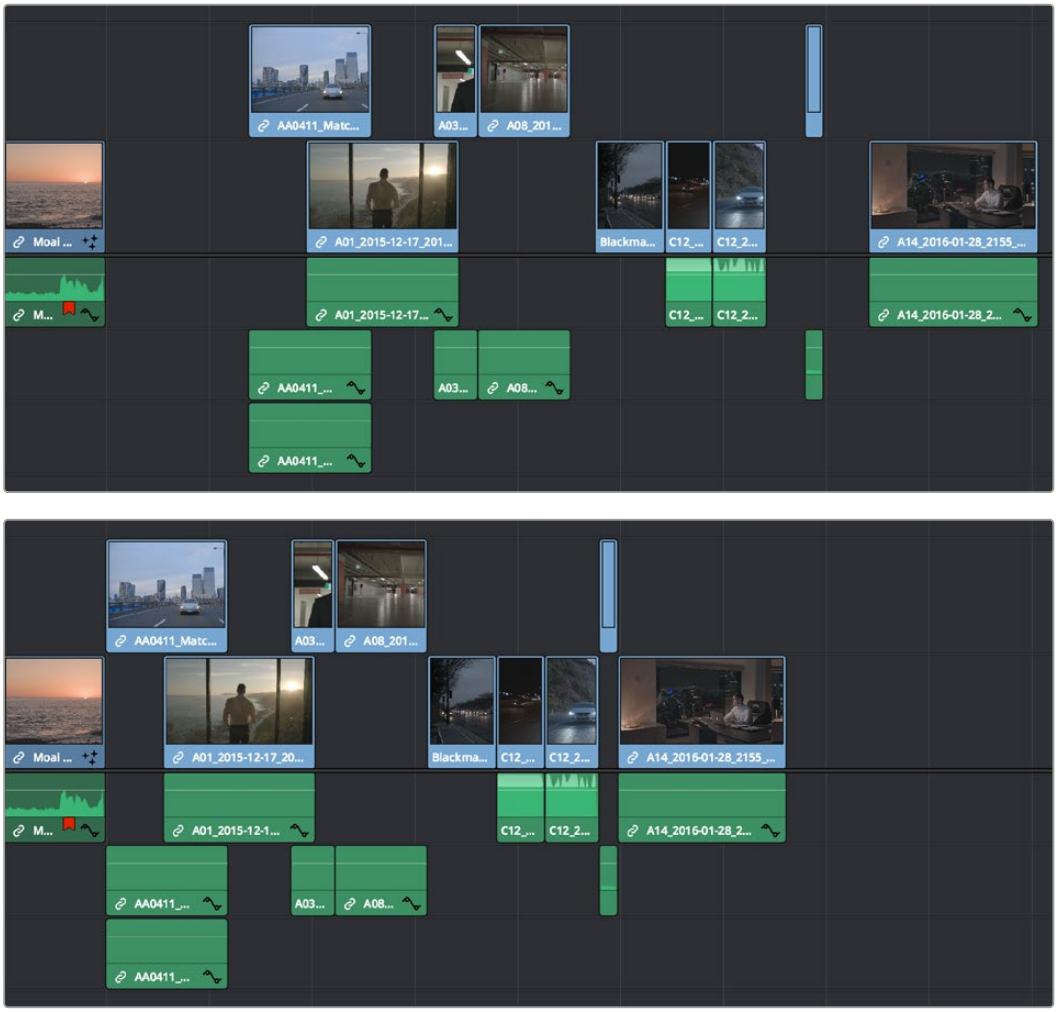
Click once to select a gap, and click that gap again to deselect it.

You can only select one gap at a time. The principal reason to select a gap is to delete it, in the process rippling the Timeline to close the gap. In the following example, there's a gap between two clips on track V1 that you'd like to close.

Selecting a gap on track V1

To delete a gap:

Press the Delete key to close the gap. All clips to the right of it on tracks with their Sync Locks enabled will be rippled to the left to close the gap. Clips on tracks with their Sync Locks disabled will not ripple.



If you select a gap in a timeline with clips on multiple tracks, which clips will be deleted depends on the state of the Sync Lock controls for each track in the Timeline.
